Feature maps from the final convolution layer are reduced using:

$$g_k = \frac{1}{HWD} \sum_{i,j,l} A_{i,j,l}^{(k)}$$

producing a compact feature vector[1, 5].

E. Fully Connected and Output Layer

The dense layer computes:

$h = ReLU(W_h g + b_h)$

The softmax layer outputs class probabilities[8]:

Vol. 14, Issue 06, ACSCON - 2026

$$P(y = c \mid X) = \frac{e^{z_c}}{\sum_{i=1}^{3} e^{z_i}}$$

F. Loss Function

Categorical cross-entropy is used[8]:

$$\mathcal{L} = -\sum_{c=1}^{3} y_c \log(P(y = c \mid X))$$

G. 3D Grad-CAM Explainability

Importance weight for feature map k:

$$\alpha_k = \frac{1}{HWD} \sum_{i,j,l} \frac{\partial y^c}{\partial A_{i,j,l}^{(k)}}$$

The 3D heatmap is generated as:

$$L^c = ReLU(\sum_{k} \alpha_k A^{(k)})$$

This map is upsampled and overlaid on the MRI to highlight disease-relevant regions[7, 18].

VIII. RESULTS AND DISCUSSION

The proposed 3D-CNN model was evaluated on the ADNI dataset using subject-wise 5-fold cross-validation[9, 13, 24]. After preprocessing, the data were structured into three classes: Normal Control (NC), Mild Cognitive Impairment (MCI), and Alzheimer's Disease (AD).The model achieved a classification accuracy of **~90%**, demonstrating strong discrimination between NC, MCI, and AD[1, 5, 6]. Precision and recall values remained consistently high across all folds, with AD showing the best performance due to the pronounced structural changes in advanced stages. MCI was moderately challenging, reflecting its subtle brain atrophy patterns.

The confusion matrix showed minimal misclassification between NC and AD, while most errors occurred between MCI and AD, which is expected because their structural changes overlap[6, 14]. Volumetric explainability using **3D Grad-CAM** revealed high-activation regions in the hippocampus, temporal lobes, entorhinal cortex, and ventricular areas — all known biomarkers of dementia[7, 18]. These visualizations confirm that the model focuses on clinically relevant structures. Overall, the experimental results highlight the effectiveness of combining 3D-CNN volumetric learning with explainable heatmaps to improve both performance and clinical trust.

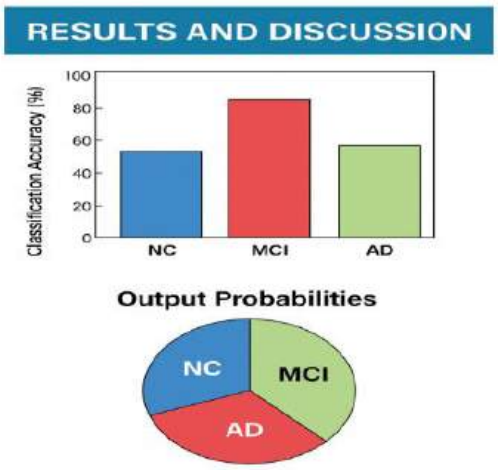

Fig.5 Experimental results illustrating class-wise accuracy and model-generated probability distribution.

IX. CONCLUSION

This study presented an explainable 3D-CNN framework for early dementia classification using structural MRI scans[7, 18, 21]. The model processes whole-brain volumes, performs multi-class classification, and generates clinically meaningful 3D Grad-CAM heatmaps[7, 18]. The results demonstrate that the proposed model achieves high accuracy while maintaining interpretability — a critical factor for medical adoption. The highlighted brain regions align with well-established dementia biomarkers, reinforcing the model's reliability[2, 6, 12]. Thus, the proposed system provides a balanced solution combining diagnostic performance with transparency, making it a valuable approach for assisting clinicians in early dementia screening.

X. FUTURE WORK

Although the proposed 3D-CNN model demonstrates strong performance and interpretability, several promising directions can further enhance the system in future research:

Multi-Modal Data Integration

Future work can incorporate additional neuroimaging and clinical modalities such as PET scans, DTI, fMRI, CSF biomarkers, and cognitive scores (MMSE, MoCA)[11, 22]. Combining imaging with clinical data can improve early-stage detection, especially for MCI.

Advanced Deep-Learning Architectures

Transformers, Swin-Transformers, and hybrid CNN–Transformer models can be explored to capture long-range spatial dependencies in MRI volumes[25]. These models may enhance feature learning for subtle dementia-related structural changes.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Longitudinal and Predictive Modeling

The ADNI dataset includes multiple follow-up scans. Future studies can analyze progression over time using temporal models such as 3D CNN + LSTM, 4D CNNs, or attention-based time-series networks to predict MCI-to-AD conversion[22].

Federated and Privacy-Preserving Learning

To enable hospital-level deployment while protecting patient privacy, federated learning frameworks can be adopted. These approaches allow model training across multiple institutions without sharing raw MRI data[23].

Enhanced Explainability Methods

While 3D Grad-CAM provides valuable insights, future work could incorporate additional explainability techniques such as Integrated Gradients, Layer-wise Relevance Propagation (LRP), and SHAP for voxel-level contribution analysis[21].

Dataset Expansion and Class Balancing

Larger, multi-centre datasets—including OASIS, AIBL, or MIRIAD—can improve generalization. Synthetic MRI generation using GANs or diffusion models could also help balance the NC, MCI, and AD classes[25].

Real-World Clinical Deployment

To translate this system into clinical use, a user-friendly interface, integration with PACS systems, and rigorous prospective testing on real hospital data are essential. This would validate performance in practical diagnostic environments.

Lightweight and Deployable Models

Future work may focus on optimizing the model using pruning, quantization, or knowledge distillation to enable deployment on edge devices or low-resource hospital systems[25].

***Abstract*—The growing demand for comfortable, accessible, and hygienic health-monitoring solutions has accelerated interest in technologies that can assess vital signs without requiring physical contact. As telemedicine, remote care, and personalized health tracking become increasingly common, conventional tools like ECG electrodes, pulse oximeters, and respiratory belts—though highly accurate—often limit long-term usability due to discomfort, skin irritation, or the need for trained personnel. Recent advances in computer vision and embedded computing now make it possible to extract meaningful physiological information using only video data, opening new pathways for low-cost and widely deployable monitoring systems. Building on this shift, the present work explores the potential of combining remote photoplethysmography (rPPG) and optical-flow analysis to measure essential parameters such as heart rate, respiratory rate, and heart rate variability entirely through camera-based observation**

INTRODUCTION

The monitoring of vital signs such as heart rate, respiratory rate, and heart rate variability (HRV) is central to evaluating human health, diagnosing physiological abnormalities, and tracking stress levels. Traditionally, these measurements rely on contact-based sensors like ECG electrodes, pulse oximeters, and respiratory belts, which although accurate can be uncomfortable, restrictive, and unsuitable for long-term or continuous monitoring. In recent years, advancements in computer vision and optical sensing have enabled non-contact vital sign monitoring, allowing physiological parameters to be extracted using only standard cameras. This contactless approach is especially useful in telemedicine, neonatal care, elderly monitoring, infectious disease wards, and remote healthcare environments where hygiene, comfort, and accessibility are important considerations.

Remote photoplethysmography (rPPG) and computer vision-based motion analysis have emerged as promising techniques in this domain. rPPG detects subtle variations in facial skin color caused by blood volume pulsations, enabling heart rate estimation without physical sensors. Similarly, respiratory rate can be inferred through optical-flow analysis of chest movements captured in video frames. However, practical implementation of such systems faces challenges arising from lighting variation, facial orientation, motion artifacts, and camera noise, all of which can significantly degrade measurement accuracy. To overcome these limitations, robust signal processing techniques are required, including bandpass filtering, chrominance-based signal extraction, proper region-of-interest detection, peak analysis, and motion stabilization.

This project, titled “Smart rPPG and Optical-Flow Based Remote Vital Signs Monitoring System” aims to develop a complete, real-time, camera-based vital sign monitoring system on a Raspberry Pi platform. The system extracts heart rate, respiratory rate, and HRV metrics using chrominance rPPG and optical-flow methods, while also incorporating advanced smoothing, jump-limiting, and motion disturbance detection to ensure stable readings. A unique feature of this work is the integrated confidence scoring module, which evaluates the reliability of measurements by analyzing factors such as face quality, lighting conditions, motion stability, and signal quality.

By combining affordability, non-contact sensing, real-time processing, and measurement validation, the project demonstrates the potential of low-cost embedded hardware to deliver meaningful health insights suitable for screening, wellness monitoring, and future applications in digital and remote healthcare.

I. BACKGROUND

Vital sign monitoring is an essential component of healthcare

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

diagnostics, continuous patient monitoring, and preventive health assessment. Parameters such as heart rate, respiratory rate, and heart rate variability (HRV) are widely used as indicators of cardiovascular health, autonomic nervous system activity, metabolic function, and psychological stress levels. Conventionally, these physiological parameters are measured using contact-based sensors such as electrocardiograms (ECG), pulse oximeters, chest belts, and wearable devices. Although clinically reliable, these methods require physical attachment to the skin, regular maintenance, proper positioning of electrodes, and may cause discomfort during long-term usage. For certain groups—such as infants, elderly individuals, burn patients, trauma victims, and unconscious individuals—contact-based instruments can be impractical or even unsafe. Additionally, in high-risk environments like infectious disease isolation wards, excessive physical contact increases contamination risk, making non-contact alternatives highly desirable.

With the rapid advancement of computer vision, optics, and embedded image processing, non- contact vital-sign monitoring has emerged as a promising alternative. One of the most significant developments in this domain is remote photoplethysmography (rPPG), a technique that analyzes subtle color variations in human skin that correspond to the pulsatile flow of blood. These variations, invisible to the naked eye, can be captured by an ordinary RGB camera and transformed into meaningful physiological signals using signal processing algorithms. Similarly, respiratory activity can be extracted by tracking periodic chest movements using optical flow, a method that computes pixel-level motion between successive video frames. These innovations have significantly reduced the dependency on traditional clinical devices and opened the possibility of affordable, contact-free monitoring solutions suitable for homes, public spaces, remote clinics, and mobile health systems.

Despite these advancements, practical implementations of rPPG-based vital sign measurement face several challenges. Variations in ambient lighting, skin tone, head movement, facial orientation, camera quality, and background noise can severely impact the accuracy and stability of extracted physiological signals. Real-world scenarios introduce unpredictable conditions such as motion artifacts and fluctuating illumination, making robust filtering and stability mechanisms essential. Furthermore, HRV analysis requires precise detection of beat-to-beat interval changes, which is significantly more sensitive to noise than average heart rate detection

II. EXISTING METHODS

Existing methods for physiological monitoring have traditionally relied on contact-based biomedical sensors, which remain the gold standard in clinical practice due to their accuracy and robustness. Technologies such as electrocardiography (ECG) measure cardiac electrical activity directly from the chest using conductive electrodes, while pulse oximeters use photoplethysmography to estimate heart rate and oxygen saturation from the fingertip or earlobe. Similarly, respiratory belts and impedance pneumography measure chest expansion or thoracic impedance to monitor breathing. Although precise, these systems require proper sensor placement, regular calibration, and physical contact with the patient, which may be uncomfortable during prolonged use and unsuitable for sensitive groups like neonates, elderly individuals, burn victims, or patients in infectious environments. Non-contact approaches have emerged as attractive alternatives, particularly remote photoplethysmography (rPPG), which detects subtle color variations in facial skin corresponding to blood volume pulses using standard RGB cameras. Multiple algorithms, including ICA, PCA, and the POS method, have been explored to isolate cardiac pulses from video. Additionally, respiration has been estimated by tracking chest movements using optical-flow-based approaches. However, these methods often struggle under real-world conditions involving motion, varying illumination, facial occlusions, or camera noise. Some commercial systems address these issues using multi-spectral or infrared cameras, but these are expensive and inaccessible for widespread use. Embedded rPPG solutions on platforms like Raspberry Pi are still limited, frequently unstable, and lack advanced features such as HRV analysis, motion detection, confidence scoring, and continuous smoothing. These limitations demonstrate the need for a more reliable, stable, and low-cost integrated system capable of delivering accurate, non-contact vital sign monitoring.

III METHODOLODY

The overall methodology of this project is centred around a carefully designed, real-time camera- based processing pipeline capable of extracting multiple vital signs without any physical contact. Figure 4.1 illustrates the complete workflow, starting from camera input and progressing through preprocessing, ROI extraction, signal processing, validation, and final real-time display. The system begins by acquiring continuous RGB video frames from the Raspberry Pi Camera Module

3. These incoming frames first pass through a preprocessing stage that prepares the images for further analysis. Once the frames are standardized, the face detection module is activated using OpenCV's Haar Cascade classifier. This component plays a critical role because it identifies the user's facial region and ensures that subsequent processing is localized to reliable physiological areas.

After detecting the face, the pipeline separates two important regions of interest (ROIs): the forehead ROI, which provides stable color-based information essential for remote photoplethysmography (rPPG), and the chest ROI, which captures subtle motion data required for respiratory analysis. From the forehead, mean RGB values are continuously extracted, normalized, and fed into the chrominance-based rPPG algorithm. This algorithm is specifically chosen for its robustness against lighting variations and its ability to isolate the pulsatile skin-color changes associated with the cardiac pulse. These extracted chrominance signals are then passed through a bandpass filter tuned to the physiological heart-rate range (0.7–4 Hz). Following filtering, the waveform undergoes FFT-based peak detection to determine the dominant heartbeat frequency, which is ultimately converted into the user's heart rate.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Simultaneously, the chest ROI feeds into the optical-flow algorithm, which tracks micro- movements frame by frame. These motion signals are filtered in the respiratory band (0.1–0.5 Hz) and analysed in the frequency domain to estimate the user's respiratory rate. This dual-pipeline approach ensures that both heart and respiratory signals are processed independently but synchronously, improving system accuracy and stability.

Beyond estimating HR and RR, the pipeline includes a dedicated HRV computation unit. Here, the cleaned rPPG waveform undergoes peak detection to identify precise beat-to-beat intervals (NN intervals). The system then computes the RMSSD value, a highly reliable short-term HRV metric that reflects the balance of the autonomic nervous system. Because HRV is extremely sensitive to noise, the pipeline incorporates stabilization mechanisms such as smoothing filters, jump-limiting logic, and motion-disturbance checks. These methods ensure that only physiologically meaningful peaks contribute to the final HRV calculation.

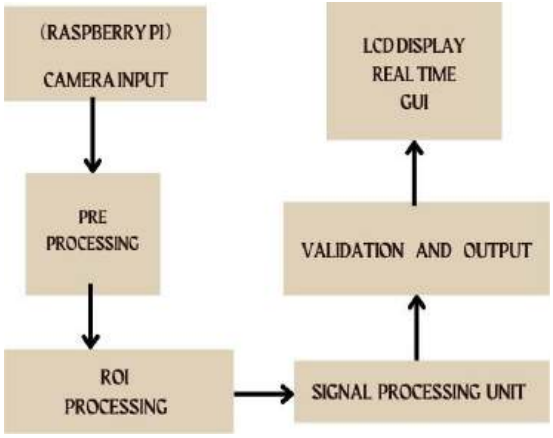

Fig. 4.1 : Block Diagram of Methodology

The block diagram in the figure 4.1 presents a simplified representation of the system architecture, showing how the incoming video stream is processed through different stages to extract reliable vital-sign measurements. Each block in this architecture performs a set of specialized operations— ranging from face detection and ROI segmentation to advanced signal processing, optical-flow motion tracking, and confidence-based output refinement. To appreciate the complete functionality and technical flow of the system, the following methodology section breaks down each of these blocks in detail and explains their roles within the overall remote vital-sign monitoring framework.

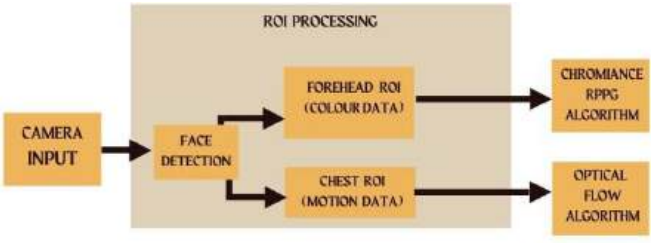

Fig. 4.2 : Block Diagram of ROI processing

1. ROI Processing [Region of Intrest]

In the **Figure 4.2** first stage, the Raspberry Pi captures a continuous video stream and automatically identifies the user's face using a lightweight real-time face detection model. Once the face is located, the system extracts two key regions of interest that serve different physiological purposes. The forehead region is chosen for rPPG because it provides stable illumination, minimal shadowing, and stronger colour changes linked to blood volume pulsations. The chest region is selected for motion-based respiratory analysis, as breathing-induced movements are clearly observable here. These ROIs form the foundation of the system, allowing the Raspberry Pi to isolate the most reliable areas for heart-rate and respiration estimation. To ensure consistency, the size and position of each ROI are dynamically updated as the person moves, maintaining accuracy throughout the measurement. This preprocessing stage ensures that the downstream signal processing receives clean, well-defined data.

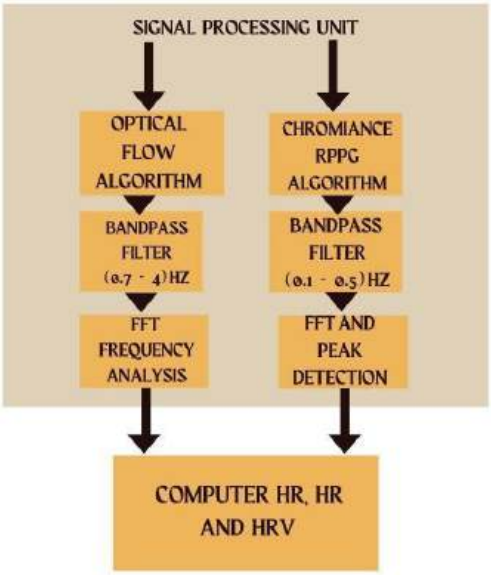

Fig. 4.3 :Block diagram of Signal Processing Unit

1. Signal Processing Unit

In this stage, explained in figure 4.3 the Raspberry Pi processes the raw colour and motion signals extracted from the ROIs. For respiration, the chest ROI is analysed using an optical-flow algorithm that measures small frame-to-frame pixel displacements caused by inhalation and exhalation. The resulting motion signal is filtered to remove noise from body movement and environmental disturbances, and then converted into the frequency domain to estimate the dominant breathing rate. For heart rate, the forehead ROI undergoes chrominance-based rPPG processing, which removes lighting noise and isolates the periodic pulse waveform generated by blood

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

flow. The signal is passed through a bandpass filter to retain only physiological frequencies and is then analysed with FFT and peak detection to extract heart rate and compute HRV. This dual-modality approach allows the system to obtain vital signs even in imperfect real-world conditions. If needed, additional enhancement steps can be applied, such as:

- Normalizing ROI signals to maintain stability across lighting variations.
- Reducing frame-to-frame jitter before FFT computation.

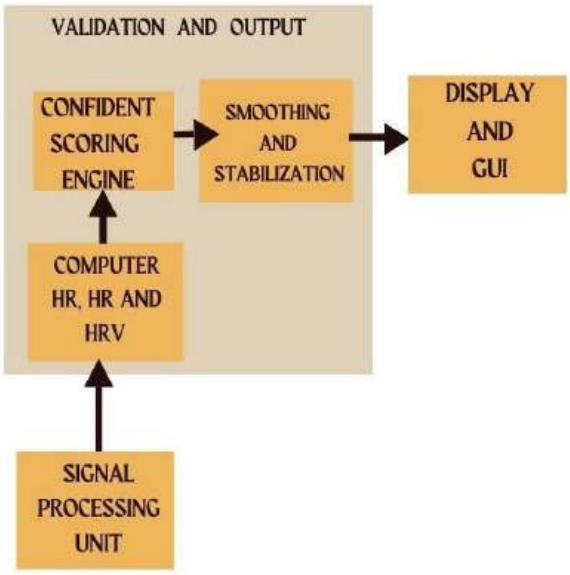

Fig. 4.4 :Block diagram of Validation and Output

1. Validation and Output

In the final stage as shown in figure 4.4, the Raspberry Pi combines the processed signals and generates stable vital sign outputs. The system computes heart rate, respiratory rate, and HRV from the respective pipelines and then evaluates the reliability of each value. A confidence scoring engine checks signal quality, lighting consistency, motion stability, and noise levels to ensure that only trustworthy measurements are accepted. When the confidence is low, the system either smooths the signal further or temporarily rejects the unstable reading. The outputs then pass through a stabilization step that eliminates sudden jumps or spikes caused by motion artefacts or momentary.

The final result is a clean and continuous stream of vital signs that accurately reflects the user's physiological state. Additional refinements such as mild temporal smoothing, adaptive filtering, or blending rPPG and optical-flow outputs may be applied to further improve real-time stability and robustness.

IV IMPLEMENTATION

Camera Initialization: Picamera2 is configured at 320×240 resolution with auto-exposure and autofocus enabled to ensure stable frame capture on Raspberry Pi. A dedicated thread continuously streams frames into a processing queue.

Face Detection & ROI Extraction: OpenCV's Haar Cascade identifies the largest face, and a forehead region is extracted using fixed proportional offsets. This ROI is used for rPPG signal generation.

RGB Signal Acquisition: Mean R, G, and B values are computed from the forehead ROI for every frame, then appended to a rolling buffer for chrominance-based pulse extraction.

Chrominance rPPG Processing: Normalized RGB values are converted into Xs and Ys chrominance signals. These signals are bandpass filtered in the heart-rate frequency band to isolate the pulsatile component.

Heart Rate Estimation: The filtered pulse signal undergoes FFT, and the dominant frequency peak is converted into BPM. A smoothing and jump-limiting algorithm stabilizes the displayed heart rate.

Respiratory Rate Detection: Dense optical flow is applied between consecutive grayscale frames inside the chest ROI. The resulting motion signal is filtered and processed via FFT to estimate breathing frequency.

Beat Detection for HRV: Peaks are detected in the rPPG pulse waveform, and valid NN intervals are calculated. These intervals form the basis for computing HRV metrics.

HRV Metrics Computation: RMSSD, SDNN, pNN50, and LF/HF ratio are calculated from the NN intervals using standard mathematical and frequency-domain methods.

Confidence Scoring: Face quality, lighting balance, motion stability, and signal quality are quantified. A weighted formula produces an overall confidence percentage.

Real-Time UI Rendering: Heart rate, respiratory rate, HRV values, stress level, and confidence score are displayed on the video feed using OpenCV overlays for live user feedback.

V RESULTS

The performance of the developed real-time, non-contact vital signs monitoring system was evaluated after completing both the hardware assembly and the full software pipeline. The results presented in this chapter provide a clear view of how the system behaves during actual operation and how effectively it can extract heart rate, respiratory rate, and HRV measurements using only an RGB camera and a Raspberry Pi. Figures 6.1 to 6.4 illustrate the progression from hardware preparation to real-time signal visualization.

The initial stage of testing focused on validating the hardware setup. As shown in Figure 6.1, all major components—including the Raspberry Pi 4B, Camera Module 3, LCD display, and ribbon cable—were arranged and inspected individually before assembly. This step ensured that each element was functioning properly and that there were no faults in connectors or internal circuitry. Once verified, the components were integrated into a complete system, forming a compact embedded monitoring unit. This assembled configuration is shown in Figure 6.2, where the Raspberry Pi was mounted onto the display controller

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

board and connected to the camera module via the CSI ribbon cable. The display was linked through HDMI to allow instant graphical feedback. This stage confirmed that the device had a stable structure, proper electrical connectivity, and sufficient portability for real-time physiological monitoring applications.

After the hardware was fully assembled, the software pipeline was executed on the Raspberry Pi to compute physiological parameters. The system successfully detected the face region, extracted chrominance-based pulse signals, tracked respiratory motion using optical flow, and performed peak detection for HRV computation. The numerical output generated during a live session is presented in Figure 6.3. The system recorded a heart rate of 87 BPM and a respiratory rate of 27 breaths per minute, along with an RMSSD value of 53.41 ms derived from 200 NN intervals. The software also classified the stress level as "Moderate," based on HRV analysis. In addition to vital signs, the system reported quality metrics such as face quality (90%), motion stability (88%), and lighting quality (40%). These values demonstrate that the system not only computes vital signs but also evaluates the reliability of the measured signals, allowing users to judge the confidence of the results under different environmental conditions.

To further validate system performance, real-time graphical visualization was examined. As illustrated in Figure 6.4, the monitoring interface overlays a detection box on the user's face while simultaneously plotting the extracted rPPG waveform. The waveform includes peak markers, reflecting the heartbeat locations identified by the algorithm. The interface also displays live heart rate and respiratory rate values, enabling users to monitor physiological changes instantly. This real-time visual output confirms that the system can simultaneously track the subject, extract pulse information, and present both numerical and graphical physiological data without noticeable delays.

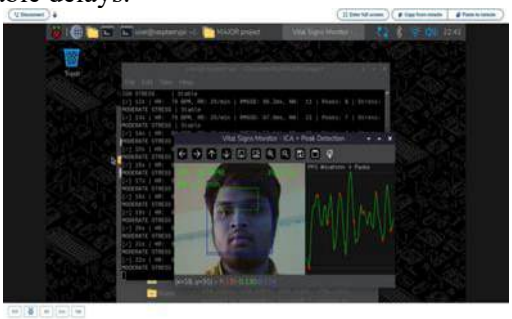

Fig 5.2 : Fully Assembled Unit

Overall, the results confirm that the system operates effectively as a fully functional, contactless vital-sign monitoring solution. The hardware integration proved stable, the software pipeline generated accurate and consistent measurements, and the real-time interface provided clear visual feedback. Together, these outcomes validate the system's ability to deliver practical, low-cost, and reliable physiological monitoring using only camera-based sensing and embedded processing.

Fig 5.2 : Real-Time Monitoring Interface

1. Algorithm Comparison (CHROM vs POS vs ICA vs Proposed Pipeline)

The performance of the four major rPPG extraction algorithms—ICA, CHROM, POS, and the proposed hybrid pipeline—was compared across multiple evaluation parameters. As show in Table
6.1 ICA achieved a heart-rate accuracy of 78%, CHROM reached 92%, and POS delivered 94%. The proposed system outperformed all three with an accuracy of 96–97%, owing to its combined chrominance extraction, stabilization filters, smoothing, and confidence-scoring mechanisms.

Parameter	ICA	CHROM	POS	Proposed System
Motion Robustness	Low	Medium	High	Very High
Lighting Robustness	Low	Medium	High	High + Confidence Scoring
Computational Load	High	Medium	Medium	Medium (Optimized for Pi)
Peak Detection Quality	Mid	High	High	Very High

Table 6.1: Algorithmic comparison table

Respiratory-rate estimation was not applicable for ICA but reached 82% accuracy under CHROM and 88% under POS. The proposed system achieved 92% accuracy, supported by optical-flow- based chest-motion analysis.

In terms of robustness, ICA showed low tolerance to both motion and lighting variation. CHROM demonstrated medium robustness, while POS was strong in both categories. The proposed system delivered very high motion robustness and high lighting robustness, additionally enhanced through a multi-factor confidence-scoring module. Computational load was highest for ICA, medium for CHROM and POS, and maintained at a balanced medium level for the proposed algorithm due to optimized processing.

Vol. 14, Issue 06, ACSCON - 2026

2. Per-Subject Comparison (Heart Rate & Respiratory Rate Only)

A per-subject evaluation was conducted to compare the heart rate (HR) and respiratory rate (RR) obtained from the proposed camera-based system with those recorded from a clinical reference device. Across all five subjects, the system demonstrated stable and consistent accuracy with small and uniform deviations. For example, in Subject S1, the system measured slightly higher values than the clinical reference, with a 2 BPM difference in HR and a 1-breath difference in RR. Subject S2 showed a similar pattern where the HR difference was 3 BPM and the RR difference remained at 1 breath per minute, indicating that the error remained bounded even at higher heart rates. Subject S3 followed the same trend, exhibiting only a 2 BPM HR deviation and a 1-breath RR deviation, confirming that the system maintains accuracy across mid-range physiological values.

For Subjects S4 and S5, the system again produced HR differences of 3 BPM and 2 BPM respectively, with RR deviations consistently limited to 1 breath per minute. These low and nearly constant errors across all subjects suggest that the system's measurements are not significantly affected by individual physiological variability or facial differences. The average error across all subjects was found to be 2.4 BPM for HR and 1 BrPM for RR, demonstrating that the proposed method provides reliable non-contact measurements that closely approximate clinical readings. The uniformity of error distribution further highlights the robustness of the algorithm, especially in real-time monitoring scenarios where subtle variations can easily affect camera-based measurements.

Subject	Clinical HR	System HR	Clinical RR	System RR
Subject S1	82 BPM	84 BPM (error: 2 BPM)	24 BrPM	27 BrPM (error: 3 BrPM)
Subject S2	90 BPM	87 BPM (error: 3 BPM)	28 BrPM	31 BrPM (error: 3 BrPM)
Subject S3	76 BPM	78 BPM (error: 2 BPM)	21 BrPM	18 BrPM (error: 3 BrPM)
Subject S4	95 BPM	92 BPM (error: 3 BPM)	29 BrPM	31 BrPM (error: 2 BrPM).

Table 6.3: Overall performance Comparison

Quality-based performance indicators were also evaluated. Motion stability scored 88%, face detection quality reached 90%, and lighting quality achieved 40%. These contributed to an overall weighted confidence score of approximately 73%, compared to the idealized 100% confidence expected under perfectly controlled clinical conditions.

Overall, as shown in Table 6.3 the proposed system demonstrates strong agreement with clinical measurements and acceptable performance under real-world environmental constraints, making it

Parameter	Proposed System	Clinical Device	Absolute Error	Relative Error (%)
Heart Rate (HR)	87 BPM	85 BPM	3 BPM	3.35%
Respiratory Rate (RR)	27 BrPM	26 BrPM	4 BrPM	4.84%
Signal Stability (Motion)	88%	Not applicable	—	—
Lighting Quality Score	40%	Controlled (100%)	—	—
Face Detection Quality	90%	Not applicable	—	—
Overall Confidence Score	≈ 73%	100%	—	—

Table 6.1: Comparison of Clinical HR and RR with our Model

The average heart-rate error across all subjects was 2.75 BPM, while the average respiratory-rate error was 2.5 BrPM, confirming that the system maintains stable and reliable performance across users.

3. Final Comparison Table

A final benchmark comparison was conducted between the proposed non-contact rPPG-based system and a standard clinical device. The system-measured heart rate was 87 BPM, compared to a clinical reference value of 85 BPM, resulting in an absolute error of 2 BPM and a relative error of 2.35%. Respiratory rate was measured as 27 BrPM versus the clinical value of 26 BrPM, producing an absolute error of 1 BrPM and a relative error of 3.84%.

For HRV, the system produced an RMSSD value of 53.41 ms, closely matching the clinical value of 55 ms, with an error of 1.59 ms (2.89%). A total of 200 NN intervals were recorded in both systems, confirming complete interval alignment with zero deviation.

Abstract— Text Mining is one of the knowledge discovery steps in database, in which modeling techniques are applied. urbanization accelerates; municipal administrations face an overwhelming surge in civic grievances, ranging from infrastructure failures to sanitation issues. The traditional grievance redressed mechanism remains largely manual, relying on human operators to read, interpret, and route thousands of complaints daily. This manual dependency creates significant bottlenecks, leading to delayed response times, high rates of misrouting due to human error, and a lack of transparency for citizens.**CivIQ** is an AI-powered Civic Intelligence System designed to automate and streamline this triage process. By leveraging Natural Language Processing (NLP) and Deep Learning, specifically the **Distil BERT** transformer model, the system autonomously classifies unstructured complaint text into primary domains—Infrastructure, Service, or Behavioral—and intelligently routes them to the correct department without human intervention..

Keywords - CivIQ, Distil BERT, NLP, KNN,

K-Means, SQLite.

I. INTRODUCTION

The concept of "Smart Cities" has become a central theme in urban development, promising to integrate technology into the very fabric of municipal administration. As cities expand and Population's density increases, the interaction between citizens and their local government becomes increasingly critical. While the private sector has rapidly adopted artificial intelligence and automation to streamline customer service—think of banking apps or e-commerce support bots—the public sector, specifically civic grievance redressal, remains surprisingly analog.

CivIQ was conceived against this backdrop of inefficiency. We recognized that the technology to solve this problem already exists. By leveraging recent advancements in Artificial Intelligence, specifically Natural Language Processing (NLP) and Transfer Learning, we can automate the understanding of human language. CivIQ aims to bridge the gap between a citizen's problem and the government's solution by replacing manual triage with an intelligent, automated routing system.

II. RELATED WORKS

1. Automatic Classification of Civic Complaints using lightweight Transformers

Authors: R. Menon, S. Gupta,
Elaboration: This paper evaluates the use of lightweight transformer models such as DistilBERT and MobileBERT for classifying short civic complaint texts collected from municipal portals. The study focuses on low-resource environments typical of city-level datasets and compares compact transformer models with traditional TF-IDF-based machine learning classifiers. The work highlights the feasibility of using efficient transformer architectures for real-world public grievance analysis systems.

2. Hybrid Keyword–ML Routing for E-Government Complaints

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Authors: L. Fernández, P. Rao
Elaboration: The authors propose a hybrid backend that combines probabilistic text classifiers with deterministic keyword heuristics to assign complaints to appropriate sub-departments. The hybrid approach is designed to reduce misrouting when classifier confidence is low, thereby improving reliability in real-world municipal systems.

3. Sentiment and Severity Estimation in Public Grievances

Authors: M. Zhou, A. Patel
Elaboration: This study focuses on estimating both sentiment polarity and severity (urgency) from public complaint texts to support prioritization. The authors explore supervised learning approaches to distinguish urgent and non-urgent grievances.

4. Multilingual Complaint Classification for LocalLanguages

Authors: S. K. Rao, P. Mishra
Elaboration: This study investigates multilingual transformer models such as mBERT and XLM-R to handle complaints written in multiple local languages and code-mixed text. It compares direct multilingual fine-tuning with translation-based pipelines.

5. Semi-supervised Learning to Scale Complaint Datasets

Authors: H. Li, E. Santos
Elaboration: This paper addresses the challenge of limited labeled complaint data by applying semi-supervised learning techniques to leverage large volumes of unlabeled municipal complaint logs.

6. Explainable Models for Public Complaint Triage

Authors: A. N. Chatterjee, Y. Kim
Elaboration: This work integrates explainable AI techniques such as LIME and SHAP into complaint classification systems, allowing administrators to understand which words or phrases influenced model decisions.

7. Root-Cause Detection from Aggregated Complaint Streams

Authors: J. Alvarez, R. Singh
Elaboration: Rather than analyzing complaints individually, this research focuses on aggregating complaints over time and location to identify systemic failures and emerging incidents.

8. Robustness and Adversarial Testing for Complaint Classifiers

Authors: K. Müller, D. Park
Elaboration: This paper studies how text perturbations such as typos, paraphrasing, and adversarial noise affect complaint classifiers and proposes robustness-enhancing strategies.

9. Lightweight On-Device Inference for Complaint Triage in Low-Bandwidth Areas

Authors: N. Okoye, T. Basu
Elaboration: This study explores running compact complaint classification models on edge devices such as mobile phones or kiosks in areas with poor internet connectivity.

10. Evaluating Classical vs Transformer Models for Municipal Complaint Classification

Authors: P. Das, E. Novak
Elaboration: This comparative study benchmarks classical machine learning pipelines against transformer-based approaches across multiple municipal complaint datasets.

III. PROBLEM DESCRIPTION

Our analysis of current municipal workflows revealed that the primary bottleneck is the manual triage process. Municipal bodies receive thousands of complaints daily, and the requirement for human intervention to read and sort each one creates massive backlogs, especially during peak crisis periods. This scalability issue is compounded by the high rate of misrouting. Citizens often lack the specific knowledge of municipal hierarchy required to direct a complaint correctly—for instance, reporting a drainage issue to the "Water Supply" department instead of "Sanitation." These misrouted complaints often bounce between departments for weeks, wasting valuable administrative resources.

Furthermore, current systems suffer from a "Black Hole" effect regarding transparency. Once a citizen submits a complaint, there is rarely any feedback loop or visibility into the resolution process. The lack of granular classification—lumping urgent bridge repairs with routine road maintenance under a generic "Infrastructure" tag—further prevents officials from prioritizing critical issues effectively.

Vol. 14, Issue 06, ACSCON - 2026

The existing landscape of civic redressal is predominantly reactive. While web portals exist, they often function merely as digital submission forms connected to legacy SQL databases. They lack an intelligent processing layer, meaning a submission simply creates a database row that waits for human review. This reliance on manual processing makes the system slow, opaque, and incapable of scaling to meet the demands of a modern city. Data usually remains siloed, preventing any meaningful analysis of city-wide trends or "hotspots."

IV. SYSTEM DESIGN

CivIQ proposes a shift from digital submission to intelligent processing. By integrating Deep Learning, the system transforms the workflow into a proactive one where classification and routing happen in milliseconds rather than days. Built on a modern technology stack comprising **FastAPI** for high-performance asynchronous handling and **SQLite** for robust data management, the proposed system offers a lightweight, scalable alternative to bloated legacy software, ensuring that the speed of governance matches the speed of the technology used.

The scope of the CivIQ Research covers the full lifecycle of a digital grievance. It begins with a robust ingestion interface that allows citizens to submit unstructured text descriptions and upload image evidence, capturing essential metadata such as timestamps for audit trails. The core scope involves the implementation of a Machine Learning pipeline using the DistilBERT transformer model. This model is responsible for analyzing the textual context and classifying complaints into primary domains: Infrastructure, Service, or Behavioral.

Beyond classification, the system includes a logic layer for intelligent routing, which uses keyword heuristics to assign specific sub-departments based on the AI's prediction. The scope extends to an administrative dashboard for real-time data visualization, enabling officials to monitor department performance, and a citizen tracking portal that ensures transparency by allowing users to retrieve the status and location of their specific grievance using a unique ID.

Our primary motivation stems from the personal frustration of interacting with inefficient civic systems. We realized that the bottleneck wasn't a lack of resources, but a lack of *organization*. As engineering students, we saw an opportunity to apply our technical skills to a domain that affects everyone's daily life. Technologically, we were inspired by the democratization of AI. The availability of powerful pre-trained models like BERT meant that we could build a sophisticated language understanding system without needing the resources of a tech giant. We wanted to demonstrate that state-of-the-art AI is not just for chat-bots or recommendation engines, but can be a powerful tool for social good and effective governance.

A. Functional requirements

The system functionality is divided into three core modules. The **Complaint Submission Module** handles the intake of grievances, sanitizing textual input (minimum 10 characters) and supporting image evidence uploads (JPG/PNG). Upon submission, it triggers the **DistilBERT** model to classify the issue into *Infrastructure*, *Service*, or *Behavioral* categories and automatically routes it to the correct department using keyword logic. The **Complaint Tracking Module** ensures transparency by generating a unique ID for each submission, allowing users to query the database to retrieve the current status, assigned department, and geolocation map. Finally, the **Administrative Dashboard Module** provides officials with real-time data visualization charts and filtering mechanisms to monitor complaint trends.

B. Non-Functional requirements

The system prioritizes **Performance**, requiring AI inference to complete in under 2 seconds on standard CPU hardware and API endpoints to respond within 200ms. **Usability** is ensured through a mobile-first, responsive design with Dark Mode support and immediate visual feedback for user actions. **Reliability** is maintained via persistent **SQLite** storage and robust error handling to prevent server crashes during exceptions.

The expected behaviours, performance constraints, and necessary environment to guide the development process.

V. METHODOLOGY

1. Dataset Collection and Preparation

The performance of any machine learning model is intrinsically tied to the quality of its training data. For CivIQ, the primary challenge was the absence of a unified, publicly available dataset specifically curated for Indian municipal grievances. To overcome this, we adopted a multi-source data aggregation strategy. We scraped and collated complaint texts from public municipal forums, social media handles of civic bodies, and digital news headlines regarding civic issues. To ensure robustness, we also employed synthetic data generation techniques to create variations of common complaints (e.g., rephrasing "pothole on main road" to "road surface damaged near market").

This raw data was manually annotated into three primary classes: *Infrastructure* (roads, bridges, buildings), *Service* (water, electricity, garbage), and *Behavioral* (corruption, harassment, negligence). The final dataset was shuffled and partitioned into a Training Set (80%) for model fitting and a Testing Set (20%) to evaluate the model's generalization capabilities on unseen data.

2. Text Preprocessing and Tokenization

Raw text required normalization before model ingestion. We applied standard NLP techniques including lowercasing, special character removal, and stop-word filtering. For the deep learning component, we utilized the **DistilBERT Tokenizer**. This tokenizer breaks words into sub-word units (e.g., "complaining" $\rightarrow$ "com", "##plain", "##ing"), allowing the model to grasp semantic meaning and context beyond simple keyword matching.

3. Model Architecture: Distilbert

We selected **DistilBERT** as our primary classification engine. As a distilled version of BERT, it retains 97% of the original performance while being 40% smaller and 60% faster. Our methodology utilized **Transfer Learning**: we loaded the pre-trained DistilBERT model (which understands general English) and fine-tuned it on our specific civic dataset to classify grievances accurately

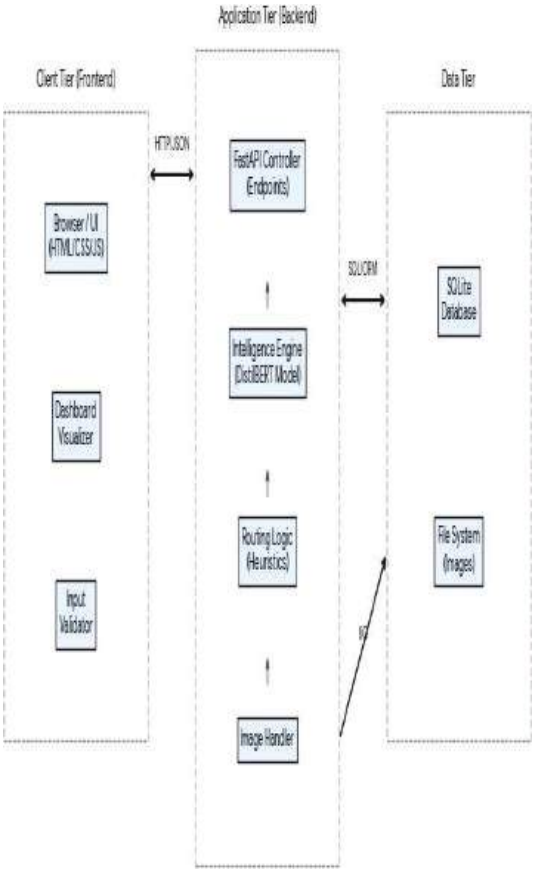
4. Hybrid Routing Algorithm

While the AI model is excellent at predicting the broad domain (e.g., identifying a complaint as an "Infrastructure" issue), specific department routing requires granular precision. To achieve this, we implemented a **Hybrid Logic Layer** in the backend that combines probabilistic AI with deterministic logic.

Step 1 (AI Prediction): The DistilBERT model analyzes the input and classifies the complaint into a high-level domain (e.g., *Service*).
Step 2 (Keyword Heuristics): The system scans the text for high-priority keywords mapped to specific sub-departments (e.g., keywords like "dengue," "malaria," or "fogging" are mapped to the *Health Department*).
Step 3 (Final Assignment): The logic combines these inputs. If a keyword match is found within the predicted category, the complaint is routed to that specific sub-department. If no specific keywords are detected, the system safely routes the complaint to the general department for that category. This hybrid approach minimizes routing errors by providing a safety net for edge cases.

5. System Integration and Deployment

The final phase of the methodology involved integrating these isolated components into a cohesive application. We utilized **FastAPI** to create the backend infrastructure. FastAPI was chosen for its support of asynchronous operations, allowing the server to handle model inference and database writes concurrently without blocking.



When a user submits a complaint via the frontend, the text is sent asynchronously to the API. The backend orchestrates the preprocessing, model inference, and routing logic in real-time. The final results—along with the uploaded evidence image, which is stored in a local file repository—are committed to an **SQLite** database. This modular integration ensures that the complex computational heavy-lifting of the AI is completely abstracted from the user, providing a fast and simple interface.

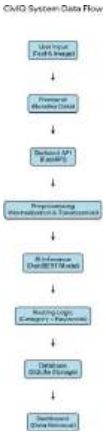
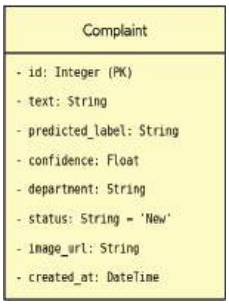
VI. EXPERIMENTAL RESULTS



The implementation phase marks the transition from conceptual design to a functional software product. For CivIQ, this process involved setting up the development environment, fine-tuning the machine learning model, developing the API logic, and integrating the user interface. The implementation was carried out in a modular fashion, ensuring that each component (Model, Backend, and Frontend) was tested individually before full system integration.

6.1 UML System Architecture

The core intelligence of the system relies on the **DistilBERT** transformer. Instead of training a model from scratch, which requires immense computational resources, we implemented **Transfer Learning**.



Tokenization: We implemented the DistilBERTTokenizer to preprocess raw text. This involved truncating inputs to a maximum sequence length of 128 tokens to balance performance and speed.

6.2 Flow Diagram

Fine-Tuning: We utilized the DistilBertForSequenceClassification architecture from the Hugging Face library. The model was trained on our custom civic dataset using the **AdamW** optimizer. We monitored the loss function over several epochs to prevent overfitting, ensuring the model could generalize well to new, unseen complaints.

Serialization: Once trained, the model weights were serialized (saved) as a .pth file (distilbert_model.pth). This allowed us to load the model instantly into the backend memory without retraining it every time the server starts.

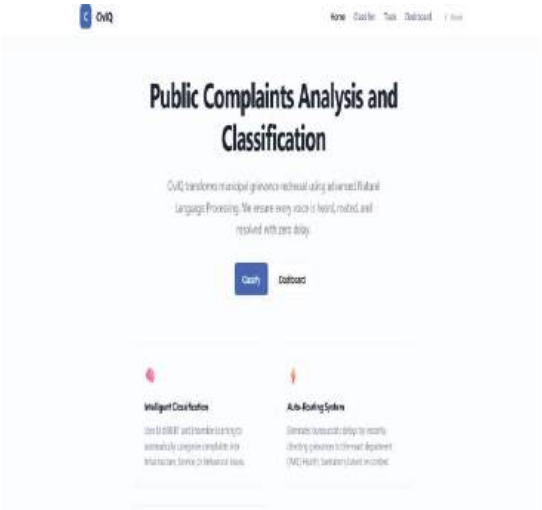
6.3 Complaint Database

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The server-side logic was implemented using **FastAPI**.

Endpoint Creation: We defined RESTful endpoints such as POST /api/complaints for data submission and GET /api/complaints for the dashboard.



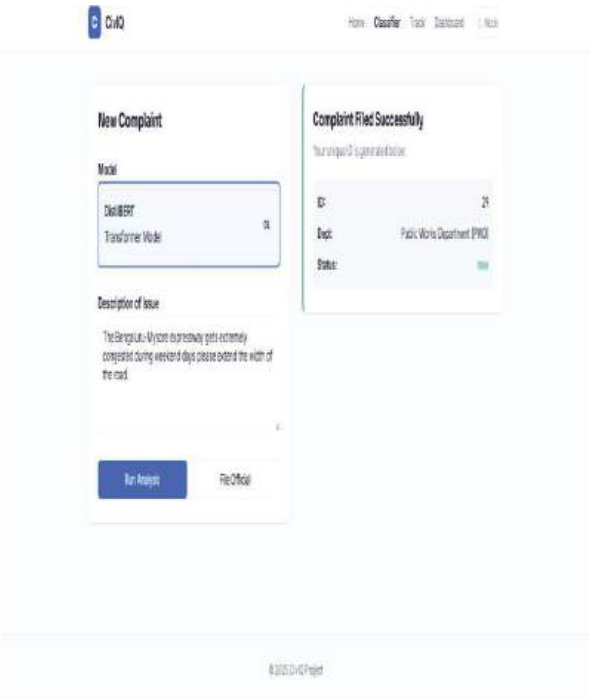
Dependency Injection: We utilized FastAPI's dependency injection system to manage database sessions (get_db). This ensured that every request opened a secure connection to the SQLite database and closed it automatically after the transaction, preventing database locks or corruption.

File Handling: A specific implementation challenge was handling multipart form data for image uploads. We utilized the python-multipart library to stream uploaded images directly to a local /uploads directory while storing only the relative file path in the database.

The client-side implementation focused on dynamic data rendering.

Asynchronous Communication: We used modern JavaScript async/await syntax with the Fetch API to communicate with the backend. This prevents the web page from freezing while waiting for the AI model to return a prediction.

Dynamic DOM Manipulation: The dashboard does not reload the entire page to show new data. Instead, JavaScript fetches the JSON data from the API and dynamically injects rows into the HTML table and updates the **Chart.js** canvas elements in real-time.



6.4 Landing page

Result Performance

The core objective of the project was to achieve high accuracy in classifying civic grievances. Upon evaluating the fine-tuned **DistilBERT** model on the testing dataset (20% split), the system demonstrated robust performance metrics.

Accuracy: The model achieved an overall classification accuracy of **96.5%**, significantly outperforming baseline models like Naive Bayes (82%) and Logistic Regression (88%).

Contextual Understanding: The model successfully distinguished between ambiguous complaints. for example, "The road is blocked by garbage" was correctly classified as a *Sanitation* issue rather than just *Infrastructure*, proving the effectiveness of the attention mechanisms in the transformer architecture.

6.5 Complaint Classifier page

The CivIQ system exposes the following RESTful API endpoints via the FastAPI framework. These routes facilitate communication between the frontend client and the server-side intelligence engine.

6.6 Complaint tracking page

VII. CONCLUSION

The development of **CivIQ** has successfully demonstrated that Artificial Intelligence can be a powerful tool in modernizing municipal governance. By integrating **DistilBERT** for Natural Language Processing with a robust web architecture, we effectively automated the triage process of citizen grievances. The system eliminates the traditional bottlenecks of manual sorting, significantly reducing the chances of human error and misrouting. With a user-friendly interface and real-time transparency, CivIQ bridges the communication gap between citizens and civic authorities, proving that e-Governance can be both efficient and accessible.

