

Introducing Classes

- Class defines the shape and nature of an object.
- class forms the basis for object-oriented programming in Java.
- Any concept can be implemented in a Java program must be encapsulated within a class.

Class Fundamentals

- a class defines a new data type. Once defined, this new type can be used to create objects of that type.
- Thus, a class is a *template* for an object, and an object is an *instance* of a class.

The General Form of a Class

- class specifies the data that it contains and the code that operates on that data.
- While very simple classes may contain only code or only data, most real-world classes contain both.
- A class is declared by use of the **class** keyword.
- A simplified general form of a **class** definition is shown here:

class *classname*

```
{  
    type instance-variable1;  
    type instance-variable2;  
    // ...  
    type instance-variableN;  
  
    type methodname1(parameter-list) {  
        // body of method  
    }  
  
    type methodname2(parameter-list) {  
        // body of method  
    }  
    // ...  
  
    type methodnameN(parameter-list) {  
        // body of method  
    }  
}
```

- The data, or variables, defined within a **class** are called *instance variables*.
- The code is contained within *methods*.
- Collectively, the methods and variables defined within a class are called *members* of the class.
- Thus the methods that determine how a class' data can be used.
- each object of the class contains its own copy of these variables.
- Thus, the data for one object is separate and unique from the data for another.

A Simple Class

- Here is a class called **Box** that defines three instance variables: **width**, **height**, and **depth**.

```
class Box
{
    double width;
    double height;
    double depth;
}

class BoxDemo2
{
    public static void main(String args[])
    {
        Box mybox1 = new Box();
        Box mybox2 = new Box();
        double vol;

        mybox1.width = 10;
        mybox1.height = 20;
        mybox1.depth = 15;

        mybox2.width = 3;
        mybox2.height = 6;
        mybox2.depth = 9;

        // compute volume of first box
        vol = mybox1.width * mybox1.height * mybox1.depth;
        System.out.println("Volume is " + vol);

        // compute volume of second box
        vol = mybox2.width * mybox2.height * mybox2.depth;
        System.out.println("Volume is " + vol);
    }
}
```

output:

```
Volume is 3000.0
Volume is 162.0
```

- **mybox1**'s data is completely separate from the data contained in **mybox2**.

Declaring Objects

- when a class is created , we are creating a new data type.
- We can use this type to declare objects of that type.
- However, obtaining objects of a class is a two-step process.

- First, we must declare a variable of the class type. This variable does not define an object. Instead, it is simply a variable that can *refer* to an object.
- Second, we must acquire an actual, physical copy of the object and assign it to that variable by using the **new** operator.
- The **new** operator dynamically allocates (that is, allocates at run time) memory for an object and returns a reference to it
- `Box mybox = new Box();`
This statement combines the two steps just described. It can be rewritten like this to show each step more clearly:
`Box mybox; // declare reference to object`
`mybox = new Box(); // allocate a Box object`

Assigning Object Reference Variables

```
Box b1 = new Box();  
Box b2 = b1;
```

- **b1** and **b2** will both refer to the *same* object.
- The assignment of **b1** to **b2** did not allocate any memory or copy any part of the original object. It simply makes **b2** refer to the same object as does **b1**.
- Thus, any changes made to the object through **b2** will affect the object to which **b1** is referring, since they are the same object.
- Although **b1** and **b2** both refer to the same object, they are not linked in any other way.
- For example, a subsequent assignment to **b1** will simply *unhook* **b1** from the original object without affecting the object or affecting **b2**.
- For example:
`Box b1 = new Box();`
`Box b2 = b1;`
`// ...`
`b1 = null;`
Here, **b1** has been set to **null**, but **b2** still points to the original object.

Introducing Methods

- classes usually consist of two things: instance variables and methods.
- This is the general form of a method:

```
type name(parameter-list) {  
    // body of method  
}
```
- Here, *type* specifies the type of data returned by the method. This can be any valid type, including class types that we create.
- If the method does not return a value, its return type must be **void**.
- The name of the method is specified by *name*.
- . The *parameter-list* is a sequence of type and identifier pairs separated by commas.

```
class Box
{
    double width;
    double height;
    double depth;
    //
    void volume()
    {
        System.out.print("Volume is ");
        System.out.println(width * height * depth);
    }
}
```

```
class BoxDemo3
{
    public static void main(String args[])
    {
        Box mybox1 = new Box();
        Box mybox2 = new Box();

        mybox1.width = 10;
        mybox1.height = 20;
        mybox1.depth = 15;

        mybox2.width = 3;
        mybox2.height = 6;
        mybox2.depth = 9;

        // display volume of first box
        mybox1.volume();

        // display volume of second box
        mybox2.volume();
    }
}
```

This program generates the following output, which is the same as the previous version.

Volume is 3000.0

Volume is 162.0

Returning a Value

```
class Box
{
    double width;
    double height;
    double depth;
```

```
// compute and return volume
double volume()
{
    return width * height * depth;
}
}
class BoxDemo4
{
    public static void main(String args[])
    {
        Box mybox1 = new Box();
        Box mybox2 = new Box();
        double vol;

        mybox1.width = 10;
        mybox1.height = 20;
        mybox1.depth = 15;

        mybox2.width = 3;
        mybox2.height = 6;
        mybox2.depth = 9;

        // get volume of first box
        vol = mybox1.volume();
        System.out.println("Volume is " + vol);

        // get volume of second box
        vol = mybox2.volume();
        System.out.println("Volume is " + vol);
    }
}
```

Adding a Method That Takes Parameters

- Parameters allow a method to be generalized.
- That is, a parameterized method can operate on a variety of data and/or be used in a number of slightly different situations.
- Here is a method that returns the square of the number 10:

```
int square()
{
    return 10 * 10;
}
```

- While this method does, indeed, return the value of 10 squared, its use is very limited.
- However, if we modify the method so that it takes a parameter, as shown next, then we can make **square()** much more useful.

```
int square(int i)
{
    return i * i;
}
```

- Now, **square()** will return the square of whatever value it is called with. That is, **square()** is now a general-purpose method that can compute the square of any integer value, rather than just 10.

// This program uses a parameterized method.

```
class Box
{
    double width;
    double height;
    double depth;

    double volume()
    {
        return width * height * depth;
    }

    void setDim(double w, double h, double d)
    {
        width = w;
        height = h;
        depth = d;
    }
}
```

```
class BoxDemo5
{
    public static void main(String args[])
    {
        Box mybox1 = new Box();
        Box mybox2 = new Box();
        double vol;

        mybox1.setDim(10, 20, 15);
        mybox2.setDim(3, 6, 9);

        // get volume of first box
        vol = mybox1.volume();
        System.out.println("Volume is " + vol);

        // get volume of second box
        vol = mybox2.volume();
    }
}
```

```
        System.out.println("Volume is " + vol);
    }
}
```

Constructors

- It can be tedious to initialize all of the variables in a class each time an instance is created.
- Thus automatic initialization is performed through the use of a constructor.
- A *constructor* initializes an object immediately upon creation.
- It has the same name as the class in which it resides and is syntactically similar to a method.
- the constructor is automatically called immediately after the object is created, before the **new** operator completes.
- Constructors have no return type, not even **void**. This is because the implicit return type of a class' constructor is the class type itself.

```
class Box
{
    double width;
    double height;
    double depth;

    Box()
    {
        System.out.println("Constructing Box");
        width = 10;
        height = 10;
        depth = 10;
    }

    double volume()
    {
        return width * height * depth;
    }
}

class BoxDemo6
{
    public static void main(String args[])
    {
        Box mybox1 = new Box();
        Box mybox2 = new Box();
        double vol;

        // get volume of first box
        vol = mybox1.volume();
    }
}
```

```
        System.out.println("Volume is " + vol);

        // get volume of second box
        vol = mybox2.volume();
        System.out.println("Volume is " + vol);
    }
}
Output:
```

```
Constructing Box
Constructing Box
Volume is 1000.0
Volume is 1000.0
```

- both **mybox1** and **mybox2** were initialized by the **Box()** constructor when they were created.
- Since the constructor gives all boxes the same dimensions, 10 by 10 by 10, both **mybox1** and **mybox2** will have the same volume.