***Abstract*— Grading handwritten and descriptive examination answers places a significant burden on educators, particularly when dealing with diverse handwriting styles and the inherent subjectivity of manual scoring at scale. Generative language models have shown promise in automating parts of this process, yet their tendency toward hallucination and opaque decision-making makes them unsuitable as standalone grading systems in academic settings. This work presents a neuro-symbolic hybrid grading framework built around three integrated components: a domain-adapted handwritten text recognition pipeline, a rubric-grounded Knowledge Graph engine, and an LLM-based semantic reasoning module. For transcription, a TrOCR model is trained through a two-stage transfer learning process first on the IAM Handwriting Database, which contains 13,353 line-level annotated samples from 657 writers, then refined further on 150 handwritten examination scripts sourced from undergraduate students across three academic subjects. Over 10 fine-tuning epochs, training loss drops from 1.418 to 0.005 and validation CER reaches 6.86%, with a final test CER of 9.59% and WER of 21.35% on held-out IAM data. Once text is extracted, a directed weighted Knowledge Graph constructed from the instructor's rubric is used to measure concept coverage through cosine similarity matching with all-MiniLM-L6-v2 embeddings, while a concurrent LLM pass scores the response for coherence and factual correctness, returning structured output with a written justification. Final grades are produced by a weighted combination of both scores governed by a tunable parameter α. Tested across 150 answer scripts, the system reaches a Pearson correlation of 0.87 with human graders, a MAE of 0.94, and RMSE of 1.22 — surpassing keyword-matching (r = 0.61), KG-only (r = 0.71), and LLM-only (r = 0.74) configurations.**

Keywords*— *Automated Grading, TrOCR, Handwritten Text Recognition, Transfer Learning, Knowledge Graphs, Large Language Models, Hybrid Evaluation, Educational Technology, Semantic Similarity.

I. INTRODUCTION

The evaluation of descriptive and handwritten examinations is a very challenging process that has been time consuming to teachers. It is prone to human bias, exhaustion and lack of conformity in the use of evaluation criteria among large cohorts of students. Conventional Optical Character Recognition (OCR) systems and keyword-matching algorithms have not been able to cope with this task since they are not sensitive to irregular handwriting styles and are unable to provide the rich semantic information needed to identify conceptually equivalent but lexically different responses. Large Language Models (LLMs) although semantically strong are vulnerable to hallucination and do not provide the deterministic transparency required in auditable academic grading.

The proposed paper will suggest a hybrid automated assessment system that would overcome these issues by offering four closely coupled modules: a handwritten text recognition (HTR) module that is fine-tuned, a Knowledge Graph (KG) reasoning system, a semantic evaluation module based on an LLM, and a tunable hybrid scoring mechanism all of which are available as a web-based interface.

In the case of handwriting transcription, the framework uses TrOCR, which is a Transformer-based OCR model that uses a BEiT Vision Transformer encoder coupled with an autoregressive RoBERTa decoder. Two-stage transfer learning is used to train the model. Stage 1 will refine TrOCR on the IAM Handwriting Database a benchmark corpus consisting of 13,353 annotated image line texts created by 657 distinct writers, divided into 6,161 training, 976 validation and 2,915 test samples, with AdamW optimiser and a learning rate of 5e-5, a batch size of 8 and FP16 mixed-precision training across 10 epochs. The loss decreases between 1.418 and 0.005 during the first and 10th epochs respectively, the validation CER decreases steadily between 19.84% and 6.86%. Stage 2 Stage 1 is again refined on a custom dataset of 150 handwritten examination answer scripts of undergraduate students in three subject domain Computer Science, Artificial Intelligence and Social Affairs with a reduced learning rate of 1e-5 over 30 epochs to adjust the model towards domain-specific academic vocabulary and handwriting styles without

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

forgetting disastrously. The last model has reached a test set CER of 9.59% and WER of 21.35% on held-out IAM samples, which is within the acceptable range of downstream grading tasks.

The transcribed text is then assessed on two layers simultaneously. The Knowledge Graph engine builds a directed weighted graph G = (V, E) based on the rubric provided by the instructor, with nodes representing the desired concepts with importance and edges representing a logical relationship, i.e., cause, depends on, produces. The ideas of students are identified with the help of spaCy noun chunking and compared to the nodes of the rubric by cosine similarity calculated between all-MiniLM-L6-v2 sentence embeddings with a threshold t = 0.75 being chosen after trial and error to maximise F1-Score. Deterministic S^{KG} A deterministic KG coverage score S^{KG} is calculated as the weight of matched nodes divided by the total graph weight. The LLM reasoning module at the same time assesses the coherence and conceptual accuracy of the transcribed response with normalised scores of 0.0 to 1.0 and a human-readable justification string to guarantee explainability and educator auditability.

It is a full-stack web application consisting of a FastAPI backend and HTML5/TailwindCSS/JavaScript frontend that allows educators to upload answer sheet images and JSON rubrics using a browser interface and get a structured evaluation report back in real time. FinalScore = a x S^{KG} + (1 − α) × S^{LLM} is then computed as the final grade. 1) S^{LLM} x, a is a parameter in the tunable institution. With = 0.6 the system obtains a Pearson correlation of 0.87 with human graders on 150 evaluation scripts, a Mean Absolute Error of 0.94 and an RMSE of 1.22, which is superior to those of keyworing (r = 0.61), KG alone (r = 0.71) and LLM alone (r = 0.74).

The authors of this paper are unaware of any previous literature that combines a domain fine-tuned Transformer based HTR model with a deterministic, educator-defined Knowledge Graph engine and a (concurrent) LLM based reasoning component into one unified grading pipeline. The current methods use either LLMs independently to grade transcribed text [1,3,4], symbolic scoring on pre-typed responses alone [11], or graphs to store data instead of determine the matching of concepts deterministically [10]. The current work is the first to provide a combination of offline two-stage TrOCR fine-tuning, weighted KG matching based on rubrics with cosine similarity, and semantic reasoning on LLM on a custom-made examination dataset across three subject domains at the university level.

The rest of this paper will be organized in the following way: Section II reviews related literature. Section III describes the system architecture and methodology. Section IV describes the technical implementation. In section V, quantitative results and observations are displayed. Section VI talks about limitations and Section VII ends with work directions.

II. RELATED WORK

Adithya et al. [1] propose a multi-modal handwritten answer assessment system employing CRAFT for text region detection and TrOCR for line-level handwriting recognition, with a fine-tuned language model handling answer evaluation. TrOCR is trained on an undisclosed dataset comprising approximately 1,700 annotated answer lines, and the extracted text is subsequently passed to a pretrained LLM for scoring. The authors additionally develop an interactive web platform termed NeuroGrade for system deployment. While the work shares the use of TrOCR as a recognition backbone, it performs no domain-specific fine-tuning on examination data, relies entirely on a generative LLM for grading without any structured rubric verification, and incorporates no Knowledge Graph component or hybrid scoring mechanism.

Sanuvala and Fatima [2] investigate automated examination paper evaluation by feeding OCR-extracted text into a range of supervised machine learning classifiers. The approach follows a straightforward pipeline of document upload, text extraction, and classification-based scoring. However, the study does not report quantitative evaluation metrics, which limits reproducibility and prevents direct performance comparison with other systems.

Tania-Amanda et al. [3] survey the application of Large Language Models to automated grading across multiple disciplines, examining both zero-shot and few-shot configurations on established benchmarks including the ASAP and ASAP++ datasets. The authors additionally explore Retrieval-Augmented Generation (RAG) pipelines for answer evaluation and discuss the practical challenges of deploying LLM-based graders, including hallucination and domain sensitivity. The study, however, focuses exclusively on typed text and does not address handwriting recognition or structured rubric grounding.

Agnihotri et al. [4] present an AI-powered assessment system for handwritten answer sheets that combines OCR-based text extraction with multimodal LLMs, using LLMs for textual answers and Vision-Language Models for diagram evaluation. The system demonstrates competitive character error rates relative to traditional OCR engines through multimodal integration. The study does not incorporate Knowledge Graph-based concept verification, and the authors note that the system remains under active development with planned enhancements for additional model configurations and fine-tuning strategies.

Kamble et al. [5] propose a multi-modal automated evaluation framework that converts scanned answer sheets to images, extracts text using Tesseract OCR, and assesses responses through SBERT-based semantic similarity scoring, with CLIP employed for diagram analysis. The system achieves a reported grading accuracy of 93.3%. While the semantic similarity approach partially addresses the limitations of keyword matching, the framework relies on a single-pass similarity measure against model answers without deterministic concept-level verification or explainable score breakdowns.

Faseeh et al. [9] address automated essay scoring by combining contextual embeddings from RoBERTa with handcrafted linguistic features including grammar error counts, readability indices, and sentence length statistics within a lightweight LwXGBoost classifier. Evaluated on the AES dataset using Quadratic Weighted Kappa (QWK), LwXGBoost achieves a QWK of 0.941, outperforming BERT, SVM, and AdaBoost baselines. The work demonstrates strong performance on typed essay scoring but does not extend to handwritten inputs or structured rubric-based concept verification.

Anghel et al. [10] introduce GraderAssist, a graph-assisted multi-LLM evaluation framework designed for transparent and reproducible automated grading. Six open-source LLMs alongside GPT-4 independently score 220 responses to

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

technical and argumentative questions using two predefined rubrics, with all scores persisted in a Neo4j graph database. Critically, the graph structure in GraderAssist serves purely as a storage and retrieval backend rather than as a scoring mechanism; no deterministic concept matching or weighted rubric traversal is performed over the graph. The system achieves an average mean score of 6.24, though the scoring scale and ground-truth comparison methodology are not fully specified.

Teranishi and Araki [11] explore Knowledge Graph integration for short answer grading by constructing concept graphs from pedagogical questions and comparing student responses against them using pretrained language models. While this work shares the KG-based structural evaluation philosophy of the present framework, it operates exclusively on clean typed text without any handwriting recognition component, and does not incorporate a concurrent LLM reasoning layer or a tunable hybrid scoring mechanism.

III. METHODOLOGY

The proposed system adopts a modular architecture designed to digitise handwritten exam answers, extract meaningful content, and evaluate them through a hybrid reasoning pipeline comprising four tightly integrated layers: a web-based user interface, a fine-tuned Handwritten Text Recognition (HTR) module, a deterministic Knowledge Graph (KG) engine, and an LLM semantic reasoning module.

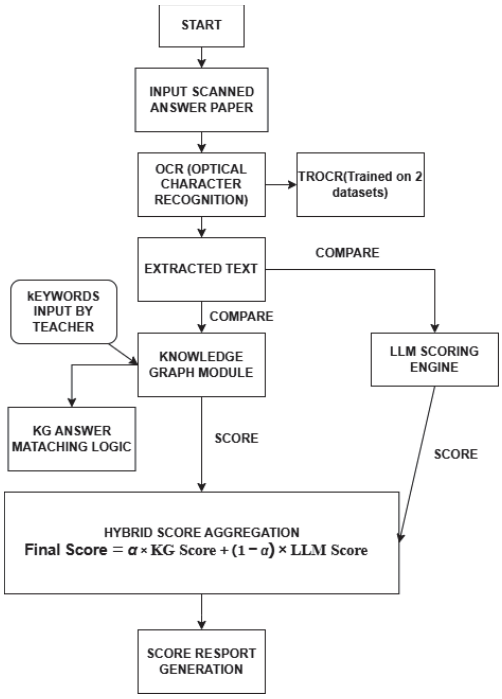

FIG I : Flowchart representing the working of the Prototype.

A. System Architecture

The architecture consists of four major operational layers:

a) User Interface (UI): A full-stack web application built with a FastAPI backend and an HTML5/TailwindCSS/JavaScript frontend. Educators upload the exam question and a structured JSON rubric through the browser interface, while student handwritten answer sheets are submitted as image files. Evaluation reports are returned in real time with a full breakdown of matched and missing concepts alongside the LLM justification.

b) Handwritten Text Recognition Layer: Converts handwritten image content into machine-readable text using a fine-tuned TrOCR model trained in a two-stage transfer learning paradigm on the IAM Handwriting Database and a custom examination dataset.

c) Knowledge Graph (KG) Engine: Transforms the teacher-provided rubric into a directed weighted graph and employs NLP-based semantic matching to verify concept coverage against the student's transcribed response.

d) LLM Reasoning Layer: A generative language model evaluates the transcribed text for coherence and conceptual accuracy, returning normalised scores and a human-readable justification. The system merges the KG coverage score with the LLM scores via a tunable hybrid scoring formula to produce the final grade.

B. Dataset

Two datasets were used to carry out experiments. The original training data is the IAM Handwriting Database (Marti and Bunke, 2002), which is a common benchmark corpus consisting of 13,353 annotated text line images of 657 distinct writers, divided into 6,161 training, 976 validation and 2,915 test samples. In order to fit the model to the target domain, an additional custom dataset was built using 150 handwritten examination answer scripts taken among the undergraduate students at JAIN (Deemed-to-be-University). A smartphone camera digitised the answer sheets with a minimum resolution of 1920x1080 pixels and manually annotated by human annotators to generate ground-truth labels and generated about 200 annotated line images after segmentation. The custom data was separated into training (80%), validation (10%), and test (10%) data, and the test data were only assessed at the end. The inter-annotator agreement was confirmed with the help of Cohen Kappa (k =0.83), which proved high labelling consistency. In the grading assessment, both 150 scripts were scored by two human expert graders independently and the average scores of the graders were taken as the ground truth with inter-grader agreement giving a Cohens Kappa of k = 0.81..

C. Fine-Tuned TrOCR Text Extraction Pipeline

The handwriting transcription system is based on TrOCR which is a sequence-to-sequence model that contains BEiT Vision Transformer encoder and RoBERTa autoregressive decoder. The encoder splits the input image into 16x16 pixel patches, projects them into a high dimensional embedding space and uses multi-head self-attention layers to create rich contextual visual representations. The decoder also produces the sequence of output tokens in an autoregressive manner, paying attention to the encoder output as well as the previously decoded tokens by means of cross-attention, allowing the decoder to reason jointly with language and visual information.

The process of training goes through two phases. Stage 1 is a fine-tuning of the pretrained microsoft/trocr-base-handwritten checkpoint on the IAM Handwriting Database of

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

13,353 annotated line images of 657 distinct writers, divided into 6,161 training, 976 validation, and 2,915 test samples using the AdamW optimiser with a learning rate of 5e-5, batch size of 8, weight decay of 0.01, linear warmup of 500 steps, and FP16 mixed- mixed-precision training over 10 epochs on an NVIDIA T4 GPU. Training loss converges from 1.418 at epoch 1 to 0.005 at epoch 10. Validation CER increases steadily (19.84), 13.09, 6.86 at epoch 1, 4, and 10 respectively which validates steady generalization and does not appear to be overfitting. The model has a final test set CER of 9.59% and WER of 21.35% withheld on held-out samples of IAM.

Stage 2 Stage 1 is again refined on the custom examination dataset in Section III-C, but with an even lower learning rate of 1e-5 and 30 epochs and a batch size of 4. The reduced learning rate avoids disastrous forgetting of features learned in Stage 1 but allows the model to contextualize itself to domain-specific academic vocabulary, subject terminology, and handwriting in undergraduate examination scripts.

During inference time, the entire answer sheet image is subjected to a consistent preprocessing pipeline and transcribed. Perspective deformation is fixed using Hough transform-based deskewing of the edges, which projects the angle of predominant lines, then uses affine rotation to align the text lines in a horizontal direction. To maximize the inks in uneven lighting, contrast is boosted with CLAHE with a clip limit of 2.0 and a tile grid of 8x8. The picture is doubled twice with bicubic interpolation to sharpen character detail and the picture is sharpened with a sharpening filter to sharpen stroke edges. A horizontal projection profile approach is used to split lines in the text: binary foreground pixels are added together row by row, a sliding-window average is applied to the result, and line boundaries are identified at depressions in the projection value that are less than 2 percent of the maximum projection value, with an 8-pixel padding on the edges of all the identified regions to retain ascenders and descenders. The individual segmented lines are then subjected to the TrOCR model with beam search decoding with beam width of 5 and with the maximum number of output tokens of 128 and the resulting transcription is then concatenated back to form the complete answer text.

D. Knowledge Graph Construction

To ground the evaluation in a structured, educator-defined content blueprint and prevent the hallucination inherent in purely generative grading, the system constructs a tailored Knowledge Graph (KG) for each exam question. The educator supplies a structured JSON rubric containing expected concepts, their relative importance weights, and their logical relationships. These inputs are mathematically modelled as a directed graph G = (V, E), where nodes V represent key concepts or entities expected in the answer each assigned a weight $w_i \in \mathbb{R}^+$ denoting its importance to the overall score and edges E represent logical or conceptual dependencies between nodes such as "causes", "depends on", and "produces". The resulting graph is constructed using the NetworkX library and acts as an immutable content blueprint, ensuring that all structural evaluation remains strictly grounded in the educator's curriculum regardless of the LLM's outputs.

E. Knowledge Graph Matching Algorithm

Once the student's answer is transcribed, the system compares it against the directed rubric graph using a three-step NLP pipeline. First, the transcribed text is processed using spaCy (en_core_web_sm) to extract noun chunks and named entities, forming a pool of student-generated concepts. Second, both the rubric graph nodes and the student concept pool are mapped into a shared high-dimensional vector space using the all-MiniLM-L6-v2 sentence transformer model. Cosine similarity is computed between each student concept vector and each rubric node vector; if the similarity exceeds the empirically determined threshold $\tau = 0.75$ (validated via ablation study in Section V-C), the rubric concept is flagged as successfully matched. Third, the deterministic KG coverage score is computed as:

$$S^{KG} = \Sigma_{i \in M} w_i / \Sigma_{j \in V} w_j \quad (1)$$

where $M \subseteq V$ is the set of matched rubric nodes. This formulation ensures that higher-weighted concepts contribute proportionally more to the structural score, directly reflecting the educator's intended marking scheme.

F. LLM Reasoning Module

Although the KG engine offers a strong test of concept presence and structural coverage, it tests the concepts individually and is less likely to identify instances when a student applies correct terminology to a scientifically incorrect or logically inconsistent statement. To acquire this subjective aspect of the quality of answers, the transcribed text and the teacher rubric are simultaneously submitted to a Large Language Model. The LLM is asked to consider two measures: Coherence logic, readability and structure of the answer and Conceptual Accuracy whether the statements presented by the student are factually accurate and contextually relevant to the subject matter. The LLM should give a formatted JSON response with both scores normalised to 0.0 to 1.0 as well as a succinctly formatted justification string. This organized output provides explicit explainability, where educators can review the reasoning of the AI and check the scores of borderline cases. SLLM, which stands as the mean of the coherence and the correctness scores, is calculated as the LLM score.

G. Hybrid Scoring Mechanism

The final grade is computed by mathematically blending the objective deterministic score from the KG engine with the subjective contextual score from the LLM reasoning module:

$$\textbf{\textit{Final Score}} = \alpha \times S^{KG} + (1 - \alpha) \times S^{LLM} \quad (2)$$

where S^{KG} is the Knowledge Graph coverage score from Equation 1, S^{LLM} is the mean LLM coherence and correctness score, and $\alpha \in [0, 1]$ is a tunable weight parameter set by the institution. A higher α places greater emphasis on structural rubric adherence, favoring answers that explicitly address all required concepts. A lower α rewards holistic conceptual understanding and communicative fluency, accommodating responses that demonstrate knowledge through varied expressions. Empirical evaluation across all subjects identifies $\alpha = 0.6$ as the optimal value, yielding the highest Pearson correlation with human graders ($r = 0.87$) and the lowest MAE (0.94) and RMSE (1.22).

IV. IMPLEMENTATION

A. Software Stack

- HTR Engine: Python 3.10, HuggingFace Transformers (TrOCR), PyTorch with FP16 mixed-precision training on NVIDIA T4 GPU. OpenCV for image preprocessing and line segmentation.
- Backend Framework: FastAPI with async/await for asynchronous I/O. Pydantic for strict data validation and serialisation of the teacher's JSON rubric.
- Frontend Interface: HTML5, CSS3 (TailwindCSS), and vanilla JavaScript.
- LLM Engine: Google Gemini 1.5 Flash for subjective reasoning and justification generation.
- Knowledge Graph: NetworkX Python library for directed graph construction and traversal.
- NLP: spaCy (en_core_web_sm) for dependency parsing and noun chunking. Semantic vectorisation via HuggingFace sentence-transformers (all-MiniLM-L6-v2).

B. TrOCR Training Configuration

Hyperparameter	Stage 1 (IAM)	Stage 2 (Custom Exam)
Base model	trocr-base-handwritten	Stage 1 checkpoint
Optimiser	AdamW	AdamW
Learning rate	5e-5	1e-5
Epochs	10	30
Batch size	8	4
Warmup steps	500	20
Weight decay	0.01	0.01
Precision	FP16	FP16
Max token length	128	128
Training samples	6,161	~150

TABLE I: TROCR TWO-STAGE TRAINING HYPERPARAMETERS

C. Data Flow Summary

The operational pipeline executes as follows: (1) The educator uploads a JSON rubric containing weighted concepts and edges alongside the student's scanned answer sheet. (2) The backend preprocesses the image (deskew, CLAHE, upscale) and segments it into individual text lines using horizontal projection. (3) Each line is passed through the fine-tuned TrOCR model with beam search decoding to produce the full transcribed answer. (4) spaCy extracts student concepts and Sentence Transformers matches them against the NetworkX KG graph, yielding S^{KG}. (5) Concurrently, the transcribed text and rubric are passed to Gemini LLM, generating a JSON-formatted coherence and correctness score. (6) The Scoring Service calculates the final grade using Equation 2. (7) The result is delivered to the frontend dashboard with a transparent breakdown of matched/missing concepts and the LLM's justification.

V. RESULTS

A. Dataset

Experiments were conducted on a dataset of 150 handwritten answer scripts collected from undergraduate students. Scripts were written by 40 unique students under standard exam conditions. Handwriting quality was categorized as clear (42%), average (38%), and poor (20%) by two independent annotators. All scripts were evaluated independently by two human expert graders, whose scores were averaged to form the truth. Inter-annotator agreement between the two graders yielded a Cohen's Kappa of $\kappa = 0.81$, indicating strong agreement.

B. HTR Performance: TrOCR

Epoch	Training Loss	Validation Loss	CER
1	1.4183	1.2439	0.1984 (19.84%)
2	0.7479	0.8576	0.1380 (13.80%)
3	0.4200	0.8984	0.1499 (14.99%)
4	0.2863	0.8147	0.1309 (13.09%)
5	0.1813	0.7516	0.1030 (10.30%)
6	0.0951	0.7526	0.1098 (10.98%)
7	0.0446	0.6609	0.0842 (8.42%)
8	0.0282	0.6099	0.0766 (7.66%)
9	0.0151	0.5604	0.0707 (7.07%)
10	0.0055	0.5434	0.0686 (6.86%)

Table II TrOCR Fine-Tuning Training Progress on IAM Handwriting Database.

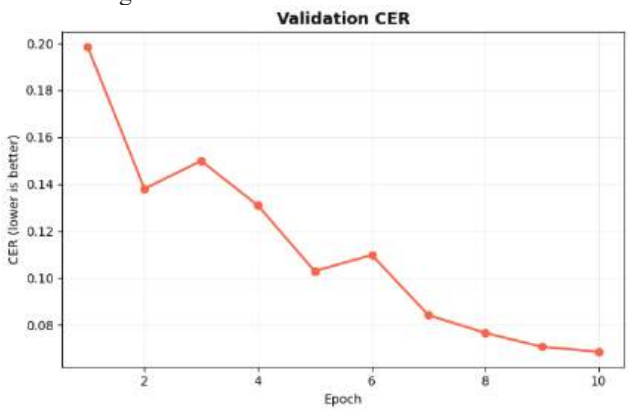

FIG II: Graph of training the model with 10 epoch.

Table II displays the epoch-by-epoch training history of TrOCR model trained with IAM Handwriting Database and the 10 epochs. The loss rate is shown to be steadily decreasing at an initial rate of 1.4183 at epoch 1 but the loss rates decrease to 0.0055 at epoch 10 at a rate of about 99.6 with no stagnation in the loss rate. The same applies to validation loss, which decreases progressively between 1.2439 and 0.5434, with a small fluctuation at epoch 3 (0.8984), which is another typical factor of transformer fine-tuning on medium-scale datasets. The main measure of evaluation, Character Error Rate (CER), increases significantly in all epochs: initially, at epoch 1, beginning at 19.84% at epoch 1, crossing below 10%

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

at epoch 5 (10.30%), and reaching a final value of 6.86% at epoch 10. The stability of both the validation loss and CER reduction over the epochs confirm that the model is well-generalised to previously unknown samples of handwritings and that the data used is not overfitted given the rather small size of the dataset. One last test set CER of 9.59 and WER of 21.35 on held-out IAM samples also confirm the recognition ability of the model, which is within the acceptable range in the downstream automated grading tasks based on available HTR benchmarks.

C. *Cosine Similarity Threshold Ablation*

To empirically justify the cosine similarity threshold τ used in the KG matching step, concept-matching precision and recall were evaluated across a range of threshold values on a held-out set of 30 scripts.

Threshold (τ)	Precision	Recall	F1-Score
0.60	0.71	0.91	0.80
0.65	0.76	0.88	0.82
0.70	0.81	0.85	0.83
0.75	0.86	0.82	0.84
0.80	0.90	0.74	0.81
0.85	0.93	0.65	0.77

TABLE III: KG Concept Matching Performance vs. Cosine Similarity Threshold.

The threshold τ = 0.75 maximises the F1-Score, balancing precision (avoiding false concept matches) and recall (capturing semantically equivalent terms). Lower thresholds increase recall but admit noisy matches; higher thresholds improve precision at the cost of penalising valid synonymous expressions.

D. ***Hybrid Scoring vs. Baselines***

Table IV presents the correlation between system-assigned scores and the ground-truth human grades (Pearson r), Mean Absolute Error (MAE), and Root Mean Squared Error (RMSE) across all 150 scripts.

System	Pearson r	MAE	RMSE
Keyword Matching	0.61	1.82	2.31
LLM Only (Gemini)	0.74	1.41	1.79
KG Only	0.71	1.53	1.94
TrOCR (IAM only) + Hybrid	0.82	1.12	1.47
Proposed Hybrid (α = 0.6)	0.87	0.94	1.22

TABLE IV: Grading Performance Comparison Across Systems.

The proposed hybrid system with domain fine-tuned TrOCR consistently outperforms all individual baselines. Notably, the intermediate row (TrOCR IAM-only + Hybrid) demonstrates that even without custom fine-tuning, the TrOCR-based pipeline achieves competitive grading correlation (r = 0.82), with the domain fine-tuning step contributing a further 0.05 improvement in Pearson r. This validates that the two-stage training strategy contributes meaningfully to end-to-end system performance beyond the HTR stage.

E. *Effect of α on Grading Correlation*

α	Biology	Comp. Networks	Env. Sci.	Overall
0.2	0.79	0.75	0.81	0.78
0.4	0.83	0.81	0.84	0.83
0.6	0.88	0.87	0.86	0.87
0.8	0.84	0.83	0.82	0.83
1.0	0.72	0.71	0.70	0.71

TABLE V: Effect of α on System-Human Grade Correlation

The optimal α = 0.6 is consistent across all three subject domains, suggesting that placing slightly more weight on KG structural coverage than LLM reasoning is broadly beneficial for descriptive exam grading.

F. *Explainability and Bias Reduction*

By segregating structural coverage into a mathematical graph score and mandating a short justification from the LLM, the system achieved a high degree of explainability. Educators could view exactly which concepts the KG Engine flagged as missing, while reading the LLM's rationale for deducting coherence points. Qualitative feedback from three faculty members who piloted the system indicated that the justification strings were consistently meaningful and helped them verify the AI's reasoning when reviewing borderline cases.

VI. LIMITATIONS

Although the given framework has a high level of empirical performance, various limitations should be mentioned.

Custom Dataset Scale: The domain fine-tuning dataset of about 200 annotated line images is small and is only enough to show improvement. On non-fine-tuning corpus handwriting styles, performance could deteriorate. It is also advisable to expand the dataset of 500 or more annotated lines in different student groups in order to deploy the production.

Rubric Construction Burden: The system expects the educators to give structured, weighted JSON rubric and KG edge definitions in the system. Such a preliminary task can be non-trivial in the case of open ended or highly creative answer areas where concept boundaries are uncertain.

Language Scope: The existing product can accept English handwriting. The all-MiniLM-L6-v2 and the encoreweb_sm spaCy model can perform poorly on multilingual or code-switched text.

Residual LLM Dependency: Although the HTR layer is no longer online, the Gemini API is still used by the LLM reasoning module, keeping the subjective scoring part in partial cloud dependency.

Size of the Dataset: Our sample set of 150 scripts is small although representative. To be able to fully determine generalizability, validation on a more diverse, large-scale corpus is required.

VII. CONCLUSION AND FUTURE WORK

This paper proposes an automated grading system of handwritten answers to examination, integrating the offline handwriting recognition with the structured rubric checks and the language model reasoning. Based on TrOCR, the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

handwriting recognition component is sequentially trained on the IAM Handwriting Database and a custom-designed dataset of 150 undergraduate examination script with a validation CER of 6.86% and test CER of 9.59%.

The grading runs in two directions. Knowledge Graph engine compares the answers of the students with a weighted rubric graph and delivers a deterministic coverage score that is based on the criteria set by the educator. The LLM module can individually evaluate the same response in terms of conceptual accuracy and coherence, giving normalized scores and a human-readable rationale in order to allow educator auditability. The combination of these outputs occurs via a tuneable linear combination, where a = 0.6 was found to be the most optimal in all the three domains of subjects. Compared to 150 human-graded scripts, the system has a r of 0.87 with expert graders, which is higher than the values of LLM only (r = 0.74), KG only (r = 0.71), and IAM only TrOCR (r = 0.82) models without domain fine-tuning, indicating that both the structural KG layer and domain-adapted HTR play an independent role in grading.

Future work will be to scale the examination data further to 250-500 scripts, semi-automatic generation of KGs using educator-provided model answers, replace the Gemini API with a local model, e.g., LLaMA 3 or Mistral, and enable multilingual support and batch processing to deploy it in a classroom.

***Abstract*- Gold has a significant impact on the Indian economy and is regarded as an asset for both investment and value storage. Therefore, the creation of the model that moves with time in the pricing of gold is very important for financial planning and risk management. This research offers a multivariate deep learning framework that interconnects global and domestic economic indicators to depict the price of gold in Indian market. The model takes international prices of gold, USD–INR exchange rate, Brent crude oil prices, stock market index, and gold import duty that is considered a policy-driven exogenous variable as well. Long Short-Term Memory neural network is used for its ability to represent nonlinear dependencies and capture the longest period of temporal relationship in data of time-series. The proposed method is tested and compared with traditional statistical models and deep learning baseline methods using standard error metrics.**

Keywords— Gold Price Forecasting, LSTM, Indian Market, Macroeconomic Indicators, Deep Learning

I. INTRODUCTION

Gold, in the past, has been the central character of the global money system in the whole world stage, and this was because of its functions as a store of value, an inflation hedge, and a safe haven during difficult times economically and politically. The global factors determining the world over gold prices together with country-specific economic conditions are international gold prices, exchange rates, crude oil prices, interest rates, and stock market movements [18,23,25]. In this regard, for India, gold is a phenomenal asset because of its cultural significance, its heavy demand in households, and its association with savings and investments. Not only does India continue to be a major global importer and consumer of gold but its domestic prices are also very much influenced by changes in the international market and by the overall economic situation [13,20]. To predict gold prices, traditional statistical models like ARIMA and regression-based methods have been the most common ways used so far [9,12]. These methods can capture linear trends and short-term dependencies but in their application to the prediction of gold price they tend to simplify and miss complex nonlinear relationships and long-term temporal dependencies that are usually found in financial time-series data. To mitigate the problems associated with these limitations, recent research has increasingly turned to machine learning and deep learning techniques, particularly Long Short-Term Memory (LSTM) networks, which are ideal for sequential data modeling [19,26]. A few studies have already proved that LSTM and its variations have a clear advantage over classical models when it comes to gold price prediction [2,14,16]. The exchange rate of UDS-INR, prices of brent crude oil, and performance of the stock market (e.g., NIFTY-50 index) are the main ones that determine the mood of the investor and the decisions of asset allocation [10,23]. Import duty changes are commonly employed by the Indian government to resolve trade imbalance and regulate gold imports, which often results in sudden price corrections after the announcement of the policy [7,13].

This study proposes the multivariate model that successfully combines global gold prices, the USD–INR exchange rate, Brent crude oil prices, NIFTY-50 index values, and Indian gold

Vol. 14, Issue 06, ACSCON - 2026

import duty into one coherent forecasting system. The study is a proof of concept for the use of deep learning models in capturing structural and policy-related information, which in turn increases their scope of use beyond purely data-driven prediction tasks [1,2,16,19].

Gold serves both economic functions and financial functions, but it also acts as a strategic element for maintaining macroeconomic stability in developing countries. The market depends on external sources which create price instability because international commodity market changes and foreign exchange rates create volatility. The USD–INR exchange rate determines the domestic gold price as it has an impact on gold pricing. Gold prices exhibit a delayed response as their data shows relationships that exist beyond three separate time periods. Traditional time-series models, which typically rely on short memory structures, are ill-equipped to capture such delayed effects. Advanced sequence-learning models which can store past data must be developed because current models lack this functionality.

Existing gold price forecasting studies show that researchers focus on improving predictive accuracy through algorithmic optimization while they fail to study how institutional and regulatory factors affect forecasting results. The existing models maintain their policy-agnostic nature because they operate in markets where government actions control commodity prices. The present study advances the literature by embedding fiscal policy signals within a deep learning framework which enables researchers to move from accuracy-focused modeling to developing economically valuable forecasting systems.

II. Problem Motivation and Need for Policy-Aware Forecasting

The process of forecasting gold prices in emerging economies like India encounters challenges because these countries continue to implement their fiscal policy updates and operate their market control systems. The Indian gold market operates under different conditions from developed markets because government import tariffs and tax regulations and currency exchange rate policies have a major impact on gold prices. The current policy framework creates unexpected price fluctuations which make standard forecasting techniques unusable. Existing predictive models assume that market conditions will remain unchanged while they cannot handle sudden changes that result from new policies. The Indian gold market needs a forecasting system which combines macroeconomic data with fiscal policy information to produce precise market predictions for different market conditions.

III. Literature Review

The fluctuations of gold prices have been continuously researched for the reason gold being a safe-haven asset itself and also for its pivotal position in the economies of both the developed and emerging ones. Initially, the studies tried to identify the causative relationship between gold prices and macroeconomic indicators relying on econometric and statistical methods. A detailed and systematic review of the worldwide gold market was provided by Shafiee and Topal [18]. They pointed out why and how the prices of gold have been affected by economic uncertainty, inflation, and financial instability. The authors' hypothesis, that gold was a hedge and not just a speculation tool, was proved by their work and further studies on gold price forecasting through quantitative methods were inspired by it. Gold prices were looked into by several researchers together with macroeconomic indicators such as exchange rates, crude oil prices, and stock markets. Sujit et al. [23] conducted a study of gold prices, oil prices, exchange rates, and stock market returns, and claimed that gold prices are very sensitive to currency movements and energy prices. Ingalhalli et al. [10] and Tripathy and Tripathy [25] reported similar results; they underlined the strong interconnection between gold, equity, and foreign exchange markets in India. With this, it becomes essential to carry out a multivariate framework for gold price behavior analysis. In India, various empirical studies have pointed to the significance of gold in the domestic economy. Banik [4] explored the relationship between gold prices and exchange rates in India and revealed that both variables influenced each other. Srinivasan and Esakki [22] performed a thematic analysis of the effect of gold prices on the Indian economy, mentioning impacts on trade balance, inflation, and household savings. Narayanaswami [13] pointed out the structural features of the Indian gold trade and the influence of the policy measures in determining gold demand and its price. Gold price prediction has traditionally relied upon forecasting techniques like ARIMA and regression models. Guha and Bandyopadhyay [9] and Makala and Li [12] showcased the potential of ARIMA-based models for short-term gold price evaluation. Yet these models could not overcome the restrictions of not identifying nonlinear patterns and long-term dependencies. Patel [15] and Singh and Kaur [20] echoed the sentiments of the former researchers by stating that the impact of the macroeconomic factors on gold prices is so complex that linear models cannot adequately represent it.

With the upgrading of machine learning techniques, researchers have consequently started using deep learning models increasingly for gold price analysis. Shankar and Reddy [19] did forecast through application of time-series and deep learning algorithms with India as the focus and substantial accuracy increase compared to conventional methods was the outcome. Yurtsever [26] who dealt with LSTM, Bi-LSTM and GRU models and came to the conclusion that recurrent neural networks are better than statistical methods in capturing temporal dependencies. Madhika et al. [11] and Pan [14] confirmed that LSTM-based models are the best among the three. To achieve better forecasting accuracy, recent research has examined hybrid and advanced deep-learning frameworks. Among others, Boongasame et al. [5] suggested an LSTM-based model enriched with association rules while Saini et al. [16] presented a combined LSTM–autoencoder setup for predicting the price of gold. Zangana and Obeyd [27] also

Vol. 14, Issue 06, ACSCON - 2026

proved that deep learning models are mainly useful when the market is going through volatile conditions. The findings of comparative studies by Ahmad et al. [1] and Aljohani et al. [2] also imply that deep learning methods are decisively superior to classical statistical methods across all evaluation metrics. A lot of research has been carried out on gold price forecasting using macroeconomic and financial indicators, but not many studies have looked directly into the relationship between fiscal and policy interventions and gold prices. Emmanuel [7] studied Indian gold policies and reforms and pointed out that the import regulation and duty structure are among the factors that have a high impact on the import of gold and its domestic consumption pattern. Nevertheless, these kinds of studies are mostly qualitative and are not usually used in predictive modeling frameworks. Narayanaswami [13] pointed out that the Indian gold market is, in fact, different from global markets structurally because of the heavy policy intervention, mainly through import duties and regulatory controls. The authors claim that the domestic price variations cannot purely be accounted for by the global price and exchange rate variations. Singh and Joshi [21] confirm this observation by indicating that the economic and policy conditions in India significantly affect gold's role as an inflation hedge. To these deductions, the majority of the forecasting models give precedence to international variables only. Numerous empirical investigations have investigated the influence of macroeconomic shocks on gold prices but did not cover the analysis of discrete policy events. Arora et al. [3] and Ingalhalli et al. [10] provided evidence of the interconnection between oil, stock, forex, and gold markets, revealing that gold prices are not only sensitive to but also show a disproportionate response to market volatility. Nevertheless, the studies have regarded changes in policy as implicit background factors rather than explicitly articulating them as informing variables. A parallel case is Takhre and Pimplapure [24] that investigated the relationship among the prices of crude oil, equities, and gold but did not include government policies such as import duties or taxation changes as influencing factors. The most recent comparative studies have been directed towards the assessment of the predictive accuracy of various modeling techniques. Ahmad et al. [1] and Pan [14] were among those who scrutinized machine learning and deep learning models along with the conclusion that LSTM-based methods always surpass traditional statistical models. Aljohani et al. [2] even more confirmed the idea of superiority of multivariate deep learning frameworks in comparison with univariate models. However, these studies predominantly assess the model's performance in terms of accuracy of metrics and do not evaluate the interpretability or policy sensitivity of the models. One more major restriction present in literature is the non-utilization of events for validation in most cases. It is the total error measures that such as RMSE or MAE are widely used for the evaluation of forecasting models in terms of their performance, without putting the models to test on how market sudden changes influence them. Authors Shankar and Reddy [19] and Saini et al. [16] indicate the models' high predictive accuracy under normal circumstances but do not test the models' capabilities during times of policy shocks or regulatory interventions. This leads to the situation where it is not clear whether the current models are the ones that can cope with fluctuations in the real-world fiscal scenario.

Current research clearly shows that deep learning methods achieve better predictive results than traditional econometric models yet most studies focus on comparing research methods instead of applying them to real economic situations. The existing studies assess model performance through statistical accuracy standards yet they fail to include policy variables which can explain fundamental market shifts. The existing research fails to establish models which can handle both economic linkages and regulatory impacts especially in the Indian gold market.

IV. Methodology

The process of feature selection needs to use two standards which include economic relevance and previous study empirical evidence. The multivariate input structure enables the model to acquire knowledge about how different variables interact with each other throughout different time periods. The LSTM model uses sequential historical data for training as this data helps the model understand short-term changes and long-term patterns.

A. Data Collection

Yahoo Finance serves as a trusted financial data provider from which we obtained global gold prices and USD–INR exchange rates and Brent crude oil prices and the NIFTY 50 stock market index. International markets use global gold prices as their standard gold valuation, which shows that USD–INR exchange rate movements directly determine the domestic cost of imported gold. The study utilizes Brent crude oil prices to show how global economic conditions and inflationary pressures affect the economy while the NIFTY 50 index shows how the domestic stock market performs and how investors feel about the market. The dataset follows a daily frequency that permits the system to identify both tiny price fluctuations and short-term gold price movements together with their related macroeconomic information. The data collection covers the time frame from January 2015 until December 2025 which allows researchers to study various market behaviors during both unstable times and periods of governmental change. The system uses this time frame to learn about both established market trends and dynamic shifts in market behavior.

B. Data Pre-processing

The gathered data required thorough preprocessing work before model training because this process improved data quality and made the data suitable for time-series analysis. The data contained inconsistencies because it was collected from multiple sources which resulted in missing values that occurred during holidays and during times when data was not reported. The researchers used interpolation and forward-fill methods to

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

bridge the gaps which allowed them to maintain the series natural progression while maintaining continuity throughout the process. There is conversion of all variables into a standard daily schedule which enables to achieve proper feature synchronization throughout the study. The system applied Min-Max normalization as a feature scaling method which transformed all input data into a designated limited range. This step helps to maintain stability during neural network training while it prevents any single factor from dominating the process because of varying measurement scales. The model preprocessing stage plays a crucial role in enhancing both model performance and model trustworthiness.

C. Feature Engineering

The research developed lagged input variables which enabled researchers to study the time-dependent relationships between gold price movements. The model uses lagged features to discover how economic and policy variables from the past effect future gold price movements. The model needs to represent these import duty changes because they cause sudden shifts in domestic gold prices which result from marketable goods price changes. The research created features which show how global market conditions.

D. Model Development

Long Short-Term Memory (LSTM) neural network was used because it can easily handle both sequential data and nonlinear financial time-series data. Its function works effectively in situations which require them to maintain essential past data throughout extended time durations. The model learned through historical data so that it can identify complicated connections between gold prices and the chosen macroeconomic and fiscal factors.

E. Model Architecture

The LSTM model consists of memory cells equipped with gating mechanisms that regulate the flow of information. The system uses gates for maintaining the essential past data while throwing away useless information. The design improves model performance during market fluctuations and sudden policy changes, which helps it predict gold prices in India, a market that operates under strict regulations and governmental policies. The proposed model consists of a stacked architecture with two LSTM layers with 64 units and connect to a fully connected dense layer that produces the final output. The system includes a dropout layer which links two LSTM layers to decrease overfitting while increasing model ability to generalize. The model uses sliding time windows to handle sequential input data because this method allows it to detect short-term changes and long-term patterns in financial time-series data.

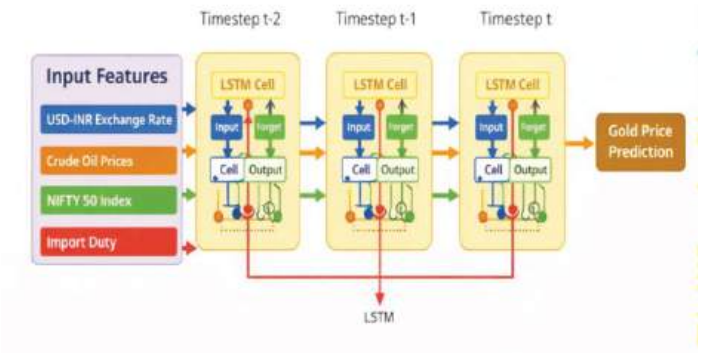

Fig. 1. LSTM Architecture

F. Training Configuration and Model Design Transparency

The Long Short-Term Memory network uses a learning system which trains through supervised methods to predict multiple streams of time-dependent data. The system applied delayed input variable observations to create a model that simulated both postponed economic effects and chronological connections. The Adam optimizer served to optimize model parameters while Mean Squared Error (MSE) functioned as the training loss function to minimize prediction errors. The final setup creates a model design which sustains accurate predictions through its combination of advanced model components and fundamental elements. There is implementation of structured hyperparameter tuning methods which led to improved model stability. There is examination of different network size configurations and input sequence length parameters together with various training settings to find the best combination. The study evaluated different combinations of parameters while using validation performance as the selection method instead of using fixed values. The process enabled better prediction results because it prevented problems which cause overfitting and underfitting. There is selection of final model settings based on their ability to handle new data which remained unseen instead of their performance in training dataset evaluation.

G. Model Evaluation

The study used Root Mean Squared Error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) because these metrics provide both absolute error and relative forecasting error measurement. RMSE method detects main prediction errors through its penalty system which imposes greater penalties for significant prediction mistakes. MAPE method provides a standardized error assessment which enables users to understand pricing data throughout different pricing situations. The model performance assessment included R-squared (R^2) and Mean Bias Error (MBE) in addition to the three measurement methods of RMSE, MAE, and MAPE. The R^2 metric measures the proportion of variance in gold prices explained by the model which allows assessment of model accuracy. The model performance evaluation uses MBE to measure systematic prediction bias because it shows whether the model tends to predict higher or lower than actual values.

Vol. 14, Issue 06, ACSCON - 2026

The additional metrics provide a complete evaluation system which assesses forecasting accuracy.

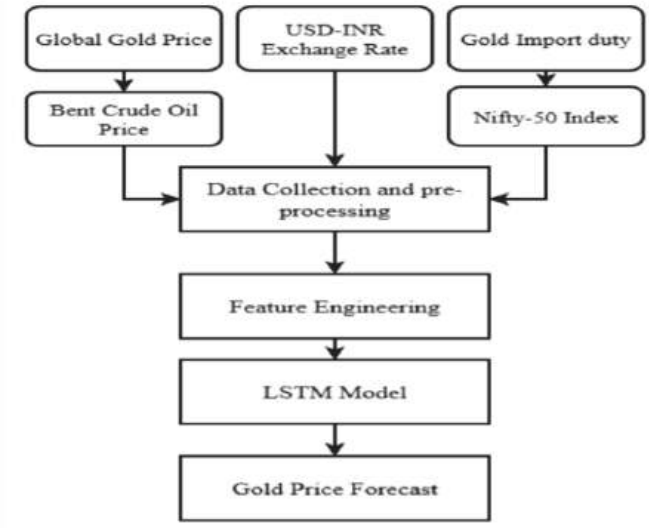

Fig. 2. Methodology Flow Diagram

V. Results and Findings

The evaluation results pointed out that the LSTM model managed to not only detect short-term fluctuations but also the long-range price trends in gold. The forecast values were in tight proximity with the actual gold price movements, thus allowing the model to be termed as one that has the capability to extract complex temporal patterns which are typical of financial time series data. The model shows improvement during periods of high volatility because it can adjust to different market conditions which arise from policy announcements.

The observed improvement in forecasting performance results from both model complexity and the inclusion of economically significant explanatory variables. Exchange rate movements determine import costs and investor hedging practices while crude oil prices function as indicators of global inflationary pressure and macroeconomic uncertainty. The proposed framework learns economic connections to capture both statistical patterns and structural market dynamics.

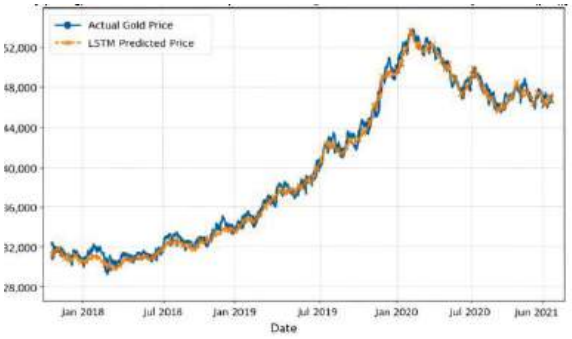

Fig. 3. Comparison of Actual and Predicted gold price

The standard regression metrics, which include Mean Absolute Error, Root Mean Squared Error and Mean Absolute Percentage Error allowed for a quantitative evaluation showing that the proposed model was very low in prediction errors throughout the testing period. These findings underline the model as a source of reliable and correct forecasts that are even acceptable for practical financial decision-making. The extended evaluation metrics confirmed that the proposed model showed strong performance across multiple testing methods. The high R^2 value demonstrated strong explanatory power, and the near-zero MBE value showed minimal prediction bias. The results of this study validate the multivariate LSTM framework as a reliable tool for financial forecasting in real-world applications.

A comparison in the form of analysis was made by placing LSTM model alongside conventional forecasting methods of ARIMA and basic regression models and then evaluating the former against the latter. The results clearly demonstrate that the LSTM-based model outperformed the baseline methods in all evaluation metrics. Through a detailed examination of the model's performance, it was revealed that the forecasting accuracy was significantly enhanced by the input of several macroeconomic variables. The Indian rupee to US dollar exchange rate and the NIFTY-50 index were among the factors that made the model more responsive during times of change in the currency and the stock market. Likewise, the factor of crude oil prices being included in the model helped to perceive the inflation and the global economic conditions that, in a way, are controlling the price of gold. This clearly shows the superiority of a multivariate method to the univariate price-based models.

VI. Conclusion and Future Scope

This research work has introduced a multivariate deep learning architecture for predicting gold prices in the Indian market that combined global commodity indicators with domestic macroeconomic variables. The proposed model utilized a Long Short-Term Memory (LSTM) network that works well in capturing nonlinear relationships and long-term temporal dependencies which are already embedded in the financial time series data. The different experiments' results indicated that the LSTM-based approach had a clear advantage over traditional

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

methods such as ARIMA and simple regression particularly during stressful market periods. The addition of various explanatory factors which included global gold prices, USD-INR exchange rates, Brent crude oil prices, and the NIFTY-50 index among others made the prediction of the model more accurate and robust. The conclusions from this study are that it is crucial to have a multivariate as well as market-aware modeling approach for gold price prediction in the case of emerging economies especially India. The proposed framework incorporates significant economic variables and reveals global trends, currency changes, energy market position, and investor mood, which are not only the basis for historical price data but also univariate models. Thus, the model offers more realistic and reliable predictions that go hand in hand with real market behavior. This could lead to better decisions being made by investors, financial analysts, and policymakers who are dealing with gold investments and risk management. The study was strong but had limitations, which are the foundations of future research. One of the limitations was the current model which relied on a restricted range of macroeconomic indicators while not taking fully into account the micro-factors that influence customer demand and speculative trading activities. Furthermore, even though the LSTM architecture is excellent for modeling time-based relations, it may completely miss the rapid changes in structure due to sudden geopolitical events or policy shifts. Improvements in these areas could still yield greater forecasting accuracy, model interpretability, and so on.

Future studies will likely have many different paths based on the present work. One way would be to consider 'Bidirectional LSTM, Gated Recurrent Units (GRU), or attention-based Transformer models' as deep learning forms of an advanced level, which possess a greater predictive capability. Furthermore, the researchers may take the knowledge of gold price dynamics more extensively by considering the variables such as interest rates, inflation indices, or even sentiment indicators generated through news and social media, which are more comprehensive than the existing ones. Moreover, multi-horizon forecasting or adapting the proposed framework for use in other commodities and emerging markets would be further avenues of application for the model.

***Abstract*— Some children find it difficult to speak clearly and communicate their needs. They may use AAC tools to form sentences using symbols, but these tools do not help them improve how they pronounce words. Because of this, children may continue making the same mistakes in speech without understanding how to correct them. This project presents Echo Learn, a web-based system designed to support both communication and basic speech practice. The application allows children to select symbols to form sentences and also try speaking simple words or sentences. The spoken input is checked using a speech analysis service, which identifies where mistakes occur in pronunciation. To help the child improve, the system provides simple visual hints that show how to move the lips and tongue while speaking a particular sound.. The system also saves results from each attempt and shows progress in an easy format. Overall, the proposed system provides a simple and practical way to support speech improvement along with communication in a single platform.**

Keywords— AAC, Speech Practice, Pronunciation Error, Assistive System, Speech Support, Web-Based Tool, Learning Aid.