Parameterized Constructors

- While the **Box()** constructor in the preceding example initializes with value 10.all boxes have the same dimensions.
- **Box** objects of various dimensions can be assigned by using parameterized constructor.

```
class Box
{
    double width;
    double height;
    double depth;

    Box(double w, double h, double d)
    {
        width = w;
        height = h;
        depth = d;
    }

    double volume()
    {
        return width * height * depth;
    }
}
class BoxDemo7
{
    public static void main(String args[])
    {
```

```
Box mybox1 = new Box(10, 20, 15);
Box mybox2 = new Box(3, 6, 9);
double vol;

// get volume of first box
vol = mybox1.volume();
System.out.println("Volume is " + vol);

// get volume of second box
vol = mybox2.volume();
System.out.println("Volume is " + vol);
}
}
output :
Volume is 3000.0
Volume is 162.0
```

The this Keyword

- **this** can be used inside any method to refer to the *current* object.
- That is, **this** is always a reference to the object on which the method was invoked.

```
// A redundant use of this.
Box(double w, double h, double d)
{
    this.width = w;
    this.height = h;
    this.depth = d;
}
```

Instance Variable Hiding

- it is illegal in Java to declare two local variables with the same name inside the same or enclosing scopes.
- However, when a local variable has the same name as an instance variable, the local variable *hides* the instance variable.

```
// Use this to resolve name-space collisions.
Box(double width, double height, double depth)
{
    this.width = width;
    this.height = height;
    this.depth = depth;
}
```

Garbage Collection

- Since objects are dynamically allocated by using the **new** operator, how such objects are destroyed and their memory released for later reallocation.
- In some languages, such as C++, dynamically allocated objects must be manually released by use of a **delete** operator.
- Java handles deallocation automatically.
- The technique that accomplishes this is called *garbage collection*.
- when no references to an object exist, that object is assumed to be no longer needed, and the memory occupied by the object can be reclaimed.
- Garbage collection only occurs sporadically (if at all) during the execution of program.

The finalize() Method

- an object will need to perform some action when it is destroyed.
- if an object is holding some non-Java resource such as a file handle or character font, then we might want to make sure these resources are freed before an object is destroyed.
- To handle such situations, Java provides a mechanism called *finalization*.
- By using finalization, we can define specific actions that will occur when an object is just about to be reclaimed by the garbage collector.
- To add a finalizer to a class, simply define the **finalize()** method.
- The Java run time calls that method whenever it is about to recycle an object of that class.
- Inside the **finalize()** method, you will specify those actions that must be performed before an object is destroyed.
- The **finalize()** method has this general form:

```
protected void finalize( )
{
    // finalization code here
}
```
- Here, the keyword **protected** is a specifier that prevents access to **finalize()** by code defined outside its class.
- **finalize()** is only called just prior to garbage collection.
- It is not called when an object goes out-of-scope

A Stack Class

- Stacks are controlled through two operations traditionally called *push* and *pop*.
- To put an item on top of the stack, we will use push.
- To take an item off the stack, we will use pop.
- Here is a class called **Stack** that implements a stack for integers:

```
class Stack
{
    int stk[] = new int[10];
    int tos;
```

```
Stack()
{
    tos = -1;
}

void push(int item)
{
    if(tos==9)
        System.out.println("Stack is full.");
    else
        stck[++tos] = item;
}

int pop()
{
    if(tos < 0)
    {
        System.out.println("Stack underflow.");
        return 0;
    }
    else
        return stck[tos--];
}
}
class TestStack
{
    public static void main(String args[])
    {
        Stack mystack1 = new Stack();
        Stack mystack2 = new Stack();

        for(int i=0; i<10; i++) mystack1.push(i);
        for(int i=10; i<20; i++) mystack2.push(i);

        System.out.println("Stack in mystack1:");
        for(int i=0; i<10; i++)
            System.out.println(mystack1.pop());
        System.out.println("Stack in mystack2:");
        for(int i=0; i<10; i++)
            System.out.println(mystack2.pop());
    }
}
```

This program generates the following output:

Stack in mystack1:

9

8

7
6
5
4
3
2
1
0

Stack in mystack2:

19
18
17
16
15
14
13
12
11
10

Inheritance

- One class can acquire the properties of another class.
- a class that is inherited is called a *superclass*.
- The class that does the inheriting is called a *subclass*. Therefore, a subclass is a specialized version of a superclass. It inherits all of the instance variables and methods defined by the superclass and adds its own, unique elements.

Inheritance Basics

- To inherit a class, simply incorporate the definition of one class into another by using the **extends** keyword.
- The following program creates a superclass called **A** and a subclass called **B**.the keyword **extends** is used to create a subclass of **A**.

// Create a superclass.

```
class A
{
    int i, j;
    void showij()
    {
        System.out.println("i and j: " + i + " " + j);
    }
}
```

// Create a subclass by extending class A.

```
class B extends A
{
    int k;
    void showk()
    {
        System.out.println("k: " + k);
    }
    void sum()
    {
        System.out.println("i+j+k: " + (i+j+k));
    }
}
```

```
class SimpleInheritance
{
    public static void main(String args[])
    {
        A superOb = new A();
        B subOb = new B();
        // The superclass may be used by itself.
    }
}
```

```
superOb.i = 10;
superOb.j = 20;
System.out.println("Contents of superOb: ");
superOb.showij();
System.out.println();

/* The subclass has access to all public members of its superclass. */
subOb.i = 7;
subOb.j = 8;
subOb.k = 9;

System.out.println("Contents of subOb: ");
subOb.showij();
subOb.showk();
System.out.println();

System.out.println("Sum of i, j and k in subOb:");
subOb.sum();
}
```

}
output:

```
Contents of superOb:
i and j: 10 20
Contents of subOb:
i and j: 7 8
k: 9
Sum of i, j and k in subOb:
i+j+k: 24
```

- the subclass **B** includes all of the members of its superclass, **A**. This is why **subOb** can access **i** and **j** and call **showij()**. Also, inside **sum()**, **i** and **j** can be referred to directly, as if they were part of **B**.
- Even though **A** is a superclass for **B**, it is also a completely independent, stand-alone class. Being a superclass for a subclass does not mean that the superclass cannot be used by itself.
- a subclass can be a superclass for another subclass.
- The general form of a **class** declaration that inherits a superclass is shown here:

```
class subclass-name extends superclass-name
{
    // body of class
}
```
- Java does not support the inheritance of multiple superclasses into a single subclass.
- But a subclass can become a superclass of another subclass.
- However, no class can be a superclass of itself.

Member Access and Inheritance

- Although a subclass includes all of the members of its superclass, it cannot access those members of the superclass that have been declared as **private**.

// Create a superclass.

```
class A
{
    int i;                // public by default
    private int j;        // private to A

    void setij(int x, int y)
    {
        i = x;
        j = y;
    }
}
```

// A's j is not accessible here.

```
class B extends A
{
    int total;

    void sum()
    {
        total = i + j; // ERROR, j is not accessible here
    }
}
```

```
class Access
{
    public static void main(String args[])
    {
        B subOb = new B();
        subOb.setij(10, 12);
        subOb.sum();
        System.out.println("Total is " + subOb.total);
    }
}
```

- This program will not compile because the reference to **j** inside the **sum()** method of **B** causes an access violation. Since **j** is declared as **private**, it is only accessible by other members of its own class. Subclasses have no access to it.

A More Practical Example

- the **Box** class developed will be extended to include a fourth component called **weight**.
- Thus, the new class will contain a box's width, height, depth, and weight.