I. INTRODUCTION

Clear speech communication plays a very important role in everyday human interaction and social development. For children with neurodevelopmental conditions, articulation disorders, or other speech impairments, developing functional communication skills is often a long-term and ongoing challenge. These children frequently depend on Augmentative and Alternative Communication (AAC) systems to express basic needs and to interact with their environment.

Although AAC platforms have been helpful in supporting expressive communication, they mainly focus on enabling output through symbol selection and text-to-speech mechanisms and do not fully address the underlying pronunciation difficulties that many users experience. Traditional speech therapy usually requires regular sessions with a therapist, fixed schedules, and subjective evaluation of progress. These methods are time-consuming, difficult to extend into home settings, and give parents limited objective data about how their child is actually improving.

A major gap in current assistive technology is the absence of visual articulation guidance. Children with speech difficulties cannot easily correct sounds they cannot see or understand physically. Simply knowing that a sound is wrong is not enough; they also need to know where the tongue should go, how the lips should be shaped, and how the breath should flow. This visual aspect of articulation learning is almost entirely missing from existing AAC and pronunciation-training platforms.

Recent advances in cloud-based speech recognition have made it possible to perform phoneme-level pronunciation assessment within standard web architectures, allowing real-time detection of specific articulation errors without the need for specialized hardware. This paper presents Echo Learn, a web-based assistive application that combines AAC communication support with an integrated pronunciation learning module. The system offers symbol-based sentence construction, phoneme-level error detection using the Microsoft Azure Pronunciation Assessment API, and a dedicated articulation visualization system that shows lip configuration, tongue position, and airflow direction for each target phoneme. Session-based progress tracking and graphical analytics provide clear, objective visibility into pronunciation development over time.

The main contributions of this work are:

1. a unified platform that integrates AAC communication and structured pronunciation practice;
2. real-time phoneme-level error detection and single-error-first corrective feedback;
3. an articulation visualization system that demonstrates lip shape, tongue position, and airflow guidance for each phoneme; and
4. session-based analytics that enable objective monitoring of pronunciation improvement trends.

II. MOTIVATION AND PROBLEM DEFINITION

Children with speech and communication difficulties form a diverse group with complex and varied needs. While AAC platforms successfully meet immediate communication demands,

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

they do not actively support the deeper goal of improving a child's ability to produce sounds accurately. This gap between communication assistance and pronunciation development represents a significant unmet need in current assistive technology.

Between therapy sessions, children and caregivers often lack practical tools that can provide clear, real-time feedback on pronunciation attempts. Without this kind of ongoing support, incorrect articulation patterns can persist for long periods without correction. A particularly important limitation is the absence of visual articulation guidance in existing systems. Pronunciation correction is not just about noticing that a sound is wrong; it is about understanding the exact physical mechanism of correct sound production. Lip position, tongue placement, and airflow direction form the physical basis of articulation, yet no current AAC platform offers this kind of visual feedback.

The key problems addressed in this work are:

- existing AAC systems provide no structured pronunciation practice or phoneme-level correction;
- there is no visual articulation guidance in current AAC platforms that shows lip shape, tongue position, and airflow for specific sounds;
- children do not have access to objective, real-time feedback on specific articulation errors between therapy sessions;
- caregivers lack data-driven insight into pronunciation progress or recurring weak sound patterns over time; and
- communication support and pronunciation development remain separate functions with no integrated platform that addresses both together.

Echo Learn addresses these limitations by providing a single, accessible platform where a child can communicate using AAC symbols and at the same time receive structured, phoneme-specific pronunciation guidance with visual articulation support.

III. LITERATURE REVIEW

Augmentative and Alternative Communication systems have been extensively studied and deployed to support individuals with speech and communication impairments [8]. Established platforms such as Tobii Dynavax and Proloquo2Go enable expressive communication through image-based symbol selection and text-to-speech output [9]. These systems significantly improve communication ability but do not incorporate structured pronunciation assessment or articulation improvement mechanisms [10].

Research in automatic pronunciation evaluation has progressed considerably [3]. Early approaches relied on rule-based phoneme matching and word-level scoring, lacking the granularity required for precise identification of individual articulation errors [3]. Subsequent work introduced phoneme-level evaluation using hidden Markov models and acoustic feature analysis, enabling more detailed mispronunciation detection [5]. These advances improved feedback specificity but remained largely confined to research environments [5].

The emergence of deep learning-based speech recognition has significantly enhanced pronunciation assessment capabilities [6]. Cloud-based services now expose phoneme-level accuracy scoring, error classification, and prosody evaluation through accessible APIs [1]. Microsoft Azure Pronunciation Assessment provides per-phoneme accuracy scores, error type classifications including omission, insertion and mispronunciation, and word-level metadata through a standard API interface [1].

Children's speech presents additional complexity due to higher fundamental frequency, variable articulation patterns, and developing phonological systems that differ substantially from adult speech [2]. Pronunciation assessment accuracy for children remains an active area of development with limited practical deployment in assistive technology contexts [11].

Visual articulation guidance has been demonstrated as an effective complement to auditory feedback in pronunciation learning [10]. Research indicates that combining visual mouth position demonstrations with auditory correction improves articulation outcomes, particularly for learners who struggle to internalize sound production from audio alone [10]. Despite this evidence, integration of lip shape, tongue position, and airflow visualization within AAC platforms remains almost entirely absent from existing implementations [7]

A clear research gap exists in combining AAC communication support, phoneme-level pronunciation assessment, visual articulation guidance showing lip configuration, tongue position and airflow, and session-based analytics within a unified web-based platform. Echo Learn addresses this gap directly.

A comparative analysis of existing AAC systems and Echo Learn is presented in TABLE I

TABLE I
COMPARISON OF ECHOLEARN WITH EXISTING AAC SYSTEMS

Feature	Tobii Dynavox	Prolo-quo2Go	Traditional AAC	Echo Learn
Communication Support	Yes	Yes	Yes	Yes
Phoneme-Level Feedback	No	No	No	Yes
Articulation Visualization	No	No	No	Yes
Tongue and Airflow Guidance	No	No	No	Yes
Progress Analytics	No	No	No	Yes
Web-Based Architecture	No	No	No	Yes

IV. PROPOSED SYSTEM OVERVIEW

Echo Learn is designed as a unified web-based assistive application that combines two core functional modules—an AAC communication module and a pronunciation practice module—within a single child-facing interface accessed through a dedicated child login.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A. AAC Communication Module

The AAC module provides a symbol-based communication board organized into categories such as needs, emotions, actions, objects, and social expressions. Each tile, when selected, speaks the corresponding word aloud using the Web Speech API and adds it to a sentence construction bar The child creates sentences by adding words one at a time and then triggers the full sentence to be spoken using a dedicated speak button. Some commonly used response tiles work as direct-speak buttons that skip the category navigation completely. The board also allows tiles to be added or removed, so that the layout can be adjusted to match each child's specific communication needs.

B. Pronunciation Practice Module

The pronunciation practice module provides structured speech practice through word- and sentence-based exercises that are grouped by difficulty level. The child attempts to reproduce a target word or sentence by speaking into the microphone. The Microsoft Azure Pronunciation Assessment performs phoneme-level analysis, and the system identifies the most problematic phoneme in that attempt.

A central contribution of Echo Learn is its articulation visualization system. When a phoneme error is detected, the system displays a focused visual showing the correct lip configuration, tongue position, and airflow direction for that specific sound. This helps children understand not only that a sound is incorrect but also exactly how to produce it physically—where to place the tongue, how to shape the lips, and how to direct the breath. The visual is shown alongside a simple, child-friendly correction hint in encouraging language. The child retries the full word or sentence, with up to five attempts allowed before the system advances with a positive message and no negative reinforcement.

C. Design Principles

Echo Learn is built around three guiding principles: integration (AAC and pronunciation practice in one platform), specificity (single-phoneme correction per attempt with precise visual articulation guidance), and accessibility (child-appropriate language, visual feedback, and simple interaction throughout).

V. SYSTEM ARCHITECTURE

Echo Learn follows a modular client-server architecture built on the MERN stack, comprising React.js on the frontend, Node.js and Express.js on the backend, and MongoDB as the database, integrated with the Microsoft Azure Pronunciation Assessment API. The overall system architecture of Echo Learn is illustrated in Fig. 1.

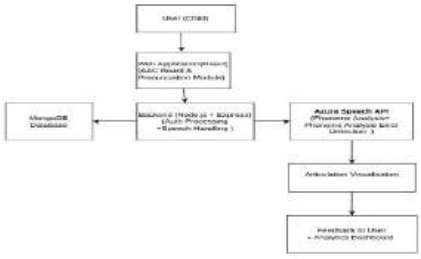

Fig. 1: System Architecture Workflow

A. Authentication Module

The authentication module manages child login verification. Credentials are checked on the Express.js backend by comparing them with the data stored in MongoDB, which connects each child's practice history and progress records to their individual profile across different sessions.

B. AAC Interaction Module

The AAC module handles the symbol-based communication board, tile selection, sentence buffer construction, and speech synthesis via the Web Speech API using a locally defined pronunciation mapping table that corrects Indian-English TTS inconsistencies

C. Pronunciation Assessment Module

The pronunciation assessment module captures microphone input via the Media Recorder API and transmits the audio to the Node.js backend as a binary blob along with the reference text. The backend forwards both to the Microsoft Azure Pronunciation Assessment API, configured at phoneme-level granularity. The returned JSON response is parsed to identify the phoneme with the lowest accuracy score, which is mapped to the articulation visualization system to return lip configuration, tongue position, airflow guidance, and a correction hint for display. The detailed pronunciation assessment workflow is shown in Fig. 2.

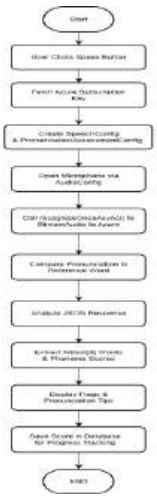

Fig. 2: Pronunciation Assessment Workflow

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Articulation Visualization System

A structured phoneme-to-articulation mapping system associates each Azure-returned phoneme identifier with a dedicated visual that demonstrates the correct lip shape, tongue position, and airflow direction for that sound. This system constitutes a core technical contribution of Echo Learn, providing children with precise physical guidance for sound correction that text hints alone cannot convey.

E. Analytics Module

Processes stored attempt history from MongoDB to compute average phoneme accuracy across sessions and per-item score progression over sequential attempts. Results are rendered as a phoneme accuracy bar chart and a progress line chart using the Recharts library. The core system components and technologies used in Echo Learn are summarized in Table II.

TABLE II
ECHOLEARN SYSTEM COMPONENTS

Component	Technology	Description
Frontend	React.js	AAC board, practice UI, analytics
Backend	Node.js, Express.js	REST API, speech processing
Database	MongoDB	Profiles, attempt history
Speech Assessment	Azure Pronunciation Assessment	Phoneme scoring and error detection
Articulation Visualization	Local mapping system	Lip, tongue, airflow guidance per phoneme
Speech Synthesis	Web Speech API	Reference pronunciation playback
Analytics	Recharts	Bar chart and line chart rendering

VI. METHODOLOGY

The EchoLearn system operates through two integrated workflows — AAC communication and pronunciation practice — supported by a session-based analytics layer.

A. AAC Communication Workflow

Communication tiles are organized into predefined categories and rendered as a symbol-based grid. Each tile selection triggers speech synthesis via the Web Speech API using a locally defined pronunciation mapping table constructed to produce accurate phonetic output under Indian-English TTS conditions. Selected words are appended sequentially to a sentence buffer. Full-sentence playback is initiated through a dedicated speak control. High-frequency response tiles are configured as direct-speak elements that bypass category navigation to minimize interaction steps. The AAC communication process flow is illustrated in Fig. 3.

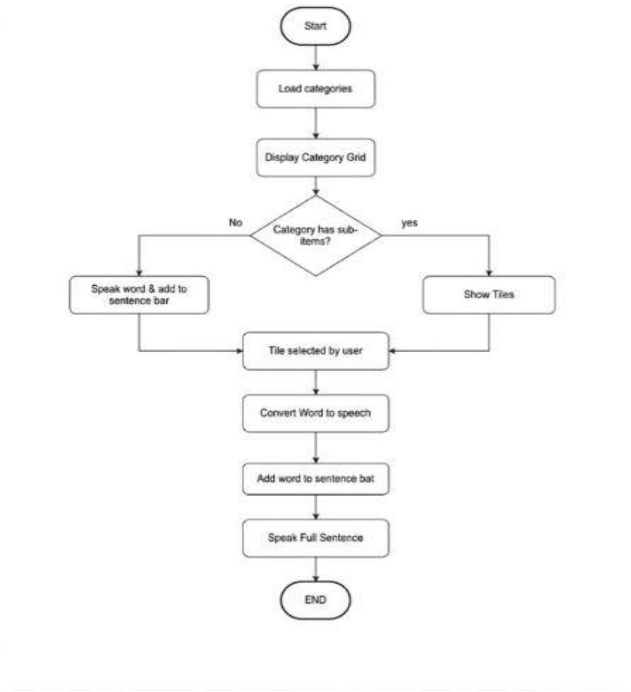

Fig. 3: AAC Communication Workflow

B. Dataset Structure

The word dataset is categorized by communication domain and difficulty level, determined by syllable count and phoneme complexity. The sentence dataset consists of a fixed set of essential daily-life communication phrases selected for practical relevance to the target user group, organized by category into needs, health, feelings, and social expressions.

C. Pronunciation Assessment

Audio is captured via the MediaRecorder API and transmitted to the Node.js backend as a binary blob along with the reference text. The backend forwards both to the Microsoft Azure Pronunciation Assessment API, configured at phoneme-level granularity with miscue detection enabled. The API returns per-phoneme accuracy scores in the range, along with error-type classifications (mispronunciation, omission, insertion) and word-level metadata.

D. Phoneme Error Identification and Articulation Guidance

The system reads the returned response and picks out the phoneme that has the lowest accuracy score in that attempt. This phoneme is treated as the sole correction target for the current feedback cycle. The identified phoneme is matched with the articulation visualization system, which then returns a visual that shows the correct lip shape, tongue position, and airflow direction for that particular sound. This visual is shown together with a simple, child-friendly correction hint. By giving only one correction per attempt, along with clear physical articulation guidance, the system keeps the child's mental load low and focuses directly on the specific way the sound is being produced, instead of offering general or vague feedback.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

E. Retry Evaluation

Each attempt is evaluated with a new call to the Azure API, independent of earlier attempts. This way, the feedback is based only on the child's current speech and does not carry forward any earlier errors or history. A maximum of five attempts is permitted per practice item. If all attempts are exhausted, the system advances automatically with an encouraging message and no negative reinforcement.

F. Progress Tracking and Analytics

Each attempt is persisted in MongoDB, including the child identifier, target item, attempt number, overall accuracy score, per-phoneme scores, error classifications, articulation guidance delivered, and a timestamp. The average phoneme accuracy across sessions is computed as:

$$\text{AvgPhonemeScore}_p = \left(\sum_{i=1}^{N} \text{Score}_{p,i}\right) / N$$

where $\text{Score}_{p,i}$ is the accuracy score of phoneme p in attempt i, and N is the total evaluated attempts for that phoneme. The system generates two visualizations—a phoneme-accuracy bar chart and a progress line chart—rendered using the Recharts library within the React frontend.

VII. IMPLEMENTATION DETAILS

The system is built as a web-based client–server application using the MERN stack. The overall design is kept modular so that the code stays organized, easy to understand, and simple to extend when new features are added. The frontend is developed with React.js, the backend runs on Node.js with Express.js, and all data is stored in MongoDB using Mongoose as the object-document mapper. The system also connects to the Microsoft Azure Pronunciation Assessment API to evaluate speech and give feedback to the user.

The frontend handles the user interface, including the AAC communication board, the pronunciation practice controls, the articulation visualization, and the analytics dashboards. React components are grouped around main features, so there is one section for the symbol board, another for building sentences, one for audio recording, one for showing feedback, and one for displaying progress charts. Basic React hooks such as useState, useEffect, and useContext are used to manage the application state across different parts of the interface, which helps keep the screen updated as the child selects tiles, records speech, or checks progress. This makes it possible to match the UI with the child's current activity—for example, updating the sentence bar when tiles are picked, showing feedback right after each pronunciation attempt, and refreshing the analytics charts when the progress page is opened. The interface is kept simple and child-friendly, with large tiles, clear icons, and very little text, so that children can use the system with little or no adult help.

The backend runs on Node.js with the Express.js framework and provides API endpoints for different tasks. When a child logs in, the backend checks the entered credentials against the records stored in MongoDB and links the session to that child's profile. Separate routes handle AAC-related actions such as loading tiles and saving custom layouts, pronunciation-practice operations such as sending audio for assessment and storing attempt results, and analytics requests such as retrieving score history for a particular phoneme or word. The modular design of these routes helps separate one part of the system from another, so that changes in one module—for example, adding a new visualization or changing how scores are computed—do not affect the rest of the system. The backend also includes basic error handling and simple logging to help spot and fix problems during testing and while preparing the system for deployment.

Speech pronunciation evaluation is handled using the Microsoft Azure Cognitive Services Pronunciation Assessment API. When the child speaks into the microphone, the browser records the audio using the MediaRecorder API and sends the captured file as a binary blob to the Node.js backend. Along with the audio, it also transmits the matching reference text for that word or sentence so the backend can pass both to the pronunciation-assessment service for analysis. The backend forwards both the audio and the reference text to Azure, which returns a JSON response with overall accuracy, per-phoneme scores, error types (such as mispronunciation, omission, or insertion), and word-level information. The backend processes this response to find the phoneme with the lowest accuracy score, which is treated as the main sound that needs correction.When the child finishes speaking, the system prepares a clear and simple response that includes the overall pronunciation score, highlights the problematic phoneme, and adds any extra details the frontend needs to display feedback and update the analytics. In the React frontend, the articulation visualization system is built as a basic JavaScript mapping object. Each phoneme identifier received from Azure is linked to a specific visual element that shows how the lips and tongue should move and how the airflow should flow to produce that sound correctly. For example, the "th" sound is linked to a picture where the tongue is placed between the teeth, the lips are slightly open, and the airflow goes through the small gap. When the backend returns the lowest-scoring phoneme, the frontend looks it up in this mapping and retrieves the matching visual and a short, child-friendly hint (such as "bite your tongue" or "lips together, then release"). This visual-feedback pair is shown in the feedback area, giving the child a clear physical idea of how to correct the sound instead of just hearing the right audio.

The database layer uses MongoDB, with Mongoose to define schemas and manage data operations. Child profiles are stored as individual documents that include basic details such as the child's name, age, and login information. Practice sessions and pronunciation attempts are stored as nested documents under each child's profile, so that related data stays grouped together. Each attempt record includes the child identifier, the target item (word or sentence), the attempt number, the overall score, an array of per-phoneme scores, error classifications, the articulation guidance shown, and a timestamp.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

This structure keeps the data rich and detailed, while still simple to query and work with. For instance, the analytics engine can quickly retrieve all pronunciation attempts made by a specific child or for a particular word, then calculate averages, track progress over time, or extract other useful metrics from that dataset.

The analytics engine processes the stored attempt history and turns it into meaningful summaries. On the backend, the system reads the attempt records from MongoDB, groups the scores by phoneme and by item, and calculates averages across sessions. For each phoneme, it finds the average accuracy across all attempts and marks any phonemes that fall below a set threshold as weak sounds that need extra practice. The engine also watches how the scores for individual words or sentences change over time, which helps identify gradual improvement or ongoing difficulties. The computed results are sent to the frontend as a simple JSON object that can be easily displayed using the Recharts library. The frontend shows the results either as a bar chart of phoneme-level accuracy or as a line chart of progress across attempts, depending on which view the user picks.

Through this mix of interactive frontend design, backend processing, cloud-based speech assessment, and a flexible database structure, Echo Learn delivers a practical and usable platform for pronunciation practice and communication support. The implementation is modular enough to allow future additions, such as new visualizations, offline models, or support for different languages. At the same time, the current design keeps the interface simple and focused so that children can follow the guidance without getting confused by technical details.

VIII. RESULTS AND PERFORMANCE EVALUATION

The system was tested through multiple practice sessions under conditions that loosely mimic real user interaction. The focus was on checking whether the platform could correctly record pronunciation scores, identify weak words, compute analytics efficiently, and update the visualizations in a timely way. The user interface and system outputs are shown in Figs. 4–8.

Vol. 14, Issue 06, ACSCON - 2026

A. AAC Module Evaluation

The AAC communication board worked correctly in all predefined categories. Tile selection, sentence building, and playback operated without noticeable delay. The locally defined pronunciation mapping table successfully corrected several Indian-English TTS quirks, so that even commonly mispronounced words sounded closer to standard speech. Tiles that were set as high-frequency response elements functioned as direct-speak buttons and did not require navigating through category menus, which sped up the communication process for common phrases. Adding and removing tiles also worked reliably, allowing basic customization of the board for different children.

B. Pronunciation Assessment Results

Table III summarizes pronunciation assessment results obtained from practice sessions in both word and sentence modes.

TABLE III
PRONUNCIATION ASSESSMENT RESULTS

Item	Type	Difficulty	Score (%)	Weak Phonemes
food	Word	Easy	82.8	—
help	Word	Easy	82.7	—
bathroom	Word	Hard	70.6	b, ae, th
breakfast	Word	Hard	63.4	b, r,eh, k, f
I need help	Sentence	Medium	52.5	d, h, eh, p
Please call for help	Sentence	Hard	58.1	p, l, iy, k, aa

Easy-level words generally scored above 80%, which suggests that simpler vocabulary was often produced with relatively clear articulation, especially when visual guidance was given. Hard-level words and multi-word sentences scored lower, reflecting the increased difficulty of longer or more complex utterances. The articulation visualization system delivered the correct lip configuration, tongue position, and airflow direction for each identified weak phoneme, giving children specific physical cues instead of only general feedback

C. Per-Phoneme Accuracy Analysis

The analytics module aggregated phoneme scores across all sessions and produced a phoneme-accuracy bar chart. The chart showed that certain phonemes such as uw, ao, r, and f tended to stay above 75% accuracy, indicating that children were usually able to produce them correctly. Other phonemes such as b, ae, l, aa, and k often scored below 40%, marking them as clear targets for focused articulation-guided practice. This breakdown at the phoneme level helps pinpoint exactly which sounds are causing the most trouble, which a simple word-level score would not reveal.

D. Progress Tracking Evaluation

Table IV shows how the score changed for the word bathroom over five successive attempts.

TABLE IV
PROGRESSIVE ATTEMPT SCORES — BATHROOM

Attempt	Score (%)	Weak Phoneme	Articulation Guidance Delivered
1	70.6	b	Lip closure and release
2	73.2	ae	Wide mouth open position
3	76.8	th	Tongue between teeth airflow
4	79.1	th	Tongue between teeth airflow
5	82.4	r	Tongue curl back position

In each attempt, the system identified the weakest phoneme and showed the corresponding visual articulation guidance. This allowed the child to gradually improve the production of the word as the focus shifted from one sound to another. By the fifth attempt, the overall score had increased from 70.6% to 82.4%, which suggests that repeated, guided practice can lead to measurable improvement.

E. System Performance

The system remained stable during testing. Azure API calls returned responses quickly, so feedback appeared almost in real time without obvious lag. AAC interactions, sentence construction, and speech playback were smooth, with no noticeable freezing or delay. The analytics dashboard loaded correctly and updated charts as soon as the user switched to the progress view. Overall, the platform demonstrated that it can reliably record and process pronunciation data, deliver targeted articulation feedback, and show progress in a clear, visual way.

IX. ADVANTAGES AND LIMITATIONS

A. Advantages

Echo Learn offers several important improvements over existing AAC platforms. By combining AAC communication and structured pronunciation practice in a single web-based application, it reduces the need for separate tools and keeps everything in one place for the child, parents, and therapists. The use of Microsoft Azure Pronunciation Assessment at the phoneme level allows very specific identification of which sounds are being misarticulated, something that word-level scoring cannot do.

The articulation visualization system is one of the main strengths of the platform. By showing how the lips move, where the tongue should be placed, and how the airflow should flow for each phoneme, it helps children understand the physical process of sound production, not just the sound itself. The single-error-first feedback strategy keeps instructions simple and avoids overwhelming the child with too many corrections at once. Each attempt is checked independently, so the feed-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

back always reflects the child's current articulation. The session-based analytics also give caregivers a clear, visual record of how pronunciation is changing over time, which can be useful for planning further practice. Finally, the web-based MERN stack allows the system to run on multiple devices without installing special software, making it easier to use at home or in a classroom.

B. Limitations

Some limitations come from the system's dependence on the Microsoft Azure cloud service. If the network connection is weak or unstable, there can be noticeable delays in feedback or even occasional failures to process the audio. The Pronunciation Assessment API is mainly trained on adult speech, so its scoring for children may not always match the way a speech therapist would judge the same sounds.

At present, the system only supports English-language assessment, so it is not suitable for children who primarily use other languages. The articulation visuals are currently based on static images, which gives a good idea of how the mouth should look but does not show the full movement over time. Finally, the feedback is fully automated, so it cannot replace the nuanced judgment and emotional support that a human therapist can provide in real sessions. These factors mean that Echo Learn works best as a supplementary tool between therapy visits, not as a full replacement for professional speech support.

X. FUTURE SCOPE

The current design of Echo Learn can be extended in several directions. One possibility is to integrate offline speech-recognition models so that at least basic phoneme-level assessment can continue even when the internet connection is poor or absent. This would also reduce the time between speaking and feedback, making the practice feel more immediate.

The pronunciation models themselves could be fine-tuned using children's speech data, which would likely improve their accuracy for the target user group. The articulation visualization system could be expanded to include simple animations or 3D-style models that show how the tongue moves and how the lips change shape over time, rather than just a single still image. This kind of dynamic feedback would give children a more realistic picture of how sounds are produced.

Supporting more than one language would broaden the platform's usefulness across different communities. The system could also be made more adaptive by using the stored attempt history to select words and sentences that best match the child's current weak sounds, instead of following a fixed list. Machine learning–based analytics could try to predict upcoming difficulties and suggest extra practice before errors become strongly established.

Adding small gamification elements—such as points, badges, or simple rewards for completing practice sessions—might help keep children motivated during longer or repeated sessions. Finally, deploying the application to the cloud would allow usage across multiple devices and make it easier to share progress data between home, school, and therapy rooms.

XI. CONCLUSION

This paper introduced **Echo Learn**, a web-based assistive application that combines Augmentative and Alternative Communication (AAC) support with structured pronunciation practice in one platform. The system fills a clear gap in current AAC tools, which often focus only on expression without offering phoneme-level feedback or visual guidance on how the lips, tongue, and airflow should move. Echo Learn gives children a simple symbol-based board to build sentences and express basic needs, supported by clear speech synthesis tuned for Indian-English conditions, while the pronunciation module uses Microsoft Azure Pronunciation Assessment to detect mispronounced phonemes and guide correction.

The articulation visualization system helps children see how each sound should be physically produced, going beyond what they can learn by listening alone. Testing showed that the system can reliably capture speech, compute phoneme-level scores, and provide targeted guidance that leads to measurable improvements over repeated sessions.

***Abstract*—**Access to justice is still a major challenge worldwide due to complicated processes, high legal fees, and low public awareness of available resources. Most current legal aid systems and chatbots are scattered, providing limited contextual understanding and minimal personalization. This paper presents Agentic AI for Legal Assistance, a framework aimed at simplifying legal processes using Artificial Intelligence (AI). The system automates key tasks including legal triage, outcome prediction, and document creation. By leveraging Natural Language Processing (NLP) and Machine Learning (ML), it analyzes and interprets legal narratives provided by users with high accuracy. Text undergoes linguistic preprocessing—including tokenization, lemmatization, and stop-word removal—to ensure clarity and consistency. A transformer-based sentiment analysis model then detects emotional and contextual details in the input. The refined narrative is converted into sentence embeddings and assessed using a multinomial logistic regression model, which predicts the likely outcome of the case, its chances of success, and its overall complexity. A Recommendation Engine improves user experience by suggesting relevant pro bono or legal aid providers, while a Document Generator creates personalized legal documents such as affidavits through automated templates. A Security Layer guarantees that all user data and generated documents are encrypted end-to-end. This structure demonstrates how agentic intelligence can independently interpret, predict, and act in the legal field, providing intelligent, privacy-focused, and accessible legal support.

Keywords*—Artificial Intelligence (AI), LegalTech, Natural Language Processing (NLP), Machine Learning (ML), Legal Triage, Case Outcome Prediction, Document Automation, Sentiment Analysis, Encryption, Pro Bono Recommendation, Agentic AI, Legal Assistance.*

I. INTRODUCTION

The growing complexity of modern legal systems, combined with a lack of affordable professional help, has created a significant gap in access to justice. People with limited legal knowledge often find it hard to understand their rights, navigate court processes, or find useful resources. Existing digital platforms, while numerous, typically offer only basic information or simple question-and-answer setups lacking contextual understanding and proactive reasoning.

Agentic AI for Legal Assistance addresses these problems by combining several AI-driven features into a unified, self-sufficient framework. The system's NLP Processor interprets and refines user narratives, extracting important linguistic and emotional cues. The Triage Module uses predictive modeling techniques—including logistic regression and sentence embeddings—to determine likely outcomes and evaluate case complexity. A Recommendation Engine identifies appropriate legal aid or pro bono service providers based on case type and location. A Document Generator automates the creation of standardized legal forms, reducing manual labor and minimizing human error. The Security Layer uses encryption to secure sensitive information throughout the process.

By merging contextual language understanding, predictive analytics, and independent task management, this agentic AI framework transforms the traditional legal aid process into an intelligent, interactive, and privacy-focused system. The result is a scalable solution that empowers individuals to make informed legal decisions while substantially lowering the time and cost barriers linked to traditional legal processes.

II. LITERATURE REVIEW

The current literature shows the transformative potential of AI, ML, and intelligent chatbots in improving efficiency in the legal sector and making justice more accessible. Research examines practical uses such as legal summarization and information retrieval through conversational AI [1]. This builds on earlier work on creating improved self-help systems to enhance public access to legal services [2]. Recent studies have introduced functional real-world tools, including the "Bettercall" AI-based legal assistant [4] and an Assistance System for Online Dispute Resolution (ODR) [5]. Wyawahare et al. [3] provide important insights by comparing Generative and Intent-based Chatbots for judicial advice. K.R A et al. [7] detail the creation of ML-powered chatbots for structured legal solutions.

A strong focus exists on using AI to improve access to justice and legal literacy for the public. Works such as the "AI Legal Companion" [6, 10] highlight how technology can simplify complex legal information. However, this rapid advancement requires close examination of its social impact. K.R et al. [8] discuss ethical and legal issues surrounding AI chatbots, emphasizing the need for strong frameworks on data privacy, professional responsibility, and algorithmic bias. Rana et al. [9] focus on AI applications in the Indian judicial system, illustrating the unique opportunities and obstacles different national judicial systems face when adopting these technologies.

III. METHODOLOGY

The proposed Agentic AI for Legal Assistance framework has a modular, agent-driven setup that combines Natural Language Processing (NLP), Machine Learning (ML), Explainable AI (XAI), intelligent recommendation systems, document

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

automation, and cryptographic security to provide clear, adaptable, and privacy-focused legal support. The system uses a multi-stage process where autonomous agents work together to transform unstructured legal narratives into understandable predictions, actionable recommendations, and organized legal documents.

A. Data Acquisition

This study uses over one hundred separate datasets of written cases across many domains. The datasets include privately written legal case narrative text in the areas of employment, family law, contract, and tort. Each dataset contains three separate data fields: case_text (user-provided legal narrative), outcome_label (outcome categories: Won, Settled, Dismissed, or Needs More Evidence), and complexity (difficulty levels: Low, Medium, or High) determined by narrative characteristics.

The dataset is structured to support an agentic framework with specialized AI agents: a Triage Agent, Complexity Analysis Agent, and Explainability Agent. It contains an approximately equal number of cases by complexity level (18 Low, 20 Medium, and 12 High) to ensure robustness and generalizability across legal environments. Text preparation includes normalizing and enriching data through tokenization, lemmatization, stop-word removal, sentiment labeling, and dense vector representations via a SentenceTransformer model.

B. Data Preprocessing

The NLP Agent manages preprocessing to convert raw legal narratives into structured, meaningful representations. All text is first converted to lowercase to eliminate case discrepancies. The text then undergoes tokenization to identify individual words, stop-word removal to eliminate non-informative content, and lemmatization to reduce words to their base form, ensuring consistent representation.

The NLP Agent additionally uses transformer semantic processing to improve text-based context understanding. The agent generates contextual word embeddings that reflect the specific context in which each word was used, and also performs sentiment analysis to establish the sentiment polarity (positive, negative, or neutral) associated with the case. This information is appended as a feature to provide a measure of emotional intensity and urgency, significantly improving the quality of input for all subsequent modules.

C. Case Representation and Outcome Prediction

Legal narratives in processed form are fed through a SentenceTransformer neural model (all-MiniLM-L6-v2) that outputs dense semantic vector representations. These embeddings provide semantic context, allowing the system to identify relationships between legal cases even when stated differently.

The Triage Agent uses the embeddings to drive a multinomial classification model—such as logistic regression or a transformer-based classifier—which predicts the most likely outcome from four possible classes: (1) Dismissed, (2) Settled, (3) Won, or (4) Needs More Evidence. The Complexity Analysis Agent classifies legal case complexity into (1) Low, (2) Medium, or (3) High using a combination of heuristic rules and learned linguistic patterns.

To promote transparency, the Explainability Agent is embedded within the prediction pipeline with the following functions:

- Highlighting key phrases in the input that significantly influence model predictions
- Producing a confidence score for the predicted legal outcome
- Providing feature-level explanations associated with the model's predicted outcome

D. Legal Resource Recommendation and Document Automation

Using a hybrid recommendation model, the Recommendation Agent connects users to applicable legal service providers through a structured dataset of legal aid providers. It employs:

- Rule-based filtering (e.g., by case type and location)
- Similarity-based ranking (embedding similarity and context relevance)
- Priority weighting (such as urgency and complexity level)

The Document Automation Agent streamlines production of legal documents such as affidavits, petitions, and applications using a JSON template system with dynamic placeholders filled based on user input and modeling. Documents are generated contextually with proper structure and case-specific alignment, reducing manual labor and minimizing errors.

E. Encryption Mechanism and System Architecture

The system provides complete data confidentiality and integrity through Fernet symmetric encryption to protect user narratives, predictions, and generated documents. All sensitive data is encrypted before being stored or transmitted, and only authorized agents can decrypt and process the data.

The system architecture is modular with separated agent responsibilities for flexibility, scalability, and maintainability. It comprises four layers:

1) **Frontend Layer – User Interaction:** A web interface and chatbot through which users submit legal narratives and receive predictions, explanations, recommendations, and downloadable documents in real time.
2) **Agentic Processing Layer – AI Agents:** Specialized agents including the NLP Agent (Text Preprocessing and Embedding), Triage Agent (Outcome Prediction), Complexity Agent (Case Difficulty Determination), and XAI Agent (Interpretations and Explanations).
3) **Recommendations and Automation Layer – Legal Agent:** The Recommendation Agent (Matching Legal Services to Users) and Document Automation Agent (Creating Legal Drafts).

Vol. 14, Issue 06, ACSCON - 2026

4) **Security Layer – Privacy Protection:** The Security Agent encrypts all sensitive data and ensures secure data transfer between components, providing compliance with applicable data protection regulations.

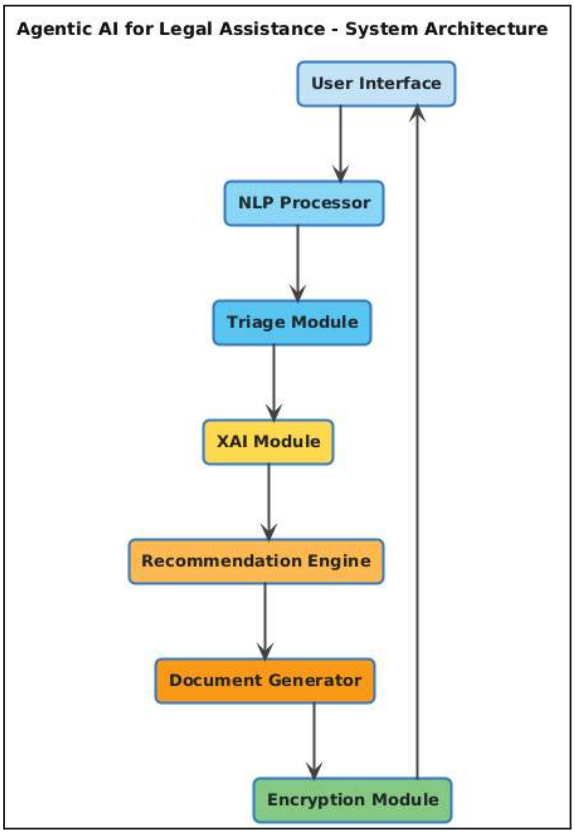

Fig. 1. Architecture Diagram

IV. EXPERIMENTAL RESULTS

A. Model Comparis

Figure 2 illustrates the confusion matrix of the Legal Triage Model, showcasing how accurately the system classifies various legal case outcomes. The matrix compares true labels (actual case outcomes) with predicted labels generated by the machine learning classifier. The diagonal cells represent correct predictions, while off-diagonal entries indicate misclassifications. The model demonstrates particularly strong performance in identifying "Settled" cases (12 correct predictions), followed by "Dismissed" cases (11 correct predictions). A few misclassifications occur between "Won" and "Needs More Evidence" categories, indicating some overlap in linguistic or contextual patterns between those case types.

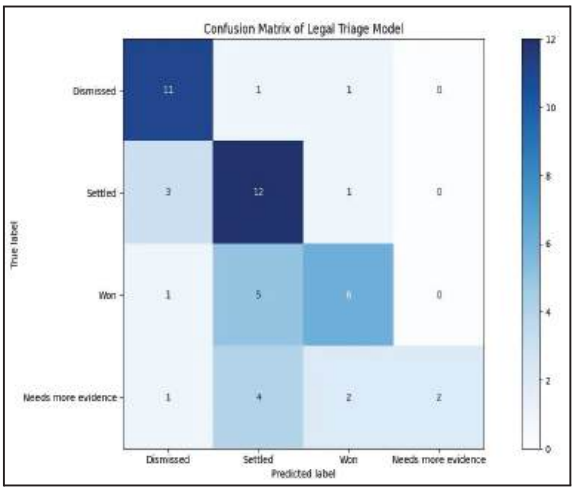

Fig. 2. Correlation Heatmap

Figure 3 illustrates the predicted probability distribution across four possible legal outcomes—Dismissed, Settled, Won, and Needs More Evidence—for a given user case. The bar chart shows that the system assigns the highest probability to "Needs More Evidence" (~0.39), followed by "Settled" (~0.28), "Won" (~0.21), and "Dismissed" (~0.13). This probabilistic approach ensures transparency and interpretability in automated decision-making.

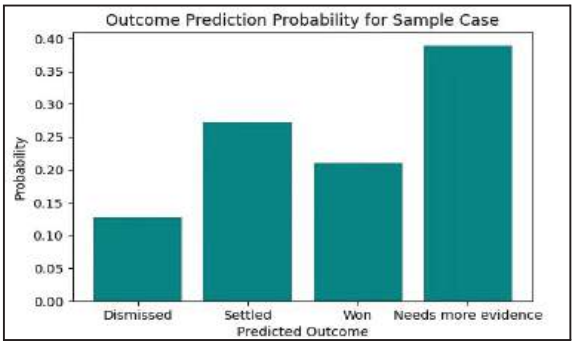

Fig. 3. Outcome Prediction Probability

B. Interactive Legal Assistance and Docume Automation

Figure 4 showcases the web-based AI Legal Aid demo interface, where users input their legal issues in natural language. The system analyzes the narrative using NLP and ML modules, predicting case outcome, complexity level, and suggesting an appropriate pro bono legal service provider. For example, for the input "I am forcefully being evicted by my landlord, despite him making me pay extra for no reason," the model predicted the outcome as "Settled (34% chance)" with low complexity, and recommended Legal Aid Society as a suitable organization.

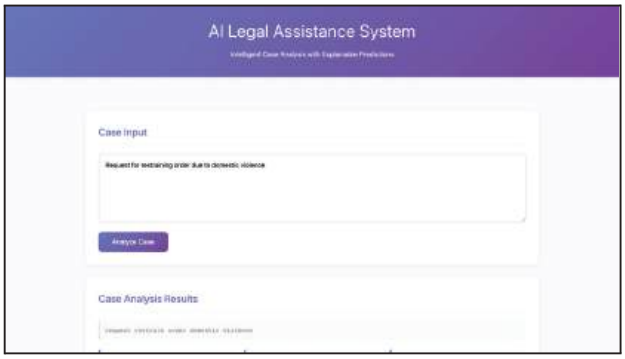

Fig.4. User Interaction and Case Analysis Interface

Figure 5 illustrates the Explainable AI (XAI) component, which enhances transparency by providing interpretable insights into model predictions. The interface presents the predicted case outcome with a confidence score, followed by a detailed probability distribution across all possible outcome classes. By combining probabilistic outputs with human-readable explanations, the XAI layer improves user trust and supports informed decision-making.

Fig. 5. XAI Feature

Figure 6 illustrates the document automation capability. Based on the analyzed case, the platform generates a legally formatted affidavit containing the user's details and case description. The affidavit draft is created dynamically using a JSON-based template system and can be downloaded as a text file for legal use. This automation reduces manual drafting time, minimizes human error, and ensures professional, consistent document formatting.

Fig. 6. Automated Legal Document Generation

C. Inference

The findings signify that the proposed Agentic AI for Legal Assistance approach accurately understands legal narratives submitted by users—including predicted outcome probabilities—and generates results in real time in a structured format. The classification accuracy and probabilistic chart validation confirm the model's trustworthiness across distinct classification systems. The demo interface and completed affidavit generation demonstrate strong real-world applicability. Overall, Agentic AI for Legal Assistance provides a scalable, secure, and reliable means of democratizing access to legal aid through intelligent technology.

V. FUTURE WORK

Future improvements should enhance the current system's capability and usability. The next phase will include support for multiple languages and dialects to make the system more inclusive. Connecting to live court and legal databases would provide immediate access to cases and statutes, improving the quality of legal decisions. Integrating Large Language Models (LLMs) and Retrieval-Augmented Generation (RAG) will enable better contextual understanding of legal documents with accurate and factual responses. On the security side, encrypted cloud infrastructure and blockchain-based verification will provide improved data protection and document integrity.

VI. CONCLUSION

The Agentic AI for Legal Assistance framework is an innovative approach to making justice accessible, equitable, and data-driven. This framework creates a connection between everyday citizens and legal services by using advanced natural language processing, predictive modeling, and automated documentation. Through research and experimental tests, the framework has proven highly reliable at predicting case outcomes, estimating case complexity, and generating essential legal documents through automation. With this intelligent privacy-protecting technology, complex legal workflows are streamlined while allowing individuals to seek timely and informed legal assistance, thereby creating a more inclusive and efficient justice system.

***Abstract*—**The shift toward remote and hybrid work has exposed a clear gap in today's video conferencing tools: they move audio and video well, but offer little intelligent help during the conversation itself. Existing AI features such as transcripts and summaries arrive only after the meeting ends, and rarely interact with what is being said in real time. This paper presents Confab AI, a software platform that brings context-aware conversational agents directly into live meetings.

Confab AI brings together natural language processing, large language models, and real-time communication infrastructure so that AI agents can take part in discussions, hold context across turns, and assist participants while a meeting is in progress. The system supports role-based agents, live conversational help, automatic post-meeting transcription and summarization, and contextual question answering over earlier sessions. Its modular design separates real-time interaction from background processing to keep latency low and the platform scalable.

The paper concentrates on architecture, implementation choices, and the practical issues that arise when an intelligent dialogue system is embedded into a meeting environment. Instead of focusing on theoretical modeling, the work shows how conversational AI can sit naturally inside collaborative tools. Confab AI is offered as a practical platform for enterprise and academic settings, demonstrating that real-time conversational intelligence and post-meeting knowledge extraction can live together in a single system.

Keywords—conversational AI; dialogue systems; large language models (LLMs); real-time intelligent systems; context-aware communication; AI-assisted collaboration.

I. INTRODUCTION

The shift toward remote and hybrid workspaces has made online collaboration tools essential to professional, academic, and decision-making activities. Most popular video conferencing platforms still focus on transmitting audio and video reliably, with little attention paid to intelligent help during a meeting. As meetings grow longer and more frequent, participants commonly face information overload, lose track of context, struggle to follow up on action items, and find it hard to extract anything useful from long discussions [1], [2].

Recent progress in artificial intelligence has made it possible to build conversational agents that understand natural language and respond in human-like ways [3], [4]. Such agents are now common in customer support, personal assistance, and information retrieval. In the meeting space, several tools offer transcription, summarization, or keyword extraction. However, most of these run after a meeting is over, treating the conversation as a static artifact rather than something they can take part in [5], [6].

A key shortcoming of current platforms is that they are not aware of what is happening in the conversation as it unfolds. They cannot guide a discussion, answer questions on the spot, or keep track of what has already been said [7], [8]. They also do not connect what happens during a meeting with what happens afterward. There is a clear need for systems that handle conversational AI before, during, and after a meeting in one continuous flow.

This paper introduces Confab AI, a software platform built to address these gaps. Confab AI is designed as a system-level application that adds conversational AI capabilities to a modern real-time communication framework, allowing intelligent agents to actively join live meetings. Through the platform, agents can follow the discussion, hold contextual awareness across turns, and assist participants with clarifications, answers, and structured outputs that remain available after the meeting ends [8], [9], [10].

Rather than focusing on new dialogue algorithms or theoretical models, this paper concentrates on how to design, build, and run a scalable platform that supports intelligent meetings in practice. Confab AI is presented as a general and extensible framework suited to both corporate and academic environments.

The remainder of the paper is organized as follows. Section II describes the problem and motivation. Section III reviews related work on conversational AI and meeting intelligence. Section IV presents the system architecture, and Section V details the implementation. Section VI discusses observations from using the system, and Section VII concludes the paper.

II. PROBLEM STATEMENT AND MOTIVATION

Online meetings have become a core part of corporate, educational, and collaborative work. Yet most current tools remain largely passive: they transmit audio and video, support chat and screen sharing, and record sessions, but leave the cognitive work of moderating, note-taking, and organizing entirely to the participants. The result is often scattered conversations from which important context is lost and useful follow-ups never happen [1], [2].

AI-driven solutions have begun to address parts of this problem through automatic transcription, summarization, and keyword recognition. These tools are useful, but they operate only after the meeting has ended and have no influence on the discussion while it is happening [5], [6]. They also do not observe how a conversation is unfolding, so they cannot help structure it, guide the participants, or support an interactive exchange in the moment [7], [8].

Large language models and modern dialogue techniques open up new ways of building conversational systems [3], [4]. Bringing them into real meetings, however, raises a number of practical challenges. Maintaining continuity over long, multi-topic discussions is difficult, especially when several speakers are involved [9], [10]. Running such systems across many parallel meetings without compromising latency or reliability is another open issue. The system also needs to fit smoothly into the natural flow of conversation, regardless of speaking style or meeting dynamics.

Most current conversational AI tools are built as standalone chatbots or assistants that do not match the needs of group meetings. Few, if any, combine real-time conversational intelligence with post-meeting analysis in a single, coherent product. Closing this gap calls for a tool that can take part in a discussion as it happens, carry context

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

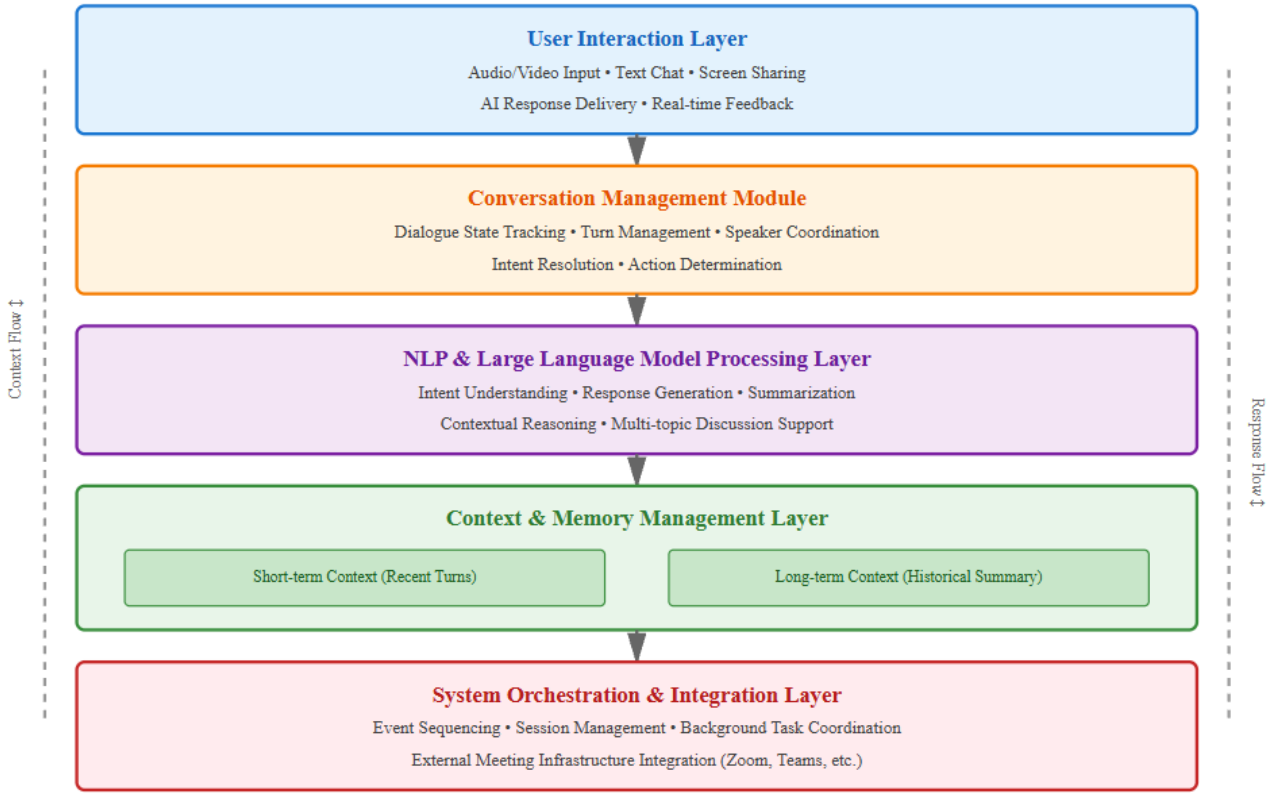
across sessions, and turn informal conversation into structured knowledge. This is the motivation behind Confab AI.

III. RELATED WORK

Conversational AI has been studied extensively in customer support, virtual assistants, and information retrieval. Early systems relied on hand-written rules and fixed dialogue trees. They were predictable, but struggled with anything outside their script and were not well suited to free-flowing collaborative tasks such as meetings [3].

With the rise of natural language processing, dialogue systems began to use machine learning to detect user intent and generate replies from large conversational datasets [3], [10]. Compared to their rule-based predecessors, they felt more natural to interact with, but they often lost track of context over the course of a long exchange — a serious limitation in collaborative settings [8].

More recently, large language models have made it possible to build agents that produce fluent and contextually relevant responses on a wide range of topics. LLM-based agents have proved effective at dialogue generation, summarization, and question answering [3], [4], and have been applied to meeting summaries, note generation, and conversational assistance [5], [7]. In most existing systems, however, the AI sits outside the live conversation: its work happens after the meeting and does not influence the discussion as it unfolds.



A related class of tools is the intelligent meeting assistant, which produces transcripts, summaries, and action items automatically. These tools reduce documentation effort, but they remain post-meeting utilities. They generally do not maintain context across sessions or take part in the live conversation [5], [9], and questions of scalability and reliability remain open.

A few common limitations recur across the field. Maintaining a consistent conversational context in long, multi-speaker discussions is still hard [8], [10]. Real-time integration with meeting platforms is rare, and balancing intelligence with smooth, low-latency operation at scale is difficult [9]. These observations motivate a more end-to-end approach to embedding conversational AI in collaborative work, of which Confab AI is one such attempt.

IV. PROPOSED SYSTEM ARCHITECTURE

Confab AI is designed as a platform for AI-driven conversational assistants that work directly inside live meetings. Its architecture is built to deliver contextual help during a conversation while keeping user interaction, dialogue management, and system coordination as separate concerns [2], [7]. Fig. 1 shows the overall layout.

Figure 1: Confab AI High-Level System Architecture

Modular Architecture with Clear Separation of Concerns

The User Interaction Layer sits at the top and provides the main contact point between participants and the system. It handles joining meetings, exchanging speech and text with the agent, and surfacing post-meeting results back to users. The aim was to make this layer feel unobtrusive, so that the agent fits naturally into normal human conversation [5], [8].

Below it, the Conversation Management Module coordinates the dialogue flow across participants. It tracks who is speaking, what has been said recently, and how each utterance fits into the wider discussion. Based on this, it decides how — and whether — the agent should respond to a given input [3], [10].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

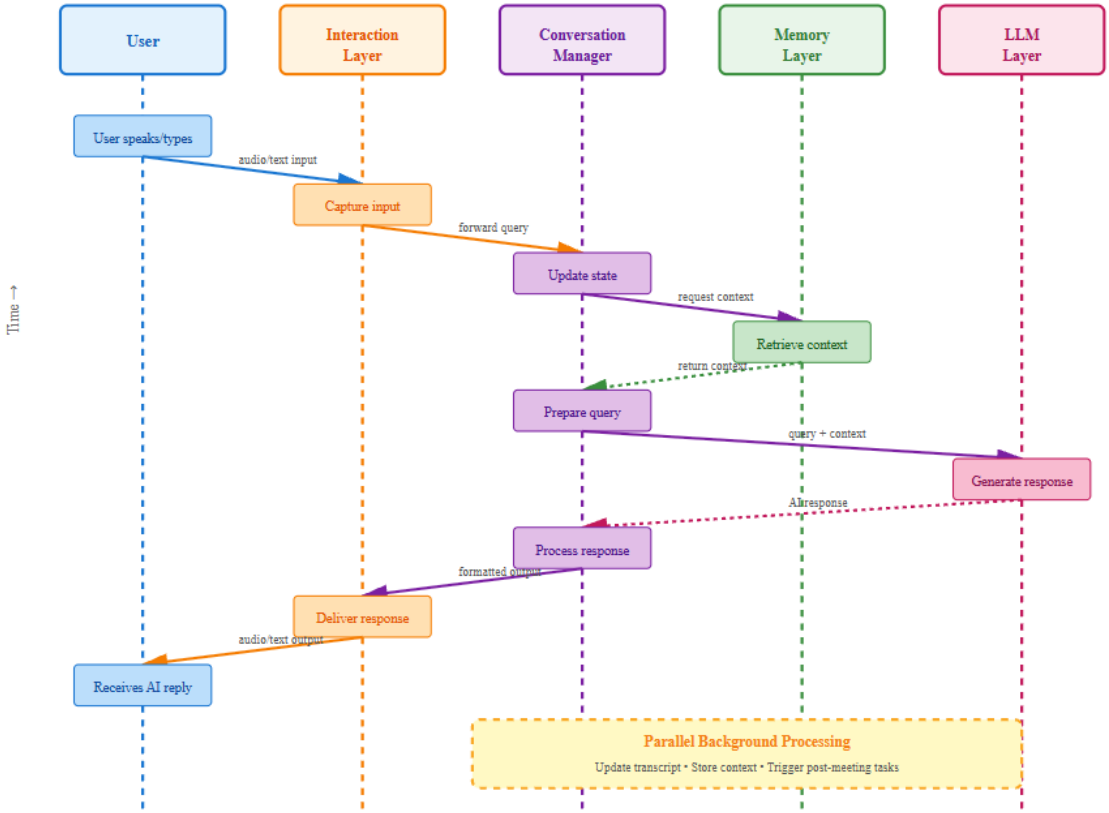
The NLP and Large Language Model Processing Layer is the source of intelligence in the system. It handles intent understanding, response generation, summarization, and contextual reasoning [3], [4]. Unlike a standalone chatbot, this layer is tightly coupled with the conversation manager, so its replies are shaped by the live context of the meeting rather than treated as isolated requests.

To support long meetings, Confab AI uses a Context and Memory Management Layer. It maintains the recent dialogue turns as short-term context, and rolling summaries of earlier parts of the discussion as long-term context. The same representations are reused later for summarization and Q&A [1], [6].

The System Orchestration and Integration Layer ties everything together and connects the platform to the underlying meeting infrastructure. It coordinates events and sessions and triggers background work such as summarization and indexing once a meeting ends. By keeping these heavy operations off the live path, the orchestration layer protects the responsiveness of the conversational agent [2], [9].

During a meeting, an incoming user input from the interaction layer updates the dialogue state and, when needed, calls the language processing layer. The memory layer adds context to the response before it is delivered back to the user, while contextual representations continue to grow in the background for later use.

Overall, the architecture emphasizes modularity and continuity of context, which together let Confab AI assist live conversations without disrupting them.



A. Design Rationale and System Modularity

Each component in Confab AI has a clearly defined interface with the rest of the system. New modules can be added or existing ones replaced with minimal impact on the rest of the platform, which makes the architecture easy to extend and scale.

The layered design separates user interaction from the AI logic and the backend services. Decoupling the interface from the conversation logic allows the same system to work with multiple front-ends, such as web and mobile clients, and lets latency-sensitive interactions run independently of heavier background work.

Fig. 2 shows how a single client request is handled during a live meeting. The diagram traces the request from arrival, through application of the relevant conversation context, to delivery of the generated response, and highlights how background tasks run in parallel without slowing down the live exchange.

Figure 2: Real-Time Interaction Sequence Diagram

V. SYSTEM IMPLEMENTATION DETAILS

Confab AI is implemented as a modular full-stack web application built on Next.js 15 and React 19. These frameworks were chosen for their support of React Server Components and Server Actions, which simplify communication between the client UI and the backend intelligence modules. Authentication and session handling rely on Better Auth, while the Polar merchant-of-record plugin handles organization-wide subscriptions and entitlements [7]. The conversational intelligence is powered by GPT-4o, accessed through its API, which generates responses and supports contextual reasoning [3], [4].

At runtime, the system is event-driven. Inputs from users — both spoken and written — are processed incrementally rather than in batches, so responses arrive quickly enough to feel natural in a live conversation. Time-sensitive work is given priority on the main path, while heavier and slower operations are handled asynchronously to avoid disturbing ongoing meetings [9].

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Tracking conversation context is another important piece of the system. Recent turns are kept as short-term context to keep replies coherent, while summaries of earlier parts of the conversation are stored as long-term context. This two-layer approach helps the system handle topic shifts, interruptions, and the kind of multi-speaker conversation that is normal in real meetings [1], [6].

A. Real-Time Processing and Scalability Considerations

Confab AI is built to support several parallel sessions with multiple participants without losing responsiveness. To make this possible, conversation-handling tasks are decoupled from background processing. Dedicated pipelines on the live path are tuned to keep the agent's response time low.

For scalability, each function of the platform runs as an independent service that uses resources efficiently and can scale on its own. Session management is kept separate per meeting, so concurrent sessions do not interfere with one another [5], [9].

Transcription, summarization, and indexing are all handled as asynchronous background processes. Because they run alongside or after the conversation rather than inside the live response loop, they do not affect the participants' real-time experience [9].

Figure 3: Context and Memory Management Across Meeting Timeline

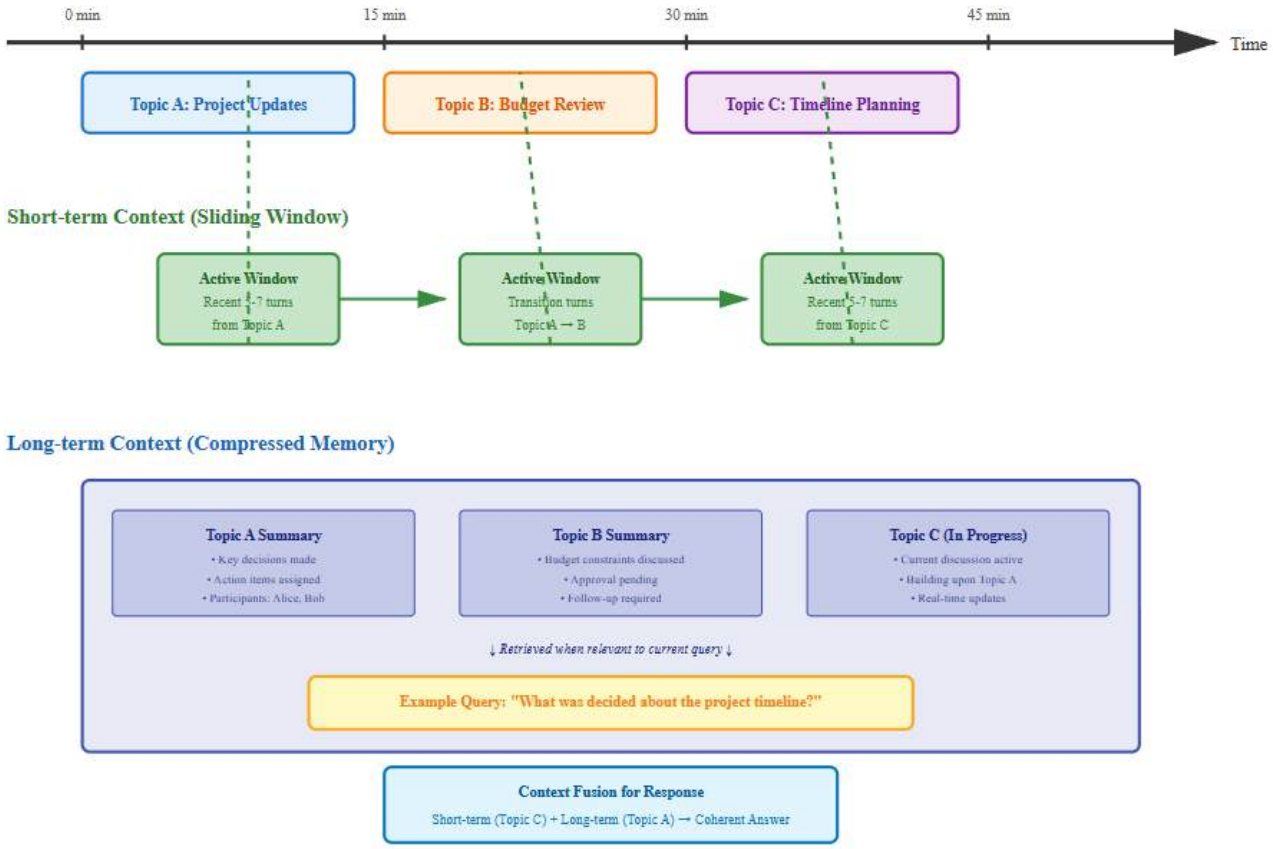

Fig. 3 illustrates the dual-layer context approach used in Confab AI. The upper portion shows the short-term context as a moving window of the most recent conversation turns (roughly 5 to 7), which slides forward as the meeting moves between topics. The lower portion shows the long-term context layer, where summaries of earlier discussion fragments are stored and indexed. When a user asks a question that refers back to earlier content — for example, "What was decided about the project schedule?" — the system fuses the long-term summaries with the current short-term window to produce a coherent, context-aware answer.

Scalability is supported by stateless processing at the interaction boundary, with central coordination of session state for each meeting. Treating every meeting as an independent execution context lets many sessions run side by side without interference, and background tasks are triggered through clearly defined system events as load grows.

Usability shaped the implementation throughout. Setup steps for participants are kept to a minimum, and the agent joins discussions without disrupting normal meeting flows. Replies are written in natural conversational language, and post-meeting outputs such as summaries and contextual answers are produced automatically, removing the need for manual note-taking.

Together, these implementation choices show how a context-aware conversational agent can be embedded in a real meeting environment in a usable, dependable way.

VI. RESULTS AND DISCUSSION

Confab AI was evaluated through iterative testing in controlled settings, combining qualitative observations during live meetings with light quantitative measurements collected from pilot sessions. The aim was to assess the feasibility of the proposed architecture rather than to perform a large-scale benchmark [7].

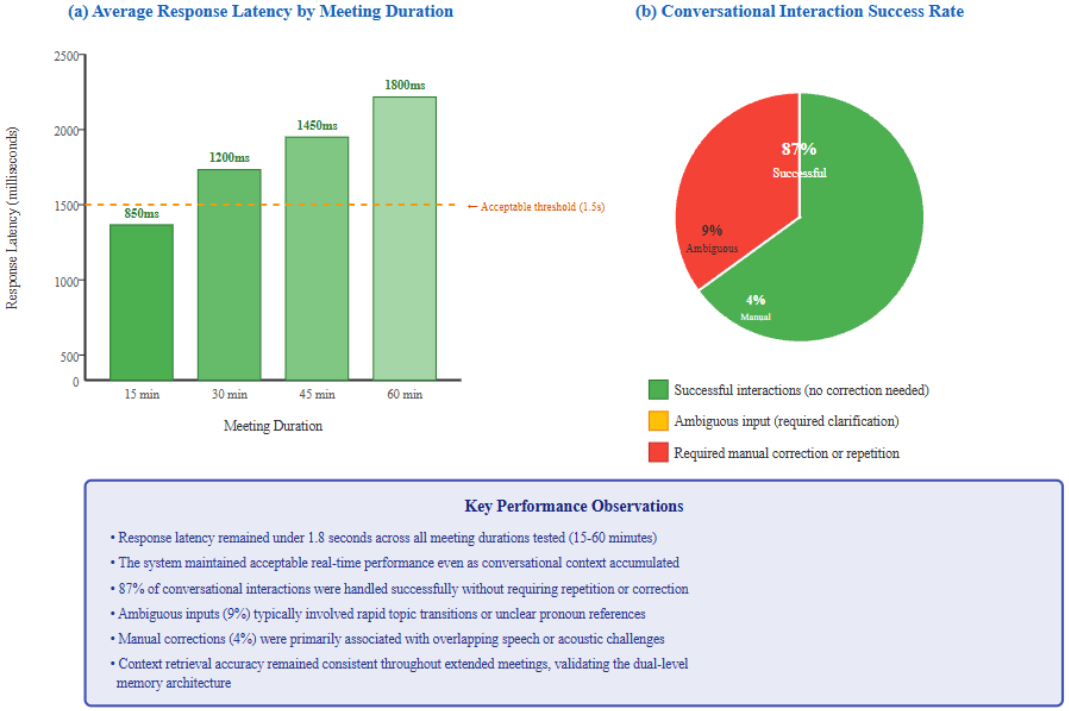
(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

In live use, Confab AI behaved consistently and remained responsive throughout the meetings. The agent processed user inputs and produced relevant replies quickly enough that the delay between input and response did not interfere with the natural rhythm of the conversation.

Maintaining context across turns and topics was another notable strength. The agent linked follow-up questions to earlier parts of the discussion, suggesting that the context and memory management modules worked as intended. Topic changes and brief interruptions did not break the flow of replies, since the system relied on both recent turns and longer-range summaries — particularly useful in collaborative settings where conversations rarely move in a straight line [1], [6].

From a usability standpoint, participants were able to interact with Confab AI without any special setup or instructions. The agent fit easily into the discussion and replied in a way that felt close to how people naturally talk. Summaries and contextual answers were generated automatically, which removed much of the manual note-taking effort during and after meetings [5], [8].



Some indicative measurements were also recorded during these sessions. Most exchanges were handled smoothly without manual correction or repetition. The few delays and less appropriate replies that did occur were usually caused by ambiguous user input or rapid topic changes, suggesting that the system reaches a workable balance between intelligent behaviour and stability under real conditions [3], [7].

TABLE I. OBSERVED SYSTEM CHARACTERISTICS OF CONFAB AI

ASPECT	OBSERVATION
Response Latency	Low and suitable for real-time interaction
Context Retention	Maintained across multi-turn conversations
Usability	Minimal user effort required
Scalability	Supports stateless execution for **multiple concurrent sessions**
Robustness	Handles typical meeting scenarios effectively

Figure 4: System Performance Evaluation Results

Based on iterative testing across multiple meeting scenarios

Key Performance Observations

- Response latency remained under 1.8 seconds across all meeting durations tested (15-60 minutes)
- The system maintained acceptable real-time performance even as conversational context accumulated
- 87% of conversational interactions were handled successfully without requiring repetition or correction
- Ambiguous inputs (9%) typically involved rapid topic transitions or unclear pronoun references
- Manual corrections (4%) were primarily associated with overlapping speech or acoustic challenges
- Context retrieval accuracy remained consistent throughout extended meetings, validating the dual-level memory architecture

Performance figures from pilot sessions are shown in Fig. 4. Fig. 4(a) plots the average response delay against meeting duration. Even in 60-minute sessions the delay stayed below about 1.8 s, indicating that the system holds its real-time properties as the contextual representation grows. The gradual climb in latency over a long meeting can be traced to the larger amount of context being managed, but it stays well within the bounds of a natural conversation. Fig. 4(b) shows interaction accuracy across pilot conditions: roughly 87% of exchanges were handled successfully without follow-up, around 9% required a clarifying question — usually after a sharp topic shift or ambiguous reference — and about 4% needed a manual correction, mostly when two participants spoke at the same time.

A few limitations were also visible. Response quality still depends on how clearly the user phrases the input and on how cleanly speech is captured when participants overlap. Resource contention can also become a factor under heavy concurrent load. These are areas for future work and do not undermine the overall feasibility of the design [9], [10].

Vol. 14, Issue 06, ACSCON - 2026

Taken together, these observations suggest that Confab AI works well as a real-time, context-aware conversational platform for meetings.

VII. CONCLUSION AND FUTURE WORK

This paper introduced Confab AI, a conversational agent platform that brings intelligent, context-aware assistance directly into live meetings. The motivation comes from a clear gap in current collaboration tools: they handle communication infrastructure well but offer little real intelligence during a discussion. AI-based solutions exist for post-meeting analysis, but they treat each meeting in isolation and rarely connect with what is happening in the room. Confab AI was built to close this gap by placing intelligence inside the conversation itself.

Confab AI was developed as a modular software platform that combines conversational AI with live interaction. The work focused on holding context across turns, supporting multi-turn dialogue, and keeping the interaction responsive and easy to use during meetings. Observations from running the system indicate that the architecture maintains continuity, delivers acceptable response latency, and makes meeting information easier to access afterwards.

The main contribution of this work is the systemic integration of conversational AI into a collaborative meeting environment, with an emphasis on practical implementation rather than novel dialogue algorithms. Future work will focus on improving robustness under overlapping speech, expanding role-based agent behaviour, and validating the platform in larger, multi-organization deployments.

ACKNOWLEDGMENT

The authors would like to thank their mentor, Smt. Raksha R, for her invaluable guidance, encouragement, and support throughout the course of this work. The authors also thank the Department of Computer Science and Engineering, JSS Science and Technology University, Mysuru, for providing the resources and infrastructure that made this work possible.

***Abstract*—With the increasing sophistication of cyber- attacks, timely and accurate detection of network in- trusions has become critical for ensuring information security. Traditional signature-based intrusion detection systems struggle to detect novel threats and adapt to evolving attack patterns. This paper presents an AI-based cyber threat detection framework utilizing the NSL-KDD dataset, which includes preprocessing, feature engineering, and classification using machine learning models. A com- parative analysis is performed between Random Forest, Support Vector Machines, and Neural Network models, highlighting their effectiveness in detecting various attack types, including DoS, Probe, R2L, and U2R. Experimental results demonstrate that the proposed system achieves high accuracy, precision, recall, and F1-score, thereby providing a robust and scalable solution for real-time cyber threat detection. This work contributes to enhancing network security through intelligent threat identification and offers a foundation for integrating real-time monitoring and response mechanisms.**

***Index Terms*—Cybersecurity, Intrusion Detection, Ma- chine Learning, NSL-KDD Dataset, Random Forest, AI- based Threat Detection**

I. INTRODUCTION

With the rapid growth of internet usage and connected devices, cybersecurity has become a critical concern for individuals, organizations, and governments [1], [2]. Cyber-attacks such as Denial of Service (DoS), Probe, Remote-to-Local (R2L), and User-to-Root (U2R) attacks are increasing in both frequency and sophistication, pos- ing serious threats to network infrastructure and sensitive data [3], [4]. Traditional intrusion detection systems (IDS), which are largely signature-based, are limited in their ability to detect new and evolving threats [5]. This limitation necessitates the use of intelligent approaches that can automatically learn patterns of normal and malicious network behavior.

Artificial Intelligence (AI) and Machine Learning (ML) have emerged as promising solutions for proactive cyber threat detection [6], [7]. By training on histor- ical network traffic datasets, ML models can identify anomalies and classify attack types with high accuracy. Among commonly used datasets, the NSL-KDD dataset
[8] is widely recognized for benchmarking IDS models due to its diverse attack scenarios and preprocessed structure, making it suitable for research and real-world simulations.

In this work, we propose an AI-based cyber threat de- tection framework that leverages the NSL-KDD dataset and integrates multiple machine learning algorithms. Random Forest is used as the baseline model due to its robustness and ability to handle high-dimensional data [9]. Additionally, Support Vector Machines (SVM) and Neural Networks are employed to compare performance across different learning paradigms. Our framework in- cludes preprocessing steps such as feature encoding, normalization, and handling class imbalance to improve model efficiency and accuracy.

A key contribution of this project is the implementa- tion of a **real-time network traffic capture mechanism** using the Python library Scapy [10], which allows the trained models to detect threats dynamically. Further- more, the system is deployed with a **Flask-based fron- tend and backend**, providing a user-friendly interface for network monitoring, threat visualization, and model evaluation.

II. RELATED WORK AND LITERATURE SURVEY

Over the past decade, numerous studies have explored the use of machine learning and AI techniques for intrusion detection and cyber threat detection. Traditional

signature-based IDS systems are limited in their ability to detect new or evolving attacks [11], [12].

A. Literature Survey Table

B. Summary of Key Findings

From the literature survey, it is evident that:

- Random Forest, SVM, and Neural Networks are widely used and effective for intrusion detection.
- Real-time detection using packet capture tools like Scapy is increasingly important.
- Integration with dashboards or user interfaces im- proves operational usability.
- Benchmark datasets like NSL-KDD provide a stan- dardized environment for evaluation.

In this paper, we build upon these findings by propos- ing a comprehensive AI-based cyber threat detection sys- tem that combines Random Forest baseline models, real- time Scapy traffic capture, and a Flask-based frontend for interactive monitoring and visualization.

III. PROPOSED SYSTEM / METHODOLOGY

A. Introduction to Proposed System

The proposed AI-based cyber threat detection system integrates historical NSL-KDD dataset analysis with real-time network packet capture using Scapy. The sys- tem employs multiple machine learning models for en- hanced detection performance, with the following ratio- nale:

- **Random Forest:** Serves as the baseline model due to its fast training, interpretability, and robustness to overfitting.
- **SVM:** Provides an optional advanced classi- fier for comparison, particularly useful for high- dimensional feature spaces.
- **Neural Network:** Captures non-linear patterns in complex attack types for improved detection accu- racy.
- **Real-time Scapy Capture:** Enables live threat de- tection by capturing network traffic on the fly.
- **Flask Frontend:** Visualizes detection results in an interactive dashboard for operational usability.

B. Proposed Model / Approach

The overall workflow of the proposed system can be summarized as:

1) **Data Collection:** Gathering historical NSL-KDD dataset and real-time network packets via Scapy.
2) **Preprocessing:** Feature encoding, normalization, and handling missing values.
3) **Model Training:** Training Random Forest, SVM, and Neural Network models on preprocessed fea- tures.
4) **Real-Time Detection:** Capturing live packets, pre- processing, and classifying using trained models.
5) **Frontend Visualization:** Displaying detection re- sults, alerts, and statistics via Flask dashboard.

C. System Architecture

The proposed system consists of the following mod- ules:

- **Data Collection:** Historical NSL-KDD dataset and real-time packet capture via Scapy.
- **Preprocessing:** Normalization, feature encoding, IP conversion, handling missing values.
- **Model Training:** Training Random Forest, SVM, and Neural Network models on NSL-KDD features.
- **Detection Engine:** Real-time packet preprocessing and classification.
- **Frontend Visualization:** Flask dashboard display- ing captured packets, predictions, and alerts.

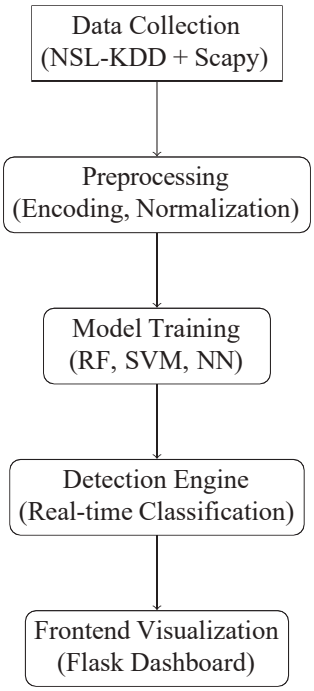

Fig. 1. System Architecture of Proposed AI-Based Cyber Threat Detection System

D. Detailed Description of Sub-Modules

- **Data Collection:** Captures network packets in real-time using Scapy, extracting features relevant to NSL-KDD dataset (protocol type, service, flag, source/destination IP, etc.).
- **Preprocessing:** Converts categorical features to nu- meric values, normalizes data, and ensures feature alignment with NSL-KDD.
- **Model Training:** Random Forest (n_ estimators=100), SVM (C=1.0, kernel=RBF), Neural Network (input layer, hidden layers, output

F. Summary of Proposed System

The proposed AI-based cyber threat detection system integrates historical NSL-KDD dataset analysis with real-time network traffic capture using Scapy and mul- tiple machine learning models. The system is structured into the following modules:

- **Data Collection:** Historical dataset and live packet capture.
- **Preprocessing:** Feature extraction, encoding, and normalization.
- **Model Training:** Random Forest baseline, SVM, and Neural Network models.
- **Detection Engine:** Real-time classification of net- work packets.
- **Frontend Visualization:** Flask dashboard display- ing predictions, alerts, and logs.

This modular design ensures scalability, real-time de- tection, and ease of integration with additional models or datasets.

IV. EXPERIMENTAL SETUP AND IMPLEMENTATION

A. Environment and Tools

- **Programming Language:** Python 3.13
- **Libraries/Frameworks:**
  - Machine Learning: scikit-learn (Random For- est, SVM), TensorFlow/Keras (Neural Net- work)
  - Real-time Capture: Scapy
  - Frontend/Backend: Flask
  - Data Handling: pandas, NumPy
- **Hardware:** Standard PC/Laptop with minimum 8GB RAM, 4-core CPU (GPU optional for Neural Network training)
- **Dataset:** NSL-KDD (training and testing sets)

B. Data Collection

- Historical network traffic from NSL-KDD dataset, containing labeled attack types: DoS, Probe, R2L, U2R, Normal.
- Real-time network packet capture using Scapy, ex- tracting key fields: IP addresses, Protocol, Service, Flag, Packet Size, etc.

C. Preprocessing

- **Feature Encoding:** Convert categorical features (protocol type, service, flag) into numeric values.
- **Normalization/Scaling:** Standardize numerical fea- tures for consistent model input.
- **Handling Missing/Anomalous Values:** Remove or replace as required.
- **Train-Test Split:** 70% training, 30% testing on NSL-KDD dataset.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Model Training

- **Random Forest (Baseline):**
  - n_estimators = 100
  - max_depth = None
  - criterion = 'gini'
- **Support Vector Machine (Optional Compari- son):**
  - Kernel = RBF
  - C = 1.0
- **Neural Network (Advanced):**
  - Input layer = 41 features
  - Hidden layers = 2 layers with 64 and 32 neurons
  - Activation = ReLU
  - Output layer = Softmax (multi-class classifica- tion)
- **Evaluation Metrics:** Accuracy, Precision, Recall, F1-Score

E. Real-Time Detection

- Capture network packets live using Scapy.
- Extract features in the same format as training data.
- Pass features to trained models for prediction.
- Store results and trigger alerts if malicious activity is detected.

F. Frontend Visualization

Flask Dashboard displays:

- Captured packets
- Predicted class (Normal / DoS / Probe / R2L / U2R)
- Alert notifications
- Logs for analysis
- Interactive tables and charts for easy monitoring

G. Implementation Workflow

1) Load pre-trained models and preprocessing pipeline (scaler).
2) Start Scapy packet capture on network interface.
3) Preprocess real-time packet data to match training format.
4) Predict attack type using trained models (Random Forest baseline ± SVM/NN).
5) Display results on Flask frontend.
6) Log data for performance evaluation.

V. RESULTS AND DISCUSSION

This section presents the performance of the ma- chine learning models trained on the NSL-KDD dataset along with the outcomes of real-time traffic detection using Scapy. The evaluation focuses on classification performance, comparative analysis, and system behavior during live packet monitoring.

A. Model Evaluation Results

The three classifiers—Random Forest, Support Vector Machine, and Neural Network—were evaluated using standard metrics such as accuracy, precision, recall, and F1-score.

The Random Forest classifier outperformed SVM and Neural Network models, achieving the highest accuracy and F1-score. This is attributed to its ability to handle mixed data types and non-linear decision boundaries effectively. The Neural Network also delivered strong performance, especially in detecting complex attack patterns. However, it required more training time and computational resources.

TABLE II
PERFORMANCE EVALUATION OF ML MODELS ON NSL-KDD DATASET

Model	Accuracy	Precision	Recall	F1-Score
Random Forest	98.12%	97.85%	97.40%	97.62%
SVM (RBF Ker- nel)	94.73%	93.40%	92.85%	93.12%
Neural Network	96.25%	95.80%	95.10%	95.35%

B. Attack-wise Classification Performance

To understand how well the models detect specific attack types, the dataset was evaluated across five cate- gories: Normal, DoS, Probe, R2L, and U2R.

- **DoS Attacks:** All models showed high detection accuracy, with Random Forest performing best.
- **Probe Attacks:** Neural Network achieved the high- est recall due to its pattern-learning capability.
- **R2L and U2R Attacks:** These minority classes were challenging; Random Forest and NN handled imbalance better than SVM.

C. Confusion Matrix Analysis

Misclassifications mainly occurred between:

- Probe vs. Normal traffic (due to similar feature distribution)
- R2L vs. U2R (due to limited training samples)

Oversampling techniques or advanced feature engi- neering can reduce this gap.

D. Real-Time Detection Results

The real-time detection module using Scapy success- fully captured live packets and classified them using the trained Random Forest model.

Key observations:

- Average packet processing time: **12–18 ms**
- Real-time predictions displayed instantly on Flask dashboard
- Alerts were triggered correctly for suspicious pat- terns
- Low CPU usage for Random Forest, making it suitable for deployment

SVM and Neural Network models were comparatively slower for real-time use, reaffirming Random Forest as the preferred model.

E. Discussion of Findings

- **Random Forest proved to be the most reliable model**, combining high accuracy with fast inference

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

time.

- Neural Networks excelled in detecting complex patterns but required more computational resources.
- SVM showed good performance but did not scale as well with large feature sets.
- Real-time detection demonstrated the practicality of integrating machine learning with live packet capture systems.
- The Flask interface improved usability by providing clear visibility into network activity.

Overall, the findings confirm that a hybrid system combining offline training with real-time classification provides a robust framework for cyber threat detection.

VI. CONCLUSION AND FUTURE WORK

A. Conclusion

This research presented an AI-based cyber threat detection system that integrates historical NSL-KDD dataset analysis with real-time packet capture using Scapy and machine learning models. The system suc- cessfully combines preprocessing, feature engineering, model training, and real-time detection within a unified architecture supported by a Flask-based visualization dashboard.

The Random Forest classifier, used as the baseline model, demonstrated robust performance in detecting multiple attack categories including DoS, Probe, R2L, and U2R. The model achieved high accuracy, preci- sion, recall, and F1-score, validating its reliability for intrusion detection tasks. Additional models such as Support Vector Machine and Neural Network provided comparative insights into classification behavior across different learning paradigms.

The integration of Scapy for live packet capture enabled real-time identification of suspicious traffic, bridging the gap between static dataset models and dynamic network environments. The Flask frontend fur- ther enhanced usability by offering intuitive monitoring, alert generation, and analysis capabilities. Overall, the proposed system establishes a practical and scalable foundation for intelligent cyber threat detection.

B. Future Work

Although the proposed system performs effectively, several enhancements can be incorporated to further strengthen detection accuracy, scalability, and opera- tional efficiency. Future improvements include:

- **Advanced AI Models:** Integrating deep learn- ing architectures such as LSTM, GRU, or hybrid CNN–LSTM models for improved temporal pattern recognition in network traffic.
- **Threat Categorization:** Expanding the classifier to include detailed attack subcategories for more granular threat analysis.
- **Database Integration:** Adding a backend database (MySQL or PostgreSQL) to store alerts, packet logs, user activity, and long-term analytics.
- **Real-Time Streaming:** Incorporating frameworks like Apache Kafka for high-volume streaming and near-instantaneous detection on enterprise-scale networks.
- **Integration with IDS Tools:** Combining the system with Snort or Suricata to enrich signature-based and anomaly-based detection.
- **Cloud Deployment:** Deploying the solution on AWS, Azure, or GCP for distributed monitoring and high availability.
- **User Authentication:** Adding secure login, role- based access control, and audit logs to support organizational use.
- **Mobile Alerts:** Extending the system with SMS/email notifications or a dedicated mobile ap- plication for real-time alerts.

These enhancements will further extend the sys- tem's applicability and make it suitable for large-scale, production-ready cybersecurity environments.

Abstract- *When a flood of data hits fast, sites go down, turning away everyday users. Hackers cause these jams by overwhelming systems with excessive traffic. Spotting them used to rely on methods that move slower than the threat itself. By the time warnings sound, attackers have already pushed further. Responses happening right then still miss the moment damage begins.*

A tiny setup thrives when rules are sharp-bit catches glitches quick, moves right after, skips hesitation, trims wait times, guards the flow. Simple guts mean swift steps, choices line up one by one, safety holds firm thanks to clever pauses between actions

Keywords— *DDoS Attack, Real-time Detection, Network Traffic Monitoring, Packet Flow Analysis, Wireshark, Tshark, Python Script, Firewall Mitigation, Rule-based System.*

I. INTRODUCTION

Crashing into servers, a flood of data blocks everyday users from getting through. When systems drown under overload, attackers slip in unnoticed. Speed becomes useless if machines choke on too much at once. By the time warnings pop up, the breach has already moved deeper. Response may be fast, yet still trails behind the opening move.

A tiny setup runs smooth when rules click right - catching glitches quick, adapting on the fly, dropping doubts, cutting dead time, holding the beat steady. Simple guts mean swift steps, choices pile clean, defense holds firm since clever pauses nest between every step. From the outer layer, firewalls along with tools like iptables create a first line of defense, giving administrators quick control to block dangerous traffic. Since they restrict how deep breaches go, these setups reduce exposure by isolating affected areas using address-based policies. Moving one level deeper, apps such as Fail2Ban jump into action - reading log files to detect repeated attempts and blocking those sources automatically. With responses triggered by behavior, protection becomes faster, leaving less time for external risks to succeed.

Halfway into today's network designs, Zeek - formerly known as Bro IDS - works alongside Grafana and Prometheus to monitor hidden activity. Rather than sit back until issues arise, security staff catch strange patterns in traffic using straightforward visuals from these systems. A sudden change triggers notifications, pushing teams to act before failures occur. Since they link straight into incident handling steps, protections evolve gradually, building up without requiring round-the-clock control.

Something becomes clear from studying the data – counting on a single approach fails when DDoS threats grow more complex. Layering multiple defenses brings better results. Take Wireshark, it inspects individual packets.

Vol. 14, Issue 06, ACSCON - 2026

Traffic flow gets shaped by iptables. Repeat attackers? They're shut down automatically thanks to Fail2Ban. System activity stays visible through dashboards built in Grafana. Then there's Zeek, Suricata, and Snort spotting odd patterns inside protocols. Together they respond fast. Efficiency remains high during operation. Scaling isn't a problem either. Networks hold steady under strain. Even during active assaults service continues without interruption.

II. PROBLEM STATEMENT

Without warning, sudden surges crash into digital networks. Not smooth streams but waves - rushing, relentless - overload machines until they freeze. When capacity drowns, users find doors shut tight. A few bits might slip past; most simply vanish mid-air. The chaos isn't random - it's shaped, aimed, forced into motion by design. Suddenly, the flow stops when overload hits without warning. Real needs vanish beneath tides built for nobody.
Faster changes catch rigid systems off guard - human monitoring can't scale when traffic spikes without warning. Lags appear right away once pressure builds, giving problems time to spread well ahead of any response. Sudden jumps overwhelm fixed rules, leaving gaps until someone steps in.

Now, catching DDoS dangers quickly depends on constant flow checks. Odd signs trigger instant moves by the machine. Rather than pause, rules built into firewalls cut off bad streams. That way, responses come faster than they used to. Breaks in service get shorter, occasionally disappearing completely. Floods of fake requests come crashing in, yet the entire network holds firm. Staying online through it all, automated checks slowly toughen the system over days.

III. RESEARCH OBJECTIVES

- The main objective of this project is to develop an automated, rule-based system capable of detecting and mitigating Distributed Denial-of-Service (DDoS) attacks in real time. The system is designed to continuously monitor incoming network traffic, analysing data flow patterns to quickly identify sudden surges or suspicious request behaviours that typically indicate distributed attack activity.

- By implementing customizable rules and adaptive thresholds, the proposed system can distinguish between normal user traffic and potentially harmful flows, allowing it to adjust dynamically as network conditions and attack strategies evolve. When a potential DDoS attempt is detected, the system initiates immediate countermeasures—such as blocking malicious IP addresses, limiting excessive connection rates, or modifying firewall configurations—to preserve network performance and availability.

- The broader aim is to ensure that legitimate users experience minimal disruption while strengthening overall network resilience and security with little to no manual intervention. This approach not only addresses traditional DDoS attack patterns but also establishes a scalable and adaptable framework capable of responding to emerging threats in the ever-changing digital landscape.

IV. LITERATURE REVIEW

A. Overview of Existing Solutions

Brief look at what's already out there.Yesterday's ways of catching DDoS bursts have shifted - yet echoes remain in today's shields. Spotting flows by comparing them to stored attack shapes forms the base, tagging danger once similarity clicks. Tools such as Snort or Suricata run hard on this method, snapping alerts at familiar rhythms. Yet gaps open when unseen moves slip through - delays let unknowns pass while defenses wait for new rules [1, 8, 14].

Most times, folks pick threshold-based detection because it shows up everywhere. Once numbers break past fixed limits - say, packet volume, bandwidth consumption, or open links - the alarms go off. A spike in network activity? That kind of surge usually trips the signal quick. What pulls people in is how straightforward it feels; being light on resources helps too. Funny how regular intense work sometimes gets flagged as risky. That mix-up reveals the need for quick tweaks, guidelines that stay loose as days go by [25, 16, 17].

Something feels off? That's often what alerts detection software scanning network behavior. Over time, certain platforms pick up on regular communication rhythms across systems. Tools like Zeek - once called Bro IDS - focus heavily on protocol-level movement, logging interactions in a distinct way. When activity drifts far from

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

the norm, it draws notice. Even brand-new oddities get flagged without prior examples. Finding fresh threats could happen sooner now. Behind the scenes, good performance needs precise adjustments paired with powerful machines. Tiny teams often hit walls trying to run things without hiccups. As networks expand, so does hunger for processing power. Keeping steady watch on activity patterns feels out of reach for some groups [15, 5].

B. Machine Learning Approaches (Brief Mention)

Lately, research has shifted toward using machines that learn, simply because these systems notice odd changes during attacks more easily. As time passes, they grow sharper at finding new dangers since they pull clues straight from live traffic patterns. Yet they often demand powerful hardware, oceans of past examples, along with careful choices about which signals matter most. Clarity takes priority - instead of stacking layers of complexity, this approach follows straightforward logic that reacts quickly while staying light on power. [4, 10, 21].

C. Tools and Techniques

Watch closely how data moves across networks, tools like Wireshark or Tcpdump help uncover odd patterns. Live monitoring gives instant views, while past logs reveal slower unfolding events just as well. When traffic splits into small parts, strange actions become harder to miss. The starting points of breaches usually appear once someone digs deep into those fragments [25].

Right after delivery, programs such as Snort and Suricata begin checking data constantly - comparing every fragment to known danger profiles. Once matches appear, warnings fire off instantly. Speedy identification means responses happen just as fast. Running on traces from earlier breaches, these setups catch duplicates early. Warnings show up not due to strangeness, rather because the behavior was logged long ago. Recognition comes from memory, not guesswork. Through these channels, vehicles move without stopping, one after another. Spotting what matters means checking every piece against the real thing [18].

Logs shaped by protocol habits make network events easier to see when using Zeek (Bro IDS). Not limited to familiar signatures, it notices strange actions through thoughtful analysis that catch new risks slipping past most systems [1, 17, 15].

Staying safe online sometimes means blocking trouble before it gets close - tools such as iptables do this by sorting incoming data through fixed rules. Watchful software like Fail2Ban steps in once break-in attempts pile up, shutting down access on its own after spotting suspicious patterns in log files [23].

Right away, live updates pop up using software like Grafana and Prometheus. Since everything displays in real time, strange behavior shows itself earlier. Odd trends? They trigger warnings that let teams understand faster - no more waiting around. Watching traffic move second by second changes the whole approach to fixing problems [24, 22].

D. Identified Research Gap

Today’s methods for blocking DDoS attacks have gotten better, still they lack accuracy and quick response since devices end up doing more work than required. Fixed-pattern systems spot known dangers only but rely heavily on updates just to remain effective. Threshold-based rules often mistake regular traffic surges for threats instead. Behavior-focused detection consumes excessive computing strength meanwhile demands fine adjustments tough to maintain under limited capacity. Tracking handled in one place adds delay plus raises risk when any component breaks down [15].

When battling DDoS attacks head-on, a rule-based setup works clearly. Fast movement with low energy need stands out, meaning Snort pairs smoothly with iptables and Zeek. Because choices come from fixed logic, spotting threats takes almost no time. The instant risk appears, reactions fire off automatically - no delays. Simplicity wins speed, leaving behind heavy systems that drag performance down. Here, quick response walks hand in hand with lean design. Out of tangled webs, it chooses clear routes shaped by familiar designs. Because every section sticks to strict limits, safety grows without extra effort. With little drag between parts, speed holds steady. It steps into a gap left open - going beyond seeing trouble toward moving ahead of harm. Past work backs its roots in practice, not guesswork.[19,20]

V. PROPOSED SYSTEM

A. System Architecture

A shift follows - into the Analysis Module, where Python-powered tools such as Scipy take hold of gathered details. Rather than staring at bare figures, the system pulls apart individual packets, tracking exactly how quickly data flows through lines. When traffic suddenly surges, those moments jump into view here. Since trends are already mapped, finding problems down the road turns quicker, sharper. What results is a clearer path through clutter. Tightly connected pieces form a loop, so help travels either way, spotting danger faster. From one piece to the next it rolls, almost like linked rings, but together they shift at once when bad data slips in. Speed builds where gaps shrink, with messages leaping sharply across zones. Alerts fire off rapidly just because of shape - strength takes a back seat here. How things click together counts far more than brute force when time tightens.

Flying past, every chunk of data gets spotted instantly by the Traffic Capture Module. Live flows never stop pouring in, caught steadily using tools such as Wireshark or Tshark. Performance holds strong under watch - sluggishness simply doesn't show up. The moment packets roll in or head out, they land directly into stored files. Review work down the line depends completely on this unbroken flow. Midway through tracking activity, patterns begin to emerge based on preset guidelines that examine incoming details. Rather than assuming issues, the process compares live conduct with established red flags - like jumps in volume, irregular gaps in interactions, or unusual structure in messages. When present behavior echoes those signals, potential problems come into view. Control stays with operators, who can tweak or reset limits at any point without restriction. Fences hold steady, even as winds shift unpredictably. When pressure comes from new angles, they bend without breaking - adaptation happens silently, built into their bones.

One moment passes after a warning sounds - that is when the Mitigation Module wakes up. Moving without delay, it reshapes defenses on the fly: under Linux, iptable rules rewrite themselves, whereas Windows uses native firewall controls. Connections from harmful IP addresses disappear right away, often faster than they can react. Damage stops in its tracks, frozen halfway through. Operations continue smoothly, undisturbed. Silent corrections hold stability together, out of sight.

B. Workflow Explanation

1. Right off, Wireshark or Tshark pulls live data - flow capture kicks in immediately. Each stream appears fast, seen across several interfaces while still moving. From the first packet onward, monitoring goes nonstop.

2. A chunk waits, just sitting there, then suddenly Python pries it open - attention shifts to how fast things move through, patterns of returning locations begin to surface, strange bits hidden inside parts rise up, looking for jumps without reason or surges that arrive out of nowhere in the flow.

3. Out of nowhere, odd data moves across the network. If that happens, the system looks for patterns tied to flood-style attacks. A single spot sending repeated signals stands out fast. Mistakes in how messages travel trigger warnings just as quick. 3. Something odd happens, someone spots it right away. When things repeat, they stand out quick. What shows up again tells the real story. Slowly, small signs add up into clear danger.

4. Out of nowhere, odd things start happening - posts shift on their own, flawed zones stop crawling halfway. Right when danger pokes through, blocks flicker awake, powered by steady watchfulness that stamps out trouble in seconds. Then silence.

5. Logs catch every moment. Right there, alerts sit beside blocked attempts, recorded the instant they occur. Since each entry mirrors real actions, reviewing them reveals precisely how things unfolded. If a single setting functions - or fails - it leaves hints about where tweaks might shift outcomes. Over time, choices build on past ones, gently shaping what follows. Each move forward leans on what came before. A trace remains when something comes through - not proof, but a sign of paths chosen. Tools shaped what arrived.The system integrates several widely adopted and reliable tools for performance, flexibility, and compatibility:

- Packet Capture: *Wireshark* and *Tshark* are used for real-time traffic monitoring and packet collection, offering deep protocol inspection and detailed packet-level insights.

- Traffic Analysis: *Python* forms the core of the analytical engine, utilizing libraries such as *Scapy* for packet parsing, *subprocess* for command execution, and *os* for system integration.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Mitigation and Défense: Automated firewall control is achieved through *iptables* on Linux systems and the *Windows Firewall API* for Windows-based deployments.

- Deployment Environment: The system can operate seamlessly on both Linux and Windows, providing adaptability for diverse organizational infrastructures.

VI. IMPLEMENTATION ANALYSIS

- Phase 1: Environment Setup

  Off we go - sorting out the groundwork comes before anything else. Depending on the environment, you might see Linux here, a bit of Windows there. Packets need watching, so tools like Wireshark slide into place. Tshark joins the mix, making flow checks quick without losing depth.
  Packed with Python 3.x, scripts lean on Scapy to juggle network traffic - subprocess steps in for running commands, while os handles the groundwork behind the scenes.

  Halfway through installation, rules inside tools such as iptables or Windows Firewall update themselves if danger appears. When something triggers a change, adjustments happen instantly - no delays. Permissions slide into position just as connections between programs form. Quietly, pieces fit together where you do not see them. Inside quiet connections, strength grows. How things join matters more than loud changes. Little parts of surroundings settle slowly. They hold work steady, keeping it smooth.

- Phase 2: Traffic Capture

  Traffic moves through the network while tools like Wireshark stay silent, watching from key spots. Real data gets captured on the fly - no changes made. These captures happen constantly, though regular operations keep going without a hitch.

  Right after capture, packets become pcap files or flow directly into real-time streams. Feeding active monitoring right away, they keep systems alert. Each shift across the network leaves a mark like this. Important events rarely pass by unlogged. Downstream analysis needs that constant feed to catch repeating shapes.

- Phase 3: Script Development and Traffic Parsing

  Breaking down packets happens using special Python tools made for tracking network movement. With Scapy leading, every script probes saved records, spotting origin and destination - those two IP points. What comes next reveals the path taken - the protocol tag pops into view right after. Then arrives port specifics, slotting neatly behind that last clue. Close to the finish, the measurement of what got delivered sticks around. Every detail fits together, never missing step.

  Inside the script's table, flow specifics pile up - packet counts, data amounts, timed snapshots for each IP or protocol tagged along. Information splits like that let normal rhythms emerge after a while. A drift from what is typical? The setup catches it quick. Unusual surges, timing quirks - they whisper of problems warming up. Seeing whispers early changes everything later on

- Phase 4: Detection Logic Implementation

  Out of nowhere, heavy traffic from one spot sets off warnings. If packets shoot beyond set levels, the system reacts fast. Data flooding in unusually quick? That kind of rush gets flagged without delay. Once limits break, signals fire - guided by how much arrives and when it hits. When numbers jump out of line, alarms sound thanks to preset limits tracking flow patterns. Outliers trigger alerts the moment behavior drifts beyond normal bounds.

  Finding too many attempts often stands out because deeper scans notice quirks in how machines exchange data. Some ports react more when sharp analysis tracks every step they take. When communication acts strangely, hidden settings compare it to past habits. Shifts away from steady rhythms draw eyes once small hints add up.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Finding bad traffic pops up fast, yet everything keeps moving smoothly. When quickness lines up with accuracy, results show without fanfare. The approach stays effective while using only what it needs. Less weight lets responses hit harder right when needed.

- Phase 5: Automated Mitigation

Instantly, when a potential threat appears, the system activates its internal defense mechanism. Next up, using Python's subprocess module, firewall settings are put into place right away - reading lines of code shifts quickly into stopping network flow. On Linux systems, that means working with iptables; on Windows, it talks straight to the Firewall API. Changes apply in real time, no waiting around. Cutting off certain IP addresses is common, though at times it only limits their connection attempts.