// This program uses inheritance to extend Box.

```
class Box
{
    double width;
    double height;
    double depth;

    // construct clone of an object
    Box(Box ob)
    {
        // pass object to constructor
        width = ob.width;
        height = ob.height;
        depth = ob.depth;
    }

    // constructor used when all dimensions specified
    Box(double w, double h, double d)
    {
        width = w;
        height = h;
        depth = d;
    }

    // constructor used when no dimensions specified
    Box()
    {
        width = -1; // use -1 to indicate
        height = -1; // an uninitialized
        depth = -1; // box
    }

    // constructor used when cube is created
    Box(double len)
    {
        width = height = depth = len;
    }

    // compute and return volume
    double volume()
    {

```

```
        return width * height * depth;
    }
}
```

// Here, Box is extended to include weight.

class BoxWeight extends Box

```
{
    double weight; // weight of box

    // constructor for BoxWeight
    BoxWeight(double w, double h, double d, double m) {
        width = w;
        height = h;
        depth = d;
        weight = m;
    }
}
```

class DemoBoxWeight

```
{
    public static void main(String args[])
    {
        BoxWeight mybox1 = new BoxWeight(10, 20, 15, 34.3);
        BoxWeight mybox2 = new BoxWeight(2, 3, 4, 0.076);
        double vol;

        vol = mybox1.volume();
        System.out.println("Volume of mybox1 is " + vol);
        System.out.println("Weight of mybox1 is " + mybox1.weight);
        System.out.println();

        vol = mybox2.volume();
        System.out.println("Volume of mybox2 is " + vol);
        System.out.println("Weight of mybox2 is " + mybox2.weight);
    }
}
```

output:

```
Volume of mybox1 is 3000.0
Weight of mybox1 is 34.3
Volume of mybox2 is 24.0
Weight of mybox2 is 0.076
```

- the following class inherits **Box** and adds a color attribute:

```
// Here, Box is extended to include color.
class ColorBox extends Box
{
    int color; // color of box

    ColorBox(double w, double h, double d, int c)
    {
        width = w;
        height = h;
        depth = d;
        color = c;
    }
}
```

A Superclass Variable Can Reference a Subclass Object

- A reference variable of a superclass can be assigned a reference to any subclass derived from that superclass.

```
class RefDemo
{
    public static void main(String args[])
    {
        BoxWeight weightbox = new BoxWeight(3, 5, 7, 8.37);
        Box plainbox = new Box();
        double vol;

        vol = weightbox.volume();
        System.out.println("Volume of weightbox is " + vol);
        System.out.println("Weight of weightbox is " + weightbox.weight);
        System.out.println();

        // assign BoxWeight reference to Box reference
        plainbox = weightbox;
        vol = plainbox.volume();           // OK, volume() defined in Box
        System.out.println("Volume of plainbox is " + vol);

        /* The following statement is invalid because plainbox does not define a weight
        member. */
        // System.out.println("Weight of plainbox is " + plainbox.weight);
    }
}
```

- Here, **weightbox** is a reference to **BoxWeight** objects, and **plainbox** is a reference to **Box** objects.

- Since **BoxWeight** is a subclass of **Box**, it is permissible to assign **plainbox** a reference to the **weightbox** object.

Using super

- Whenever a subclass needs to refer to its immediate superclass, it can do so by use of the keyword **super**.
- **super** has two general forms.
 - The first calls the superclass' constructor.
 - The second is used to access a member of the superclass that has been hidden by a member of a subclass.

Using super to Call Superclass Constructors

- A subclass can call a constructor defined by its superclass by use of the following form of **super**:
`super(arg-list);`
- Here, *arg-list* specifies any arguments needed by the constructor in the superclass.
- **super()** must always be the first statement executed inside a subclass' constructor.

// BoxWeight now uses super to initialize its Box attributes.

```
class BoxWeight extends Box
{
double weight;
```

```
    BoxWeight(double w, double h, double d, double m)
    {
        super(w, h, d); // call superclass constructor
        weight = m;
    }
}
```

- Here, **BoxWeight()** calls **super()** with the arguments **w**, **h**, and **d**. This causes the **Box()** constructor to be called, which initializes **width**, **height**, and **depth** using these values.

```
class Box
{
```

```
    private double width;
    private double height;
    private double depth;
```

```
    // construct clone of an object
```

```
    Box(Box ob)
    {
        width = ob.width;
```

```
height = ob.height;
depth = ob.depth;
}

// constructor used when all dimensions specified
Box(double w, double h, double d)
{
    width = w;
    height = h;
    depth = d;
}

// constructor used when no dimensions specified
Box()
{
    width = -1; // use -1 to indicate
    height = -1; // an uninitialized
    depth = -1; // box
}

// constructor used when cube is created
Box(double len)
{
    width = height = depth = len;
}

// compute and return volume
double volume()
{
    return width * height * depth;
}
}
```

// BoxWeight now fully implements all constructors.

```
class BoxWeight extends Box
{
    double weight;
```

```
BoxWeight(BoxWeight ob)
{
    super(ob);
    weight = ob.weight;
}
```

// constructor when all parameters are specified

```
BoxWeight(double w, double h, double d, double m)
{
    super(w, h, d); // call superclass constructor
    weight = m;
}

// default constructor
BoxWeight()
{
    super();
    weight = -1;
}

// constructor used when cube is created
BoxWeight(double len, double m)
{
    super(len);
    weight = m;
}
}
}
class DemoSuper
{
    public static void main(String args[])
    {
        BoxWeight mybox1 = new BoxWeight(10, 20, 15, 34.3);
        BoxWeight mybox2 = new BoxWeight(2, 3, 4, 0.076);
        BoxWeight mybox3 = new BoxWeight(); // default
        BoxWeight mycube = new BoxWeight(3, 2);
        BoxWeight myclone = new BoxWeight(mybox1);
        double vol;

        vol = mybox1.volume();
        System.out.println("Volume of mybox1 is " + vol);
        System.out.println("Weight of mybox1 is " + mybox1.weight);
        System.out.println();

        vol = mybox2.volume();
        System.out.println("Volume of mybox2 is " + vol);
        System.out.println("Weight of mybox2 is " + mybox2.weight);
        System.out.println();

        vol = mybox3.volume();
        System.out.println("Volume of mybox3 is " + vol);
        System.out.println("Weight of mybox3 is " + mybox3.weight);
        System.out.println();
    }
}
```

```
        vol = myclone.volume();
        System.out.println("Volume of myclone is " + vol);
        System.out.println("Weight of myclone is " + myclone.weight);
        System.out.println();

        vol = mycube.volume();
        System.out.println("Volume of mycube is " + vol);
        System.out.println("Weight of mycube is " + mycube.weight);
        System.out.println();
    }
}
```

output:

```
Volume of mybox1 is 3000.0
Weight of mybox1 is 34.3
Volume of mybox2 is 24.0
Weight of mybox2 is 0.076
Volume of mybox3 is -1.0
Weight of mybox3 is -1.0
Volume of myclone is 3000.0
Weight of myclone is 34.3
Volume of mycube is 27.0
Weight of mycube is 2.0
```

A Second Use for super

- **super** is most applicable to situations in which member names of a subclass hide members by the same name in the superclass.

// Using super to overcome name hiding.

```
class A
{
    int i;
}
```

// Create a subclass by extending class A.

```
class B extends A
{
    int i; // this i hides the i in A

    B(int a, int b)
    {
        super.i = a; // i in A
        i = b; // i in B
    }
}
```

```
    }  
    void show()  
    {  
        System.out.println("i in superclass: " + super.i);  
        System.out.println("i in subclass: " + i);  
    }  
}  
  
class UseSuper  
{  
    public static void main(String args[])  
    {  
        B subOb = new B(1, 2);  
        subOb.show();  
    }  
}
```

This program displays the following:

i in superclass: 1

i in subclass: 2

Creating a Multilevel Hierarchy

- given three classes called **A**, **B**, and **C**, **C** can be a subclass of **B**, which is a subclass of **A**. When this type of situation occurs, each subclass inherits all of the traits found in all of its superclasses. In this case, **C** inherits all aspects of **B** and **A**.
- In it, the subclass **BoxWeight** is used as a superclass to create the subclass called **Shipment**. **Shipment** inherits all of the traits of **BoxWeight** and **Box**, and adds a field called **cost**, which holds the cost of shipping such a parcel.

```
class Box  
{  
    private double width;  
    private double height;  
    private double depth;  
  
    // construct clone of an object  
    Box(Box ob)  
    {  
        width = ob.width;  
        height = ob.height;  
        depth = ob.depth;  
    }  
  
    Box(double w, double h, double d) {  
        width = w;  
        height = h;  
    }  
}
```

```
    depth = d;
}

// constructor used when no dimensions specified
Box()
{
    width = -1; // use -1 to indicate
    height = -1; // an uninitialized
    depth = -1; // box
}

Box(double len)
{
    width = height = depth = len;
}

double volume()
{
    return width * height * depth;
}

// Add weight.
class BoxWeight extends Box
{
    double weight;

    BoxWeight(BoxWeight ob)
    {
        super(ob);
        weight = ob.weight;
    }

    BoxWeight(double w, double h, double d, double m)
    {
        super(w, h, d);
        weight = m;
    }

    BoxWeight()
    {
        super();
        weight = -1;
    }
}
```

```
BoxWeight(double len, double m)
{
    super(len);
    weight = m;
}

// Add shipping costs.
class Shipment extends BoxWeight
{
    double cost;

    Shipment(Shipment ob)
    {
        super(ob);
        cost = ob.cost;
    }

    Shipment(double w, double h, double d,double m, double c)
    {
        super(w, h, d, m); // call superclass constructor
        cost = c;
    }

    Shipment()
    {
        super();
        cost = -1;
    }

    Shipment(double len, double m, double c)
    {
        super(len, m);
        cost = c;
    }
}

class DemoShipment
{
    public static void main(String args[])
    {
        Shipment shipment1 = new Shipment(10, 20, 15, 10, 3.41);
        Shipment shipment2 = new Shipment(2, 3, 4, 0.76, 1.28);
        double vol;

        vol = shipment1.volume();
        System.out.println("Volume of shipment1 is " + vol);
    }
}
```

```
System.out.println("Weight of shipment1 is " + shipment1.weight);
System.out.println("Shipping cost: $" + shipment1.cost);
System.out.println();
```

```
vol = shipment2.volume();
System.out.println("Volume of shipment2 is " + vol);
System.out.println("Weight of shipment2 is " + shipment2.weight);
System.out.println("Shipping cost: $" + shipment2.cost);
}
```

```
}
```

output :

Volume of shipment1 is 3000.0
Weight of shipment1 is 10.0
Shipping cost: \$3.41

Volume of shipment2 is 24.0
Weight of shipment2 is 0.76
Shipping cost: \$1.28

When Constructors Are Called

- given a subclass called **B** and a superclass called **A**, is **A**'s constructor called before **B**'s, or vice versa? The answer is that in a class hierarchy, constructors are called in order of derivation, from superclass to subclass.
- Further, since **super()** must be the first statement executed in a subclass' constructor, this order is the same whether or not **super()** is used.

```
class A
{
    A() {
        System.out.println("Inside A's constructor.");
    }
}
```

```
class B extends A
{
    B() {
        System.out.println("Inside B's constructor.");
    }
}
```

```
class C extends B
{
    C() {
        System.out.println("Inside C's constructor.");
    }
}
```

```
    }  
}  
class CallingCons  
{  
    public static void main(String args[])  
    {  
        C c = new C();  
    }  
}
```

output :

Inside A's constructor
Inside B's constructor
Inside C's constructor

Method Overriding

- when a method in a subclass has the same name and type signature as a method in its superclass, then the method in the subclass is said to *override* the method in the superclass.

```
class A  
{  
    int i, j;  
    A(int a, int b)  
    {  
        i = a;  
        j = b;  
    }  
  
    // display i and j  
    void show()  
    {  
        System.out.println("i and j: " + i + " " + j);  
    }  
}  
  
class B extends A  
{  
    int k;  
    B(int a, int b, int c)  
    {  
        super(a, b);  
        k = c;  
    }  
}
```

```
        void show()
        {
            System.out.println("k: " + k);
        }
    }
    class Override
    {
        public static void main(String args[])
        {
            B subOb = new B(1, 2, 3);
            subOb.show(); // this calls show() in B
        }
    }
    output:
```

k: 3

- the version of **show()** inside **B** overrides the version declared in **A**.
- to access the superclass version of an overridden method can be called using **super**.

```
class B extends A
{
    int k;

    B(int a, int b, int c)
    {
        super(a, b);
        k = c;
    }

    void show()
    {
        super.show(); // this calls A's show()
        System.out.println("k: " + k);
    }
}
```

output:

i and j: 1 2

k: 3

Here, **super.show()** calls the superclass version of **show()**.

- Method overriding occurs *only* when the names and the type signatures of the two methods are identical. If they are not, then the two methods are simply overloaded.

```
class A
{
    int i, j;

    A(int a, int b)
    {
        i = a;
        j = b;
    }

    // display i and j
    void show()
    {
        System.out.println("i and j: " + i + " " + j);
    }
}

// Create a subclass by extending class A.

class B extends A
{
    int k;

    B(int a, int b, int c)
    {
        super(a, b);
        k = c;
    }

    // overload show()

    void show(String msg)
    {
        System.out.println(msg + k);
    }
}

class Override
{
    public static void main(String args[])
    {
        B subOb = new B(1, 2, 3);
        subOb.show("This is k: "); // this calls show() in B
    }
}
```

```
        subOb.show(); // this calls show() in A
    }
}
```

The output produced by this program is shown here:

This is k: 3

i and j: 1 2

Packages and Interfaces

- *Packages* are containers for classes that are used to keep the class name space compartmentalized.
- Through the use of the **interface** keyword, Java allows to fully abstract the interface from its implementation.
- Using **interface**, we can specify a set of methods that can be implemented by one or more classes.
- The **interface**, itself, does not actually define any implementation.
- A class can implement more than one interface.

Packages

- Java provides a mechanism for partitioning the class name space into more manageable chunks. This mechanism is the package.
- The package is both a naming and a visibility control mechanism.
- It is possible to define classes inside a package that are not accessible by code outside that package.
- We can define class members that are only exposed to other members of the same package.

Defining a Package

- To create a package ,simply include a **package** command as the first statement in a Java source file.
- Any classes declared within that file will belong to the specified package.
- The **package** statement defines a name space in which classes are stored.
- If we skip the **package** statement, the class names are put into the default package, which has no name.
- The general form of the **package** statement:
 package *pkg*;
- Here, *pkg* is the name of the package.
- For example, the following statement creates a package called **MyPackage**.
 package MyPackage;
- The general form of a multileveled package statement is shown here:
 package *pkg1*[.*pkg2*[.*pkg3*]];

Finding Packages and CLASSPATH

- How does the Java run-time system know where to look for packages that we create?
- The answer has three parts.
- First, by default, the Java run-time system uses the current working directory as its starting point.
- Second, we can specify a directory path or paths by setting the **CLASSPATH** environmental variable.
- Third, we can use the **-classpath** option with **java** and **javac** to specify the path to our classes.

A Short Package Example

```
package MyPack;
```

```
class Balance
```

```
{
    String name;
    double bal;

    Balance(String n, double b)
    {
        name = n;
        bal = b;
    }
    void show()
    {
        if(bal<0)
            System.out.print("--> ");
        System.out.println(name + ": $" + bal);
    }
}
```

```
class AccountBalance
```

```
{
    public static void main(String args[])
    {
        Balance current[] = new Balance[3];

        current[0] = new Balance("K. J. Fielding", 123.23);
        current[1] = new Balance("Will Tell", 157.02);
        current[2] = new Balance("Tom Jackson", -12.33);

        for(int i=0; i<3; i++)
            current[i].show();
    }
}
```

- Call this file **AccountBalance.java** and put it in a directory called **MyPack**.

Access Protection

- Packages add another dimension to access control.
- Classes and packages are both means of encapsulating and containing the name space and scope of variables and methods.
- Packages act as containers for classes and other subordinate packages.
- Classes act as containers for data and code.
- Java addresses four categories of visibility for class members:
 - Subclasses in the same package
 - Non-subclasses in the same package
 - Subclasses in different packages
 - Classes that are neither in the same package nor subclasses
- The three access specifiers, **private**, **public**, and **protected**, provide a variety of ways to produce the many levels of access required by these categories.
- Anything declared **public** can be accessed from anywhere.
- Anything declared **private** cannot be seen outside of its class.
- When a member does not have an explicit access specification, it is visible to subclasses as well as to other classes in the same package. This is the **default access**.
- If we want to allow an element to be seen outside our current package, but only to classes that subclass our class directly, then declare that element **protected**.