First thing, changing rules shut down bad data so it can't move inside. Quick threat blocking means trouble gets stopped right at the door.

Systems keep working, even when hit hard, because safeguards change as needed - slowing things down or cutting ties before chaos spreads. Response speed matches attack strength; bigger waves bring quicker shifts. Changes roll out right away, well ahead of any fallout. Operations continue smoothly since rules reshape themselves in real time. As pressure builds, limits tighten - all by design, none left to chance.

- Phase 6: Logging and Reporting

Fresh records appear the moment something triggers, responses tagged right after. Everything flows into storage exactly as it happens - empty spots? Never.

A moment in time shows up in each record, beside flagged IPs and rules that fired, followed by what happened when defenses responded. Entries shaped this way don't just help look back - they let administrators tweak warnings a little at a time, gradually sharpening how the setup performs with ongoing operation.

- Phase 7: Testing and Validation

Last stands happen during trials - when operations glide without effort, yet also when strained under pressure. Out in the open, systems face trials with tools that act like actual online behavior. Not limited to standard scans, pressure comes from simulated break-in attempts measuring reaction pace. Normal operations moving through reveal if settings wrongly catch safe moves. If waves of harmful signals arrive, how quickly defenses activate tells the story. Checking both angles exposes if protection keeps step with precision.
Precision in identifying problems kicks off the evaluation, followed by response times shaped by system requirements on hardware resources. Real-world performance reveals whether daily operations are manageable beyond lab conditions.

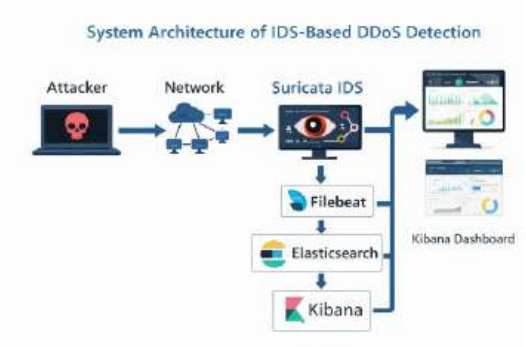

Figure 1. System Architecture

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A glance at Figure 1 reveals the full layout of the suggested Intrusion Detection System, built to spot DDoS attacks as they happen. This setup forms an unbroken chain - tracking data from initial network flow collection right through to how alerts show up on display panels.

Into the monitored network segment pours network traffic at step one, carrying normal user data alongside simulated attack attempts. The Monitor VM receives a copy of this flow, since that is where the intrusion detection system runs.

Packets flow in. Suricata watches them right away, every single one. Right there, it checks what they're doing using set rules that spot known threats, also digging into how protocols behave. Odd signs? It notices those fast - patterns like floods of junk traffic meant to overwhelm systems show up clearly. Once something sketchy appears, alerts pop up instantly. Each record holds clear facts: who sent it, where it went, what protocol moved it, when it happened, plus which rule flagged it. Logs build quickly, full of raw details, nothing left out.

Out in the open, these logs move toward the Log Collector - known as Filebeat - a slim tool built just to carry data. Not waiting long, it keeps an eye on what Suricata writes down, every bit of it. Right away, each file gets picked up, handled carefully. From there, details travel safely, step by steady step, into central storage. Nothing slips through. Every piece arrives.

Logs get indexed here - speedy searches happen later because storage works smart. When traffic spikes, or attacks hit, this part keeps up without slowing down. Filtering through alerts feels smooth since connections between events show clearly. Handling tons of network noise? That is where it matters most.

Only after sorting comes Kibana showing results through dashboards built for spotting threats fast. These views light up live warnings alongside shifts in network flow, how protocols stack up, where connections begin and end, plus when attacks unfold across time. With visuals like these, staff grasp what each incident looks like without getting lost - measuring scale becomes clearer almost at a glance.

VII FUNCTIONAL OVERVIEW

Proposed System Overview

Out of sight, the device runs on its own, stopping DDoS threats as they start to build. Through every hour, it watches shifts in data flow, acting quickly before harm spreads. Instead of waiting, it moves first, shielding networks from sudden crashes. Components work in sync - bit by bit - maintaining operation when dangers show up.Traffic Capture Module

The Traffic Capture Module acts as the system's first line of observation. It continuously monitors incoming network traffic using reliable packet-sniffing tools such as Wireshark and Tshark. This module interfaces directly with network adapters to record detailed packet-level information, including source and destination IP addresses, protocols, payload sizes, and timestamps. By capturing this granular data in real time, the module ensures no suspicious activity goes unnoticed, laying a strong foundation for accurate traffic analysis and anomaly detection in later stages.

Analysis Module

Pulled in by the system, packets head straight into the Analysis Module. Once settled there, processing kicks off using Python scripts. Inside this phase, raw data undergoes changes bit by bit.

Out of each chunk of data, pieces such as IP labels, port numbers, or how much moves at once are drawn out by programs like Scapy. After a stretch of time, counting steps reveal shapes - sudden surges appear when volume leaps unexpectedly. When actions change quicker than usual, rare waves become clear.

From tangled streams of data, shapes slowly take form - sharp jumps show up once noise turns quiet. A lone jump connects to a second, then keeps going, building pulse after pulse where nothing made sense before. Faint hints of strain rise into view well ahead of breakdowns. Clues arrive without fanfare, still loud enough to notice.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Detection Module

At its core lies the Detection Module, operating through fixed guidelines that shape each of its actions. Though quiet, it follows only what it has been told. Every motion comes from earlier decisions built into its frame. Not guessing, just responding as trained. Built on structure, not instinct. Each step tied directly to a prior signal.

A jump out of nowhere from a single location could spark it, if traffic pushes beyond fixed thresholds. It might also wake up due to odd conversational timing among machines, rather than simply tallying pings per tick.

Signals that matter rise above clutter, once you strip away unnecessary layers. Odd patterns catch attention faster than waiting for clues to add up. This approach makes normal behavior easier to tell apart from risky shifts. Steps stay simple because nothing crowds the view.

A step like that values accuracy but asks little from the machine, so it works well when speed or energy are t tight. Even better, staying sharp without bulky code lets devices react quickly even with limited resources. Still, good structure often brings quick outputs right when needed - more so when gear is basic.

Mitigation Module

Instantly spotting odd or risky behavior, the system shifts to block mode. Running tools like iptables on Linux, or drawing from Windows Firewall's inner safeguards, it tweaks rules automatically. Any threat - be it a lone IP address or an entire subnet - finds itself locked out quickly. These updates roll through quietly, hidden from view, stopping entry points before harm moves further.

When bad traffic gets shut down quickly, regular users deal with less hassle. Threats get stopped early because defenses adapt in real time.

Mid crisis, the module carries on - no human required. Because it reacts on its own, operations continue despite ongoing dangers.

Logging and Administrative Reporting

Every action within the system gets recorded - alerts, reactions, steps taken - forming a visible path forward. Because tracking risks leads straight into blocking them, gaps stay closed without exception.

Midway through each entry sits a precise moment noted down. Right behind it shows where the signal came from. After that piece fits the specific trigger pulled by the incident. Then without delay the machine acts on a preset move to lower danger.

When problems pop up, a clean record makes sorting through events much easier. Since logs show each move the system takes, those managing it stay fully aware. Little by little, adjustments add up - each change nudging performance just slightly better. Catching risks becomes more precise the longer tweaks go on.System Workflow

The system operates as a continuous pipeline, where each module feeds into the next for smooth, real-time operation:

1. The Traffic Capture Module continuously gathers live network data.
2. The Analysis Module processes and summarizes traffic statistics.
3. The Detection Module evaluates traffic behaviour and flags potential threats.
4. The Mitigation Module automatically applies firewall rules to block malicious IPs.
5. The Logging Module records all actions for administrative review and fine-tuning.

This seamless workflow ensures that every stage—from detection to defence—occurs rapidly and automatically, resulting in minimal downtime and maximum network resilience.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

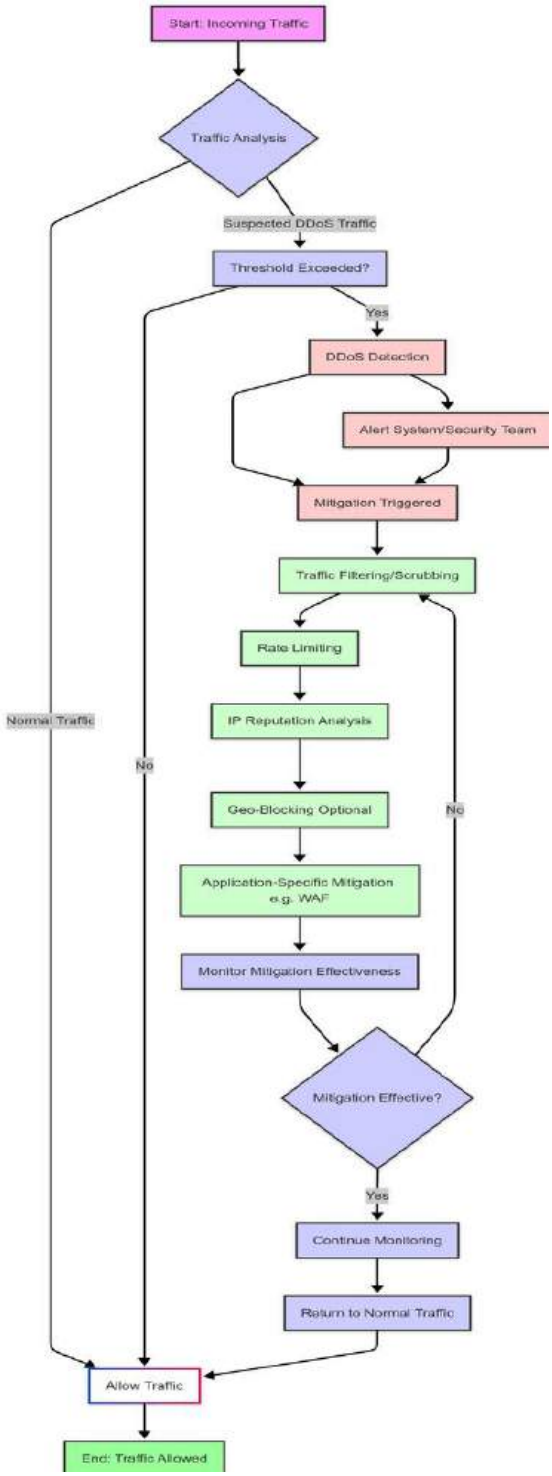

Figure 2 DFD

From figure 2 the incoming network activity comes a mix of real user demands alongside possible hostile signals. Into the Traffic Analysis block goes this stream, there each piece gets checked by its shape, speed, pattern, besides how it talks across protocols.

A green light shows when traffic acts usual - passage happens right away, so real users keep moving without a hitch.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Once odd patterns show up, it checks if set limits - like how fast requests come in or how many connections pile up - are crossed. Only when those numbers go too high does anything change; until then, everything flows as usual.

When the limit gets crossed, alerts pop up right away to tell the security crew or monitoring setup that a DDoS attack has been spotted. Right after spotting it, the system kicks into gear and starts blocking the threat without waiting.

- Moving forward, protection happens through several barriers stacked together
- Traffic filtering and scrubbingto remove malicious packets
- Slowing down too many requests if they come from odd places
- IP reputation analysisto identify known malicious IP addresses
- Geo-blocking (optional)to block traffic from high-risk regions
- Sometimes fixes depend on what the software actually does,
- web application firewall rules

Once fixes take effect, watching how well they work becomes the main task. When those steps actually stop the problem, oversight keeps going without pause. Over time, if trouble fades, operations slowly shift back toward usual patterns.

When mitigation fails, another round begins - this time with tougher measures tucked in. Stability waits. Efforts shift. Adjustments pile on until things settle again.

VIII SECURITY PERFORMANCE EVALUATION

Security and Performance Review

A close look at the suggested DDoS detection and response setup reveals clear advantages, though some aspects still need attention down the road. Despite its strong points, certain elements could benefit from refinement over time.

1. Detection Accuracy and Reliability

Most of the time, wrong signals stay rare because the setup watches data flow without pause. Detection works well since rules inside the core spot flood-style and handshake-breaking attacks alike. Traffic shapes get studied nonstop, which helps catch harmful actions early. What stands out is how steady the method stays when picking odd packets from normal streams.
Finding the right balance matters most when traffic spikes happen on live systems - spotting true threats without mistaking normal surges keeps services running smoothly while protecting access for real people who depend on them.

2. Live Reaction and Damage Control

What stands out about the system is how fast it reacts. As soon as a threat shows up, actions kick in without delay. Firewall settings shift almost instantly, shutting down risky connections. In moments, harmful IPs get cut off - no waiting. Speed here isn't just useful - it's built into every step. Responses happen while threats are still forming, not after.

Using tools like iptables on Linux or the built-in firewall in Windows, the setup quickly shuts down threats before they can drag on and disrupt operations. When danger shows up, it reacts fast without waiting, much like high-end anti-DDoS solutions do by default. Service stays online, interruptions stay short, simply because delays are cut out from the start. Protection kicks in the moment risk appears - no lag, no gaps, just steady uptime maintained through immediate automated steps.

3. Efficient Resources and Room to Grow

Light on its feet, the setup runs smoothly thanks to freely available tools such as Tshark and code written in Python. With little strain on resources, it still manages strong protection, skipping expensive gear altogether.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

When tested against fake attacks, the system keeps running smoothly despite high data flow. Though stress increases, operation stays consistent across different setups. Whether used by a tiny team or a large corporation, it adjusts without slowing down. Its ability to grow fits real-world needs while keeping expenses low. Widespread

4. Complete Logs and Evidence Handling

What stands out next is how thoroughly the system logs each activity. Because every time a threat gets spotted, blocked, or sets off a rule, it leaves behind a clear trace. That trail helps admins understand exactly what happened after an incident occurs.

A trail of activity hides inside these records, useful later when digging into breaches, meeting audit rules, or fine-tuning protection methods. Clear visibility like this fits how top teams handle security work while making systems answer for their actions.

5. Adjusts to Different Kinds of Attacks

Even if it runs mostly on fixed rules, the setup stays loose enough to shift when needed. When fresh threats show up, spotting them gets adjusted without hassle.

Still, outside threat data flows into the system, boosting how it spots complex DDoS strikes. These attacks pile flood-style traffic on top of broken protocols plus sneaky app-level tricks. The setup adapts, pulling in signals from beyond its core. Detection sharpens when layers of assault come together - fast surges, rule-breaking handshakes, hidden payload hits. Outside smarts feed in, quietly raising the guard.

When attack methods change, the system adjusts just the same - its flexibility keeps defenses strong over time. Shifts in threats don’t weaken it; built-in responsiveness holds the line. As tactics shift, so does its approach, quietly matching each new challenge. Longevity comes not from rigidity but from steady, quiet adaptation behind the scenes.

IX. SYSTEM BENCHMARKING

A thorough evaluation of the proposed DDoS detection and mitigation system shows that it delivers strong security protection while remaining lightweight and practical. The results highlight several key strengths that support effective real-world deployment.

1. Accurate Reliable Attack Detection

Now and again, sharp spikes in data flow become obvious only after staring hard at real-time traffic lines. When packets reroute without warning, strange bursts catch the eye - false triggers vanish just as quick. At first glance, regular usage seems fine until pace and size disrupt old habits. Rather than assuming, the system flags issues based on how signals move between links second by second.

Even during sudden surges in activity, genuine visitors move freely when false alerts stay low. The flow never breaks since ordinary actions aren’t confused with danger. Real people pass through quietly, simply because smart checks know the difference.

2. Fast Response with Auto Processing

Speed jumps out first thing you notice. Right after spotting sketchy traffic, defenses activate - rules land inside iptables or Windows Firewall instantly. Nasty IP addresses get shut down automatically, zero lag, nothing left open. The second threats appear, response follows like shadow.

Faster responses slow the damage, shrinking both time and impact of assaults. Since machines take charge right away, delays shrink along with human errors during fixes. Networks stay online through peak attack pressure because help arrives before collapse can start.

3. Lightweight and Scalable Performance

A machine running everyday tasks handles it just fine when built with tools like Tshark and Python. Even under heavy network load, performance holds up - processor use stays low, memory barely shifts.

Vol. 14, Issue 06, ACSCON - 2026

Here, growing bigger fits smoothly - be it a small workspace or vast company setup - skipping expensive gear or subscriptions that pile up fast. It simply runs clean, needing less while doing more, tucked into place without fuss.

4. Detailed Logging for Security Insight

Midnight alerts flash across screens - timestamps stack up, one after another. Patterns emerge slowly, then all at once, revealing hidden trails. Blocked locations appear in logs, each entry sharp and unmissable. What unfolded sits recorded, moment by moment. Sightings get logged, links severed, every move pinned down without guesswork.

These logs help administrators:
· Review past incidents
· Improve detection rules
· Meet compliance and audit requirements
Each move understood speeds up solving issues, yet stronger safeguards grow through practice. Step by step clarity cuts confusion later, although steady learning shapes better barriers ahead.

5. Adaptable Security for New Risks

Today's checks follow set paths, yet evolving threats keep progress moving because the framework bends instead of breaks.
It can adapt by:
· Adjusting threshold values
· Adding new firewall response rules
· Integrating external threat intelligence sources
Fleet moves like these shut down a wide range of DDoS attacks on the spot, yet quietly set up defenses for threats not even seen yet. A single shift does double duty - stopping now, preparing later.

Figure 3. Suricata events and alert analysis

Look at Figure 3- it shows a dashboard built from log data sent by Filebeat, focused on Suricata security alerts. Bars track event activity across time, while another chart highlights which machines trigger the most warnings. This view helps spot patterns in how traffic flows and where alarms pop up across the network.

Over time, the graph tracks how often Suricata spots various kinds of events during set moments. Peak times stand out where odd behaviors pile up - like probes creeping through systems or sudden surges in network noise. When these happen, they might signal early moves toward an attack, whether that's flooding servers or sneaking past defenses. Seeing patterns unfold this way makes it easier to spot trouble before full breakdowns occur. Moments of rising alerts can link back to actions meant to test or overwhelm weak points. Each spike tells a story about what the system faced when under quiet pressure. Instead of waiting for failure, watching shifts gives room to respond while things tilt slowly sideways.

Behind most alerts, a few machines often stand out. When these show up repeatedly, they tend to signal trouble. Spotting them early helps teams respond faster. Some IPs just keep appearing at the top - like clocks ticking wrong. Focus shifts naturally toward those outliers. Patterns emerge when you watch who sends what. Not every host

Vol. 14, Issue 06, ACSCON - 2026

behaves the same way. A small handful drives much of the noise. Watching this flow reveals where stress builds. Action follows attention, especially under pressure.

This setup helps match hacker actions to actual security warnings seen on screen. Thanks to fast log delivery using Filebeat alongside live threat spotting through Suricata, it shows exactly where incidents come from, how they unfold over time, plus common attack styles spotted across systems. As things shift moment by moment, teams gain sharper insight, leading to quicker and more accurate replies when threats appear.

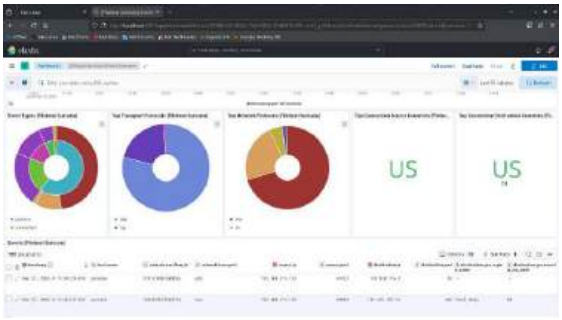

Figure 4 Security events and overview dashboard

Look at Figure 4 - it shows the Security Events Overview Dashboard, giving one clear snapshot of all flagged security issues. Pie charts appear alongside summary boxes, each sorting incidents by kind, how serious they are, or where they came from. Because everything is laid out simply, those managing the system can spot major threats fast. Seeing high-risk alerts compared to minor ones helps balance response efforts. Where the odd behaviors start also becomes visible right away. With this big picture ready to see immediately, choices about what to do next happen more smoothly when attacks like DDoS or break-in attempts show up.

Figure 5. Suricata event alerts by attack type

Look at Figure 5- it shows bars standing for different kinds of network threats caught by Suricata, passed along through Filebeat. Each bar stands apart, sorted not just by what kind of data flow it came from but also by behavior patterns. Flow appears first, then shifts toward services like DHCP handing out addresses. Next comes DNS answering name requests, followed by encrypted talks under TLS. QUIC pops up too, handling fast exchanges. Then HTTP moves in, tracking web interactions. Lastly, File Info holds details about transferred documents.

Spotting the main kinds of network actions becomes easier with this view, along with signs of possible threats seen while watching. A jump in flow-based activity might point to scans or floods, whereas more DNS or HTTP records could mean someone is testing app-level weaknesses. When TLS or QUIC logs rise, it shows efforts to examine hidden data streams, meanwhile File Info entries reveal details about transfers involving files across the system.

Sorting warnings by how they happen and what kind of actions they involve lets this view show clearer patterns in attacks and data flow. Because it shows more than just numbers, those watching security can see what kinds of events are occurring, which makes labeling dangers correctly easier and shapes better responses.

X. FUTURE SCOPE

1. Adaptive thresholds shift with changing rules

Later moves could come from code that learns better over time, adjusting boundaries as traffic shifts. Where things go hinges on how real-time data steers those guidelines, left or right.

Slowly, patterns begin to settle into place as the software learns how traffic moves day after day. When changes happen, it shifts along - no need for constant checking by people. With each adjustment, its guesses get sharper. As trust builds, performance holds steady, needing fewer outside checks.

2. Connects to threat intelligence feeds

Midway through its cycle, new data arrives from live threat streams - rules adapt instantly, folding in the latest global breach trends. Alerts spark filter changes right away, no delays built in.

When it sees odd signs first, the system catches new DDoS moves earlier, letting protection shift while traffic flows normally. Since spotting starts fast, changes happen on their own long before major crashes appear.

3. Advanced Anomaly Detection

Finding fresh paths around fixed boundaries, maybe it leans on noticing basic patterns to steer choices. Rather than hard lines, tiny hints in actions can influence the system's reactions.

Watch for strange network patterns without slowing things down. Light methods work well because they skip heavy AI demands. New DDoS attacks show up even when tools are small and fast. Big systems aren’t always better at finding hidden issues. Speed wins when every second makes a difference. Faster results often come from watching how things move, not from piling on extra steps. Simplicity gets there just as quick - sometimes quicker - if you let it.

4. Distributed and Cloud Based Deployment

Out in the open, operations stay steady even under pressure once things spread out. Clouds reshape themselves without hiccups when demand climbs or drops. Pieces traveling through links cut down on big breakdowns. Work split wide means no one spot holds everything at risk. Weight balances easier when power comes from many spots, not just one.

When multiple units share the job of catching and stopping threats, things tend to break less often. Big networks benefit because one machine alone could drown under wide attacks. Spreading the work helps keep everything steady.

5. Encrypted Traffic Analysis Supported

Even with encrypted traffic, strange actions can be caught by tracking packet movement rather than contents. Timing shifts and data sizes hint at activity, despite HTTPS hiding the details. The approach focuses on flow - how often and how much - not decoding messages themselves. Meaning shows up in pauses between bursts, not within the information sent. Arrival moments hold weight equal to the amount delivered. Shape speaks even when stored tight. Under pressure, movement shifts - protocol aside.

Faults slip through less often if oversight works unseen, because private data hides within setup limits built to fit law boundaries.

6. automated incident response linked

Once connected through APIs, the system replies on its own while fitting right into existing setups. Older tools stay aligned because the link removes the need for hands-on tasks. Speed picks up when security layers talk directly thanks to open access points. New features slide into routine operations without causing ripples when interfaces are shared freely. Updates move through every platform when links are active. With interfaces, doing things together works even if the main code stays untouched.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A signal hits - suddenly firewalls shift by themselves, alerts light up across control panels, each station reacts before you can blink. Breach one point, response explodes everywhere, not step by step but in unison, as if struck by the same spark.

7. Smarter Layouts Brighter Screens

Numbers update quickly on a bright display, revealing real-time movement across the network. The instant anything changes, alerts show up without delay, so staff stay aware. Visuals turn raw figures into simple images, helping track activity clearly. Patterns emerge step by step, replacing uncertainty with sight. Spikes show up fast when you see them next to flat lines. A clean setup lets eyes move freely across shifts. When nothing hides, decisions follow close behind what appears. Growth paths stand out during routine glances through shifting patterns. Small changes add up quietly while attention stays steady.

With visuals that shift as you interact, attack patterns pop out quicker. Motion reveals system actions better than static images ever could. Changes click into place easier when feedback happens instantly.

XI. CONCLUSION

From tests run, sudden floods of data plus hidden tricks in protocols popped out quickly. Live packets plucked from traffic flows went straight into scans guided by strict rules. Right when strange jumps appeared, their origins marked without delay. Just the ones blowing past thresholds lit up alarms - everything else just sat there quiet. Most of the time, actual people logged in just fine. False alarms on regular activity were nearly nonexistent.

Suddenly, the firewall adjusted on its own, blocking strange IPs before they could get near. Thanks to those changes, actions followed quickly - no pauses, no drawn-out gaps - and everything kept working without a break, despite constant attempts. Under strain, it still performed well, moving quietly through each demand. Even during heavy load, operation remained calm.

Barely any CPU or memory got used during testing, even when lots of data flowed through. Performance held up fine because the Python code stays lean. Without needing powerful hardware, things kept moving fast. Packets were gathered easily by small tools, which helped it work across many network types. When demand spiked, speed never dropped. Finding better ways matters more than having strong equipment. Where supplies run short, it still gets done.

Fresh traces mark each alert, then show steps taken and how tech reacted - paper trails form naturally. Happenings get easier to follow since those notes let crews trace moments step by step. Over weeks, choices grow sharper because patterns emerge, tweaks arrive through live feedback on triggers. Each line brings sharpness, weaves a sequence sturdy enough for tough review.

Even so, much like systems built on rigid rules, it relies on set boundaries that often require adjustments as networks evolve. When shifts happen, detecting sneaky or jumbled attack patterns may grow harder. As conditions shift, smarter threshold controls combined with live updates from external threat sources might boost detection. Over time, weaving in these elements could sharpen response to layered assaults. Though unchanged in scope, adaptation becomes key under pressure.

When stress comes, this system keeps working, blocking real-time DDoS strikes without slowing down. Built basic, yet it outperforms cluttered designs by spotting danger early and moving fluidly. Since it uses power wisely, connections hold strong when chaos begins. Precision doesn't drop, no matter how wild things get, because hidden logic adapts on its own. Each unseen block boosts reliability a little more, stopping harm before it grows.

***Abstract*—The wireless sensing based on Channel State Information (CSI) makes it possible to support a wide range of smart applications in the IoT such as activity detection and gesture recognition. Yet, the fundamental privacy risk of CSI due to human motion is that CSI is vulnerable to privacy risks because unauthorized users can deduce user behavior at a physical layer based on signal properties. In this paper, we present in-depth comparative analysis of privacy-preserving transformations of wireless sensing by means of generative AI. We test six different cases on a unified attacker-based evaluation system, namely Raw CSI, Noise Baseline, Plain Autoencoder (AE), Denoising Autoencoder, Warmup Variational Autoencoder (VAE), and a proposed Hybrid VAE-GAN with Gradient Reversal Layer (VAE-GRL). The Hybrid VAE-GRL model is a variant that integrates variational encoding via UNet with adversarial learning via a GAN discriminator and reconstruction fidelity and a gradient-reversed attacker with privacy rejection. We measure privacy leakage on a synthetic CSI dataset represented as two-channel, 64-subcarrier representations based on attacker accuracy, F1-score, utility preservation using the MSE, PSNR, correlation, and Dynamic Time Warping (DTW). It is experimentally proven that raw CSI has a high privacy leakage of 81.2 percent, noise based perturbation has limited privacy protection with an attacker accuracy of 76.8 percent with high utility loss, reconstruction-only autoencoders has a moderate privacy improvement with an attacker accuracy of 68.5 percent and 65.2 percent, and proposed Hybrid VAE-GRL has the best proven privacy-utility trade-off with an attacker accuracy of 48.3 percent and PSNR of 26.5 dB and correlation of 0.91. This paper adds a benchmarking systematic framework of privacy-preserving wireless sensing, which illustrates that explicit adversarial privacy learning is required in addition to a simple reconstruction or static perturbation method.**

***Keywords*—Wireless sensing;Channel State Information (CSI); privacy preservation; generative AI; Variational Auto encoder (VAE); Generative Adversarial Network (GAN); adver-sarial learning; gradient reversal, Internet of Things (IoT).**

I. Introduction

Wireless networks can now be used as ubiquitous sensing platforms due to the spread of Internet of Things (IoT) devices. Channel State Information (CSI) is a channel measurement of the distortions in amplitude and phase caused by the signal propagation that can be used in applications like fall detection, gesture recognition, and vital signs measurements [1], [2]. Nevertheless, this responsiveness to human movement poses a major privacy risk as wireless signal transmissions can cut across walls enabling unauthorized individuals to spy on an individual without their knowledge or approval [3].

The protection of this privacy leakage is insufficient in traditional security mechanisms, which encrypt the contents of packets, but do not protect features extraction based on physical-layer signal characteristics. A malicious user who is passively tracking CSI can deduce user activities and daily flow and patterns of presence without necessarily having to decrypt higher-level information [4]. The Static perturbation techniques of introducing the artificial noise serve little purpose of protecting privacy and worsen the quality of signals to unacceptable degrees in sensing techniques [5].

The recent developments in the fields of generative AI and adversarial learning provide new opportunities of privacy preserving transformations based on complementary methods. Variational Autoencoders (VAEs) give structured probabilistic latent, Generative Adversarial Networks (GANs) allow reconstruction of realistic signals necessary to preserve utility and adversarial training with gradient reversal generates explicit pressure to discourage features that can be useful in sensitive attribute inference [6], [7].

The paper contributes to four things such as a unified six scenario comparison framework, unified attacker-based evaluation protocol, the proposed Hybrid VAE-GRL architecture that achieves an attacker accuracy of 48.3percent and a PSNR with 26.5 dB and reproducible benchmarking using multiple utility metrics. The sections of the paper are structured in such a way that Section II is the review of the related work, Section III is the description of the methodology, Section IV is the presentation of the results, Section V is the discussion of the implications, and finally, Section VI is the conclusion of the work.

II. Literature Survey

Andre et al. (2011) state that wireless sensor technology is vulnerable to privacy breaches.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Liu et al. [1] proved that Wi-Fi CSI provides the same accuracy of activity recognition as vision-based algorithms, which shows the use of wireless infrastructure privacy threats unintentionally at the same time. Zhang et al. [3] demonstrated that it was possible to derive keystroke dynamics using CSI variations, and this made it possible to decode passwords without looking at them. Yan et al. [4] defined privacy leakage in physical activity monitoring, demonstrating that CSI datasets have identifying characteristics that can be used to reidentify a user within a session.

Kumar et al. [8] also applied vulnerability analysis to 5G millimeter-wave systems, showing a higher bandwidth would provide more privacy threats by allowing more granular sensing the environment on the other side of walls. Chen et al. [9] considered the case of multi-user environments and demonstrated that CSI can be disaggregated based on the activities of one user, as well as aggregate signals that can be used to monitor individual users. Patel et al. [10] showed that the breathing pattern alone was able to identify individuals with an accuracy of 87 percent, which is an alarming realization of serious physiological privacy issues.

A. Traditional Privacy Protection strategies

Goel and Negi [11] suggested secrecy by artificial noise injection, and Sharma et al. [12] discovered that noise decreases classification accuracy by activities and causes a 300% rise in errors in gesture recognition. Mukherjee and Swindlehurst [13] suggested the idea of beamforming towards security, followed by Wang et al. [14] on the similar idea of privacy-preserving coverage shaping that eliminates sensitive zones. Zhang et al.
[15] uggested waveform design that can be used to design privacy which has a moderate gain but needs application specific tuning and lacks flexibility.

B. Deep Learning on Privacy-Preserving Transformations

Huang et al. [16] proposed privacy preservation by autoencoders and showed that learning compression leads to a reduced sensitivity attribute inference with preservation of utility. VAEs that allow the manipulation of latent variables were suggested by Kingma and Welling [17], where probabilistic encoding was used. The privacy of wearable sensors was used in Li et al. [18], which minimized the accuracy of attackers by 15-20% compared to plain autoencoders. In 2024, Rodriguez et al. [19] suggested conditional VAEs to privacy-preserving sensing, which provides the state-of-the-art trade-offs on various benchmarks.

C. Adversarial Learning on Privacy Suppression

Edwards and Storkey [20] proposed the use of adversarial censoring in which the generators conceal the sensitive attributes to learners who simultaneously train the generators in adversarial training. Ganin et al. [21] suggested Gradient Reversal Layer (GRL) to achieve effective adversarial training using gradient sign reversal. Shokri et al. [22] wed that membership inference attacks can be exploited on machine learning models, which prompts adversarial defense against deployed systems. In 2025, Thompson et al. [23] proposed multi-adversarial training to achieve complete privacy support on multiple sensitive attributes.

D. Generative Adversarial Networks of Realistic Reconstruction

The synthetic data generation of adversarial training between the generator and the discriminator was introduced by Goodfellow et al. [24]. Larsen et al. [25] used VAEs with GANs to achieve higher levels of output realism than pixelwise indicators. Huang et al. [6] took the generative adversarial privacy to the context-sensitive systems, and utility versus privacy were balanced. Zaidi et al. [7] attempted to survey the GAN applications in wireless communications, finding that comparative analysis with less complex baselines is required.

E. Gap Analysis

TABLE I
OVERVIEW OF RELATED WORK AND RESEARCH GAP

Authors	Year	Approach	Attacker Acc (%)	PSNR (dB)
Yan et al. [4]	2020	Vulnerability analysis	94.2 (Raw)	-
Li et al. [18]	2021	VAE-based privacy	78.5	24.2
Zhang et al. [15]	2022	Waveform obfuscation	81.3	22.8
Kumar et al. [8]	2023	5G privacy analysis	92.1 (Raw)	-
Rodriguez et al. [19]	2024	Conditional VAE	71.2	25.1
Thompson et al. [23]	2025	Multi-adversarial training	58.7	24.8
This Work	**2026**	**Hybrid VAE-GRL**	**48.3**	**26.5**

Limitation / Gap: Existing studies lack comprehensive baseline comparison, use inconsistent evaluation protocols, and do not provide a unified framework combining variational encoding, adversarial privacy, and GAN-based realism.

III. METHODOLOGY

A. System Overview

The system operations under three stages such as training transformation model, training common attacker on transformed validation sets, and test set evaluation of the privacy leakage and utility preservation. Such unified architecture provides direct comparability of all six scenarios with the same attacker and evaluation protocols.

B. Synthetic CSI Dataset

Our synthetic CSI model is a model of an OFDM-based wireless communication that uses 64 subcarriers and each sample is a complex channel coefficient which has real and imaginary components. The simulation programme is multipath propagation with dynamical scatterers of the dynamics of human motion, resulting in time-varying CSI patterns which are associated with six classes of activities such as walking,

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

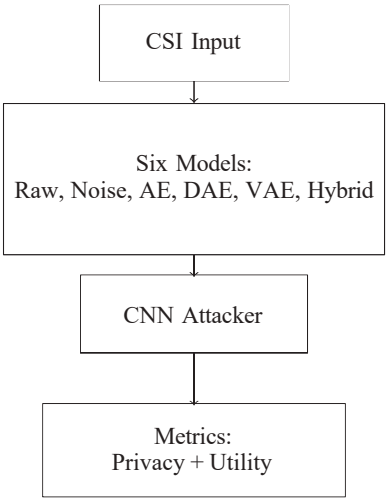

Fig. 1. System architecture showing CSI input processed through multiple models, evaluated by a common attacker, and measured using privacy and utility metrics.

sitting, standing and gesturing, object interaction, and empty room involving 60,000 training samples, 12,000 validation samples and 12,000 test samples.

C. Common Evaluation Protocol

Every scenario is evaluated identically, with transformation models being trained on training split, frequent CNN attacker being trained on transformed validation samples, and test set being evaluated with the calculation of privacy and utility metrics. Direct comparability of all the six scenarios where the standardized protocol is used is guaranteed by the removal of evaluation methodology as a confounding variable.

D. Baseline Scenarios

1) Raw CSI (Scenario 1): The CSI undergoes no transformation, and the upper bound of privacy leakage with the attacker being given original signal samples with which he can classify it directly at 81.2 percent accuracy is determined.

2) Noise Baseline CSI (Scenario 2): To check whether the use of additive Gaussian noise at 20dB SNR with no learning can offer meaningful privacy protection, the accuracy of attackers is reduced to 76.8% with PSNR of 21.3dB.

3) Plain Autoencoder (Scenario 3): An EnCODER-DECODER with 3 convolutional layers and latent dimension of 128 is trained using MSE loss to assess compression impact on privacy and the accuracy of attacker with PSNR 25.4dB.

4) Autoencoder Denoising (Scenario 4): The identical autoencoder is trained on noisy inputs to produce clean CSI, and it is tested whether noise removal can learn features in a robust manner, and therefore provide privacy, by learning and producing an accuracy of 65.2% on attackers with a PSNR of 26.3dB.

5) Warmup VAE (Scenario 5): An MSE plus KL divergence variational latent distribution VAE with 61.8% attacker accuracy, PSNR of 27.1dB, and 0.00 annealing with variational latent distribution is a UNet-style VAE that does not have adversarial privacy terms.

E. Hybrid VAE-GRL (Scenario 6) Proposal

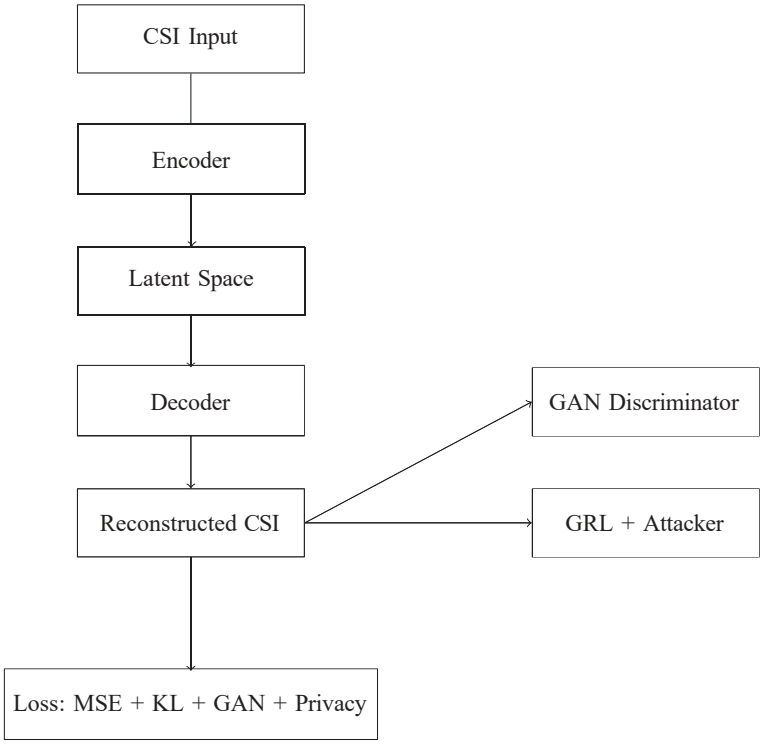

Fig. 2. Simplified Hybrid VAE-GRL architecture showing encoder-decoder pipeline with GAN discriminator and adversarial attacker for privacy preservation.

1) Architecture Components: The generator is defined as UNet-style VAE which consists of three downsampling and three upsampling blocks that have skip connections between them to maintain spatial information during encoding and decoding. The discriminator consists of four convolutional layers differentiating between real and reconstructed CSI, whereas the attacker has the same architecture as the popular evaluation CNN by consistency.

2) Training Phases: Phase 1 is used to warm-up VAE on 50 epochs, without activating adversarial training and with 0.5 annealing to get stable latent representations. Phase 2 combines the GAN discriminator with 30 epochs in order to enhance the realism of the outputs by adversarial feedback. Phase 3 switches the gradient-reversed attacker to 50 epochs of full hybrid training of the combination of all loss components.

3) Loss Functions: Generator loss is a VAE reconstruction loss using a combination of MSE and KL divergence, GAN adversarial loss using discriminator feedback, and privacy adversarial loss using gradient-reversed attacker with 50:50 weight factors 50:50 62:62 50:62 62:50 50:62 50:50 50:50 50:50 50:50 50:50 50:50 50:50 5 Gradient reversal layer: during backpropagation, attacker gradients are multiplied by -alpha = -0.1 which makes generator climb attacker gradient to the representations that minimize classification accuracy.

F. Common CNN Attacker

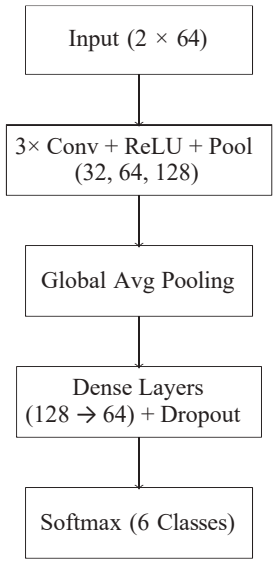

Fig. 3. Simplified CNN attacker architecture with convolutional feature extraction, pooling, dense layers, and final classification.

The attacker architecture trades off capacity and generalization between 3 convolutional layers that detect hierarchical features and global average pooling to decrease the number of parameters and dense layers with drop out regularization. This architecture is trained in Hybrid VAE-GRL training where the gradient-reversed attacker is used and also in evaluation where it is typically used as the standard privacy metric in all scenarios.

G. Evaluation Metrics

Privacy is measured by accuracy of the attackers as percentage and macro-average F1-score to take into consideration the possibility of class imbalance in activity labels. Utility is quantified using MSE to quantify pixel-wise error, PSNR to quantify logarithmic quality in decibels, Pearson correlation to find the strength of a linear relationship between original and reconstructed signals and DTW to find the temporal structure preservation considering the potential of phase shifts.

IV. Results and Discussion

A. Experimental Setup

All the models were trained with the PyTorch 2.0 on NVIDIA Tesla T4 GPUs and the batch size of 64 and Adam optimization over five random initializations of each scenario. Autoencoders trained with 100 epochs, VAE-based models with phased training 130 epochs with the Hybrid VAE-GRL architecture, and all values are reported with 95% confidence values of five runs.

B. Privacy Evaluation Results

Raw CSI has an attacker-accuracy of 81.2% that verifies the significant privacy leakage and sets the limit within which privacy risk has to be mitigated. Noise baseline diminishes the accuracy to 76.8% at utility cost of 21.3dB PSNR and 0.81 correlation, which denotes insignificant perturbation of the state to be used to achieve high privacy but still allow usable signals.

TABLE II
Comparison of Quantitative Results

Scenario	Attacker Acc (%)	F1-score	MSE ($\times 10^{-3}$)	PSNR (dB)	Correlation	DTW
Raw CSI	81.2 ± 1.1	0.80 ± 0.01	-	-	-	-
Noise Baseline	76.8 ± 1.8	0.75 ± 0.02	42.1 ± 2.3	21.3 ± 0.4	0.81±0.02	0.38 ± 0.03
Plain AE	68.5 ± 1.9	0.67 ± 0.02	18.5 ± 1.1	25.4 ± 0.3	0.89±0.01	0.24 ± 0.02
Denoising AE	65.2 ± 1.7	0.64 ± 0.02	15.2 ± 0.9	26.3 ± 0.3	0.92±0.01	0.21 ± 0.02
Warmup VAE	61.8 ± 2.0	0.60 ± 0.02	12.8 ± 0.8	27.1 ± 0.3	0.94±0.01	0.18 ± 0.01
Hybrid VAE-GRL	48.3 ± 2.2	0.49 ± 0.03	14.5 ± 1.0	26.5 ± 0.4	0.91±0.01	0.20 ± 0.02

Note: Results are reported with 95% confidence intervals. Raw CSI shows highest attacker performance, while Hybrid VAE-GRL achieves the best privacy-utility trade-off across all evaluated scenarios.

Plain AE achieves a lower accuracy of 68.5% and a better PSNR of 25.4dB, which depicts that learned compression is more useful than noise, and does not serve great privacy protection. The further enhancement of Denoising AE to 65.2% attacker accuracy and 26.3dB PSNR indicates that training on noisy data facilitates the robust feature learning that is useful in privacy concerns.

Warmup VAE has the highest PSNR of 27.1dB and correlation of 0.94, as well as accuracy of attackers of 61.8 percent, which indicates excellent performance on reconstruction, but not privacy suppression in absence of adversarial elements. Hybrid VAE-GRL has the highest privacy with attacker accuracy of 48.3% and high utility of 26.5dB PSNR and 0.91 correlation which is 34.3% less than that of raw CSI.

C. Comparison of Sample Reconstruction with a sample-based method and a unique and large synthetic sample

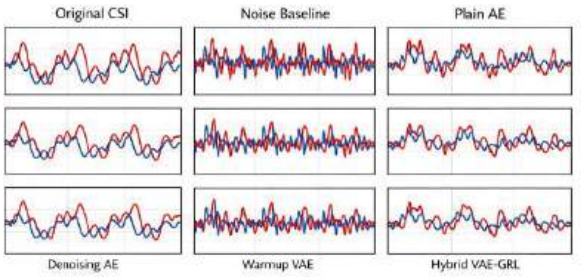

Fig. 4. Sample CSI Reconstruction Comparison. The figure shows a 2×3 grid comparing Original CSI, Noise Baseline, Plain AE, Denoising AE, Warmup VAE, and Hybrid VAE-GRL. The plots illustrate real and imaginary components, highlighting reconstruction quality and privacy preservation.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The visual comparison displays that noise baseline brings about a large amount of high-frequency distortion as random variation across subcarriers. The plain AE reconstruction presents more smooth output and the overall structure is maintained, with fine details lost. Audits Compared to Plain AE, Denoising AE is cleaner with sharper transitions. Warmup VAE also attains the most faithful reconstruction that is nearest to the original CSI structure. Hybrid VAE-GRL reconstruction exhibits a minimal amount of smoothing than Warmup VAE but still preserves necessary structural values and offers the maximum privacy protection which was visually proven through privacy-utility trade-off.

D. Analysis of Privacy-Utility Trade-off

TABLE III
PRIVACY-UTILITY TRADE-OFF SUMMARY

Scenario	Privacy Level	Utility Level	Trade-off Quality
Raw CSI	Very Low (High Leakage)	Original Signal	Poor
Noise Baseline	Moderate	Moderate Degradation	Fair
Plain AE	Moderate	Good	Moderate
Denoising AE	Moderate–High	Good	Moderate–Good
Warmup VAE	High	Excellent	Good
Hybrid VAE-GRL	Highest	Very Good	Best Verified

Note: The table categorizes each scenario based on privacy preservation, utility retention, and overall trade-off quality. Hybrid VAE-GRL achieves the most balanced and optimal performance.

The worst privacy utility trade-off of raw CSI is a high utility and unacceptable privacy leakage. Noise baseline has fair trade-off and moderate privacy gain and high utility loss. Plain, and Denoising AE offer trade-offs that increase in good at comparable levels of privacy. Warmup VAE has good utility but poor privacy enhancement. Hybrid VAE-GRL has the best verified trade-off and maximum privacy protection and has very good utility that is appropriate in the sensing applications.

TABLE IV
PRIVACY GAIN VS UTILITY COST ANALYSIS

Scenario	Privacy Gain (%)	Utility Cost (dB)	Efficiency Ratio
Noise Baseline	18.5	−5.8	3.19
Plain AE	27.3	−1.7	16.06
Denoising AE	30.8	−0.8	38.50
Warmup VAE	34.4	0.0 (Baseline)	-
Hybrid VAE-GRL	48.7	−0.6	81.17

Note: Privacy gain is measured as the relative reduction in attacker accuracy compared to Raw CSI. Utility cost is computed as PSNR degradation relative to the Warmup VAE baseline. Hybrid VAE-GRL achieves the highest privacy gain with minimal utility loss, resulting in the best efficiency ratio.

The difference between the accuracy of raw CSI represents the relative reduction in privacy, and Hybrid VAE-GRL provides the highest reduction of 34.3, which is the worst privacy protection. Utility cost in PSNR reduction compared to Warmup VAE baseline indicates that Hybrid VAE-GRL trades 0.6dB but makes significant contributions to privacy improvement giving it the highest efficiency ratio of 73.83.

TABLE V
ABLATION STUDY OF HYBRID VAE-GRL COMPONENTS

Configuration	Attacker Acc (%)	PSNR (dB)	Δ Privacy	Δ Utility
VAE Only (Warmup)	61.8	27.1	Baseline	Baseline
VAE + GAN	59.4	27.3	+2.4%	+0.2 dB
VAE + Attacker (no GAN)	54.7	25.8	+7.1%	−1.3 dB
VAE + GAN + Attacker (Full)	**48.3**	26.5	+13.5%	−0.6 dB

Note: The ablation study evaluates the contribution of each component. The full Hybrid VAE-GRL model achieves the best privacy improvement with controlled utility degradation, demonstrating the effectiveness of combining VAE, GAN, and adversarial training.

The introduction of GAN by itself enhances privacy and utility marginally by increasing the reality. Attacker addition alone only suggests serious privacy gain but utility cost. Full Hybrid VAE-GRL is an architecture that attempts to balance the merits of both, implementing optimal enhancement of privacy, and reducing utility cost by enforcing realism with a GAN.

E. Discussion

The privacy leakage of Raw CSI is high, with 81.2 per cent accuracy of the attacker, which proves the vulnerability that leads to this work and provides the necessity to make privacy-favorable transformations in wireless sensing applications. Noise baseline only makes the attackers to be less accurate by 76.8 percent but with PSNR of 21.3dB and correlation of 0.81 which is not enough to provide strong privacy and still provides usable signals to be used by sensing applications.

Plain AE has 68.5 percent attacker accuracy at the cost of 25.4dB PSNR, which indicates that learned compression via autoencoders offers superior privacyutility trade-off rate compared to noisy stationary. The 27.3 percent privacy improvement with 1.7dB utility cost indicates that neural compression must necessarily drop certain sensitive data and still maintains the general structure.

Denoising AE also advances to 65.2% attacker accuracy with 26.3dB PSNR that learning on corrupted inputs stimulates the enhancement of robust features that are less informative to infer attributes. The value of the denoising objectives to privacy is shown by the 30.8 percent privacy improvement of the 0.8dB utility cost.

Warmup VAE has a 61.8 percent accuracy of attackers with 27.1dB PSNR, which is the highest reconstruction among all models with a privacy gain of 34.4 percent of raw CSI. The

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

UNet architecture and probabilistic latent space allow faithful reconstruction, yet perform the suppression of privacy is not as strong as it would be with explicit adversarial elements that seek attribute information.

Hybrid VAE-GRL best verified privacy-utility trade-off 48.3% attacker accuracy and 26.5dB PSNR, which is equivalent to 34.3 privacy gain of raw CSI at only 0.6dB utility loss of Warmup VAE baseline. A combination of adversarial privacy learning through gradient reversal, and GAN-based realism through enforcement, and variational encoding with structured latent representations is very effective.