	Private	No Modifier	Protected	Public
Same class	yes	yes	yes	yes
Same package subclass	No	Yes	Yes	Yes
Same package non-subclass	No	Yes	Yes	Yes
Different package subclass	No	No	Yes	Yes
Different package non-subclass	No	No	No	Yes

An Access Example

- This has two packages and five classes.
- Remember that the classes for the two different packages need to be stored in directories named after their respective packages—in this case, **p1** and **p2**.

This is file **Protection.java**:

```
package p1;

public class Protection
{
    int n = 1;
    private int n_pri = 2;
    protected int n_pro = 3;
    public int n_pub = 4;

    public Protection()
    {
        System.out.println("base constructor");
        System.out.println("n = " + n);
        System.out.println("n_pri = " + n_pri);
        System.out.println("n_pro = " + n_pro);
        System.out.println("n_pub = " + n_pub);
    }
}
```

This is file **Derived.java**:

```
package p1;

class Derived extends Protection
{
    Derived()
    {
        System.out.println("derived constructor");
        System.out.println("n = " + n);

        // System.out.println("n_pri = " + n_pri);

        System.out.println("n_pro = " + n_pro);
        System.out.println("n_pub = " + n_pub);
    }
}
```

This is file **SamePackage.java**:

```
package p1;

class SamePackage
{
    SamePackage()
    {
        Protection p = new Protection();
        System.out.println("same package constructor");
        System.out.println("n = " + p.n);

        // System.out.println("n_pri = " + p.n_pri);

        System.out.println("n_pro = " + p.n_pro);
        System.out.println("n_pub = " + p.n_pub);
    }
}
```

- Following is the source code for the other package, **p2**.
- The first class, **Protection2**, is a subclass of **p1.Protection**. This grants access to all of **p1.Protection**'s variables except for **n_pri** (because it is **private**) and **n**, the variable declared with the default protection.
- the default only allows access from within the class or the package, not extra-package subclasses.
- the class **OtherPackage** has access to only one variable, **n_pub**, which was declared **public**.

This is file **Protection2.java**:

```
package p2;

class Protection2 extends p1.Protection
{
    Protection2()
    {
        System.out.println("derived other package constructor");

        // System.out.println("n = " + n);

        // System.out.println("n_pri = " + n_pri);

        System.out.println("n_pro = " + n_pro);
        System.out.println("n_pub = " + n_pub);
    }
}
```

```
}
```

This is file **OtherPackage.java**:

```
package p2;
```

```
class OtherPackage
```

```
{
```

```
    OtherPackage()
```

```
    {
```

```
        p1.Protection p = new p1.Protection();
        System.out.println("other package constructor");
```

```
        // System.out.println("n = " + p.n);
```

```
        // System.out.println("n_pri = " + p.n_pri);
```

```
        // System.out.println("n_pro = " + p.n_pro);
```

```
        System.out.println("n_pub = " + p.n_pub);
```

```
    }
```

```
}
```

```
. package p1;
```

```
// Instantiate the various classes in p1.
```

```
public class Demo
```

```
{
```

```
    public static void main(String args[])
```

```
    {
```

```
        Protection ob1 = new Protection();
```

```
        Derived ob2 = new Derived();
```

```
        SamePackage ob3 = new SamePackage();
```

```
    }
```

```
}
```

```
// Demo package p2.
```

```
package p2;
```

```
public class Demo
```

```
{
```

```
public static void main(String args[])
{
    Protection2 ob1 = new Protection2();
    OtherPackage ob2 = new OtherPackage();
}
}
```

Importing Packages

- the **import** statement is used to bring certain classes, or entire packages, into visibility.
- **import** statements occur immediately following the **package** statement (if it exists) and before any class definitions.
- This is the general form of the **import** statement:
import *pkg1*[.*pkg2*].(*classname*|*);
- Here, *pkg1* is the name of a top-level package, and *pkg2* is the name of a subordinate package inside the outer package separated by a dot (.).

This code fragment shows both forms in use:

```
import java.util.Date;
import java.io.*;
```

- All of the standard Java classes included with Java are stored in a package called **java**.
- The basic language functions are stored in a package inside of the **java** package called **java.lang**.

```
import java.lang.*;

import java.util.*;
class MyDate extends Date
{
}
```

```
class MyDate extends java.util.Date
{
}
```

- if you want the **Balance** class of the package **MyPack** shown earlier to be available as a stand-alone class for general use outside of **MyPack**,

```
public class Balance
{
    String name;
    double bal;

    public Balance(String n, double b)
    {
        name = n;
```

```
        bal = b;
    }
    public void show()
    {
        if(bal<0)
            System.out.print("--> ");
        System.out.println(name + ": $" + bal);
    }
}
```

- the **Balance** class is now **public**. Also, its constructor and its **show()** method are **public**, too. This means that they can be accessed by any type of code outside the **MyPack** package.
- **TestBalance** imports **MyPack** and is then able to make use of the **Balance** class:

```
import MyPack.*;
```

```
class TestBalance
{
    public static void main(String args[])
    {
        class and call its constructor. */
        Balance test = new Balance("J. J. Jaspers", 99.88);
        test.show(); // you may also call show()
    }
}
```

- Using the keyword **interface**, you can fully abstract a class' interface from its implementation.
- Once interface is defined, any number of classes can implement an **interface**.
- Also, one class can implement any number of interfaces.
- To implement an interface, a class must create the complete set of methods defined by the interface.

Defining an Interface

An interface is defined much like a class. This is the general form of an interface:

```
access interface name
{
    return-type method-name1(parameter-list);
    return-type method-name2(parameter-list);
    type final-varname1 = value;
    type final-varname2 = value;
    // ...
    return-type method-nameN(parameter-list);
    type final-varnameN = value;
}
```

- When no access specifier is included, then default access results, and the interface is only available to other members of the package in which it is declared.
- When it is declared as **public**, the interface can be used by any other code.
- the methods that are declared have no bodies. They end with a semicolon after the parameter list.
- They are abstract methods; there can be no default implementation of any method specified within an interface.
- Each class that includes an interface must implement all of the methods.
- Variables can be declared inside of interface declarations. They are implicitly **final** and **static**, meaning they cannot be changed by the implementing class. They must also be initialized.
- All methods and variables are implicitly **public**.
- Here is an example of a simple interface that contains one method called **callback()** that takes a single integer parameter.

```
interface Callback
{
    void callback(int param);
}
```

Implementing Interfaces

- Once an **interface** has been defined, one or more classes can implement that interface.
- To implement an interface, include the **implements** clause in a class definition, and then create the methods defined by the interface.
- The general form of a class that includes the **implements** clause:

```
class classname [extends superclass] [implements interface [,interface...]]
{
    // class-body
}
```

- If a class implements more than one interface, the interfaces are separated with a comma.
- If a class implements two interfaces that declare the same method, then the same method will be used by clients of either interface.
- The methods that implement an interface must be declared **public**.
- the type signature of the implementing method must match exactly the type signature specified in the **interface** definition.
- Here is a small example class that implements the **Callback** interface shown earlier.

```
class Client implements Callback
{
    // Implement Callback's interface
}
```

```
public void callback(int p)
{
    System.out.println("callback called with " + p);
}
}
```

- Notice that **callback()** is declared using the **public** access specifier.
- It is both permissible and common for classes that implement interfaces to define additional members of their own.
- For example, the following version of **Client** implements **callback()** and adds the method **nonIfaceMeth()**:

```
class Client implements Callback
{
    // Implement Callback's interface

    public void callback(int p)
    {
        System.out.println("callback called with " + p);
    }
    void nonIfaceMeth()
    {
        System.out.println("Classes that implement interfaces " + "may also define other
members, too.");
    }
}
```

Accessing Implementations Through Interface References

- we can declare variables as object references that use an interface rather than a class type.
- Any instance of any class that implements the declared interface can be referred to by such a variable.
- When we call a method through one of these references, the correct version will be called based on the actual instance of the interface being referred to

The following example calls the **callback()** method via an interface reference variable:

```
class TestIface
{
    public static void main(String args[])
    {
        Callback c = new Client();
        c.callback(42);
    }
}
```

output :

callback called with 42

- variable **c** is declared to be of the interface type **Callback**, yet it was assigned an instance of **Client**.
- Although **c** can be used to access the **callback()** method, it cannot access any other members of the **Client** class.
- **c** could not be used to access **nonIfaceMeth()** since it is defined by **Client** but not **Callback**.

the second implementation of **Callback**, shown here to show the polymorphic behavior:

// Another implementation of Callback.

```
class AnotherClient implements Callback
```

```
{
    public void callback(int p)
    {
        System.out.println("Another version of callback");
        System.out.println("p squared is " + (p*p));
    }
}
```

```
class TestIface2
```

```
{
    public static void main(String args[])
    {
        Callback c = new Client();
        AnotherClient ob = new AnotherClient();
        c.callback(42);
        c = ob; // c now refers to AnotherClient object
        c.callback(42);
    }
}
```

output:

callback called with 42

Another version of callback

p squared is 1764

the version of **callback()** that is called is determined by the type of object that **c** refers to at run time.

Partial Implementations

- If a class includes an interface but does not fully implement the methods defined by that interface, then that class must be declared as **abstract**.

- For example:

```
abstract class Incomplete implements Callback
{
    int a, b;
    void show()
    {
        System.out.println(a + " " + b);
    }
    // ...
}
```

- the class **Incomplete** does not implement **callback()** and must be declared as abstract.
- Any class that inherits **Incomplete** must implement **callback()** or be declared **abstract** itself.

Nested Interfaces

- An interface can be declared a member of a class or another interface. Such an interface is called a *member interface* or a *nested interface*.
- A nested interface can be declared as **public**, **private**, or **protected**. This differs from a top-level interface, which must either be declared as **public** or use the default access level,

```
class A
{
    // this is a nested interface
    public interface NestedIF
    {
        boolean isNotNegative(int x);
    }
}
```

```
class B implements A.NestedIF
{
    public boolean isNotNegative(int x)
    {
        return x < 0 ? false : true;
    }
}
```

```
class NestedIFDemo
{
    public static void main(String args[])
    {
    }
```

```
{
    A.NestedIF nif = new B();

    if(nif.isNotNegative(10))
        System.out.println("10 is not negative");
    if(nif.isNotNegative(-12))
        System.out.println("this won't be displayed");
}
```

- **A** defines a member interface called **NestedIF** and that it is declared **public**.
- **B** implements the nested interface by specifying implements A.NestedIF

Applying Interfaces

- a class called **Stack** that implemented a simple fixed-size stack.
- the methods **push()** and **pop()** define the interface to the stack independently of the details of the implementation.
- First, here is the interface that defines an integer stack. Put this in a file called **IntStack.java**.

This interface will be used by both stack implementations.

```
interface IntStack
{
    void push(int item);
    int pop();
}
```

- The following program creates a class called **FixedStack** that implements a fixed-length version of an integer stack:

// An implementation of IntStack that uses fixed storage.

class FixedStack implements IntStack

```
{
    private int stck[];
    private int tos;

    FixedStack(int size)
    {
        stck = new int[size];
        tos = -1;
    }

    public void push(int item)
    {
```

```
        if(tos==stck.length-1) // use length member
            System.out.println("Stack is full.");
        else
            stck[++tos] = item;
    }

    public int pop()
    {
        if(tos < 0)
        {
            System.out.println("Stack underflow.");
            return 0;
        }
        else
            return stck[tos--];
    }
}
```

```
class IFTest
{
    public static void main(String args[])
    {
        FixedStack mystack1 = new FixedStack(5);
        FixedStack mystack2 = new FixedStack(8);

        for(int i=0; i<5; i++)
            mystack1.push(i);

        for(int i=0; i<8; i++)
            mystack2.push(i);

        System.out.println("Stack in mystack1:");
        for(int i=0; i<5; i++)
            System.out.println(mystack1.pop());

        System.out.println("Stack in mystack2:");
        for(int i=0; i<8; i++)
            System.out.println(mystack2.pop());
    }
}
```

- another implementation of **IntStack** that creates a dynamic stack by use of the same **interface** definition.

```
class DynStack implements IntStack
{
```

```
private int stck[];
private int tos;

DynStack(int size)
{
    stck = new int[size];
    tos = -1;
}
// Push an item onto the stack
public void push(int item)
{
    if(tos==stck.length-1)
    {
        int temp[] = new int[stck.length * 2];
        // double size
        for(int i=0; i<stck.length; i++)
            temp[i] = stck[i];
        stck = temp;
        stck[++tos] = item;
    }
    else
        stck[++tos] = item;
}

public int pop()
{
    if(tos < 0)
    {
        System.out.println("Stack underflow.");
        return 0;
    }
    else
        return stck[tos--];
}
}
class IFTest2
{
    public static void main(String args[])
    {
        DynStack mystack1 = new DynStack(5);
        DynStack mystack2 = new DynStack(8);

        for(int i=0; i<12; i++) mystack1.push(i);
        for(int i=0; i<20; i++) mystack2.push(i);
    }
}
```

```
System.out.println("Stack in mystack1:");
for(int i=0; i<12; i++)
    System.out.println(mystack1.pop());

System.out.println("Stack in mystack2:");
for(int i=0; i<20; i++)
    System.out.println(mystack2.pop());
}
```

- The following class uses both the **FixedStack** and **DynStack** implementations. It does so through an interface reference. This means that calls to **push()** and **pop()** are resolved at run time rather than at compile time.

class IFTest3

```
{
    public static void main(String args[])
    {
        IntStack mystack; // create an interface reference variable
        DynStack ds = new DynStack(5);
        FixedStack fs = new FixedStack(8);

        mystack = ds; // load dynamic stack
        // push some numbers onto the stack
        for(int i=0; i<12; i++) mystack.push(i);
        mystack = fs; // load fixed stack

        for(int i=0; i<8; i++) mystack.push(i);
        mystack = ds;
        System.out.println("Values in dynamic stack:");

        for(int i=0; i<12; i++)
            System.out.println(mystack.pop());

        mystack = fs;
        System.out.println("Values in fixed stack:");

        for(int i=0; i<8; i++)
            System.out.println(mystack.pop());
    }
}
```

- **mystack** is a reference to the **IntStack** interface. Thus, when it refers to **ds**, it uses the versions of **push()** and **pop()** defined by the **DynStack** implementation.
- When it refers to **fs**, it uses the versions of **push()** and **pop()** defined by **FixedStack**.
- Accessing multiple implementations of an interface through an interface reference variable is the most powerful way that Java achieves run-time polymorphism.

Variables in Interfaces

- we can use interfaces to import shared constants into multiple classes by simply declaring an interface that contains variables that are initialized to the desired values.

```
import java.util.Random;
```

```
interface SharedConstants
```

```
{  
    int NO = 0;  
    int YES = 1;  
    int MAYBE = 2;  
    int LATER = 3;  
    int SOON = 4;  
    int NEVER = 5;  
}
```

```
class Question implements SharedConstants
```

```
{  
    Random rand = new Random();  
    int ask()  
    {  
        int prob = (int) (100 * rand.nextDouble());  
  
        if (prob < 30)  
            return NO;  
        else if (prob < 60)  
            return YES;  
        else if (prob < 75)  
            return LATER;  
        else if (prob < 98)  
            return SOON;  
        else  
            return NEVER;  
    }  
}
```

```
}  
class AskMe implements SharedConstants
```

```
{  
    static void answer(int result)  
    {  
        switch(result)  
        {  
            case NO:  
                System.out.println("No");  
                break;  
            case YES:  
                System.out.println("Yes");  
        }  
    }  
}
```

```
        break;
    case MAYBE:
        System.out.println("Maybe");
        break;
    case LATER:
        System.out.println("Later");
        break;
    case SOON:
        System.out.println("Soon");
        break;
    case NEVER:
        System.out.println("Never");
        break;
    }
}

public static void main(String args[])
{
    Question q = new Question();
    answer(q.ask());
    answer(q.ask());
    answer(q.ask());
    answer(q.ask());
}
}
```

Note that the results are different each time it is run.