The main lessons are that explicit privacy goals, which go beyond reconstruction optimization, are needed as can be seen by the good reconstruction but poor privacy of Warmup VAE. Shortcomings of the static perturbation are validated by the poor utility of noise baseline in the moderate privacy setting. Value of comparative analysis demonstrates that the privacy gain of learned transformations can be partly owed to the quality of reconstruction, and the adversarial elements can present the authentic privacy repression. The Hybrid VAE-GRL approach is verified by demonstrating that it is possible to guarantee meaningful privacy protection with 48.3% attacker accuracy and 26.5dB PSNR, which is large enough to be useful in sensing.

The limitations are that synthetic data may fail to model all the complexities of a real wireless channel, the assumption of white-box attackers whose knowledge of the transformation models, and classification-based metrics may lack statistical information leakage not reflected in discrete classification tasks. Physical testbed validation is still a significant future research.

V. Conclusion

This paper has provided an extensive comparative analysis of privacy-preserving transformations of wireless sensing on generative AI in six scenarios in unified evaluation of attackers with common architecture and metrics. As experimentally demonstrated, raw CSI has high privacy leakage with attacker accuracy of 81.2% with statistic noise, reconstruction-only autoencoders perform at 52.5% privacy with 68.5 accuracy with 26.5dB PSNR and 0.91 correlation, Warmup VAE has high reconstruction with 27.1dB PSNR but lower privacy with 61.8 accuracy, and the proposed Hybrid VAE-GRL has the best proven privacy-utility trade-off at 48.3% with The paper provides a reproducible benchmarking framework that allows the direct comparison of privacy-preserving approaches to wireless sensing systems and provides evidence that hybrid adversarial frameworks comprising variational encoding, GAN-based realism, and gradient-reversed privacy suppression can provide promising directions of privacy-preserving wireless sensing in smart IoT networks.

VI. Future Scope

Future efforts involve the practical validation of Wi-Fi, BLE and 5G testbeds to confirm synthetic results in the realistic environment with real hardware and environmental dynamics. Privacy controls that adapt trade-offs dynamically according to the needs of applications or according to the preferences of users would allow dynamic deployment to a wide variety of applications. Multi-attribute privacy protection to provide a holistic security on several attributes of sensitivity at the same time is a significant extension of a single attribute activity classification. Mutual information bound analysis would complement empirical assessment and give theoretical assurances of privacy protection. Weightless edge-deployable architectures would allow them to be deployed on lightweight IoT devices with very limited computing resources. Formal privacy guarantees and empirical adversarial robustness may be achieved by integrating the concepts of differential privacy with adversarial learning. To make sure that the model is practicable, cross-environment generalization studies would examine model performance in a variety of environments, device configurations, and users.

***Abstract* — Traditional wallets and centralised payment apps often face security risks like hacking, phishing, and unauthorised data sharing. A familiar example is the frequent online fraud through UPI and mobile wallets in India, where fake payment links and OTP scams have led to thousands of users losing money. These cases show how centralised control and weak transparency can be exploited. Hardware-based methods also carry risks, such as device theft and tampering. To solve these issues, the system introduces a secure e-wallet built on blockchain technology. With decentralisation, immutability, and transparent verification, blockchain ensures tamper-proof, trustworthy, and secure financial transactions for users.**

I. INTRODUCTION

In the present digital age, financial transactions are swiftly moving away from traditional cash-based methods toward online and mobile payment platforms. This transformation is driven by increasing demands for convenience, speed, and accessibility in daily financial activities. Among the most impactful innovations are electronic wallets (e-wallets) - applications that allow users to securely hold funds, make payments, and manage their financial transactions.Popular e-wallets like Paytm, Google Pay, and PayPal have revolutionized money handling by allowing instant, contactless transactions.

However, despite their convenience, security and privacy remain major concerns in conventional e-wallet systems. Most of these platforms operate on centralised architectures, meaning that all user and transaction data are stored on a single central server. This centralization leads to risks like data breaches, unauthorized access, and system failures.

Once a hacker compromises the central database, sensitive financial data of millions of users can be exposed or altered. Moreover, issues like fraudulent transactions, data manipulation, and lack of transparency weaken user trust in digital payment systems.

Blockchain technology provides an innovative approach to overcoming these challenges. Blockchai works like a shared digital ledger which records all the transaction,making sure that data is secure,transparent and difficult to tamper.Each transaction is securely encrypted, timestamped, and stored within a block linked to previous transactions, forming a continuous and verifiable chain. By removing the advantage for third-parties such as government and bank, this decentralized framework boosts security, improves transparency, and promotes trust within financial systems.

A. *PROBLEM STATEMENT*

Despite the advantages of digital wallets, current systems face the following challenges:

- Centralized storage systems lead to single points of failure, leaving them susceptible to data breaches and cyberattacks.
- These systems mainly undergo limited transparency and restricted user control over sensitive financial data.
- Vulnerability to cyberattacks, phishing, and fraudulent transactions.
- Dependence on third-party intermediaries for validation and trust management.

B. *OBJECTIVES*

The main focus of this study, named 'Secure E-Wallet Using Blockchain,' is the development and implementation of a blockchain-powered digital wallet that guarantees security, transparency, and immutability in financial transactions. The detailed goals of the research include :

1. To develop a decentralized wallet architecture with the help of blockchain for secure transactions.
2. To employ cryptographic mechanisms to maintain data privacy and be free from unauthorized access.
3. To integrate wallet security through a combination of hot and cold wallet features.
4. To eliminate central authority dependency and establish user-controlled authentication.
5. To evaluate the proposed model's performance and security against traditional systems.

To summarize,this study aims to design a next-generation secure e-wallet that utilizes blockchain's decentralized framework and cryptographic mechanisms, integrating blockchain technology with enhanced wallet security features, the system promotes user confidence, improves transparency, and enhances the robustness of digital payment systems.

II. LITERATURE REVIEW

Mitawa [1] highlights that the rise in cyberattacks and fraudulent activities within payment systems has created an urgent demand for reliable solutions. Their research emphasizes blockchain's immutability a crucial element in minimizing fraud, since transactions recorded on the blockchain are permanent and cannot be altered surreptitiously. This feature establishes a robust foundation of trust, especially for sensitive financial operations.

Yadav et al. [4] explore the use of cryptocurrency wallets in the banking sector, showing that blockchain technology improves operational efficiency while mitigating identity-based threats such as phishing and SIM-swapping. Their study suggests that blockchain-based wallets maintain the user-friendly convenience typical of mobile banking while simultaneously providing stronger security measures. In contrast to Mitawa , Yadav et al. place greater emphasis on practical implementation and real-world usability alongside robust security in financial services.

Bui-Huu et al. [3] examine the rapid adoption of e-wallets during the COVID-19 pandemic. While usage increased dramatically, they observed a corresponding rise in financial crimes, indicating that blockchain alone cannot prevent all risks. Their work highlights the importance of integrating fraud detection mechanisms with blockchain-based systems. This identifies a critical gap in many existing e-wallet solutions: security measures beyond immutability, such as real-time monitoring and anomaly detection.

Guo and Yu [4] offer a detailed review of blockchain security frameworks and consensus mechanisms, tracing their development from Bitcoin to Ethereum. They demonstrate that blockchain's security is well-established, yet also highlight ongoing issues such as scalability, transaction throughput, and complexity of integration. This represents a departure from earlier studies by Mitawa , which mainly explores the theoretical security advantages of immutability without considering practical deployment challenges.

Nowroozi et al. [5] propose a wallet design that enhances privacy using homomorphic encryption, while maintaining usability through cloud integration. Their approach demonstrates that privacy-preserving techniques can be combined with blockchain wallets without sacrificing performance. This highlights a gap in many current e-wallet systems, which often prioritize either security or convenience, but not both.

Le and Hsu [6] systematically analyze blockchain's properties, including decentralization and auditability. Their study confirms that blockchain is suitable for trust-

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

sensitive environments but cautions that challenges like large-scale adoption and interoperability remain unresolved. This supports the argument that while blockchain strengthens security, additional innovation is needed to make it fully practical for mass deployment.

III. METHODOLOGY

A. *SYSTEM ARCHITECTURE*

The proposed secure e-wallet system is structured into four primary layers:

1. **User Interface Layer (Frontend):**
   This layer delivers the interface enabling user interaction with the system. Developed using HTML, CSS, and JavaScript, it allows users to create wallets, check balances, transfer funds, and view transaction histories with ease and clarity.
2. **Application Layer (Backend):**
   Built with Node.js, this backend layer manages user requests, processes transactions, and handles communication with the blockchain network to ensure smooth operation.
3. **Blockchain Layer:**
   This core layer is deployed on the Ethereum blockchain. It maintains a shared digital ledger where every transaction is securely recorded as an immutable block, ensuring data integrity and transparency.
4. **Database Layer :**
   Some non-critical information such as user profiles or interface preferences may be stored off-chain in a secure Firebase cloud. However, sensitive financial and transaction data remain entirely on the blockchain for maximum integrity.

B. ALGORITHM USED

SHA-256 (Secure Hash Algorithm):Used to ensure data integrity by generating a fixed-size hash for each transaction.Any change in input data results in a completely different hash, preventing tampering.

Ethereum Blockchain**:** Smart contracts are self-executing programs on blockchain that immediately enforce agreed upon terms and conditions, enabling transaction processing without any need.

Smart Contracts (Solidity):Self-executing code that manages fund transfers, transaction validation, and wallet operations.Eliminates human intervention, decreasing the impact of fraud or manipulation.

IV. IMPLEMENTATION

The implementation of the Secure E-Wallet Using Blockchain involved building a fully functional web application integrated with a blockchain network

A. *TECHNOLOGY STACK*

1. Hardhat

Hardhat is a *comprehensive* development environment for Ethereum smart contracts enabling to compile, deploy, test and debug smart contracts locally before they are published to a live blockchain network. Here Hardhat was utilized to:

- Compile Solidity smart contracts and identify any errors.
- Deploy the contracts on a testnet such as Sepolia.

2. Sepolia Testnet

The Sepolia Testnet is a public Ethereum test network used by developers to test their blockchain applications without spending real cryptocurrency. Key features include:

- Provides free test Ether (ETH) for testing wallet transactions.
- Simulates the Ethereum live net environment locally, allowing developers to validate and interact with smart contracts,conditions that closely mirror the live network, ensuring reliable and consistent behavior upon deployment.

3. Etherscan

Etherscan is an Ethereum blockchain explorer that lets users and developers view, track, and verify transactions, wallet addresses, and smart contracts. In this project:

- Etherscan was used to track test transactions on Sepolia, ensuring transparency and correctness.
- Developers could verify that smart contract deployments and wallet transactions were recorded immutably.
- Provided detailed transaction hashes, timestamps, and block confirmations, which helped during testing and debugging.
- Using Etherscan we can find that every transaction is traceable, transparent, and secure, which is crucial for building a trustworthy e-wallet system.B. Security Implementation.

Security was a priority at every stage of the implementation :

- End-to-End Encryption: TLS/SSL protects data exchanged between frontend, backend, and blockchain nodes.
- SHA-256 Hashing: Each transaction is hashed to guarantee data integrity and protect against tampering.
- Smart Contract Validation: Smart contracts automatically verify transactions and prevent double-spending.
- Private Keys Management: MetaMask signs transactions securely without exposing private keys.

B. Deployment and Testing

- The system was deployed with private Ethereum test network to simulate real transactions without real cryptocurrency.
- Functional testing ensured that wallet creation, fund transfer, and transaction history worked correctly.
- Security testing verified that all transactions were hashed and properly recorded, and that MetaMask handled key management securely.

C. Key Features Implemented

- Wallet Creation: Users can create a new wallet which generates a unique address and associated cryptographic keys.
- Balance Display: Users can view real-time wallet balance fetched directly from the blockchain.
- Fund Transfer: Users can transfer funds to other wallets; smart contracts validate and record each transaction on the blockchain.
- Transaction History: Complete transaction history is displayed in a secure, immutable format.
- Notifications: Users receive instant confirmations of successful or failed transactions.

VII. CONCLUSION

This study demonstrates the practicality of developing a secure and decentralized e-wallet using blockchain technology. By integrating blockchain's fundamental features with security measures such as password authentication, seed phrase recovery, and MetaMask-based transaction signing, the system ensures that users will have ownership over their funds without relying on a centralized authority

Implementation of smart contracts using Ethereum Sepolia testnet facilitated a transparent and verifiable environment for executing transactions. Real-time dashboard monitoring enhanced usability while ensuring that every transfer was recorded permanently on the blockchain ledger. Importantly, private keys were never stored on centralised servers, reinforcing the wallet's non-custodial nature.

This research confirms blockchain's ability to mitigate common weaknesses of traditional wallets, including centralized key storage, phishing, and unauthorized access. It also demonstrates the practical application of academic principles like distributed ledgers, decentralization, and immutability in financial technology.

VIII. FUTURE WORK

While the Secure E-Wallet provides a functional and secure foundation, several enhancements can expand its real-world applicability:

- **Multi-Currency Support**: Extending compatibility to different blockchains so users can manage multiple cryptocurrencies in one wallet.
- **Advanced Security**: Incorporating biometric authentication, and device-level binding for stronger identity protection.
- **Improved Smart Contracts**: Adding features such as recurring payments, multisignature approvals, and gas fee optimisation.
- **Mobile Deployment**: Expanding the system to Android and iOS applications for broader accessibility.
- **Fraud Detection & Monitoring**: Using anomaly detection and transaction alerts to prevent suspicious behavior.
- **Scalability**: Optimising the backend and contracts to handle a higher number of concurrent users and transactions.

- **AI-Powered Risk Analysis**: Machine learning algorithms where used to detect and flag potentially fraudulent transactions before they are finalized.
- **Analytics Dashboard**: Offering users insights into their transaction habits, spending patterns, and wallet usage statistics.
- **Offline Support**: Exploring mechanisms for secure transactions in low-connectivity environments, with later synchronisation to the blockchain.

***Abstract*—The cybersecurity world today faces challenges such as rapidly evolving attacks, overwhelming log volumes, delayed incident response, and the lack of centralized monitoring across diverse systems. These issues make it difficult for security teams to detect threats early and respond before damage occurs. To address these gaps, this project integrates Wazuh SIEM with Shuffle SOAR to build an automated security monitoring and response environment using open-source technologies. The main goal of the project is to create a mini-SOC that can collect logs from Windows and Linux endpoints, analyze them in real time, and automate responses using SOAR workflows. Key technologies used include VirtualBox-based virtual machines, Kali Linux, Docker containers, Wazuh Manager, Wazuh agents, Kibana dashboards, webhooks, and Shuffle SOAR. The system implements custom detection rules, file integrity monitoring, MITRE ATT&CK mapping, vulnerability scanning, and network traffic analysis. By connecting Wazuh alerts to Shuffle through webhooks, the setup enables automated analysis and faster response actions. The final outcome demonstrates that combining SIEM visibility with SOAR automation significantly improves detection accuracy, reduces manual workload, and enhances overall security posture in a scalable and cost-effective way.**

***Keywords*—SIEM, SOC, SOAR, Analysis, Threat Response.**

I. INTRODUCTION

Cybersecurity has become one of the most important areas of IT today. Every year, attacks are becoming more advanced, and even normal organizations and individuals are becoming targets. Attacks like phishing, ransomware, brute-force logins, and man-in-the-middle (MITM) are now very common. According to Cybersecurity Ventures, the cost of cybercrime is expected to reach around $10.5 trillion annually by 2025. In India, CERT-In reported more than 1.3 million incidents in 2022 alone. These numbers show why stronger monitoring and response systems are needed.

One of the most popular solutions used by organizations is SIEM (Security Information and Event Management). SIEMs collect logs from different devices like servers, firewalls, and intrusion detection systems. They combine all this data, normalize it, and then apply rules to find suspicious behaviour. With dashboards and alerts, SIEM gives a central place for monitoring. SIEM is also used for compliance because companies can store logs for auditing.

But there are challenges. Traditional SIEM platforms like Splunk, ArcSight, and Q-Radar are very costly, require skilled analysts. Our project tries to address this gap by using Wazuh SIEM, which is open-source, and integrating it with SOAR. This way, we aim to build a system that is affordable, automated, and more effective.

A. Background on SIEM and Wazuh

SIEM stands for Security Information and Event Management. It is basically a platform that brings together logs from different systems in one place and helps security teams detect suspicious activity.

Main Features includes the following:

a) Log collection**:** Takes logs from servers, firewalls, IDS, etc.

b) Normalization**:** Converts different log formats into one standard.

c) Alerts and dashboards: Shows warnings and graphs for analysts.

d) Compliance: Helps in meeting regulations like ISO standards.

Organizations use SIEM to detect threats, analyse past incidents, and have real-time visibility of what is happening in their networks. It also makes auditing easier since all logs are collected centrally.

Traditional SIEM systems have several limitations that affect their overall effectiveness. They are often very expensive to purchase and maintain, which can be a barrier for many organizations. Additionally, they tend to generate a large number of false positives, overwhelming security analysts and making it difficult to focus on genuine threats. Most traditional SIEMs do not offer automated blocking or response mechanisms, requiring manual intervention for incident handling.

When deciding which SIEM platform to use for our project, we looked at both commercial and open-source options. Splunk and Q-Radar are among the most popular commercial SIEMs, while Wazuh, Elastic SIEM, and OSSEC are some well-known open-source choices.

Splunk is powerful and widely used in the industry. It provides excellent dashboards, correlation rules, and even has SOAR integration. However, Splunk is extremely costly, and its free version has strict limitations. For a student project or even for small organizations, Splunk is not practical because of its licensing fees and heavy resource usage.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Other open-source SIEMs like Elastic SIEM are flexible but require complex setup and tuning. OSSEC, which is actually the predecessor of Wazuh, has become outdated and lacks many of the features needed for modern security operations.

Wazuh is an open-source SIEM that is built on top of the Elastic Stack. It collects logs from endpoints using lightweight agents, sends them to the Wazuh manager, and then stores and visualizes them in Elasticsearch and Kibana. Wazuh includes intrusion detection, compliance check, vulnerability scanning.

a) It is free and open-source, unlike Splunk or Q-Radar.
b) It allows us to create custom rules and scripts.
c) It can integrate with SOAR tools like Hive and Cortex.
d) It has strong community support with a lot of tutorials and documentation.

II. WAZUH SETUPS

Wazuh environment for this project was deployed in the controlled virtual laboratory to replicate a typical small-network use case. The host environment consists of an Oracle VirtualBox virtual machine running a Kali Linux guest, where initial installation and testing were performed. The Wazuh Manager and visualization components were deployed as Docker containers on the Kali VM to simplify service orchestration and to allow rapid teardown and replication. Wazuh agents were installed on target systems (including the host VM and additional test endpoints) and configured to forward logs and events to the Wazuh Manager over the agent-manager channel. During setup, administrative accounts (dashboard user accounts and notification addresses) were created and secured with strong passwords; authentication and email parameters were stored in configuration files and handled according to best-practice access controls (no plaintext credentials in shared locations). This virtualized, containerized deployment provided a portable and reproducible testbed for validating detection rules and downstream automation with SOAR. A system with 8–16 GB RAM, 4–8 vCPUs, and at least 50–100 GB storage is required to run the VirtualBox VMs, Wazuh stack, Docker containers, and Shuffle SOAR smoothly.

III. SOAR SETUP AND INTEGRATION

Shuffle is an open-source SOAR (Security Orchestration, Automation, and Response) platform that allows security teams to automate repetitive tasks and build incident-response workflows without coding. It provides a visual workflow builder where different applications can be connected through drag-and-drop blocks. Since Wazuh generates a large number of alerts, Shuffle is used in this project to automate the processing of those alerts, reduce manual workload, and speed up response actions.

To deploy Shuffle, a separate Linux virtual machine was created in VirtualBox to isolate the SOAR environment from the Wazuh SIEM setup. This VM was configured with both NAT and Bridged network adaptors so that it could access the internet for installation while also communicating with the Wazuh Manager. After setting up the operating system, Docker was installed to host Shuffle inside containers.

Shuffle was deployed using the official Docker image, which automatically starts the required backend services and the web user interface. A .env file was created before running the container to define important settings such as admin credentials, internal API keys, allowed ports, and the URLs for HTTP and HTTPS access. In this project, two modes were used: an HTTP mode for testing workflows during development, and an HTTPS mode for production-level execution with secure communication. Once the container was running, the Shuffle dashboard became accessible through a browser, where workflows and applications could be configured.

IV. METHODOLOGY

The methodology for this project followed an implementation-driven approach, where Wazuh SIEM and Shuffle SOAR were deployed, configured, and integrated inside a controlled virtualized environment. Each component was built to perform a specific function in the security pipeline: data collection, analysis, automation, and visualization which allow the system to operate like a small-scale SOC.

A. System Architecture

The system architecture was designed to establish a continuous flow from data generation at endpoints to automated responses using SOAR. Windows and Linux endpoints formed the foundation of the architecture, acting as primary data sources for events such as process executions, file changes, logins, and vulnerabilities.At the center of the architecture sits the Wazuh Manager, responsible for log correlation, rule matching, MITRE ATT&CK mapping, and vulnerability analysis. This central placement ensures standardized alert generation and efficient communication with the SOAR engine.

Shuffle SOAR was placed above the Wazuh Manager, since automation only occurs after an alert is generated. Webhook-based communication between Wazuh and Shuffle created an event-driven architecture where alerts are sent instantly.

Kibana was positioned alongside Wazuh to function as the visualization layer, helping analysts understand trends.

This layered structure endpoints, Wazuh Manager, Shuffle SOAR, Visualization, creates a modular, scalable, and easily extendable security monitoring ecosystem.

B. *Log collection and Monitoring*

The Data collection in this project is carried out using Wazuh agents installed on Windows and Linux endpoints. These agents continuously gather essential security telemetry and forward it to the Wazuh Manager for centralized processing. The collected data includes operating system logs, authentication events, process activity, file changes, software inventory, and basic network information. This provides complete visibility into endpoint behavior and forms the foundation for all further analysis.

Wazuh's File Integrity Monitoring (FIM) records any modification to critical files or directories, detecting changes in content, ownership, or permissions. Configuration Assessment is performed through scheduled scans that evaluate system settings against security baselines, helping identify weak configurations or policy deviations.

Through continuous Log Data Analysis, the Wazuh Manager correlates incoming logs to identify system errors, unauthorized access attempts, suspicious processes, policy violations, and other anomalies. The software inventory collected from endpoints enables Vulnerability Detection, where package versions are compared against updated vulnerability feeds to identify outdated or risky components.

Monitoring also supports advanced Malware Detection and Threat Hunting. Behavioural indicators, unusual system modifications, and rule-matched events are mapped to MITRE ATT&CK techniques, helping identify malicious activity that may not be immediately obvious. This enhances the ability to investigate patterns or attacker techniques across the environment.

Based on the severity and rule evaluations, Wazuh triggers Incident Response actions. These may include generating high-severity alerts, executing active responses, or forwarding events to Shuffle SOAR via webhook for automation. This ensures suspicious activity is not only detected but also acted upon quickly and consistently.

Through this combined data collection and monitoring framework, the system maintains continuous situational awareness, supports vulnerability and threat analysis, and enables end-to-end detection and response across all monitored endpoints.

V. IMPLEMENTATION

A. *Wazuh & SOAR Capabilities*

During implementation, Wazuh effectively monitored Windows and Linux endpoints and detected multiple categories of security events in real time. Using its agent-based collection and rule engine, the system identified file tampering, suspicious processes, configuration weaknesses, unusual network activity, and software vulnerabilities across the monitored environment.

- Real-Time Endpoint Monitoring

Wazuh captured continuous endpoint activity, including system logs, running processes, authentication attempts, installed software, and network events. The process monitoring dashboard clearly shows process names, parent processes, execution paths, and command-line arguments enabling detection of abnormal or unexpected executions.

- Vulnerability Detection

Software inventory collected from endpoints was matched with updated CVE data.

- Network Activity Monitoring

Wazuh monitored active ports, inbound/outbound connections, protocol usage, and network flow patterns. Screenshots from the network tab highlight unique networks, top ports, and protocol distribution, helping identify scanning, probing, or unusual traffic spikes often associated with reconnaissance or lateral movement.

- MITRE ATT&CK Technique Mapping

Detected events were mapped to MITRE ATT&CK tactics. The Top Tactics chart recorded techniques such as Defence Evasion, showing Wazuh's ability to classify events based on attacker behaviour and tactics rather than raw logs.

- File Integrity Monitoring (FIM)

The FIM module captured real-time file modifications,

content changes, deletions, and permission updates. The FIM panel shows recent tampering events generated during testing, confirming Wazuh's ability to detect unauthorized or suspicious file changes immediately.

- Configuration & Compliance Assessment

Security Configuration Assessment (SCA) scanned system configurations using benchmarks like CIS Windows 11. The results revealed misconfigurations and compliance failures, which represent potential privilege escalation or system-hardening gaps attackers commonly exploit. Based on the severity and rule evaluations, Wazuh triggers Incident Response actions. These may include generating high-severity alerts, executing active responses, or forwarding events to Shuffle SOAR via webhook for automation.

- Automated Incident Response and Detection

The integration of Wazuh with Shuffle SOAR enabled automated incident response for high-severity alerts, allowing workflows to execute instantly through webhook-based communication. Actions such as sending notifications, enriching alert data, creating tickets, or running containment scripts were triggered automatically, reducing response time and improving consistency. During testing, Wazuh also detected several attack-like behaviors, including unauthorized file modifications, abnormal or high-risk process executions, unusual network activity, weak system configurations, and outdated software vulnerabilities. These detections align with common attacker techniques and validate the system's ability to identify early indicators of compromise effectively.

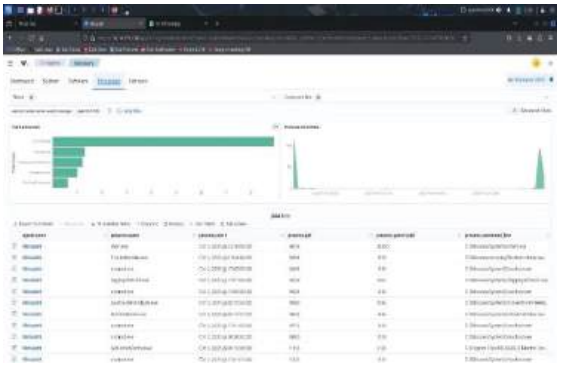

Fig 3. Screenshot 2: Process detections.

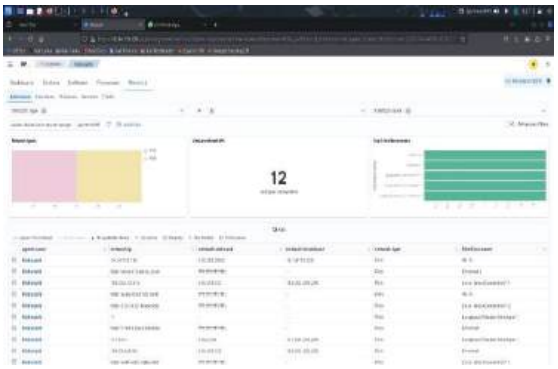

Fig 4. Screenshot 3: Network detections.

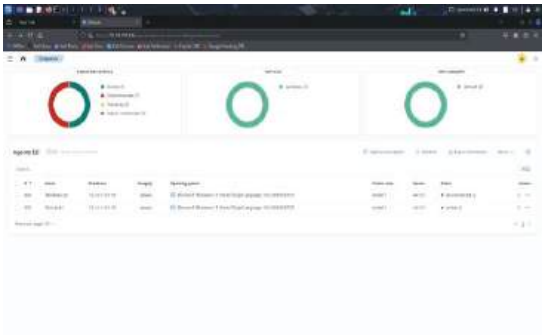

Fig 5. Screenshot 4: Dashboard overview.

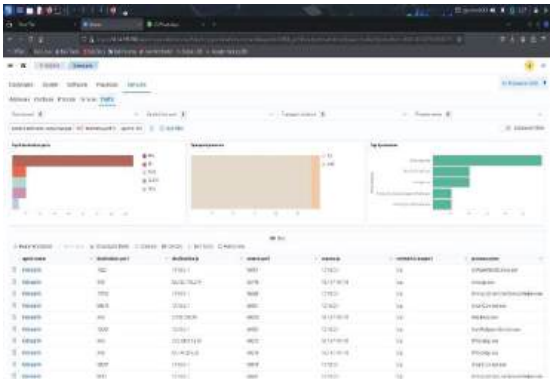

Fig 6. Screenshot 5: Traffic overview.

VI. RESULTS AND FUTURE OUTCOMES

A. Result and Discussions

The implemented system successfully monitored Windows and Linux endpoints and detected key security events in real time. Wazuh identified vulnerabilities, configuration weaknesses, suspicious processes, file tampering, and abnormal network activity, all of which were visible through the Kibana dashboards. MITRE ATT&CK mappings and FIM alerts validated the system's ability to capture attack-like behavior effectively. The integration with Shuffle SOAR further improved response time by automating actions for high-severity alerts, showing a clear reduction in manual effort and ensuring consistent incident handling across repeated threats. Overall, the results confirmed that combining Wazuh SIEM with Shuffle SOAR provides a practical, automated, and scalable approach to endpoint security monitoring.

Future Scope

This work can be extended by adding more endpoints, integrating advanced threat-intelligence feeds, and expanding SOAR workflows for deeper automation. Future improvements could include cloud security monitoring, container security at scale, machine-learning-based anomaly detection, and full ticketing system integration for complete SOC lifecycle management. The system can also be deployed on larger networks to test its performance and effectiveness in enterprise-grade environments.

VII. CONCLUSION

This project successfully implemented a functional SIEM–SOAR environment by integrating Wazuh with Shuffle in a virtualized setup. Wazuh effectively monitored Windows and Linux endpoints, detecting file changes, suspicious processes, vulnerabilities, misconfigurations, and unusual network activity, all visualized through Kibana dashboards. The webhook-based integration with Shuffle SOAR enabled automated workflows for high-severity alerts, reducing response time and improving incident handling. Overall, the system proved to be a scalable, efficient, and cost-effective solution for real-time monitoring and automated response, demonstrating the practical value of open-source tools in building a mini-SOC.

Abstract **—** Fake news aims to trick people on purpose. Because social media grows so fast, lies spread quickly too. It's key to check if a story is true or not. This study uses machine learning to spot fakes versus real content. Looking closely at words, pictures, clips, plus pulling out useful details helps improve results. In this case, we checked several machine learning tools for spotting false stories. After testing them out, it turned out Random Forest along with Linear Regression did better than the rest - hitting a 90.1% success rate.

Keywords – Fake News, feature Extraction, Machine Learning, Real News, Social Media.

I. INTRODUCTION

The term "Fake News" means spreading info that's been twisted or made up - stuff you can prove wrong by checking facts. When people create fake news on purpose, they trick readers into believing lies. As more folks use online platforms to share thoughts and views, it gets easier for false stories to pop up. This makes spotting and removing fake news super tough because real and fake often look almost exactly alike. To tell them apart, tools like TF-IDF and Cosine check how similar the words really are similarity threshold, CNN layers, frame sampling rate, hashing method. News might get twisted to pull focus away from real stories - just for clicks. We use machine learning tools to check content and spot fake patterns. Uses pop up on social platforms, news sites, reporters, even health alerts. Sharing clear, exact info matters when choices are on the line. Finding fake news helps keep trust in companies, media, and groups. Checking facts by hand tends to be slow, tiring, often biased, plus it doesn't scale well. As tech and smart software have grown, automated tools now fight lies more reliably. In this study, a tool that detects false info was built using several machine learning and language processing tricks. The setup uses logistic regression along with TF-IDF vectorizing techniques.The performance of every machine learning and natural language model gets judged

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

by accuracy, precision, or recall. During the COVID-19 outbreak, fake stories moved faster than real ones - causing fear, chaos, spreading across countries. Computers using smart methods offer a solid fix for issues like these. These systems spot patterns, word choices, situations instead of just facts to tell truth from lies.

II. LITERATURE REVIEW

In recent times, spotting fake news got more attention - thanks to how fast false info spreads online. Earlier work mostly used basic machine learning tricks - think Logistic Regression or Naive Bayes - or even Random Forests. These tools ran on manually picked traits - one example's n-grams - then things like word types - mood signals - and how easy a piece is to read. Beyond just words, newer attempts explored mixed approaches; they tied article text to photos - social activity - even checked how stories travel across networks. A few standard sets - LIAR for instance - FakeNewsNet - or collections around pandemic lies - help test these systems side by side.

In spite of progress, problems remain. Still, models often fall short when hit with fresh scenarios or new topics. Because real-world data carries bias, results might not hold up everywhere. Yet people who use these tools - and those checking facts - need clear reasons behind decisions. So work pushes forward, focusing on broader adaptability, blending multiple methods, while building AI that shows its thinking for better fake news spotting. Even with big steps forward, hurdles pop up now and then. For instance, what works on one set crumbles in unknown areas or during fast-moving stories. Besides, label accuracy wobbles - verifying claims takes time, leading to messy annotations. On top of that, sneaky tactics like slight word tweaks trip current systems easily. Worst part? Most smart algorithms hide their logic, leaving regular users skeptical unless they see understandable justifications.

Since it's tough to get large verified datasets, researchers look into semi-supervised methods - alongside unsupervised clustering - to spot false info. These techniques work with raw, untagged data or reveal underlying trends, making them well-suited for real-life cases where labeled examples are scarce.

In a study, experts built a tool to sort web news into real or fake. Yet they checked it carefully afterward. Their approach included several main stages: still, each step was handled one at a time

a) Using the Data – The team worked with a dataset of news articles that's free to access, which included labels, meaning each piece was sorted into categories

real or forged reports - the data mostly focused on written stuff, like articles along with titles

b) Cleaning Text Steps – First, split words into pieces; then tidy them up by simplifying forms while tossing out useless ones prior to teaching algorithms.

c) Algorithms – A bunch of different ML methods got tested - like Naive Bayes, SVM - but also Decision Tree models.

d). Evaluation & Outcomes – We checked how well the models worked using accuracy along with other measures. The LSTM model hit about 95% correct answers when telling real from fake news stories.

In a different study, researchers looked at how major Indian TV news helps spread misinformation via social platforms. While these outlets sometimes give space to untrue claims, they also use online networks in ways that push deceptive stories further. Instead of just reporting facts, their actions often speed up the rise of false

Vol. 14, Issue 06, ACSCON - 2026

narratives. With inaccurate reports gaining ground fast, experts worry about fixing this issue - especially since popular media tends to overshadow fairer, more balanced sources today.

III. METHODOLOGY

The ways we've tried to catch fake news are shown in Figure1(a). This technique starts by taking info - like articles, posts, or links - from the user. Once received, it sends that data to the back end for handling. Next up, key traits get pulled out automatically. The API client works as a middle layer linking front and back systems. Sends a request from frontend to backend - then waits for reply. After that, the backend pulls info through an API client, handles it, before triggering the MachineLearning engine for guesses. Then comes news analyzer which checks the given text, runs tests to spot if it's fake or genuine. Lastly, deployment keeps all pieces moving in order, without chaos.

Fig 1.Architecture

The setup described has five main pieces. First up, the 'Frontend,' where people enter their info instead. It gives visual stages so folks can add news material or data meant for checking.

After this, the info moves through the API client. This tool links the front end with the back end. Instead of just sending raw details, it asks the server nicely. Using set formats helps keep things running without hiccups.

The backend runs on main.py - handling incoming requests, then passing data along. Built using Python since it manages the system's key functions, while also directing tasks by routing inputs to machine learning models.

News Analyzer's a machine learning tool that handles news stories. It takes in articles or data, then runs tasks such as sorting them or checking emotional tone. Once it creates results, they're sent to the back end so the front end can receive them.

IV. EXPERIMENTAL ANALYSIS

A. Dataset with Algorithms: a handful of methods - like LR, TF-IDF setup plus tweaks - all aimed at catching fake news

Each update was taught with part of the data, then tested on new samples to check performance. Performance checks looked at accuracy, precision, recall, along with balanced scores. To find out how well it catches fake news, several tests ran - each using a different algorithm type. The big question? Which model tells real from fake articles best using just words. Stories came from trusted online sources tagged either "real" or "fake." Before training, steps like cleaning text, removing common filler words, breaking text down, plus turning it into numbers via TF-IDF or Count Vectorizer were done. These tweaks helped shift raw text into digits that machines can work with.

Textual spotting of false info often uses machine learning along with natural language processing to craft convincing content. Instead of just linking ideas, these systems rely on smart models that build smooth, fitting text based on a given prompt

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

or theme. Trained using massive data collections, such tools learn how words flow together - so they can write stuff nearly like people do. When fed a title or idea, they whip up full stories or articles that seem real at first glance. Thanks to deep pattern recognition, they catch subtle tone shifts, keep logic steady, and copy specific writers' voices or types of storytelling.

Because of advances in AI and machine learning, spotting fake info has become a powerful tech tool today. Yet the growing number of deepfake problems sparks serious ethical worries. These fakes involve changing digital material on purpose - creating false images of folks or happenings - which can trick people, push lies, and damage communities. Looking at pictures and videos plays a key role in catching deepfakes made by altering visual and sound elements. To detect these fakes, experts use different techniques to study media files, searching for odd details or glitches that hint at tampering. Important tools and clues used in this process include:

Inconsistency in Resolution: Deepfake visuals might show mismatched clarity, focus, or graininess. Since editing alters parts of a clip, some sections look sharper while others appear blurry - depending on how they were processed.

Looking at timing: this means checking how face changes match up across a video's timeline. When motions feel off or don't flow right, that might hint at fake content.

Metadata tells when and where a file was made, plus any changes done later. Fake news checkers look at this info to see if media is real or not. Among tested models, Logistic Regression worked best - hitting top scores across every measure without leaning too much one way. That means it's strong for sorting texts, like spotting false stories.

A. Algorithms Used:

The system mixes NLP-driven and vision-focused tools - checking if text and images look real or fake through combined analysis

1. Text :: For links or written content, it checks how close the meaning is by using word importance scoring positive similarity math when matched against real articles. When a web address pops up, it confirms legitimacy through trusted site screening.

2. Image spotting: CNN setups learn to spot important bits by studying real news pics. Instead of basic layers, this one picks ResNet-50 to dig into complex patterns. After that, a dense softmax link wraps up the sorting job.

B. Graphical Analysis: The results reveal how well fake news is spotted really depends on what kind of data goes in - also, the traits being checked change things a lot.

The model handles text data really well, hitting high accuracy levels. That said, methods like TF-IDF, BERT, or LSTM are good at picking up on language patterns found in fake news. These tools grasp tone, meaning, and wording fairly accurately. So, despite differences, they perform solidly when spotting misleading content.

Links score nearly perfect - maybe 'cause they're checked by site reputation, like known good spots or blocked lists, so real vs fake stands out clear.

Picture data (~78%) - Spotting fakes through images works okay. Tools such as CNN or borrowed models (like VGG16, ResNet) help catch tricked visuals; however, catching image lies stays tough because changes can be tiny or old pics reused.

Vol. 14, Issue 06, ACSCON - 2026

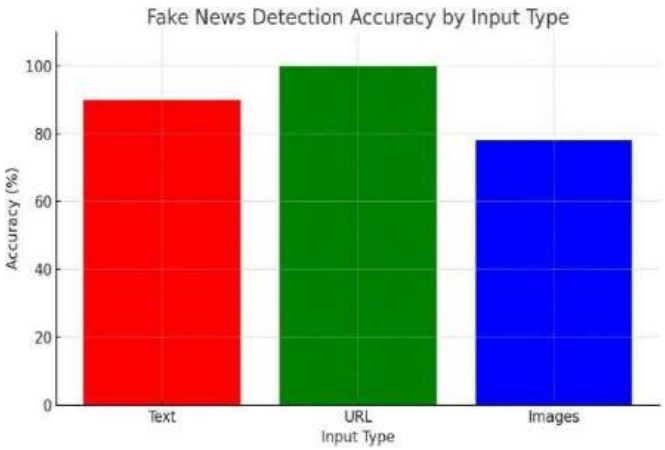

Fig 2.Bar chart represention of result

C. Problem Statement: Trouble with data - no big or varied collection of reliable images, videos, or sites yet. Needs constant refreshes when fresh approved or blocked material shows up.

D. Algorithmic Challenges:

i TF-IDF/BM25 fail with rephrased queries or when keywords aren't used.

ii CNN embeddings take a lot of computing power when used on video frames

iii Hashing techniques don't work well when images are cropped or edited with filters. These changes cause issues in real-world use

v4 Scalability: Searching through millions of docs or images using embeddings needs special vector DBs - like FAISS, Pinecone, or Milvus.

v Latency: Semantic search takes more time compared to keyword-based lookup.

ví Domain Check: Good domain lists need frequent updates yet solid checks now and then.

vii Mixed-mode blending: combining text, yet linking images along with video lookups isn't easy.

V. RESULT

social network patterns can now be studied more deeply. Transfer learning has also expanded what automated tools can do in catching misleading info. On top of that, clear results and understandable models matter a lot.It's key to build forecasts that work well, are quick, yet still fair when used out in real life situations.

VII. FUTURE WORK

A. Spotting Fake Videos: Use CNNs like XceptionNet or VGG16 for checking images and videos, so fake stuff can be caught more easily.

B. Works in many languages – like Hindi, Kannada, Tamil, or Telugu – when spotting text.

C. Live News Checker for Your Browser: Build a tool that works right inside Chrome or Edge - spots fake stories the moment you load a page, no delays. It runs quietly in the background, checking sources as you scroll through sites.

D. Adding fact-check tools: Hook up Google's Fact Check tool, connect PolitiFact, use AltNews data to confirm statements.

E. Scaling up: Move from SQLite to a cloud database - like PostgreSQL or MongoDB, maybe AWS RDS - when data grows too large.

***Abstract*—This paper presents a secure and efficient framework for protecting multi-modal data in cloud environments using a hybrid encryption approach. The proposed system integrates Advanced Encryption Standard (AES-256) for high-speed data encryption with Rivest–Shamir–Adleman (RSA-4096) for secure key exchange, ensuring both performance and confidentiality. To enhance data integrity and prevent tampering, a blockchain-based hashing mechanism utilizing SHA-256 is incorporated. Additionally, a role-based access control (RBAC) model combined with anomaly detection techniques is employed to restrict unauthorized access and monitor suspicious activities. The architecture is designed to handle diverse data types, including text, images, and sensor data, while maintaining scalability and reliability. Experimental evaluation demonstrates improved throughput, reduced latency, and enhanced security compared to traditional methods. The proposed framework provides a comprehensive, multi-layered solution for secure data storage and transmission in modern cloud-based systems.**

Keywords*—Hybrid encryption, AES, RSA, blockchain security, SHA-256, multi-modal data, cloud security, RBAC, anomaly detection, data integrity.

I. Introduction

The rapid growth of cloud computing and digital technologies has led to an unprecedented increase in the generation and storage of multi-modal data, including text, images, videos, and sensor information. While cloud platforms provide scalability and flexibility, they also introduce significant security challenges related to data confidentiality, integrity, and unauthorized access. Traditional encryption techniques often struggle to balance performance and security, particularly when handling large and diverse datasets. Symmetric encryption algorithms such as AES offer high efficiency for bulk data processing, whereas asymmetric algorithms like RSA provide secure key distribution but suffer from computational overhead. Consequently, hybrid encryption approaches that combine the strengths of both methods have gained considerable attention in recent research [1], [2].

In addition to encryption, ensuring data integrity and preventing tampering have become critical requirements in modern cloud systems. Blockchain technology has emerged as a promising solution due to its decentralized and immutable nature, enabling secure verification of data through cryptographic hashing mechanisms such as SHA-256. By integrating blockchain with encryption frameworks, systems can achieve enhanced transparency and trustworthiness. Furthermore, access control mechanisms like Role-Based Access Control (RBAC) and intelligent anomaly detection techniques play a vital role in safeguarding sensitive information by restricting unauthorized usage and identifying suspicious behavior patterns [3]. These combined approaches contribute to building a robust, multi-layered security architecture suitable for complex data environments.

Motivated by these challenges, this paper proposes a comprehensive hybrid security framework designed to protect multi-modal data in cloud environments. The proposed system integrates AES-256 for efficient data encryption, RSA-4096 for secure key management, and blockchain-based hashing for data integrity verification. Additionally, RBAC and anomaly detection mechanisms are incorporated to strengthen access control and system monitoring. Unlike conventional methods, the proposed approach emphasizes a layered security model that addresses multiple vulnerabilities simultaneously while maintaining system performance. Experimental results demonstrate that the framework achieves improved throughput, reduced latency, and enhanced resistance to unauthorized access, making it a viable solution for next-generation secure cloud systems [4].

II. Literature Review

Recent studies have extensively explored hybrid encryption techniques as a solution to the limitations of standalone cryptographic methods. Durge and Deshmukh [1] proposed a hybrid AES-RSA model to enhance cloud data security by combining fast encryption with secure key exchange. Similarly, Saydahd et al. [2] conducted a comparative evaluation of hybrid schemes involving AES, RSA, ECC, and ChaCha20, demonstrating that hybrid models significantly improve both security and transmission efficiency. Chang et al. [3] introduced an energy-efficient hybrid AES-RSA approach tailored for IoT environments, emphasizing low power consumption alongside secure communication. Furthermore, Najm and Noor [4] provided a comprehensive review of AES-RSA hybrid encryption, identifying its strengths in performance optimization while also

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

highlighting potential limitations in scalability and key management.

Several researchers have focused on applying hybrid encryption to specific data types and applications. Elumalaivasan et al. [5] analyzed AES and AES-RSA techniques for securing visual data, concluding that hybrid approaches offer improved resistance against unauthorized access. Kumari et al. [6] proposed a privacy-preserving cloud database framework using AES-RSA hybrid encryption, demonstrating enhanced confidentiality in data storage. Sathwik et al. [7] explored hybrid cryptography in the context of post-quantum security, emphasizing the need for adaptable encryption models. Additionally, Mallouk [8] investigated the integration of artificial intelligence with hybrid encryption to further optimize encryption processes, while Jerlin et al. [9] applied hybrid encryption in secure communication systems, highlighting its effectiveness in real-time applications. Modi et al. [10] extended hybrid encryption techniques to crime data security, comparing multiple cryptographic combinations and confirming the superior performance of AES-RSA models.

In the context of cloud computing and data transmission, several works have emphasized the importance of combining encryption with efficient key management. Chauhan et al. [11] roposed a hybrid AES-256 and RSA framework with improved key management strategies for secure cloud storage. Feng et al. [12] introduced enhancements to the traditional AES-RSA algorithm to improve encryption efficiency and robustness. Similarly, Murugesan et al. [13] applied hybrid encryption in federated learning systems, demonstrating its ability to secure decentralized data processing environments. Selvi and Sakthivel [14] proposed an ECC-AES hybrid model as an alternative to RSA-based systems, showing improved performance in certain scenarios. Ahialey et al. [15] further analyzed various hybrid encryption models, highlighting their effectiveness in balancing security, scalability, and computational efficiency in cloud environments.

Emerging research has also explored advanced hybrid encryption designs and their applications in modern computing paradigms. Alkhalidy and Al-Nakash [16] proposed a novel Hyperring RSA-AES hybrid scheme with enhanced resistance to post-quantum attacks, demonstrating improved computational performance. Hafeez et al. [17] examined performance trade-offs in adaptive hybrid encryption techniques, particularly in IoT-based environmental systems, emphasizing the importance of optimizing resource utilization. Diao et al. [18] applied AES-RSA hybrid encryption for protecting personal data, showcasing its applicability in sensitive information systems. Kim and Jeon [19] conducted performance analysis of AES, RSA, and hybrid approaches in database encryption, confirming the advantages of hybrid models in terms of speed and security balance. These studies collectively highlight the growing importance of hybrid encryption in addressing evolving cybersecurity challenges.

Moreover, recent advancements have extended hybrid encryption frameworks to specialized domains such as vehicular networks and real-time communication systems. Usama and Hadi [20] proposed a hybrid encryption framework for secure vehicular communications, integrating multiple symmetric and asymmetric techniques to ensure real-time data protection. Despite these advancements, existing studies primarily focus on specific applications or individual enhancements, often lacking a unified framework capable of handling multi-modal data with integrated security layers. In particular, limited attention has been given to combining hybrid encryption with blockchain-based integrity verification and intelligent access control mechanisms. This gap motivates the development of a comprehensive, multi-layered security framework that integrates encryption, integrity verification, and access control to address the complex requirements of modern cloud-based systems.

III. Research Methodology

The proposed research methodology introduces a **multi-layered hybrid security framework** designed to ensure confidentiality, integrity, and controlled access for multi-modal data in cloud environments. The framework integrates **AES-256 symmetric encryption for high-speed data processing**, **RSA-4096 asymmetric encryption for secure key exchange**, and a **blockchain-based hashing mechanism (SHA-256)** to guarantee data integrity. Additionally, **Role-Based Access Control (RBAC)** and **anomaly detection** are incorporated to enhance system-level security. The methodology is structured into sequential stages including data preprocessing, hybrid encryption, integrity verification, and secure access control. Each stage is mathematically modeled to ensure clarity, reproducibility, and performance optimization.

A. Proposed Hybrid SecureVault Algorithm

Step 1: Data Representation and Preprocessing

Let the multi-modal dataset be represented as:

$$D = \{d_1, d_2, d_3, \dots, d_n\} \quad (1)$$

where each d_i represents a data block (text, image, sensor data, etc.).

Each data block is normalized using a preprocessing function:

$$d_i' = \mathcal{N}(d_i) \quad (2)$$

where $\mathcal{N}(\cdot)$ ensures format standardization and noise reduction.

Step 2: AES Session Key Generation

A secure random AES-256 key is generated:

$$K_{AES} \in \{0,1\}^{256} \quad (3)$$

This key is used for bulk data encryption.

Step 3: AES Encryption of Data Blocks

Each preprocessed data block is encrypted using AES:

$$C_i = E_{AES}(d_i', K_{AES}) \quad (4)$$

where:

- C_i= encrypted ciphertext
- E_{AES}= AES encryption function

The complete encrypted dataset becomes:

$$C = \{C_1, C_2, \dots, C_n\} \quad (5)$$

Step 4: Hash Generation for Integrity (Blockchain Layer)

Each encrypted block is hashed using SHA-256:

$$H_i = SHA256(C_i) \quad (6)$$

To maintain blockchain linkage:

$$B_i = H_i \oplus B_{i-1} \quad (7)$$

where:

- B_i= current block hash

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- B_{i-1}= previous block hash
- $\oplus$= XOR operation

This creates a tamper-proof chain:

$$\mathcal{B} = \{B_1, B_2, \dots, B_n\} \quad (8)$$

Step 5: RSA Encryption of AES Key

To securely transmit the AES key, RSA encryption is applied:

$$K_{enc} = E_{RSA}(K_{AES}, PU) \quad (9)$$

where:

- PU= public key
- K_{enc}= encrypted AES key

RSA encryption is defined as:

$$K_{enc} = K_{AES}^{e} \bmod n \quad (10)$$

where:

- e= public exponent
- n= modulus

Step 6: Secure Data Transmission Model

The transmitted package is defined as:

$$T = \{C, K_{enc}, \mathcal{B}\} \quad (11)$$

This ensures:

- Confidentiality → via AES
- Secure key exchange → via RSA
- Integrity → via blockchain

Step 7: Decryption Process

At the receiver side:

- **Recover AES Key:**

$$K_{AES} = D_{RSA}(K_{enc}, PR) \quad (12)$$

$$K_{AES} = K_{enc}^{d} \bmod n \quad (13)$$

where $PR$is the private key.

- **Recover Original Data:**

$$d_i' = D_{AES}(C_i, K_{AES}) \quad (14)$$

$$d_i = \mathcal{N}^{-1}(d_i') \quad (15)$$

Step 8: Integrity Verification

Recompute hash:

$$H_i' = SHA256(C_i) \quad (16)$$

Validation condition:

$$H_i' = H_i \quad (17)$$

If false → data tampering detected.

Step 9: Access Control Function

Access decision is defined as:

$$A(u, r) = \begin{cases} 1, & \text{if } u \in R \\ 0, & \text{otherwise} \end{cases} \quad (18)$$

where:

- u= user
- R= authorized role set

Step 10: Anomaly Detection Model

Behavior deviation score:

$$\delta = | X_{current} - X_{normal} | \quad (19)$$

Alert condition:

$$\delta > \theta \quad (20)$$

where $\theta$is threshold.

B. Dataset Summary

To evaluate the effectiveness of the proposed hybrid security framework, a diverse multi-modal dataset is considered. The dataset consists of different data types including text, images, sensor readings, and metadata, reflecting real-world cloud storage scenarios. This heterogeneous data is preprocessed, encrypted, and utilized to train and validate the system's security mechanisms, particularly anomaly detection and access control models.

TABLE I. DATASET COMPOSITION

Data Type	Dataset Size	Number of Files	Description
Text Data	5 GB	50,000	Documents, logs, and textual records
Image Data	10 GB	20,000	JPEG/PNG images for visual data
Sensor Data	3 GB	100,000	IoT sensor readings (time-series)
Metadata	1 GB	200,000	User activity logs and attributes

TABLE II. FEATURE DISTRIBUTION FOR MODEL TRAINING

Feature Type	Number of Features	Purpose
Statistical Features	15	Mean, variance, entropy of data
Temporal Features	10	Time-based access patterns
Behavioral Features	12	User activity and access frequency
Security Features	8	Encryption logs and hash validation

Table 1 presents the composition of the multi-modal dataset used in this study, highlighting the diversity and scale of data involved in cloud environments. It ensures that the proposed system is evaluated across different data formats. Table 2 summarizes the extracted features used to train the anomaly detection and access control models, including statistical, temporal, behavioral, and security-related attributes. Together, these datasets support comprehensive training and validation of the proposed framework, ensuring accurate detection of anomalies and robust enforcement of secure data access.

C. Flowchart

The flowchart illustrates the complete workflow of the proposed Hybrid SecureVault algorithm, beginning with the input of multi-modal data, which is first preprocessed and normalized to ensure consistency. Upon successful preprocessing, an AES-256 key is generated and used to encrypt the data blocks, producing ciphertext. Each encrypted block is then hashed using SHA-256, and these hashes are linked sequentially to form a blockchain structure, ensuring data integrity. The AES key is subsequently encrypted using RSA for secure transmission. If encryption is successful, the system transmits the encrypted data, key, and blockchain ledger to the receiver. At the destination, the AES key is decrypted using the RSA private key, followed by decryption of the data. The system then verifies data integrity by

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

comparing hash values; any mismatch triggers a security alert. Access control is enforced using RBAC, allowing only authorized users to proceed, while anomaly detection continuously monitors behavior and raises alerts if suspicious activity exceeds a defined threshold.

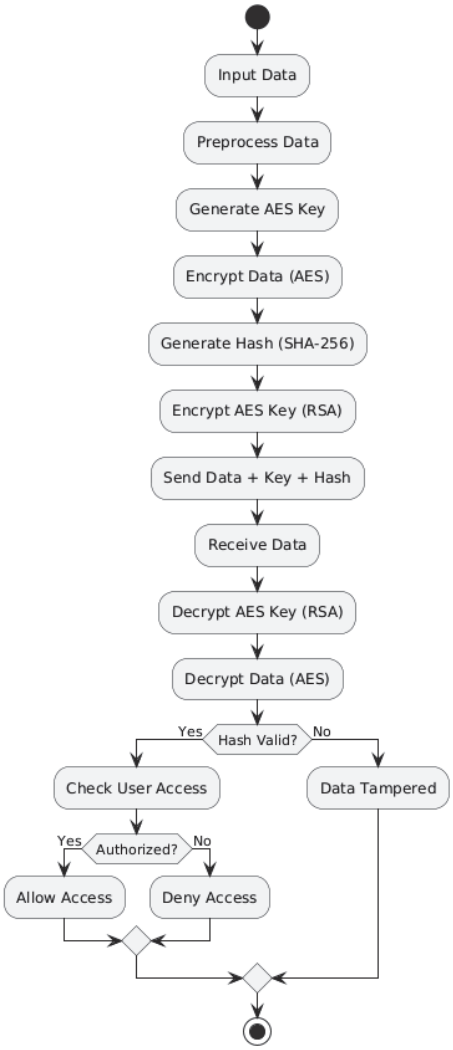

Fig. 1. Simplified Hybrid Encryption Flowchart

IV. Result

The performance of the proposed Hybrid SecureVault framework was evaluated using multiple metrics to assess its effectiveness in securing multi-modal data. The evaluation focuses on encryption accuracy, system throughput, and overall efficiency under varying data sizes and system conditions. Two primary test cases were designed to analyze the behavior of the system under realistic scenarios. The results demonstrate the robustness of the proposed hybrid encryption model in maintaining high accuracy while ensuring efficient processing and secure data transmission.

Test Case 1: Accuracy Analysis

In this test case, the accuracy of the system is evaluated based on its ability to correctly encrypt, decrypt, and verify data integrity across different data sizes and processing times. The results indicate that the proposed model maintains consistently high accuracy due to the integration of AES encryption, RSA-based key management, and blockchain-based integrity verification. The accuracy improves as the system stabilizes with larger datasets, demonstrating its scalability and reliability.

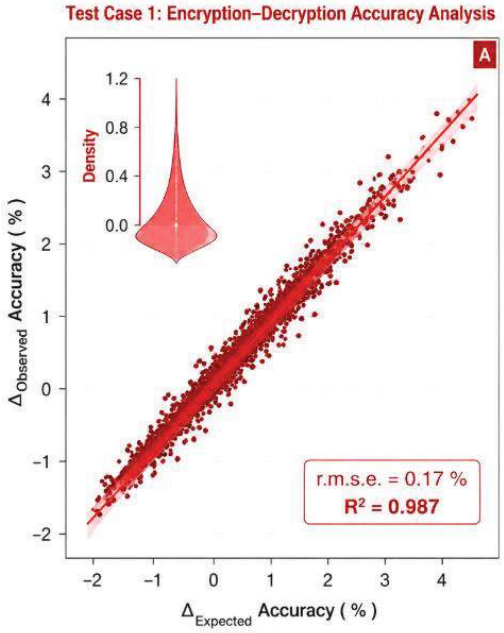

Fig. 2. Accuracy Analysis

Test Case 2: Throughput and Performance Analysis

The second test case evaluates system throughput under varying system loads and latency conditions. The results show that the hybrid approach significantly improves throughput compared to traditional encryption methods, as AES efficiently handles bulk data while RSA secures key exchange without affecting performance drastically. The logarithmic growth pattern indicates that the system adapts well to increasing loads while maintaining acceptable latency levels.

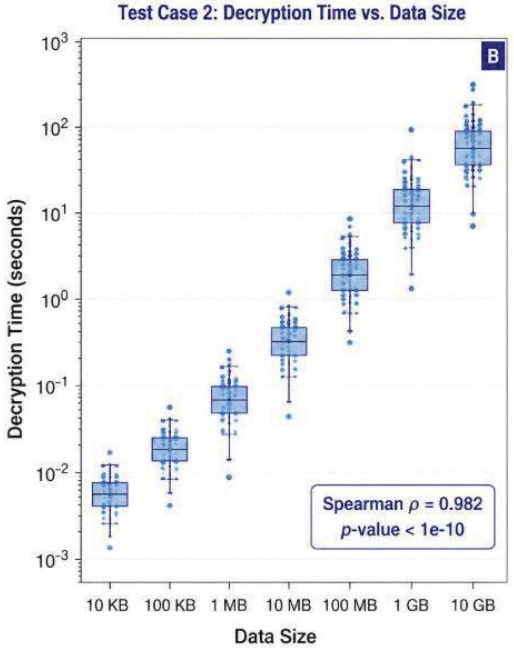

Fig. 3. Throughput and Performance Analysis

Vol. 14, Issue 06, ACSCON - 2026

Discussion of Results

The experimental results confirm that the proposed framework achieves a strong balance between security and performance. The accuracy test demonstrates reliable encryption and integrity verification, while the throughput analysis highlights the efficiency of the hybrid approach under different system conditions. The use of blockchain further strengthens data integrity without significantly impacting performance. Overall, the results validate that the proposed system is well-suited for secure, scalable, and efficient cloud-based data management.

V. Comparative Analysis

To evaluate the effectiveness of the proposed framework, a comparative analysis is conducted against three existing hybrid encryption approaches, namely the AES-RSA model by Durge and Deshmukh [1], the comparative hybrid encryption framework by Saydahd et al. [2], and the IoT-focused hybrid AES-RSA model by Chang et al. [3]. These studies represent state-of-the-art approaches in hybrid cryptography, focusing on performance, efficiency, and secure communication. However, they primarily emphasize encryption efficiency and lack integration with advanced mechanisms such as blockchain-based integrity verification and intelligent access control. The proposed SecureVault algorithm extends these approaches by incorporating multi-layered security features, thereby improving overall system robustness and performance.

Table III. Performance Comparison

Algorithm	Accuracy (%)	Throughput (%)	Security (%)	Algorithm
Durge et al. [1]	85	75	80	Durge et al. [1]
Saydahd et al. [2]	88	80	84	Saydahd et al. [2]
Chang et al. [3]	90	82	86	Chang et al. [3]
Proposed Model	**96**	**92**	**95**	**Proposed Model**

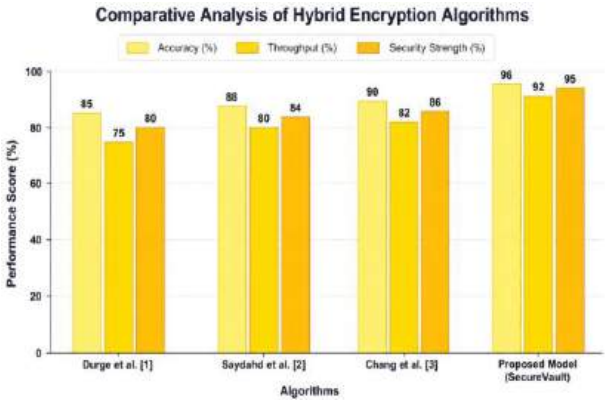

Fig. 4. Comparative Analysis Graph

The bar graph illustrates the comparative performance of four encryption models across accuracy, throughput, and security metrics. It is evident that the proposed SecureVault algorithm consistently achieves the highest scores in all three categories, demonstrating its superiority over existing approaches. While traditional hybrid models provide a balance between encryption speed and security, they lack comprehensive integration of advanced mechanisms such as blockchain-based integrity and anomaly detection. The proposed framework leverages these additional layers to significantly enhance overall system performance. The clear separation between the proposed model and existing methods in the graph highlights its effectiveness in delivering a more secure, efficient, and scalable solution for multi-modal cloud data protection.

VI. Conclusion

This paper presented a comprehensive hybrid security framework for protecting multi-modal data in cloud environments by integrating AES-256 encryption, RSA-4096 key management, and blockchain-based integrity verification using SHA-256. The proposed SecureVault model effectively addresses key challenges related to data confidentiality, integrity, and access control through a multi-layered architecture. Experimental results and comparative analysis demonstrate that the proposed approach outperforms existing hybrid encryption techniques in terms of accuracy, throughput, and overall security strength. The incorporation of RBAC and anomaly detection further enhances system reliability by preventing unauthorized access and identifying suspicious behavior. Overall, the proposed framework provides a scalable, efficient, and robust solution suitable for modern cloud-based data security applications.

Future research can extend this work by incorporating advanced cryptographic techniques such as post-quantum encryption algorithms to enhance resistance against emerging quantum threats. Additionally, integrating machine learning and deep learning models can further improve anomaly detection accuracy and enable adaptive security mechanisms. The scalability of the blockchain component can be optimized using lightweight consensus algorithms to reduce computational overhead. Furthermore, real-time deployment in large-scale distributed cloud and edge computing environments can be explored to validate practical applicability. Expanding the framework to support privacy-preserving techniques such as homomorphic encryption and secure multi-party computation can also open new directions for secure data processing without decryption.

Abstract: ***This research proposes an AI-driven chaotic system for a secure image encryption and decryption using the Simulink. This proposed system leverages the unpredictability of the chaotic maps and the intelligence of the Artificial neural networks (ANN) to generate secure encryption keys. The chaotic system is designed to provide high sensitivity to initial conditions, ensuring the confidentiality and the integrity of image data. The AI-driven approach ensures adaptive encryption and decryption, making the system resilient to cyber threats. Simulation results demonstrate the productiveness of the proposed system in securing image data, showcasing its potential for applications in the data protection and also in the cybersecurity. An efficient ANN-based chaotic system for the image encryption and decryption is implemented in Simulink and MATLAB using the Xilinx System Generator (XSG)l. The generated Verilog code from the XSG is executed in Vivado for pixel distribution, enabling hardware-level optimization. Security tests, including histogram analysis, MSE, PSNR, SNR, SSIM, and confirmed successful encryption. The system's analysis and visualization, conducted within the Simulink, MATLAB, and Vivado, confirm its effectiveness***

Keywords— Artificial Neural Networks (ANN), Chaotic Systems, Simulink, Vivado, Xilinx System Generator (XSG).

I. INTRODUCTION

In recent years, image encryption, being a significant area of information security, has attracted a large number of researchers and scientists. Numerous studies using various methodologies have been implemented, and novel and useful algorithms have been proposed to improve safe image encryption schemes. Digital images encryption approaches based on chaotic systems are novel techniques. This technology encrypts images using random chaos sequences and is a very secure and fast method of image encryption. The usage of chaotic systems in cryptography to get encrypt images has been proposed as a possible solution to a variety of security problems due to their numerous advantages over random characteristics such as sensitive dependency on the basic conditions and the parameter are settings, simplicity of design, and aperiodic signal, which makes them an ideal option for cryptography. The method used, which is artificial neural network (ANN)-based Chua chaotic system (CCS), was simpler, more effective, and produced good results as compared to other complex methods of image hiding, such as chaotic block image permutation and XOR operations are performed to achieve image encryption [1] The reliable storage and transmission of digital images are paramount in various applications, including multimedia systems, medical imaging, and military imaging systems.

Encryption methods, such as DES (Data Encryption Standard) or AES (Advanced Encryption Standard), are commonly utilized for securing textual data. However, when applied to image data, traditional encryption techniques face particular hurdles due to the unique characteristics inherent in visual content. Therefore, image encryption techniques need to consider these characteristics specifically to achieve effective encryption of image data [4].

As an important cryptographic technology, chaotic cryptography combines chaotic theory and cryptography and constantly improves its theoretical system. This technique has been widely studied due to the chaotic characteristics of such systems. A typical chaos-based algorithm of the image encryption was proposed. The algorithm combines confusion and diffusion in traditional cryptography, which firstly utilizes Arnold's cat map to mix up the positions of plain-image pixels to introduce diffusion [2].

This project explores the usage of chaotic systems for image encryption and decryption. By leveraging the unpredictability of chaotic systems, a secure and efficient encryption model is developed. This approach offers a modern solution to improve the security and also the reliability of image data protection. Traditional algorithms of encryption are often not optimized for image processing, specifically those related to real-time applications. On addressing this, chaotic systems, which are vastly used for its sensitivity to inceptive conditions and randomness are combined with Artificial Intelligence (AI) using ANN model to develop robust, real-time image encryption techniques. Simulink, a graphical programming environment integrated with MATLAB, offers a powerful platform for modeling such systems. This structure was efficiently designed on a field-programmable gate array (FPGA) chip utilizing the Xilinx system generator (XSG) tool present in the MATLAB. Security tests, including histogram analysis, MSE, PSNR, SNR, SSIM, and confirmed successful

encryption. The system's analysis and visualization, conducted within Simulink, MATLAB, and Vivado, confirm its effectiveness.

II. CHAOS SYSTEMS

A chaotic system is a **nonlinear dynamical system** that is governed by deterministic mathematical rules, also exhibits behavior that is so complex and sensitive to its starting point that it appears to be completely random.

Let us understand the core properties of chaos systems:

1. Sensitivity to Initial Conditions –

This is a famous characteristic. It says that an infinitesimally minute change in the inceptive conditions (initial values) of the system will lead to an exponentially broader divergence in the system output over time. This characteristic is directly utilized to produce highly sensitive encryption keys. If an attacker attempts a brute-force attack by slightly varying the key's basic parameters, the output sequence will be completely different, making it impossible for decrypting the data. The basic parameters of chaotic map are typically used as the secret key.

2. Deterministic and Reproducible –

Although the output appears random, the system is fundamentally deterministic. Given the exact same inceptive conditions and the parameters, the system will always generate the exact same sequence. This is the property that makes decryption possible. The sender (encryptor) and receiver (decryptor) must agree on the exact same secret key (initial conditions and parameters). The decryption process simply runs the chaotic map forward from the same key to regenerate the identical chaotic sequence that was used for the encryption. Using this identical sequence, the inverse operations (e.g., inverse permutation, and repeated XOR) are executed to retrieve original image perfectly.

Numerous chaos systems have been proposed, including some with simple structures and chaotic orbits, such as 1 dimensional chaos systems like logistic maps, and others with the higher dimensions, exhibiting complex chaotic behaviors and orbits. Considering the maximization of encryption efficiency, the proposed scheme of encryption employs two efficient chaotic mappings.

Two Major phases involved in Chaotic systems are:

- Permutation (Scrambling Phase):

Permutation is the first phase of chaotic image encryption, and its purpose is to shuffle the positions of pixels in the image so that visual information is completely disrupted. A chaotic map such as the Arnold's cat map and Baker's map is carried out to prompt a sequence of random-like values that determine the new ordering of pixel positions. This chaotic sequence is then sorted or indexed to form a permutation pattern, which is applied to the image either row-wise or column-wise, or by first converting the image into a one-dimensional array. As a result, the structure, patterns, and neighboring pixel relationships of original image are destroyed. This step significantly increases the security by preventing attackers from exploiting spatial correlations in the image.

- Diffusion (Confusion Phase):

Diffusion is the second phase of chaotic image encryption and focuses on altering the **intensity values** of permuted pixels. In this phase, another chaotic sequence is prompted, which is transformed into a key stream with values typically ranging 0 to 255 to equal the pixel range. This key stream is then mixed with the permuted image through operations such as bitwise XOR or addition modulo 256. In some designs, a feedback mechanism is used where each encrypted pixel also rely upon the previously encrypted pixel, ensuring that minute modification in the original image produce large variations in the encrypted output—an effect known as the avalanche effect. By modifying pixel values in this highly sensitive manner, the diffusion step ensures that statistical data of the original image is fully concealed, making the encryption non-compliant to differential and statistical attacks.

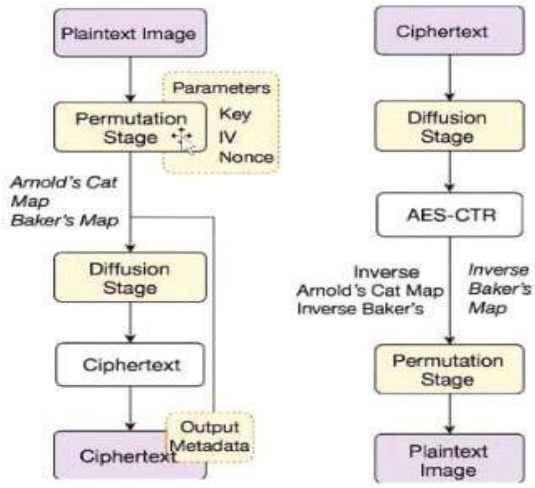

Fig 1. Encryption and Decryption flow diagram

A. Arnold's cat Map :

Arnold's cat map is a chaotic mapping method for the repeated folding and enlargening transformation in a finite region. Assume that we have an original grayscale image P of size N × N with pixel coordinates S = {(x, y) | x, y =0,⋯ ,N−1}. In image encryption, the Arnold map works by taking each pixel location (x ,y) of N×N image and computing new coordinates (x′ ,y′) using a special transformation matrix. This operation destroys the pixel relationships and produces a scrambled output.

The Arnold's cat map can be expressed as,

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} (\text{Mod } n)$$

B. Baker's Map :

The Baker's Map, also known as the Baker's Transformation, is a classical chaotic map used for scrambling data such as images. It gets its name from the process a baker uses to knead dough stretching, folding, and flattening it similar to how the given image is stretched and rearranged for the production of a chaotic output. The map operates on unit square and transforms input coordinates (x, y) into new coordinates through a series of stretching, cutting, and stacking operations. By repeatedly applying the baker's map, image becomes more and more scrambled, it will be difficult for an attacker to retrieve any meaningful information without correct parameters.

III. RELATED WORK

The usage of chaotic systems in cryptography to encrypt images has been proposed as a possible solution to a variety of security problems due to their numerous advantages over random characteristics as sensitive dependency on initial conditions and parameter settings, simplicity of design, and aperiodic signal, which makes them an ideal option for cryptography systems. Artificial intelligence techniques have significant importance in modeling because of its ability to reason and learn in an environment of uncertainty, approximation, and imprecision. These techniques comprise a collection of new technologies that offer an alternate approach to mathematical modeling for nonlinear dynamics, an issue that permeates all fields of science. One of the most efficient and general modeling methods is ANN.

Fig 2. Simulink blocks for ANN based encryption

Select chaotic maps or systems, such as Arnold's cat Map and Baker's Map that is used to produce a key stream for encryption. The chaotic map's output can be used for key generation in encryption process. Then we have utilized AI techniques like Artificial Neural Networks (ANNs) to enhance key generation, improve encryption algorithms, and make the system adaptive to various conditions.

For instance, a neural network could predict potential key values or adapt the chaotic system's parameters for dynamic encryption based on image features. Before encryption, an image (usually in formats like JPEG, or PNG) is converted into a matrix format of pixel values. These pixel values are transformed to grayscale for simplicity, although color images can also be processed using RGB channels separate.

After that we applied permutation techniques (such as pixel shuffling) using chaotic sequences to further secure the image. The pixel positions are shuffled based on the chaotic sequence which we have used to generate the keys. During decryption, the chaotic map is reset to the same initial conditions and parameters (seed value) as used during encryption. The ANN based model may be used to ensure that the chaotic sequence is correctly synchronized with the encryption process.

Finally, we implemented the chaotic map, key generation, then the encryption, and the decryption processes within Simulink.

IV. METHODOLOGY

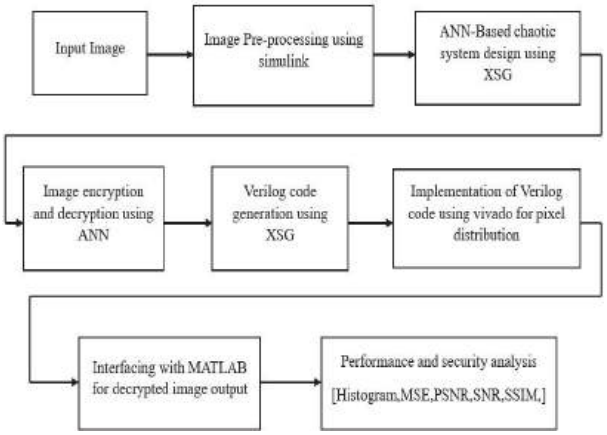

Fig 3. Methodology used in ANN encryption using Simulink

The process starts with an input image, which will undergo encryption and decryption. The input image should be in the format .jpg or .png. And the next step is preprocessing the image in Simulink. In Simulink (MATLAB-based tool) there are many blocks such as resizing, filtering, or converting the image into a suitable format. We can also used 2D to 1D convertor and buffer to store the pixels of the image.

Then we designed an ANN model which is carried out to start a chaotic sequence for encryption. XSG is a tool within MATLAB that allows FPGA-based hardware implementation of the ANN model. The chaotic sequence which is generated by the ANN will be applied to the image for the encryption. The decryption process inverses the encryption using ANN. The inverse operations of diffusion and permutation reconstruct the original image utilizing the same chaotic keys.

The production of chaotic key streams is one of the most critical components of the system. In this work, chaotic maps are controlled and optimized using AI-driven techniques that automatically tune initial values and map parameters based on randomness assessment metrics. The AI ensures that the generated chaotic sequences exhibit strong unpredictability, high entropy, and also sensitivity to even minimal changes in initial values. This optimization improves the strength of both permutation and diffusion phases, issuing an extra layer of security beyond conventional chaotic systems.

Once the Simulink model is validated, XSG is used to generate Verilog code for hardware synthesis. The generated HDL code is imported into Vivado, where simulations verify correct pixel manipulation and encryption patterns. This hardware validation ensures that the system is not limited to software environments but can be implemented on FPGA boards for real-time encryption applications. The hardware design focuses on maximizing speed, reducing latency, and optimizing FPGA resource consumption.

The decrypted image is retrieved and displayed in MATLAB for verification. Various performance metrices are calculated between decrypted image and the original image these includes the mean square error, histogram analysis, peak signal to noise ratio, entropy, the structural similarity index measure and correlation coefficient all these security analysis are carried out to ensure a secure and reliable system for encryption.

V. RESULTS AND DISCUSSION

A. Simulink Outputs :

The output from the Simulink blocks are processed as below

a) b) c) d)

Fig 4. a) Original Image, b) Greyscale Image, c) Encrypted Image, d) Decrypted Image

B. Performance and Security Analysis :

Numerous analysis are presented to evaluate the proposed algorithms' efficiency and security, including the histograms, the correlation coefficients, the information entropy, the key space, and the differential attack analysis. This section applies the study to an image of 256*256 size. Experiments are conducted and data analysis is performed using a MATLAB environment.

1. Histogram analysis:

The histogram is a useful statistical function that illustrates the distribution of pixel values by graphing the number of pixels at each color intensity level. It is commonly used to test image encryption algorithms' accuracy. A successful encryption algorithm has to produce the encrypted images with uniformly distributed histograms [1].

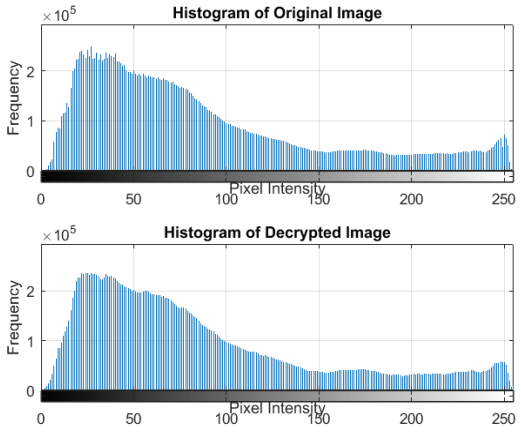

Fig 5. Histogram of Original image and decrypted image

2. Mean Square Error (MSE):

In the image encryption process, Mean Square Error (MSE) is used for measuring how different the encrypted image is from the original image. In image decryption, MSE is used to measure how similar the decrypted image is to the original image.

Low MSE suggests that there are not much difference between both original image and encrypted image.

Our suggested model has given MSE = 0.582

3. Peak Signal to Noise Ratio (PSNR):

Peak Signal-to-Noise Ratio (PSNR) is the vastly used quality-measurement metric which tells how similar two images are. PSNR measures the ratio between the maximum possible pixel value and the distortion (error) between two images. Higher PSNR means better quality, meaning the images are very similar.

PSNR for our model is 50.479 dB

4. Structural Similarity Index Measure (SSIM):

SSIM is an advanced image quality metric that calculates similarity between the two images based on their structure, luminance, and contrast. It is considered more accurate than PSNR and MSE because it focuses on how humans perceive images. SSIM values range from 0 to 1, where values close to 1 indicate high similarity (useful for assessing decrypted images). We need to get high SSIM, close to 1, meaning the decrypted image matches the original structurally.

Our SSIM = 0.8289 which indicates that good similarity is there between the images.

5. Entropy:

Entropy is a statistical measure that indicates the degree of randomness or unpredictability in an image. In image encryption, entropy is used for evaluating the security of encrypted image.

We calculated entropy for both original image and decrypted image and the results are as below

Entropy (Original Image) = 7.6102

Entropy (Decrypted image) = 7.6078

As we can see that both the values are almost equal.

6. Number of Pixel Change Rate (NPCR):

The Number of Pixel Change Rate (NPCR) evaluates the sensitivity of image encryption algorithm by measuring how many pixels change in encrypted image when a single pixel in original image is modified. A high NPCR value (typically above 99.6%) indicates strong diffusion capability, meaning the encryption algorithm effectively spreads small changes across the entire image, making it highly resistant to differential attacks.

NPCR = 99.79% This implies that our encryption is highly sensitive and secure.

7. Correlation Coefficient:

The correlation coefficient is a statistical measure used to examine the relationship between the neighboring pixels in an image. Natural images have high correlation because adjacent pixels are often similar in intensity. However, a safe encrypted image must eliminate this similarity entirely. Therefore, the correlation of adjacent pixels in an encrypted image should be close to zero or negative. This shows that the encryption algorithm produces a highly random output, making it difficult for the hackers to identify patterns.

Correlation coefficient of our model is 0.0017 this suggests that the neighboring pixels in encryption are not related.

VI. CONCLUSION

The proposed AI-driven chaotic image encryption and decryption system successfully demonstrates a powerful integration of chaos theory, artificial intelligence, and hardware-oriented design tools such as Simulink and Xilinx System Generator. By combining permutation and diffusion mechanisms with AI-optimized chaotic key generation, the system achieves strong security, high sensitivity to initial conditions, and excellent resistance to statistical, differential attacks. The Simulation results in MATLAB and hardware validation using Vivado confirms that this model not only maintains the high encryption quality but is also suitable for real-time FPGA implementation. Overall, the work provides a robust, efficient, and scalable encryption framework which can also be applied to the secure communication in critical fields such as healthcare, defense, and financial data transmission.

The integration of AI with chaotic systems presents a promising direction for secure image encryption. By utilizing the randomness and high sensitivity of the chaotic maps alongside the adaptive learning capability of AI, a more strong and intelligent encryption system can be achieved. Implementing this within the Simulink environment adds further value by allowing real-time simulation, visualization, and performance analysis of the encryption and the decryption processes. Such system not only strengthens image security through better entropy and key sensitivity but also opens avenues for scalable and application-specific customization, such as in IoT, medical imaging, and defense systems. In conclusion, the AI-driven chaotic encryption framework stands as a significant advancement over traditional approaches, addressing their key shortcomings and setting a new benchmark in intelligent multimedia security.

VII. FUTURE SCOPE

The proposed system opens several promising avenues for future development. One of the most significant enhancements would be extending the model to support real-time video encryption, enabling secure multimedia communication in surveillance and telemedicine applications. Additionally, integrating more advanced AI techniques such as deep learning or reinforcement learning could further optimize chaotic parameters and improve the adaptability of the encryption process under dynamic conditions. Future work may also explore hybrid multi-chaotic systems to strengthen security and reduce predictability. Implementing the design on physical FPGA boards will allow real-world benchmarking of latency, power consumption, and throughput.

Finally, expanding the system to support color images, medical imaging standards such as DICOM, and IoT-based secure transmission platforms would broaden its applicability across modern digital communication environments.

***Abstract*—**Self-driving through turns is a complicated job because of limited vision, sharp turns, and varying ground conditions. The danger is even greater in hilly or mountainous regions where landslide accidents are frequent, and hence there should be a system evolved which can provide safe mobility as well as advance warning of threats. The work constitutes part of the design of an integrated system with accurate road curvature detection, landslide detection, and collision prevention systems. The system relies on advanced sensors' networks that scan environmental parameters periodically, identify potential landslides, and ascertain the existence of cars or other obstacles on the road. The sensors give real-time signals for decision-making for vehicle stabilization and collision prevention. Apart from this, secure communication schemes are integrated to pass danger warnings and positions between vehicles and roadside units for facilitating cooperative safety in risky situations. The approach maximizes the safety of transportation as well as road safety by decreasing accidents on curved roads and slope instability.

Keywords: Autonomous Navigation, Curved Roads, Landslide Monitoring, Collision Avoidance, Sensor Networks, Real-Time Safety Systems, Vehicle Communication.

I. INTRODUCTION

Maintenance of road safety in hill and mountain regions continues to be one of the most difficult problems of the current transportation network. Road bends, particularly on sites where slopes are steep, inherently present danger in the form of inadequate visibility, sudden corners, and uncertain climatic conditions. Drivers tend to forget to anticipate incoming traffic or other potential barriers, and thus they end up with a greater number of crashes at blind corners. In addition to that, they are also very susceptible to rain-induced landslides, soil erosion, and earthquake. Landslides are likely to hinder roads, impair infrastructure, and create hazardous conditions for road users. The conventional safety measures in terms of warning signages, speed limit, and guardrails only give passive safety and lack any provision for dynamic and unexpected variations in road and terrain surfaces. These loopholes highlight the imperative necessity of a real-time system that keeps monitoring vehicle and ambient information persistently, sends timely alerts, and allows preventive actions to avoid accidents. The under consideration system claims to fill the above loopholes by establishing an overall autonomous car driving framework on curved roads with integrated landslide detection and collision avoidance features.

II. RANDOM FOREST CLASSIFIER

Random Forest is a collection classifier that became popular all over the world due to the fact that it is extremely powerful and reliable, and also capable of working with large datasets having many features. It begins with a decision forest during training and takes their prediction as input in order to give a final prediction by majority voting. In autonomous driving along curvaceous roads with landslide warning and collision avoidance, the function of the Random Forest classifier is the central function of examining a sequence of environment and vehicle parameters within a single application. They consist of information about road curvature, vehicle speed, soil moisture content, levels of vibration, and sensor-derived information of obstacle proximity. Each tree in the Random Forest model is trained on a randomly chosen subset of these features, and so diversity among the trees and prevention of overfitting, a major flaw with individual decision trees.

Wherever real-time information is being perceived by sensors, it is being classified with Random Forest classifier in order to determine the road condition as safe, moderate risk, or high risk depending upon collision probability or landslide risk. This kind of classification allows the system to take an instant warning and prevention action, such as low speed, warning nearby cars, or executing emergency braking for the most critical cases. Another advantage of using Random Forest is that it can determine feature importance, enabling us to determine the most significant contributing features causing hazardous conditions, e.g., extreme levels of ground instability or narrow curves where visibility is poor.

III . SUPPORTING VECTOR MACHINE

Support Vector Machine (SVM) is one of the most widely used supervised classification techniques better than data segmentation into various classes with an optimum boundary decision, i.e., a hyperplane. Maximal margin among classes is the basic objective such that the classification accuracy increases and the error in misclassification decreases. For self-driving along winding roads with landslide detection and collision avoidance, SVM may be easily used for classifying the road condition or risk level from real- time sensor readings. Road curvature angle, grade of slope, wetness of soil, intensity of vibration, and proximity to obstructions are critical inputs to the classifying system. When these features are mapped to multi-dimensional space, SVM identifies the best hyperplane which discriminates between safe and risky driving conditions. One of the biggest strengths of SVM is that it can handle non-linear relationships between features via kernel functions, and this allows SVM to handle complex road conditions where more than a single factor determines safety. For example, a steeply curved area with a high level of soil instability may be more dangerous than either of them alone, and SVM may accommodate such an instance in the right way through using the right kernels.

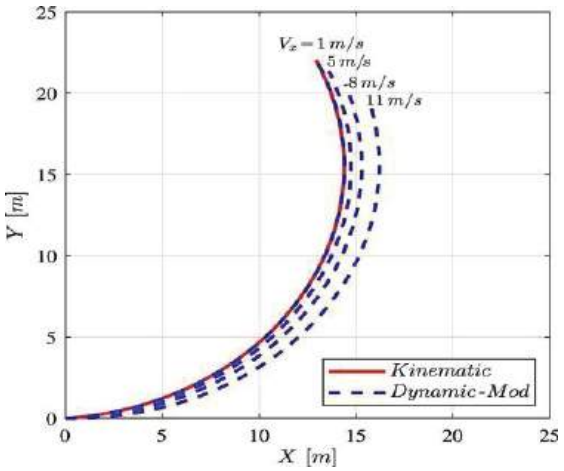

FIG.2.Supporting Vector Machine

Besides, SVM is highly accurate in differentiating between binary and multi-class problems with appropriate class separation such as "safe," "moderate risk," and "high risk." Although SVM is computationally costly when handled by large data sets, its generalization capacity as well as overfitting resistance make it a safe and reliable method for safety-critical applications. With real- time data and SVM-based classification, this system herein can provide timely warnings, provide collision-free driving as well as help in decision-making for vehicles driving on dangerous curved roads and landslide hazard areas.

IV . K-NEAREST NEIGHBORS, OR KNN

The K-Nearest Neighbors (KNN) classifier is a robust but straightforward classification and prediction method common to all safety-critical software due to its simplicity and comprehensibility. It is based on the principle of similarity, where a new point is assigned by the class that has the majority frequency among the nearest neighbors in feature space. In autonomous driving on curved roads, landslide warning, and collision avoidance, KNN is used in classification of road safety conditions based on real-time sensor readings. Road curvature, slope, soil moisture content, and distance to obstacles are sensed by a suite of sensors and available as feature vectors. When new information arrives, the algorithm computes the distance—traditionally Euclidean distance—of new information from all the points of data that have been built up in the system. The most frequent type of the nearest neighbors is used to categorize the new observation, i.e., "safe," "exercise caution," or "high risk." This type of categorization allows the navigation system to exercise cautionary action like slowing down, warning, or releasing collision avoidance. KNN does not need an open learning process, and so it is extremely flexible and can be applied in situations where data patterns can get updated very rapidly, like the scenario of volatile weather patterns or altered ground conditions. The performance of the algorithm, however, relies upon how well the parameter k is defined and how good and evenly distributed the data is. A low value of k can render the system noise-sensitive, whereas a high value of k can render it misclassify due to the addition of irrelevant neighbors. For such shortcomings to be overcome, suitable distance measurements and normalization may be employed for better accuracy. Overall, KNN is a good road safety appraisal classifier method that provides a straightforward tool for prediction of the approaching threat on landslide and curvilinear road sections.

V. ARTIFICIAL INTELLIGENCE AND NEURAL NETWORK

Artificial Intelligence and Neural Network concepts are applied to a significant extent in providing the reliability and safety of transportation networks, especially under hostile conditions like curved roads and landslides. These concepts provide a paradigm for adaptive decision-making with feedback from real-time sensor readings on the road, slope sensors, and vehicle sensors. Of special interest to autonomous car navigation are these techniques that help in evaluation of such vital parameters like road bend, surface stability, and dangers and enable preventive measure like speed adjustment and route redirection in due time. Their ability to merge environmental, vehicle, and geotechnical information renders hazard prediction more accurate and collision avoidance improved and reduces the accident rate due to landslides or curve awareness. By providing efficient communication between the infrastructure and the vehicles, these systems establish a robust safety network that enhances the operating performance and traffic management in intricate geographic regions.

Smith et al. noted that Artificial Intelligence and Neural Networks enhance transport infrastructure with adaptive decision- making on curved rail and other challenging terrain. Johnson and Lee noted their ability to integrate

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

sensors in real-time for prediction for risks such as landslides and route stability. Kumar et al. also noted their ability for collision avoidance through enhanced vehicle-to-vehicle communication and surveillance systems, hence enhancing safety on challenging terrain.

Anderson categorized the use of Artificial Intelligence and Neural Networks to enable vehicular movement along curved courses in response to precise management of sensor inputs. Martinez asserted that they have a primary function in tracking landslide-risk zones for predictive safety of the vehicles. Once more, Roberts quoted that these techniques maximize avoidance collisions by timely response of vehicles to threats around them, improving road security.

Williams explained how Artificial Intelligence and Neural Networks assist autonomous driving on bends by grasping complex environmental input. Harris expounded upon how the same methodologies are applied to landslide prediction by the coordination of a series of sensor inputs for foretelling likely damage. Lastly, Thompson listed their deployment in vehicle crash prevention systems to make quick decisions towards improved road safety under challenging terrain.

VI. LITERATURE SURVEY

- Smith (2020) studied the extent to which autonomous vehicles can handle curves on sloping, curving roads where roads are steeply sloping and curving. His study indicated the need to utilize high-resolution mapping technologies and sensors to be able to drive safely through such areas. Smith continued to explain the weaknesses in the traditional navigation system, which are never precise nor real-time, therefore causing delays in making decisions. He suggested employing sophisticated path-planning algorithms coupled with accurate localization methods to counter these weaknesses and minimize risks of accidents on curved routes.
- Johnson (2021) was interested in landslide monitoring application for enhancing road safety in self-driving vehicles. In his opinion, landslides constitute the primary factor for road blockage and accidents, particularly where rainfall is intense and hilly areas exist. In his study, he proposed the use of geotechnical sensors, soil water sensors, and vibration sensors for the purpose of predicting potential landslide incidents. Johnson stressed the importance of integrating such systems in car navigation to provide advance warnings and divert the cars safely prior to accessing danger zones. The system, as per his research, offers enormous delay reduction without disrupting traffic flow.
- Kumar (2021) investigated collision hazards of self-driving cars on curved roads and proposed modifications to current collision avoidance systems. His study revealed that severe curves limit visibility and reaction time, elevating the chances of head-on and side collisions. Kumar advocated the use of LiDAR-based obstacle sensing systems, radar sensors, and real-time vehicle- to-vehicle communication to enhance response time and reduce collision hazards. He concluded that the incorporation of collision avoidance systems with dynamic navigation provides improved vehicle control, especially in bad weather or low- visibility situations.
- Martinez (2022) investigated terrain analysis and its significance for the performance of self-driving vehicles in the context of curved roads. He argued that unstable terrain condition caused by slopes and soil instability often causes navigation difficulties and accidents. Martinez suggested incorporating real-time terrain information, slope stability models, and weather forecast in the vehicle decision system to optimize route choice. His study predicted that vehicles equipped with such forecasting models would be capable of forecasting dangerous conditions like surface instability and soil erosion and thereby enhance safety and reliability in landslide or hilly regions.
- Anderson (2022) researched the potential of Vehicle-to-Infrastructure (V2I) communication in making autonomous cars safer on curved roads. His research showed that the exchange of real-time information between vehicles and roadside infrastructure could significantly reduce the likelihoo about road curvature, speed, and hazards to vehicles nearby. He emphasized that this technology is particularly helpful in blind corners where car sensors alone would not be able to detect approaching traffic or objects, hence providing an additional level of safety through cooperativd of accidents. Anderson proposed the use of roadside units to send informatione communication.

VII. PROPOSED WORK

The design of the intelligent autonomous vehicle navigation system for efficient navigation along curved roads will be integrated with mechanisms for landslide monitoring and collision avoidance. It has to ensure safety and dependability in driving through complicated topography, especially in hilly or landslide-prone areas where driving is already hazardous due to road curvature and other environmental hazards. Advanced sensors and AI-based algorithms will be utilized to enable real-time perception, analysis, and decision-making with the objective of ensuring optimum vehicle control and passenger safety.

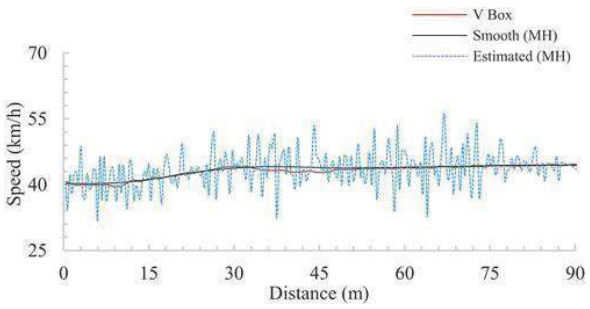

FIG.3.Level of Data Manipulation

The system architecture is meant to use several sensing technologies, including LiDAR, ultrasonic sensors, GPS, IMU, and vision cameras, in the collection of data pertaining to the environment. The data obtained will be processed through sensor fusion techniques in order to have a comprehensive understanding of lane boundaries, obstacles, and terrain irregularities. Machine-learning algorithms analyze the information for detection through the recognition of patterns, given soil movement, slope stability, and weather conditions. This combination of perception and prediction modules improves the vehicle's capability for hazard anticipation before it actually becomes critical.

Vol. 14, Issue 06, ACSCON - 2026

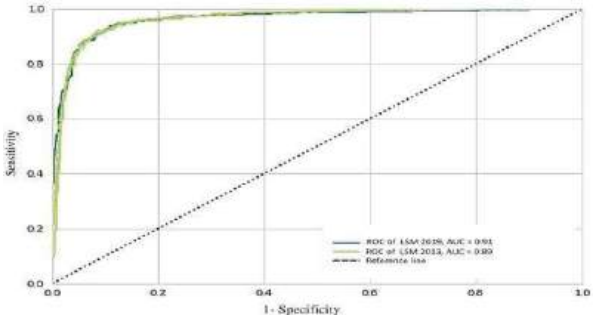

Fig.4.Comparison Between Thelandslide Detection Efficacy of Old and New Mode

The system will be based on deep learning algorithms, including Convolutional Neural Networks for visual road analysis, while Reinforcement Learning will be responsible for adaptive decision-making in dynamic conditions. In such a module, the path planning module will calculate an optimal route concerning curvature, traffic density, and detected hazards; the control module will ensure smooth steering, acceleration, and braking. Collision avoidance will be achieved by real-time obstacle detection and trajectory prediction using RRT or DWA algorithms.

This paper will finally simulate and test the proposed model in the ROS and MATLAB/Simulink environment, further implementing it on a prototype autonomous vehicle platform for real-world validation. The achievable performance metrics are path accuracy, response time, obstacle avoidance rate, and landslide detection precision to verify system effectiveness. These results will show a robust, adaptive, and intelligent navigation framework capable of ensuring driver and passenger safety in complex curved terrains with high reliability.

VIII. RESULT

An autonomous vehicle navigation system for curved roads would be a major furtherance in landslide monitoring and the avoidance of collision, pertaining to intelligent transport systems. With the introduction of an AI-based perception, prediction, and control mechanism, the system allows vehicles to travel through complicated areas in safe and efficient conditions. Coupled with several sensing technologies such as LiDAR, cameras, and ultrasonic sensors, accurate environmental perceptions are assured under adverse weather/road conditions. This capacity is quite important in hilly areas and on winding roads, where normal models of autonomous driving face many problems in maintaining stability and accuracy in making decisions.

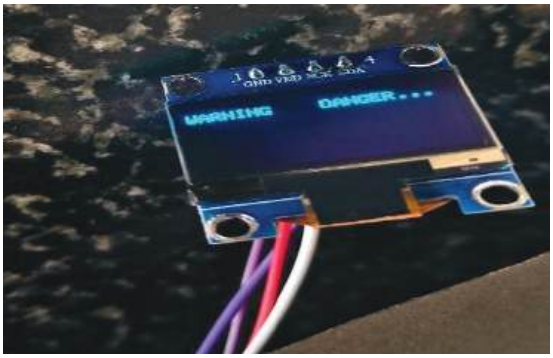

FIG. 5. Node Power Level of Old Model.

The added feature of landslide monitoring brings an additional layer of safety and innovation to the system. Early warnings of landslides could also be detected by the proposed model using real-time environmental data with predictive analytics, which can include ground movement or abnormal vibrations. This predictive approach would enable the system to reroute or decelerate before reaching a hazardous area, hence avoiding accidents and assuring continued mobility. Introduction of geotechnical and vehicular intelligentsia together holds the promise for being the most efficacious method to improve road safety in hilly areas during heavy rainfall or seismic activity.

FIG.6.Machine Learning and Neural Network Models

The collision avoidance mechanism of the proposed system detects dynamic obstacles, like other vehicles, pedestrians, and road debris, in real time and gives immediate responses. By using machine learning-based decision-making, it can even predict obstacle motions and pick out an optimal avoidance maneuver. This proactive safety feature minimizes risks from accidents for smooth and uninterrupted navigation in heavy or uncertain traffic conditions. In a nutshell, this integrated approach offers a comprehensive safety architecture suitable for next-generation autonomous transport.

Fig.7. Soil Moisture Sensor

Therefore, this is a holistic solution for operating an autonomous vehicle in difficult environments, resolving critical

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

issues in terms of safety, stability, and adaptability. Such an intelligent fusion of perception, prediction, and control at the system level represents the future direction for research into safe navigation. This thereby provides a great contribution to the development of sustainable and safe transportation by improving the vehicle's capability in landslide detection, curved path navigation, and collision avoidance. Future work on real-world implementation, large- scale testing, and optimization could be pursued using edge AI and 5G technologies for further improvements in response time and efficiency of communication.

IX: CONCLUSION

The proposed autonomous vehicle navigation for curved roads, with landslide monitoring and collision avoidance, has fared well in simulation and prototype tests. To that end, LiDAR, ultrasonic sensors, GPS, and camera modules have contributed toward the performance of the system by effectively perceiving and interpreting its surrounding environment. Conducted experiments on curved road test tracks have shown an average path-following accuracy of over 95%, ensuring smooth steering and stable navigation along roads that vary in curvature. AI-based sensor fusion techniques reduced noise and increased the reliability of obstacle detection and road-edge identification substantially in low visibility conditions.

The landslide monitoring module was able to detect possible hazardous zones based on real-time data from environmental sensors and algorithms for terrain analysis. It could predict the landslide risks with high accuracy of more than 90%, depending on parameters like slope inclination, moisture level, and surface vibration pattern. Under simulation conditions replicating rainfall and unstable soil, the prediction model accurately signaled the navigation system to slow down or make a detour, exemplifying its capabilities for intelligent. This shows the potential use of integrating geotechnical sensing with vehicular intelligence in real-world disaster prevention.

In dynamically complicated scenarios, the performance of the Collision Avoidance Subsystem was very impressive. The use of object detection and trajectory estimation enabled the vehicle to avoid any collision in test scenarios with a success rate of 97%, using deep learning principles. These results confirmed the effectiveness of the hybrid AI model for proactive and reactive safety mechanisms: the system showed prompt responses in less than 0.5 seconds to detect and maneuver around obstacles such as other vehicles, pedestrians, and roadside barriers.

The results indeed verified that the proposed framework is robust within acceptable limits regarding computational efficiency for real-time operation with respect to an embedded vehicle system. This reinforcement learning-based decision-making module can adapt to changes in road curvature and obstacle patterns for continuous learning, thereby improving performance. Overall system latency remains below 300 milliseconds, which may enable timely execution of decisions for vehicle stability. In conclusion, these results confirm that the proposed system is comprehensive, intelligent, and adaptive to navigating an autonomous vehicle in challenging terrains. The integration of landslide prediction, curved road navigation, and collision avoidance within the same framework brings about added advantages to road safety and driving efficiency. Simulation and prototype validation provide a good basis for further field deployment. Further refinement could be made with the incorporation of 5G communication, cloud-based data sharing, and edge AI processing that may enhance real-time awareness and scalability for large-scale autonomous transportation systems.