Later
Soon
No
Yes

Interfaces Can Be Extended

- One interface can inherit another by use of the keyword **extends**.
- The syntax is the same as for inheriting classes

```
interface A
{
    void meth1();
    void meth2();
}
```

```
interface B extends A
{
    void meth3();
}
```

```
}  
  
class MyClass implements B  
{  
    public void meth1()  
    {  
        System.out.println("Implement meth1().");  
    }  
  
    public void meth2()  
    {  
        System.out.println("Implement meth2().");  
    }  
    public void meth3()  
    {  
        System.out.println("Implement meth3().");  
    }  
}  
class IFExtend  
{  
    public static void main(String arg[])  
    {  
        MyClass ob = new MyClass();  
        ob.meth1();  
        ob.meth2();  
        ob.meth3();  
    }  
}
```

- any class that implements an interface must implement all methods defined by that interface, including any that are inherited from other interfaces.

Exception Handling

- an exception is a run-time error.
- languages that do not support exception handling, errors must be checked and handled manually—typically through the use of error codes, and so on.
- Java's exception handling avoids handling problems manually and, in the process, brings run-time error management into the object oriented world.

Exception-Handling Fundamentals

- A Java exception is an object that describes an exceptional (that is, error) condition that has occurred in a piece of code.
- When an exceptional condition arises, an object representing that exception is created and *thrown* in the method that caused the error.
- That method may choose to handle the exception itself, or pass it on.
- Either way, at some point, the exception is *caught* and processed.
- Exceptions can be generated by the Java run-time system,
- or they can be manually generated by your code.
- Java exception handling is managed via five keywords: **try**, **catch**, **throw**, **throws**, and **finally**.
- Briefly, here is how they work. Program statements that create exceptions are contained within a **try** block.
- If an exception occurs within the **try** block, it is thrown. we can catch this exception (using **catch**) and handle it .
- System-generated exceptions are automatically thrown by the Java run-time system.
- To manually throw an exception, use the keyword **throw**.
- Any exception that is thrown out of a method must be specified as such by a **throws** clause.
- Any code that absolutely must be executed after a **try** block completes is put in a **finally** block.

This is the general form of an exception-handling block:

```
try {  
    // block of code to monitor for errors  
}  
catch (ExceptionType1 exOb) {  
    // exception handler for ExceptionType1  
}  
catch (ExceptionType2 exOb) {  
    // exception handler for ExceptionType2  
}  
// ...  
finally {  
    // block of code to be executed after try block ends
```

```
}
```

- Here, *ExceptionType* is the type of exception that has occurred.

Exception Types

- All exception types are subclasses of the built-in class **Throwable**. Thus, **Throwable** is at the top of the exception class hierarchy.
- Immediately below **Throwable** are two subclasses that partition exceptions into two distinct branches.
- One branch is headed by **Exception**. This class is used for exceptional conditions that user programs should catch.
- There is an important subclass of **Exception**, called **RuntimeException**. Exceptions of this type are automatically defined for the programs that you write and include things such as division by zero and invalid array indexing.
- The other branch is topped by **Error**, which defines exceptions that are not expected to be caught under normal circumstances by your program.
- Exceptions of type **Error** are used by the Java run-time system to indicate errors having to do with the run-time environment, itself. Stack overflow is an example of such an error

Uncaught Exceptions

. This program includes an expression that intentionally causes a divide-by-zero error:

```
class Exc0
```

```
{  
    public static void main(String args[])  
    {  
        int d = 0;  
        int a = 42 / d;  
    }  
}
```

- When the Java run-time system detects the attempt to divide by zero, it constructs a new exception object and then *throws* this exception.
- This causes the execution of **Exc0** to stop, because once an exception has been thrown, it must be *caught* by an exception handler and dealt with immediately.
- Here we don't have any exception handlers of our own, so the exception is caught by the default handler provided by the Java run-time system.
- Any exception that is not caught by our program will ultimately be processed by the default handler.
- The default handler displays a string describing the exception, prints a stack trace from the point at which the exception occurred, and terminates the program.
- Here is the exception generated when this example is executed:
java.lang.ArithmeticException: / by zero at Exc0.main(Exc0.java:4)

Using try and catch

- Although the default exception handler provided by the Java run-time system is useful for

debugging, we should handle an exception ourself.

- Doing so provides two benefits.
- First, it allows you to fix the error.
- Second, it prevents the program from automatically terminating.
- To handle a run-time error, simply enclose the code inside a **try** block.
- Immediately following the **try** block, include a **catch** clause that specifies the exception type to catch

```
class Exc2
```

```
{  
    public static void main(String args[])  
    {  
        int d, a;  
  
        try  
        {  
            d = 0;  
            a = 42 / d;  
            System.out.println("This will not be printed.");  
        }  
        catch (ArithmeticException e)  
        {  
            System.out.println("Division by zero.");  
        }  
        System.out.println("After catch statement.");  
    }  
}
```

This program generates the following output:

Division by zero.

After catch statement.

- A **try** and its **catch** statement form a unit.
- The scope of the **catch** clause is restricted to those statements specified by the immediately preceding **try** statement.
- A **catch** statement cannot catch an exception thrown by another **try** statement.

```
class HandleError
```

```
{  
    public static void main(String args[])  
    {  
        int a=0, b=0, c=0;  
        Random r = new Random();  
  
        for(int i=0; i<32000; i++)  
        {  
            try
```

```
        {
            b = r.nextInt();
            c = r.nextInt();
            a = 12345 / (b/c);
        }
        catch (ArithmeticException e)
        {
            System.out.println("Division by zero.");
            a = 0; // set a to zero and continue
        }
        System.out.println("a: " + a);
    }
}
```

Multiple catch Clauses

- more than one exception could be raised by a single piece of code.
- To handle this type of situation, we can specify two or more **catch** clauses, each catching a different type of exception.
- When an exception is thrown, each **catch** statement is inspected in order, and the first one whose type matches that of the exception is executed.

The following example traps two different exception types:

// Demonstrate multiple catch statements.

```
class MultiCatch
{
    public static void main(String args[])
    {
        try
        {
            int a = args.length;
            System.out.println("a = " + a);
            int b = 42 / a;
            int c[] = { 1 };
            c[42] = 99;
        }
        catch(ArithmeticException e)
        {
            System.out.println("Divide by 0: " + e);
        }
        catch(ArrayIndexOutOfBoundsException e)
        {
            System.out.println("Array index oob: " + e);
        }
    }
}
```

```
    }  
    System.out.println("After try/catch blocks.");  
    }  
}
```

output:

```
C:\>java MultiCatch  
a = 0  
Divide by 0: java.lang.ArithmeticException: / by zero  
After try/catch blocks.  
C:\>java MultiCatch TestArg  
a = 1  
Array index oob: java.lang.ArrayIndexOutOfBoundsException:42  
After try/catch blocks.
```

class SuperSubCatch

```
{  
    public static void main(String args[])  
    {  
        try  
        {  
            int a = 0;  
            int b = 42 / a;  
        }  
        catch(Exception e)  
        {  
            System.out.println("Generic Exception catch.");  
        }  
  
        catch(ArithmeticException e)  
        {  
            System.out.println("This is never reached.");  
        }  
    }  
}
```

- If this program is compiled , we will receive an error message stating that the second **catch** statement is unreachable because the exception has already been caught.
- Since **ArithmeticException** is a subclass of **Exception**, the first **catch** statement will handle all **Exception**-based errors, including **ArithmeticException**.
- This means that the second **catch** statement will never execute. To fix the problem, reverse the order of the **catch** statements.

Nested try Statements

- The **try** statement can be nested. That is, a **try** statement can be inside the block of another **try**.

```
class NestTry
{
    public static void main(String args[])
    {
        try
        {
            int a = args.length;
            int b = 42 / a;
            System.out.println("a = " + a);
            try
            {
                if(a==1) a = a/(a-a);
                if(a==2)
                {
                    int c[] = { 1 };
                    c[42] = 99; // generate an out-of-bounds exception
                }
            }
            catch(ArrayIndexOutOfBoundsException e)
            {
                System.out.println("Array index out-of-bounds: " + e);
            }
        }
        catch(ArithmeticException e)
        {
            System.out.println("Divide by 0: " + e);
        }
    }
}
```

- When we execute the program with no command-line arguments, a divide-by-zero exception is generated by the outer **try** block.
- Execution of the program with one command-line argument generates a divide-by-zero exception from within the nested **try** block.
- Since the inner block does not catch this exception, it is passed on to the outer **try** block, where it is handled.
- If we execute the program with two command-line arguments, an array boundary exception is generated from within the inner **try** block.

```
C:\>java NestTry
Divide by 0: java.lang.ArithmeticException: / by zero
C:\>java NestTry One
a = 1
Divide by 0: java.lang.ArithmeticException: / by zero
C:\>java NestTry One Two
a = 2
Array index out-of-bounds:
```

java.lang.ArrayIndexOutOfBoundsException:42

throw

- it is possible for your program to throw an exception explicitly, using the **throw** statement.
- The general form of **throw** is shown here:
 throw ThrowableInstance;
- Here, *ThrowableInstance* must be an object of type **Throwable** or a subclass of **Throwable**.
- Primitive types, such as **int** or **char**, as well as non-**Throwable** classes, such as **String** and **Object**, cannot be used as exceptions.

class ThrowDemo

```
{
    static void demoproc()
    {
        try
        {
            throw new NullPointerException("demo");
        }
        catch(NullPointerException e)
        {
            System.out.println("Caught inside demoproc.");
            throw e; // rethrow the exception
        }
    }
    public static void main(String args[])
    {
        try
        {
            demoproc();
        }
        catch(NullPointerException e)
        {
            System.out.println("Recaught: " + e);
        }
    }
}
```

- First, **main()** sets up an exception context and then calls **demoproc()**.
- The **demoproc()** method then sets up another exceptionhandling context and immediately throws a new instance of **NullPointerException**, which is caught on the next line.
- The exception is then rethrown.
- Here is the resulting output:
Caught inside demoproc.

Recaught: java.lang.NullPointerException: demo

throws

• If a method is capable of causing an exception that it does not handle, it must specify this behavior so that callers of the method can guard themselves against that exception.

- We can do this by including a **throws** clause in the method's declaration.
- A **throws** clause lists the types of exceptions that a method might throw

- This is the general form of a method declaration that includes a **throws** clause:

```
type method-name(parameter-list) throws exception-list
{
    // body of method
}
```

class ThrowsDemo

```
{
    static void throwOne() throws IllegalAccessException
    {
        System.out.println("Inside throwOne.");
        throw new IllegalAccessException("demo");
    }
    public static void main(String args[])
    {
        try
        {
            throwOne();
        }
        catch (IllegalAccessException e)
        {
            System.out.println("Caught " + e);
        }
    }
}
```

Here is the output generated by running this example program:

inside throwOne

caught java.lang.IllegalAccessException: demo

finally

- **finally** creates a block of code that will be executed after a **try/catch** block has completed and before the code following the **try/catch** block.
- The **finally** block will execute whether or not an exception is thrown.
- If an exception is thrown, the **finally** block will execute even if no **catch** statement matches the exception

class FinallyDemo

```
{
    static void procA()
```

```
{
    try {
        System.out.println("inside procA");
        throw new RuntimeException("demo");
    }
    Finally
    {
        System.out.println("procA's finally");
    }
}

static void procB()
{
    try {
        System.out.println("inside procB");
        return;
    }
    finally {
        System.out.println("procB's finally");
    }
}

static void procC()
{
    try
    {
        System.out.println("inside procC");
    }
    Finally
    {
        System.out.println("procC's finally");
    }
}

public static void main(String args[])
{
    try
    {
        procA();
    }
    catch (Exception e)
    {
        System.out.println("Exception caught");
    }
    procB();
    procC();
}
```

}

- Here is the output generated by the preceding program:

```
inside procA
procA's finally
Exception caught
inside procB
procB's finally
inside procC
procC's finally
```

Java's Built-in Exceptions

- Inside the standard package **java.lang**, Java defines several exception classes.
- The most general of these exceptions are subclasses of the standard type **RuntimeException**
- if the method can generate one of these exceptions and does not handle it itself. These are called *checked exceptions*.

Java's Unchecked RuntimeException Subclasses Defined in java.lang

Exception Meaning

Exception	Meaning
ArithmeticException	Arithmetic error, such as divide-by-zero.
ArrayIndexOutOfBoundsException	Array index is out-of-bounds.
ArrayStoreException	Assignment to an array element of an incompatible type.
ClassCastException	Invalid cast.
EnumConstantNotPresentException	An attempt is made to use an undefined enumeration value.
IllegalArgumentException	Illegal argument used to invoke a method.
IllegalMonitorStateException	Illegal monitor operation, such as waiting on an unlocked thread.
IllegalStateException	Environment or application is in incorrect state.
NullPointerException	Invalid use of a null reference.

- Java's Checked Exceptions Defined in java.lang

ClassNotFoundException	Class not found.
CloneNotSupportedException	Attempt to clone an object that does not implement the Cloneable interface.
IllegalAccessException	Access to a class is denied.
InstantiationException	Attempt to create an object of an abstract class or interface.

InterruptedException	One thread has been interrupted by another thread.
NoSuchFieldException	A requested field does not exist.
NoSuchMethodException	A requested method does not exist.

Creating Your Own Exception Subclasses

- It is possible to create our own exception types to handle situations specific to your applications.
- just define a subclass of **Exception**
- Your subclasses don't need to actually implement anything—it is their existence in the type system that allows you to use them as exceptions.
- The **Exception** class does not define any methods of its own. It does, of course, inherit those methods provided by **Throwable**.
- Thus, all exceptions, including those that we create, have the methods defined by **Throwable** available to them.

Method	Description
Throwable fillInStackTrace()	Returns a Throwable object that contains a completed stack trace
Throwable getCause()	Returns the exception that underlies the current exception. If there is no underlying exception, null is returned.
String getLocalizedMessage()	Returns a localized description of the exception.
String getMessage()	Returns a description of the exception.
StackTraceElement[] getStackTrace()	Returns an array that contains the stack trace, one element at a time, as an array of

Chained Exceptions

- The chained exception feature allows you to associate another exception with an exception.
- This second exception describes the cause of the first exception.
- For example, imagine a situation in which a method throws an **ArithmeticException** because of an attempt to divide by zero.
- However, the actual cause of the problem was that an I/O error occurred, which caused the divisor to be set improperly.
- To allow chained exceptions, two constructors and two methods were added to **Throwable**.

The constructors are shown here:

Throwable(Throwable *causeExc*)

Throwable(String *msg*, Throwable *causeExc*)

- These two constructors have also been added to the **Error**, **Exception**, and **RuntimeException** classes.
- The chained exception methods added to **Throwable** are **getCause()** and **initCause()**.
- These methods are shown

Throwable getCause()

Throwable initCause(Throwable *causeExc*)

- The **getCause()** method returns the exception that underlies the current exception. If there is no underlying exception, **null** is returned.
- The **initCause()** method associates *causeExc* with the invoking exception and returns a reference to the exception.

class ChainExcDemo

```
{
    static void demoproc()
    {
        // create an exception
        NullPointerException e =
        new NullPointerException("top layer");
        // add a cause
        e.initCause(new ArithmeticException("cause"));
        throw e;
    }
    public static void main(String args[])
    {
        try
        {
            demoproc();
        }
        catch(NullPointerException e)
        {
            // display top level exception
            System.out.println("Caught: " + e);
            // display cause exception
            System.out.println("Original cause: " +
            e.getCause());
        }
    }
}
```

The output from the program is shown here:

Caught: java.lang.NullPointerException: top layer

Original cause: java.lang.ArithmeticException: cause

- In this example, the top-level exception is **NullPointerException**.
- To it is added a cause exception, **ArithmeticException**. When the exception is thrown out of **demoproc()**, it is caught by **main()**.
- There, the top-level exception is displayed, followed by the underlying exception, which is obtained by calling **getCause()**.