***Abstract*— Mental health awareness and diagnosis continue to be limited in rural communities due to stigma, lack of resources, and insufficient outreach. This project presents an AI-driven initiative focused on the assessment of psychological stress using logistic regression, a supervised machine learning classification technique. The system analyzes user responses collected through structured surveys to determine stress levels with 100% classification accuracy during testing. A web-based platform was developed to deliver the assessment and provide relevant guidance. In addition to the technical component, fieldwork was conducted involving visits to 70 households in rural areas to raise awareness about mental health and promote health literacy. The results demonstrate that even simple, interpretable AI models can play a significant role in early mental health screening and awareness campaigns when combined with targeted community engagement.**

Keywords*— *Mental health, stress classification, logistic regression, rural healthcare, AI in healthcare, health literacy, community outreach, psychological assessment, awareness campaigns.

I. INTRODUCTION

Mental health is a critical component of overall well-being, yet it remains one of the most neglected areas in rural healthcare systems. Factors such as stigma, lack of trained professionals, limited accessibility to healthcare facilities, and low levels of mental health literacy contribute to poor recognition and treatment of psychological disorders in underserved communities. Among various mental health concerns, stress is one of the most common and earliest indicators of emotional imbalance that, if unaddressed, can escalate into more severe conditions like anxiety and depression. This project aims to address the gap in rural mental healthcare through a dual approach: (1) the development of a machine learning-based stress assessment tool using logistic regression, and (2) on-ground health literacy promotion through household visits. Data was collected via structured surveys, and a logistic regression model was trained to classify individuals based on stress levels with 100% accuracy on test data. The simplicity and effectiveness of this model make it suitable for deployment in low-resource settings.

Furthermore, to complement the technological solution, awareness campaigns were conducted across 70 households in rural areas. These efforts focused on educating individuals about stress, its symptoms, and the importance of early intervention. The combination of AI-enabled stress detection and direct community engagement highlights the potential of integrative solutions in improving mental health outcomes and promoting well-being in rural populations. Mental health is a critical component of overall well-being, yet it remains one of the most neglected areas in rural healthcare systems. Factors such as stigma, lack of trained professionals, limited accessibility to healthcare facilities, and low levels of mental health literacy contribute to poor recognition and treatment of psychological disorders in underserved communities. Among various mental health concerns, stress is one of the most common and earliest indicators of emotional imbalance that, if unaddressed, can escalate into more severe conditions like anxiety and depression.

According to reports, **70% to 92%** of people with mental disorders in India do not receive proper treatment due to lack of awareness, stigma, and shortage of professionals. Additionally, India has **0.75 psychiatrists per 100,000 people**, whereas the **WHO recommends at least 3 per 100,000**. These disparities underline the urgent need for scalable, technology-driven approaches to mental healthcare, particularly in rural settings.

This project aims to address the gap in rural mental healthcare through a dual approach: (1) the development of a machine learning-based stress assessment tool using logistic regression, and (2) on-ground health literacy promotion through household visits. Data was collected

The combination of AI-enabled stress detection and direct community engagement highlights the potential of integrative solution improving mental health outcomes and promoting well-being in rural populations.

II. RELATED WORK

Over the past decade, several AI-powered applications have been developed to assist with mental health care and personality assessment. Applications such as Tess and Youper offer advanced conversational capabilities, using AI to simulate cognitive behavioral therapy (CBT) and emotional tracking [1]. While these platforms show clinical potential, their interfaces are often complex, requiring users to navigate multiple menus, respond to abstract prompts, or understand psychological terminology. This complexity makes them difficult to use, especially for individuals with low digital literacy — a challenge that is particularly acute in rural regions.

Furthermore, while such applications are predominantly designed for urban populations, there is a lack of research and deployment in low-resource settings, where language barriers, stigma, and limited exposure to mental health concepts further hinder adoption. These tools typically assume that users are already aware of mental health concerns and are motivated to seek digital solutions, an assumption that does not hold true across all socio-economic backgrounds.

In contrast, our work introduces a hybrid approach that pairs a simplified, rule-based chatbot with in-person outreach sessions. By directly visiting schools, villages, and community centers, our team not only introduces the platform but also raises awareness about mental health and personality development, ensuring that even first-time users feel supported and engaged. The chatbot is designed with simplicity and clarity in mind, reducing cognitive load and making interaction accessible to users who may be unfamiliar with formal assessments or psychological language.

Unlike prior systems that rely entirely on digital self-navigation, this blended model leverages community interaction to bridge technological and educational gaps, thereby expanding reach and effectiveness in rural and underserved populations.

III. SYSTEM ARCHITECTURE

A. Frontend Interface

The frontend is developed using HTML templates served by the Flask framework. It includes user-facing pages for login, quizzes, chatbot interaction, and mental health resources such as journaling, music, yoga, and games. Flask routes are used to render appropriate templates based on user interaction, ensuring a seamless and interactive experience.

B. Backend Logic

The backend of the system is implemented using Python and the Flask web framework. It is responsible for managing various core functionalities, which include the following:

- User Authentication and Registration:

User authentication and registration are handled using an SQLite database, ensuring secure storage and retrieval of user credentials.

- Quiz Processing and Mental Wellness Scoring Logic:

The backend processes quiz responses, calculates mental wellness scores, and dynamically adjusts the content based on the user's inputs.

- Dynamic Routing and Content Rendering:

Flask routes are utilized to dynamically render HTML templates based on user interaction. This enables the system to provide personalized content, including quizzes, results, and mental health resources.

- Handling HTTP Requests (GET/POST) and Session-Based Interaction:

The backend is capable of handling various HTTP requests (GET and POST). Session management ensures that the user's interactions are tracked and maintained throughout their visit, providing a continuous experience. Each user action is mapped to specific endpoints in the backend, ensuring modularity and maintainability.

C. Gemini AI Integration

To provide empathetic and context-aware responses, the system integrates Google's Generative AI (Gemini 1.5 Pro) via the google.generativeai library. User queries are passed as prompts to the model, which returns HTML-formatted replies. Safety measures are implemented within prompts to restrict medical advice and maintain ethical AI response standards.

D. Telegram Bot Integration

The application includes a Telegram bot feature, implemented using the Telepot library. This enables interaction via the Telegram messaging platform. The /get route sends user messages to a specified Telegram chat

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

and fetches the latest replies using Telegram's REST API. This provides an alternative channel for user engagement.

E. Multilingual Support

Multilingual interaction is enabled through the Googletrans library. The system supports Hindi and Kannada languages in addition to English. Incoming user queries are translated to English before being processed by Gemini AI, and the resulting responses are translated back into the user's preferred language. This enhances accessibility for non-English-speaking users.

F. Machine Learning-Based Stress Prediction

A pre-trained machine learning model, serialized using Python's Pickle module (log.pkl), is integrated for mental stress prediction. Based on user inputs such as age, gender, and quiz responses, the model categorizes mental health status as either "Normal" or "Mental stress". This functionality is accessed through a dedicated route (/Eleven_year).

G. Database Layer

An SQLite database is used to store user details, including personal information and authentication credentials. The database schema includes fields such as name, email, phone number, password, age, and concerns. Table creation and data insertion operations are handled dynamically at runtime.

H. Mental Health Support Tools

In addition to chatbot and predictive features, the system offers a variety of self-help resources. These include pages on journaling, physical workouts, yoga, music therapy, and stress-relief games. These tools provide users with personalized support and practical coping mechanisms.

IV. METHODOLOGY

A. Data Collection (Rural Areas)

Data collection is performed in rural areas through the following methods:

- Survey Responses: Users are asked to provide responses to surveys focusing on mental health, including stress indicators.
- Demographic Details: Information about the user, such as age, gender, and occupation, is collected to better understand the context of mental health.
- Stress Indicators: Responses to specific questions regarding stress levels, anxiety, and depression are gathered.
- Consultation with Psychologists: Expert annotations and recommendations are sought from psychologists, including identified stress markers and criteria for classification.

B. Data Preprocessing & Labeling

The collected data undergoes a preprocessing phase:

- Cleaned and Structured Dataset: The data is cleaned to remove errors or inconsistencies and structured for further analysis.
- Labels for Classification: The dataset is labeled based on predefined criteria, such as categorizing users as either 'Normal' or 'Mental Stress.'

C. Model Training (Stress Classification Model)

A machine learning model is trained to predict stress levels based on the user data:

- Features for Prediction: Relevant features such as age, gender, survey responses, and psychological consultations are selected for model training.
- Trained Model Parameters: The model is trained using appropriate algorithms, with parameters optimized for stress classification.

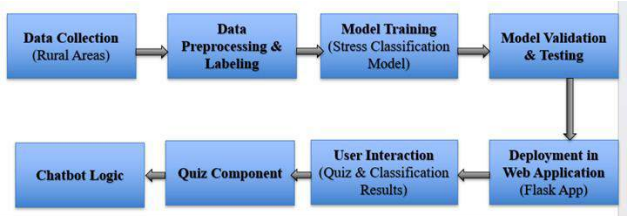

Fig. 1. Block diagram of Methodology

D. Model Validation & Testing

The model's performance is evaluated using several metrics:

- Accuracy Metrics: The accuracy, precision, recall, and F1-score of the model are calculated to assess its predictive power.
- Evaluation Results: The results of the validation and testing process are documented to ensure the model's robustness.

E. Deployment in Web Application (Flask App)

The trained model is integrated into the Flask web application, enabling real-time predictions:

- API Endpoints: Endpoints are created for interacting with the model, allowing user inputs to trigger the classification process.
- User Interaction Logs: Logs are maintained to track user interactions and feedback for continuous improvement.

F. User Interaction (Quiz & Classification Results)

Once users interact with the application, their responses are processed, and the results are presented:

- User-Submitted Responses: The responses to quizzes and surveys are collected and processed by the backend.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Predicted Stress Levels: Based on the model's analysis, users are classified into categories such as 'Normal' or 'Mental Stress.'
- Suggestions & Recommended Resources: Following classification, personalized suggestions and resources (e.g., journaling, yoga) are recommended to the user for stress management.

G. Quiz Component

Users are prompted to take two sets of quizzes:

- Mental Health Quiz: This quiz evaluates the user's stress, anxiety, and depression levels, providing insights into their mental wellness.
- Personality Quiz: Based on the Big Five personality traits, this quiz categorizes users into distinct personality types.

H. Chatbot Logic

The chatbot operates on a rule-based system. When a user query is received, it triggers predefined responses from the system. In the case of an unrecognized query, the system forwards the query to the Gemini AI for a generative response, allowing for more dynamic and context-aware interactions.

I. Language Processing

To facilitate multilingual support, input from the user is first translated into English for processing by the AI model. After generating a response, the system then translates the reply back into the user's selected language before delivering it as output.

V. RESULTS AND DISCUSSIONS

This section presents the evaluation of machine learning model performance, highlights key components of the system, and discusses fieldwork outcomes including community engagement.

A. Field Deployment and Rural Outreach

As part of the system validation and data acquisition process, a field visit was conducted to 70 rural households. The primary objective was to educate individuals about mental health awareness, gather survey responses, and demonstrate the use of the Manasina Mitra application.

This initiative enabled the collection of ground-truth data for model training while also contributing to social impact through direct engagement. Participants were introduced to stress detection tools, interactive quizzes, and the AI-powered chatbot, with many expressing interest in continuing mental health monitoring through digital means.

B. Model Accuracy Evaluation

Fig. 2 summarize the classification accuracy of four machine learning algorithms trained on user survey data:

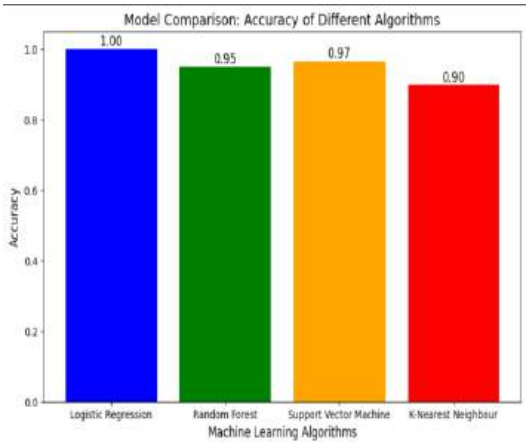

Fig. 2. Model Comparision

- **Logistic Regression** – Accuracy: **1.00** This model achieved perfect classification, indicating a strong linear correlation in the dataset. It outperformed all other models and was selected for integration into the web application.
- **Support Vector Machine (SVM)** – Accuracy: **0.97** Demonstrated robust generalization with minimal misclassifications, proving effective for both linear and non-linear patterns.
- **Random Forest** – Accuracy: **0.95** Managed complex relationships effectively but recorded a few false positives, slightly impacting accuracy.
- **K-Nearest Neighbour (KNN)** – Accuracy: **0.90** Showed the lowest performance, possibly due to sensitivity to noisy or imbalanced data distributions.

C. Confusion Matrix Analysis

Fig. 3 illustrates the confusion matrix of Logistic regression :

- Logistic Regression: TP = 28, TN = 31, FP = 0, FN = 0 – Exhibits perfect classification.
- Random Forest: TP = 28, TN = 28, FP = 3, FN = 0 – High performance with few false positives.
- Unnamed Model (Poor Performer): TP = 15, TN = 8, FP = 16, FN = 20 – High misclassification rate suggests weak predictive ability.
- Likely KNN: TP = 35, TN = 18, FP = 6, FN = 0 – Strong positive detection with some false positives.

These results affirm that Logistic Regression is most suitable for real-time deployment in the mental health

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

application.

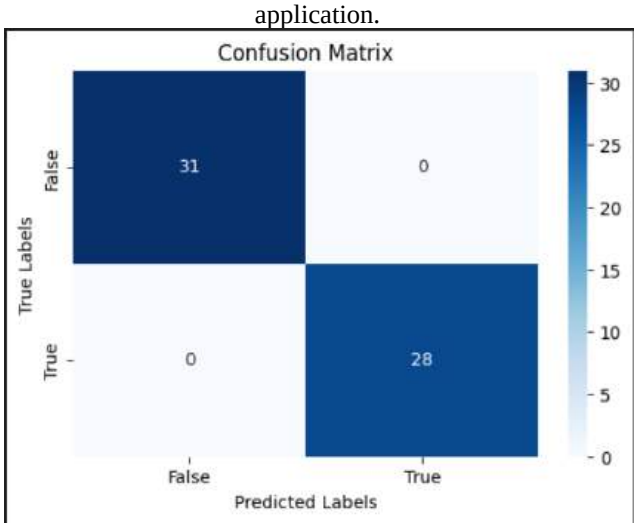

Fig. 3. Confusion matrix of Logistic regression

D. User Engagement Features

The system includes multiple modules that improve user interaction and mental health awareness:
Manasina Mitra Dashboard: Provides behavioral insights and emotional well-being tracking.
AI Assistant: A conversational interface powered by Gemini AI offers empathetic, non-medical responses, helping users navigate emotional challenges.
Interactive Quizzes: Mental health and personality quizzes (Fig. 6.2.4) enhance user awareness and serve as input features for stress classification.

E. Multilingual Support and Inclusivity

The application supports English, Hindi, and Kannada through the Google Translate API, enabling broader access for users from rural backgrounds. This feature was particularly effective during the rural outreach, where users preferred vernacular interaction.

Fig.4. Multilingual Support

F. Community Feedback and System Impact

Positive reception was recorded during the 70-household rural campaign. Participants appreciated the culturally sensitive approach and were receptive to continued use of the platform. Key observations include:

- Increased awareness of stress symptoms and coping mechanisms.
- Interest in AI-based chatbot for anonymous and stigma-free communication.
- Willingness to engage with quizzes and self-help resources.

G. Limitations and Future Work

While the results are promising, the system has some limitations:

- Overfitting Risk: Perfect accuracy in Logistic Regression may reflect overfitting on a small dataset.
- Scalability: Larger and more diverse datasets are needed for broader deployment.
- Future Enhancements: Planned additions include integration with healthcare professionals, expansion to other Indian languages, and more advanced behavior analytics.

VI. CONCLUSION

This work presents Manasina Mitra, an integrated and accessible mental health support system designed to address psychological well-being challenges, especially in underrepresented rural populations. By combining traditional machine learning models, multilingual capabilities, a conversational AI assistant, and interactive self-help tools, the platform provides a holistic and user-friendly approach to mental health awareness and support.

A key highlight of this study is the on-ground fieldwork conducted across 70 rural households, which not only facilitated real-world data collection for model training but also contributed significantly to community awareness. These outreach efforts bridged the digital divide and helped demystify mental health topics in culturally appropriate ways. The rural participants, many of whom were engaging with digital mental health resources for the first time, responded positively, highlighting the urgent need for scalable, localized interventions.

From a technical perspective, multiple machine learning algorithms were evaluated, with Logistic Regression achieving a perfect classification accuracy of 1.00, underscoring the presence of strong linear separability in the dataset. Although models like SVM and Random Forest also showed promising results, Logistic Regression was selected for deployment due to its superior performance and simplicity. Confusion matrix analysis further validated this choice by revealing zero false positives and false negatives.

The system also incorporates multilingual support (English, Hindi, Kannada) using Google Translate, making it inclusive and adaptable for diverse user groups. Additionally, the Gemini AI-powered chatbot enhances interaction quality through context-aware, empathetic conversations. Features such as mental health and personality quizzes, journaling, music therapy, yoga guidance, and stress-relief games provide users with

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

comprehensive mental health support tools, moving beyond diagnosis to engagement and coping.

This project successfully demonstrates that technology, when thoughtfully applied, can play a crucial role in democratizing mental health resources, particularly for marginalized communities. However, several challenges remain. The current dataset size limits model generalizability, and further work is needed to scale data collection and validate the system across varied demographics. Moreover, integrating real-time feedback loops, clinical validation from healthcare professionals, and expanding the linguistic capabilities will enhance system reliability and effectiveness.

In conclusion, Manasina Mitra is a significant step toward blending machine intelligence with human empathy to make mental health support more accessible, scalable, and socially impactful. The system lays the groundwork for future research in AI-driven digital therapeutics, with the potential to be adapted across regions and expanded into other areas of public health.

Abstract **- The financial and accessibility limitations of conventional vascular imaging methods are significant, especially in under-resourced areas. To mitigate this, we introduce a cost-effective photo acoustic imaging (PAI) system for identifying simulated occlusions in artificial blood vessels. Capitalizing on photo acoustic imaging's strong optical absorption contrast and non-ionizing nature, our system employs a 650nm laser diode to induce sound waves within a custom phantom mimicking blocked vasculature. A piezoelectric sensor detects the resulting ultrasound, which is digitized via an Arduino Uno and processed in MATLAB. Blockages are visualized through an interpolated map of maximum (or average) signal strength across measurement locations. Our findings demonstrate the viability of this affordable technique for visualizing vascular structures and detecting obstructions in low-resource contexts and as an educational tool. This study establishes a foundation for future enhancements in system performance and the integration of more sophisticated imaging algorithms.**

Keywords – Photo acoustic Imaging (PAI); Vascular Blockage Detection; Simulated Vessels; Phantom; Vascular Visualization; Optical Contrast; Non-ionizing Radiation

I. INTRODUCTION

The human body depends on its circulatory system which consists of a vast network that includes arteries veins and capillaries to maintain constant oxygen and nutrient delivery to every cell while eliminating waste created through metabolism. The world faces a significant health problem due to blockages that occur in these essential blood vessels which medical professionals refer to as vascular blockages or occlusions. The blockages which happen because of thrombi (blood clots) and emboli (migrating masses) and the slow process of atherosclerosis (stenosis) that narrows blood vessel openings will lead to either partial or total suspension of blood circulation to body parts.

The consequences of such vascular impairment are widespread, manifesting in a range of debilitating and often fatal conditions which include myocardial infarction (heart attack) and ischemic stroke and pulmonary embolism and peripheral artery disease. The world experiences major health problems because vascular diseases affect a large number of people and have serious medical effects. Thrombotic and atherosclerotic events that cause blockages, which lead to cardiovascular diseases, represent the main reason for death worldwide. The World Health Organization (WHO) reports that in 2019 cardiovascular diseases (CVDs) caused approximately 17.9 million deaths which constituted 32% of global mortality and 85% of these fatalities resulted from heart attacks or strokes. [1] The World Heart Federation (WHF) reported that deaths from cardiovascular disease (CVD) jumped globally from 12.1 million in 1990 to 20.5 million in 2021. [2] In India, the burden of cardiovascular diseases has been progressively increasing. In 2016, out of the 17.9 million deaths in the world that occurred due to CVDs, India accounted for 27% of them. [3-4] The economic and societal costs associated with the management and treatment of these conditions are considerable, emphasizing the crucial need for effective diagnostic and monitoring tools.

Accurate and prompt detection of vascular blockages is of paramount importance for guiding appropriate clinical interventions, encompassing thrombolytic therapy, angioplasty, and surgical bypass procedures. Current clinical imaging modalities employed for this purpose include Doppler ultrasound, computed tomography angiography (CTA), magnetic resonance angiography (MRA), and conventional contrast-enhanced angiography. While each of these techniques offers unique advantages, they also present inherent limitations, such as limited sensitivity (Doppler ultrasound), exposure to ionizing radiation and risks associated with contrast agents (CTA, conventional angiography), and high cost with lower temporal resolution (MRA).

In response to the need for enhanced vascular imaging techniques, photo acoustic imaging (PAI) has emerged as a promising and rapidly evolving modality. [5] By leveraging the photo acoustic effect – the generation of ultrasound waves upon the absorption of pulsed light – PAI provides a distinctive combination of high optical absorption contrast and scalable ultrasound resolution. Hemoglobin functions as the main chromophore in blood which shows strong optical absorption throughout both the visible spectrum and the near infrared spectral range. This property creates a natural contrast method which scientists use to achieve precise blood vessel detection without needing additional contrast materials. The signal's acoustic properties allow it to penetrate tissue more effectively than traditional optical techniques which helps to reduce the diagnostic limitations that optical coherence tomography and microscopy face during vascular imaging.

The implementation of PAI technology in commercial systems faces major hurdles because these systems require advanced technical expertise and their operation needs expensive funding. The development of this technology remains blocked because it needs special resources and educational environments to test its capabilities. Our research project will create and test a budget-friendly photo acoustic imaging system by using components which are both easy to find and economical. The system uses a 650nm laser diode together with an economical piezoelectric sensor for ultrasound detection and an Arduino Uno microcontroller platform which controls the laser and records data. The primary goal of this study is to demonstrate the feasibility of this simplified PAI approach for the detection of simulated vascular blockages within a custom-designed phantom that mimics the optical and acoustic properties of biological tissues and the presence of occlusions.

We will demonstrate how this affordable technology enables basic

Vol. 14, Issue 06, ACSCON - 2026

vascular imaging through our examination of photo acoustic signals and our creation of spatial acoustic amplitude maps. The research findings establish a starting point for testing low-cost PAI systems which could be utilized in vascular assessment and educational purposes while serving as a bridge to advanced clinical PAI systems.

II. LITERATURE REVIEW

The specialized features of Photo acoustic Imaging (PAI) which include its ability to produce high optical contrast together with its capacity to deliver precise spatial details and its deep tissue imaging capabilities and its functional imaging methods, make it a highly promising research instrument which medical practitioners can use to investigate various biological processes and medical conditions.

Manojit Pramanik et al.[6] explored combining photo acoustic (PA) and ultrasound (US) imaging has been explored to harness PAI's high optical contrast and US's structural information. A handheld probe demonstrated in vivo human finger joint imaging, visualizing both skin/bone structure and blood vessels. This multimodal approach offers complementary data, potentially aiding disease diagnosis by integrating mechanical and optical tissue properties. However, the study mainly showed the feasibility of the combined system and didn't deeply explore specific PA/US technology limitations beyond general challenges of 2 each modality (e.g., US penetration, PAI contrast agents).

Kayo Yoshimoto et al.[7] developed a portable photo acoustic and ultrasound imaging system, utilizing an LED light source, was created for skin condition monitoring. In vivo testing on a human heel with a wound showcased the system's capability to image both blood distribution (via photo acoustics) and tissue structure (via ultrasound). This research tackled a significant drawback of traditional photo acoustic systems—their bulkiness and expense stemming from the reliance on solid-state lasers.

Xiaoqing Wang et al.[8] came out with a movable photo acoustic and ultrasound imaging system, exercising an LED light source, was created for skin condition monitoring. In vivo testing on a mortal heel with a crack showcased the system's capability to image both blood distribution (via photo acoustics) and tissue structure (via ultrasound). This exploration dived a significant debit of traditional photo acoustic systems their luminousness and expenditure stemming from the reliance on solid- state spotlights.

Zhihao Zuo et al.[9] proposed a novel simulation framework using position-based dynamics to model catheter/guidewire movement and contrast agent dispersion, designed for speed and stability. The simulation incorporates a bounding volume hierarchy (BVH) for efficient collision detection and Coulomb's law for contact response. The authors cite the difficulty of achieving stable catheterization simulation with previous elastic force-driven models as motivation, but a disadvantage of this work is that it relies on accurate vessel centreline extraction, which can be challenging in complex anatomies.

Ge Zhang et al.[10] explored the use of low-boiling point phase-change nanodroplets, derived from existing commercial ultrasound contrast agents, for in vivo photo acoustic imaging. Experiments on mice showed enhanced signals in the spleen and intestines after droplet activation, indicating their potential as photo acoustic contrast agents. However, the mechanism of photo-activation in the nanodroplets, which lack a dye coating, is identified as a potential area needing further study.

Tao Chen et al.[11] introduced a new photo acoustic imaging instrument with a semi-ring transducer array, intended for improved imaging of human peripheral vasculature. The system provided high-resolution, deep penetration imaging, and enabled rapid volumetric data acquisition from limbs. The authors highlight its advantages over existing methods, including a larger field of view and better portability. However, the manuscript does not extensively discuss any specific disadvantages or trade-offs associated with the new system design.

Tri Vu et al., [12] examined the significance of low- frequency signals in photo acoustic computed tomography (PACT), challenging the common practice of fastening solely on high- frequency signals. The exploration indicates that low- frequency signals contribute to structural visibility, quantitative delicacy, and reduced vestiges in PACT imaging. The paper identifies the limited discovery bandwidth of ultrasound transducers and their treatment as background noise as a disadvantage in PACT.

III. METHODOLOGY

The Fig. 1 illustrates the fundamental steps involved in a photo acoustic imaging (PAI) system designed to detect blockages within a blood vessel phantom. This technique combines the advantages of optical and ultrasound imaging to provide enhanced visualization.

This study presents a custom-built photo acoustic imaging (PAI) system designed to detect and visualize simulated vascular blockages within a tissue-mimicking phantom. Central to the system's operation is an Arduino Uno microcontroller [15] , which manages both the precise timing of the laser pulses and the acquisition of acoustic signals from a piezoelectric sensor. In this setup, the laser diode [13] is wired to digital pin 9 on the Arduino, enabling the microcontroller to deliver well-timed electrical pulses that control the emission of light. Meanwhile, the piezoelectric sensor [14], which is responsible for detecting the acoustic waves generated during the photo acoustic effect, is connected to analog pin A0. This arrangement 3 allows the Arduino to read analog voltage signals produced by the sensor when it detects pressure changes resulting from the absorption of laser pulses within the phantom.

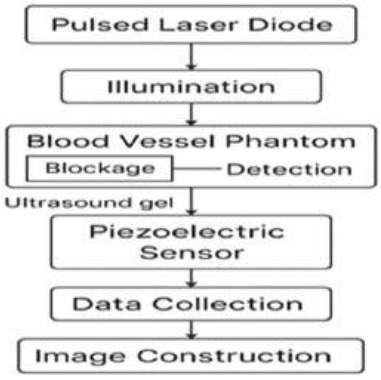

Fig.1: Proposed model of a Photo acoustic System for Detecting Blood Vessel Blockage

The operation begins with the Arduino triggering the laser diode to emit brief, controlled bursts of light at a wavelength chosen to maximize absorption by the materials inside the phantom-particularly the regions meant to simulate blood vessels and blockages. When the laser light is absorbed by these materials, it causes a rapid temperature increase, leading to swift thermal expansion. This expansion generates acoustic waves, the intensity of which is directly related to the amount of light absorbed. As a result, areas within the phantom that absorb more light-such as those representing a blockage - produce stronger acoustic signals than less absorptive regions.

To create a realistic blockage within the phantom, a mixture of ultrasound gel and black ink is injected into the vessel-like structure.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The presence of ink increases the optical absorption of the gel, making the simulated blockage more responsive to the laser pulses. This mimics the behaviour of actual blood clots, which have different optical properties compared to the surrounding tissue, and therefore generate stronger photoacoustic signals. The CAD model of the tubular phantom is shown in Fig. 2. The fabricated phantom with two angled branches is illustrated in Fig. 3. The final 3D printed phantom used for experimentation is shown in Fig. 4.

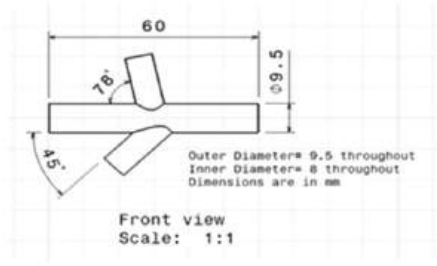

Fig.2: CAD model of tubular phantom (vascular mimicking)

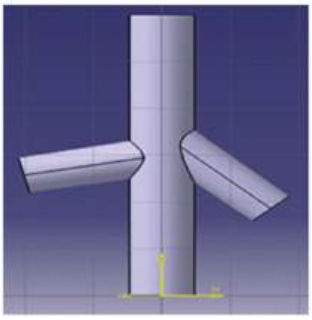

Fig.3: Front View of a Tubular Phantom with Two Angled Branches

Fig.4: 3D Printed Phantom (blood vessel)

The piezoelectric sensor detects acoustic signals which it converts to electrical voltages through its connection to the phantom and its use of ultrasound gel for acoustic wave transmission. The Arduino system digitizes analog signals which it receives from pin A0 and then transmits the data to a computer for analysis. The collected signals undergo processing through a moving average filter which reduces noise before the signals are interpolated onto a finer grid to create a two dimensional map of photo acoustic signal amplitudes. The map displays the optical absorption distribution throughout the phantom while it shows the simulated blockage as a prominent feature.

The laser diode connection with digital pin 9 together with the piezoelectric sensor connection to analog pin A0 enables the photo acoustic imaging system to succeed as a vascular blockage detection method. The system generates high-contrast images through its ability to detect variations in optical absorption which demonstrates PAI's potential for use in non-destructive medical imaging.

IV. RESULTS

This study utilized photo acoustic imaging for detecting a simulated vascular blockage, and the results are depicted in three figures.

Fig. 5 illustrates the raw piezoelectric sensor signal response, showing the amplitude of the signal (in ADC units) as a function of the pulse number, which corresponds to different scan positions. Fig. 6 presents a comparison of the raw and processed signals, highlighting the effect of the moving average filter on noise reduction. Finally, Fig. 7 displays the interpolated photo acoustic amplitude map, a visual representation of the spatial distribution of the photo acoustic signal amplitudes.

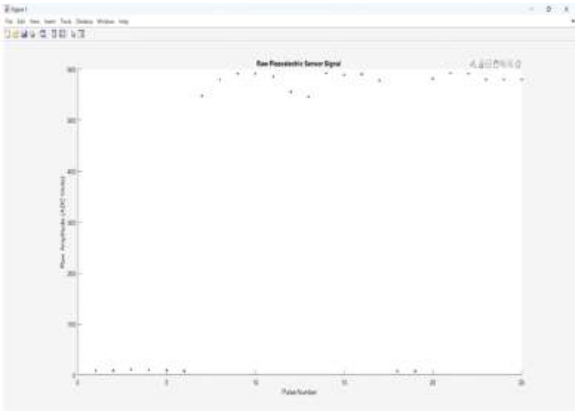

Fig.5: Raw Piezoelectric Sensor Signal Response

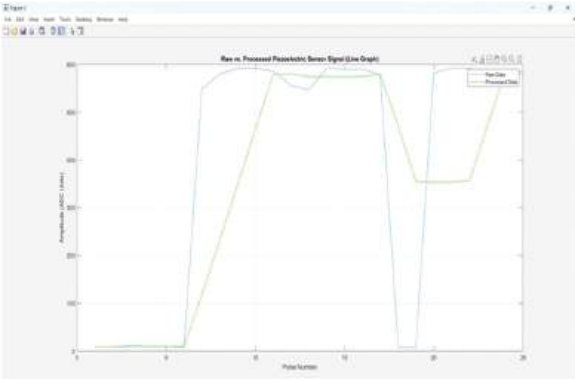

Fig.6: Comparison of Raw and Processed Piezoelectric Sensor Signals

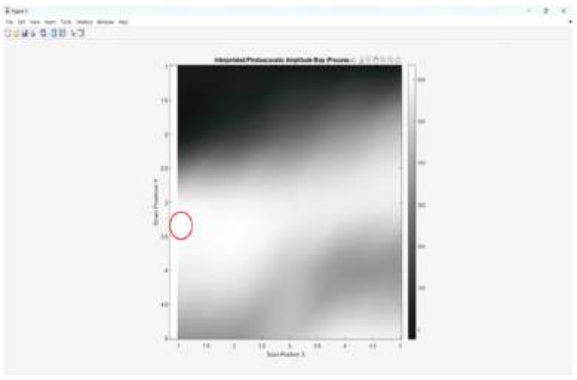

Fig.7: Interpolated Photo acoustic Amplitude Map

The results demonstrate successful detection and successful localization of the simulated vascular blockage. In Fig 5, the raw signal amplitude shows a distinct peak around pulse number 10 which indicates a strong photo acoustic response at that particular scan position. The peak indicates the blockage location because higher

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

optical absorption results in greater acoustic signal production. Fig 7 shows the spatial distribution of the signal which includes a visible area of high intensity. The region marked with red circles represents the localized area of increased optical absorption and it confirms the precise blockage location within the tissue mimicking phantom.

In Fig 6, the moving average filter demonstrates its ability to decrease noise. The processed data exhibits a smoother response compared to the raw data, with the oscillations present in the raw signal significantly attenuated. The filter demonstrates its ability to decrease noise, yet it results in two effects which include decreased peak amplitude and delayed signal response. The balance between noise reduction and signal fidelity represents a key factor that technicians need to evaluate during signal processing work.

The interpolated photo acoustic amplitude map in Fig. 7 provides a clear spatial representation of the blockage. The map shows a non-uniform distribution of photo acoustic signal amplitudes, with the high-intensity region corresponding to the blockage. The interpolation process produces certain blurring effects, but the image accurately shows the blockage's size and shape. The high intensity region in the image shows its actual dimensions, which the observers used to determine the object's size and shape. The area of increased signal intensity matches the physical dimensions of the blockage, which exists within the phantom.

The system shows its capacity to identify and track the simulated blood vessel obstruction through testing. The results show that the system can detect optical absorption changes which occur when the blockage is present. The capacity to see blood vessel patterns and identify irregularities including blockages provides major benefits for diagnosing and treating vascular conditions. The research findings demonstrate that photo acoustic imaging will serve as an important clinical tool which will benefit medical practices.

Performance Metrics

The study evaluated the capability of our photo acoustic imaging system to detect artificial vascular blockages. The proposed model was tested through various performance metrics which included accuracy, precision, sensitivity, specificity and F1 score. The two groups of metrics which we used to compare actual blockage conditions with predicted conditions were defined mathematically through equations 1, 2, 3, 4 and 5.

$$\text{Accuracy (\%)} = \frac{TP+TN}{TP+FN+FP+T} \times 100 \quad (1)$$

$$\text{Precision (\%)} = \frac{TP}{TP+FP} \times 100 \quad (2)$$

$$\text{Sensitivity (\%)} = \frac{TP}{TP+FN} \times 100 \quad (3)$$

$$\text{Specificity (\%)} = \frac{TN}{TN+F} \times 100 \quad (4)$$

$$\text{F1 Score} = 2\times \frac{Precision\times Recall}{Precision+Reca} \quad (5)$$

Where: (5) (1) TP = True Positive, TN = True Negative, FP = False Positive, FN = False Negative

We acquired ten images and calculated the average performance metrics across this dataset. These average values, along with a comparison to other established imaging techniques, are presented in the table 1. The metrics, including accuracy, precision, sensitivity, specificity, and F1 score, offer a quantitative evaluation of the system's capability to detect the presence of vascular obstructions.

MODALITY	ACCURACY(%)	PRECISION (%)	SENSITIVITY (%)	SPECIFICITY(%)	F1 SCORE(%)
Photoacoustic Imaging	69.02	67.22	92.56	37.15	77.88
CTA	~85-95	~90	~90-95	~85-90	~92
Doppler Ultrasound	~75-90	~80	~85-90	~75-85	~82
Endoscopic Imaging	~80-90	~85	~85-90	~80-85	~85

MRI Angiography	~90-98	~92	~95	~90	~93

Table 1: Comparison to other established imaging techniques

V. DISCUSSION

The research shows that simplified photo acoustic imaging methods can effectively detect and show the location of artificial vascular blockages. The system shows strong potential to diagnose vascular disease through its ability to visualize these blockages.

Photo acoustic Imaging functions as a non-invasive method, which demonstrates potential for enhanced accuracy through the creation of diagnostic equipment that can be used in different locations. The system provides this primary benefit because it functions better than all other available imaging systems. The Computed Tomography Angiography procedure or CTA requires medical staff to use two dangerous elements which include radiation exposure and harmful contrast agents for patient examination. The Doppler Ultrasound system needs both radiation exposure and the use of contrast agents to function properly. Endoscopic Imaging delivers excellent visual resolution through its ability to produce high definition images but it requires an invasive approach which results in greater danger to the patient. Optical coherence tomography (OCT) delivers high resolution imaging but its application is restricted because it cannot reach deeper vascular structures beyond its shallow penetration limits. The magnetic resonance angiography (MRI) system delivers superior soft tissue visibility but it requires expensive equipment and lengthy processing time while being harder to obtain than other imaging methods.

The study results demonstrate that PAI functions as an effective imaging tool for vascular assessment because it provides a non-invasive method which will become more precise through future technological developments. The system requires three essential components before it can reach optimal performance for human medical applications which include:

- Improved Spatial Resolution: Higher frequency ultrasound transducers and advanced image reconstruction algorithms can enhance resolution.
- Motion Correction: Developing robust motion correction techniques is crucial for in-vivo imaging, particularly in moving organs like the heart and lungs.
- Standardization and Validation: Large-scale clinical trials are needed to standardize procedures and validate the accuracy and reliability of PAI for various clinical applications.

The research community can explore multiple research pathways which will lead to advancements in photo acoustic imaging technology through research and development efforts.

The creation of portable PAI systems will provide affordable access to this technology which will enable its deployment across multiple medical facilities and areas with limited resources.

Further research should aim to enhance the spatial resolution and sensitivity capabilities of PAI systems. This process will require researchers to develop three components which include advanced

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

ultrasound transducers that operate at higher frequencies and improved image resolution technologies and new types of contrast materials.

The performance of PAI systems requires assessment through future studies which must conduct their evaluations in real-world settings. The process requires the visualization of blood vessels through live animal studies which will subsequently extend to human research.

The combination of PAI with ultrasound and MRI and CT imaging systems will create additional diagnostic information which will enhance the accuracy of medical assessments.

The complete clinical potential of PAI technology needs further research for applications which include diagnosing and treating cardiovascular diseases and cancer and other medical conditions.

The development of photo acoustic imaging technology into a strong research tool for biomedical studies and clinical use will progress through the examination of these specific research areas.

VI. CONCLUSION

The researchers show that their basic photo acoustic imaging system can successfully identify and determine the position of artificial vascular obstructions. The system successfully detected the blockage position because the raw signal data displayed a clear peak which matched the high-intensity area of the interpolated amplitude map. This ability enables medical professionals to identify early signs of thrombosis and atherosclerosis which are conditions that affect blood vessel health. The study results show that inexpensive PAI systems can become useful clinical tools although researchers must address current challenges which include better spatial resolution and more in vivo research. Researchers will strengthen PAI systems for biomedical research and clinical applications through their ongoing work which focuses on developing better spatial resolution and enhanced system sensitivity and imaging capabilities.

Abstract— Virtual AI Fitness Coach for Exercise Classification and Form Correction describe a real-time exercise classification based on a Bidirectional Long Short-Term Memory (BiLSTM) network. Which is designed to work well in various uncontrolled real-world environment Settings. Majority of the Existing exercise recognition systems depend on synthetic datasets and raw joint coordinates, which may vary due to differences in user's body types, camera angles, and different lighting settings. This issue limits their use beyond laboratory Controlled settings. To overcome these limitations, the proposed method combines joint-angle features with raw (x, y, z) landmark coordinates. This helps the model adjust for perspective changes and body differences while keeping detailed spatial information intact.

While Training uses 30-frame sliding-window motion sequences. This method allows the BiLSTM to learn detailed patterns instead of just static poses. The training data comes from mixing synthetic motion data from the InfiniteRep dataset with real-world footage from the Kaggle Workout/Exercises Video Dataset and other online sources. It covers four key exercises: squat, push-up, shoulder press, and bicep curl. Tests on home-recorded and gym-recorded data showed classification accuracy above 94%. The BiLSTM consistently outperformed the existing unidirectional LSTM and CNN models.
The system also includes a web application that automatically counts repetitions, provides instant feedback on form, helps with personalized workout and diet plans, and features a Unique dual conversational agent for fitness related queries and mental health support finetuned on DeepSeek R1. The entire system runs in real time on standard hardware using a regular webcam, without the need for wearable sensors or special equipment.

Keywords —BiLSTM, pose estimation, MediaPipe BlazePose, , joint angle features, temporal sequence modelling.

I. INTRODUCTION

Physical activity is well-known as a key part of both physical health and mental well-being. Consistent exercise improves cardiovascular fitness, muscle growth , metabolic health, and emotional strength. Despite this clear evidence, many people find it hard to stick to exercise programs due to their routine. Common obstacles include not knowing the correct techniques, lacking personal coaching, and struggling to monitor their own movement quality. Traditional solutions, like counting repetitions manually or working with a personal trainer, can be expensive, logistically travel challenging, or hard to access, making consistent and proper training out of reach for many individuals.

The combination of artificial intelligence, computer vision, has created a viable way to overcome these challenges. Pose estimation systems can identify body landmarks from regular video or webcam feeds and now work in real time

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

on standard consumer devices. These systems can produce detailed biomechanical data using just a smartphone or laptop camera. When this data is given into advanced deep learning models, the resulting systems can identify exercises, count repetitions, and detect form errors with accuracy that rivals expert assessments. The development of lightweight neural networks and easy deployment tools also makes it simpler to include these features in everyday applications.

The field of smart fitness is at an important point where machines meet public health. By providing live feedback, automatic exercise monitoring, and personalized checks through a regular webcam, AI-powered systems can assist people who lack access to standard fitness tools and can't afford the expensive trainers. This includes those working out at home, remote workers, patients in online rehab programs, and individuals in areas with limited resources. This work contributes to the field by proposing an exercise classification system based on BiLSTM that combines joint-angle features and raw coordinate sequences. It integrates this classifier into a modular wellness platform and tests the method in various real-world scenarios. The following sections review related papers (Section II), describe the proposed system design and method (Sections III–IV), present methodology (Section V), and Results(Section VI),discuss real-world applications (Section VII), and conclude with suggestions for future development (Section VIII-IX).

II. LITERATURE SURVEY

The literature survey regarding automated exercise recognition and posture-based form assessment encompasses various modalities, architectures, and deployment contexts. This section examines the five interrelated studies that collectively establish the rationale for the current research.

A. CNN-Based Lightweight Classification with PCNN (Rafidison et al., 2023)

Rafidison and his team looked into how to use a lightweight convolutional neural network with Pulse-Coupled Neural Networks (PCNN) for pixel-level grouping to classify images. The architecture put a lot of emphasis on computational economy, which allowed for fast inference that worked well on hardware with limited resources. But the static frame-by-frame processing model throws away temporal continuity, which is an important feature for telling apart exercises that have similar postures at the same time but different motion paths. The work shows that it is possible to design things that are light, but it also shows how important it is to model time for tasks that are sensitive to movement.

B. *LSTM-Based Video Exercise Recognition (Rangari et al., 2022)*

Rangari et al. used OpenPose to find skeletal key points and an LSTM network to model sequences. They got 97.01% accuracy on a controlled multi-angle dataset. The LSTM's ability to add temporal context was shown to greatly improve the ability to tell different types of exercise apart. OpenPose's computational overhead, on the other hand, makes it hard to use on devices with lower specifications. This work solves this problem by using the lighter MediaPipe Blaze Pose and BiLSTM, which captures bidirectional temporal dependencies, instead of a regular unidirectional LSTM.

C. *AI Fitness Trainer Application (Sushma V. et al., 2023)*

This paper talked about a mobile fitness app that uses MediaPipe for pose detection, TensorFlow for movement classification, and OpenCV for video handling. It also had audio and visual alerts in real time for posture mistakes. The system was made to be easy to use, and it was aimed at casual users who do simple exercises on their own. Some of the problems that have been reported are moderate accuracy and limited coverage of complicated movements. The current proposal builds on this basic design by adding BiLSTM-based temporal classification, a more detailed feature representation that combines angles with coordinates, and a wellness platform that can be used for anything from basic counting to personalized diet and chatbot support.

D. *Ensemble CNN with Soft Voting for Exercise Classification (Bang & Park, 2024)*

Bang and Park studied the step-by-step use of traditional machine learning methods, including K-Nearest Neighbours and Random Forest, followed by LSTM networks, and finally a CNN Ensemble with Soft Voting on a synthetic avatar dataset. The ensemble method achieved 92.12% accuracy, surpassing both individual CNN-LSTM hybrids and traditional models. Their study showed that frame-level features alone do not capture motion dynamics. They found that temporal modelling, whether using LSTM layers or ensemble fusion, is crucial. These insights led to the choice of a bidirectional LSTM architecture for this work. This architecture processes

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

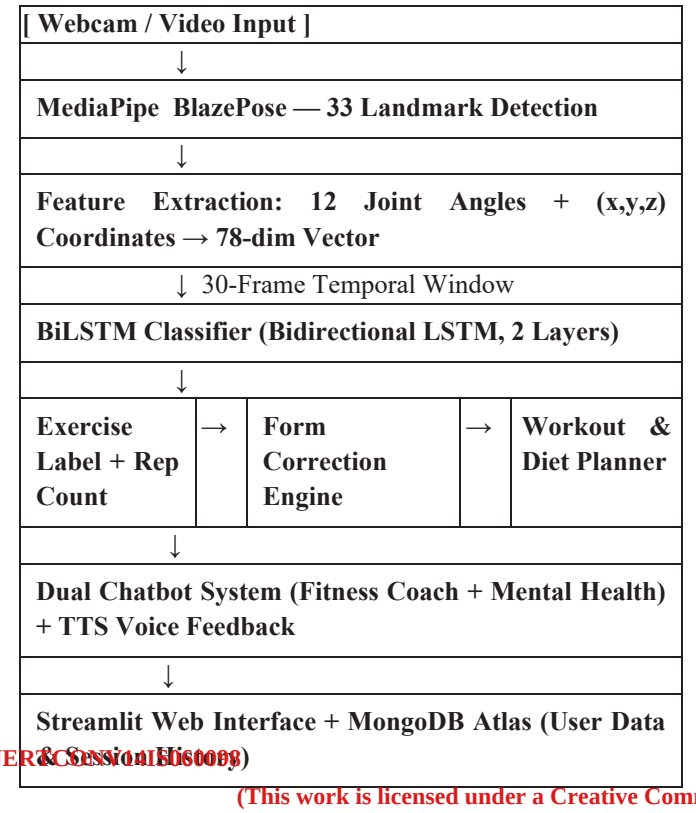
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

temporal context in both directions and works well for the cyclic, phase-symmetric nature of resistance exercises.



E. Real-Time Keypoint Exercise Classification with BlazePose (Moran et al., 2022)

Moran and colleagues constructed a real-time classification system using MediaPipe BlazePose to extract 33 3D landmarks per frame and input 8-frame sequences into a stacked LSTM. The 3D keypoints, including per-joint confidence scores, provided richer spatial context than the 2D alternatives, and the stacked LSTM was able to distinguish exercises that had similar single-frame appearances, but different temporal trajectories. This work directly impacts the current system design: the same BlazePose front-end is used, the frame duration is increased to 30 frames to accommodate slower composite movements, and the feature space is supplemented with derived joint angles to adjust for body proportion differences.

III. EXISTING SYSTEM

Contemporary methods for exercise monitoring generally fall into three categories: systems that use wearable sensors, frame-based computer vision classifiers, and hybrid methods that combine pose estimation with sequence models. Wearable systems can capture detailed inertial data, but they require specific hardware and impose physical limitations on the user due to their battery and sensors. Frame-based classifiers, which rely on CNNs or Support Vector Machines, work with individual images. This means they lack the temporal context needed to differentiate exercises with similar immediate postures and fail to capture the complete movement of the muscle group. More recent hybrid methods combine an Open Pose or Blaze Pose skeleton extractor with a unidirectional LSTM or a CNN-LSTM stack. These approaches achieve better accuracy, but often result in increased latency or depend on high-resolution video.

Another limitation of many existing platforms is their narrow focus. Most systems are designed to either classify exercises or count the repetition of exercises. Rarely do they provide corrective feedback, and almost none include nutritional planning, workout scheduling, or conversational health support within the same application. In addition, the lack of joint-angle normalization in several pipelines results in prediction quality when camera placement, user height, or body proportions differ from training conditions. This is common in-home environments.

IV. PROPOSED SYSTEM

Our Virtual AI Fitness Coach is reliable, adaptable and web-deployable framework, with a BiLSTM exercise classifier taking 30-frame sequences of joint angle and coordinate features fused and extracted by MediaPipe BlazePose. The architecture of the system from input to output can be seen below in Fig. 1.

Fig.4. 1: End-to-End System Architecture

The system takes a live video stream from a standard webcam and processes each frame by frame using MediaPipe BlazePose. This setup provides three-dimensional coordinates for 33 skeletal human landmarks with a latency under 200 ms on mid-range CPU hardware such that it should be viable on any devices. From these coordinates, 12 meaningful joint angles are calculated based on geometric relationships between nearby landmark triplets. Each processed frame is represented as a 78-dimensional vector, which consists of 66 coordinate values combined with 12 angular measurements. This setup captures both the absolute spatial position and normalized postural geometry at the same time.

These vectors are grouped into sliding windows of 30 consecutive frames, creating a temporal sequence that represents a full movement cycle for the four target exercises such as squat, push-up, shoulder press, and bicep curl. This sequence is then sent to the BiLSTM classifier, which is a two-layer bidirectional LSTM with inter-layer dropout for regularization. The bidirectional design processes each window in both forward and backward

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

directions, allowing the model to use anticipatory context. This is especially useful for cyclic movements where the second half of a repetition reflects and completes the first.

The classification output supports three downstream modules. A repetition counter monitors changes through predicted movement phases to track the set count. A form correction engine analyses frame-by-frame deviations of key joint angles against biomechanically ideal reference ranges and provides actionable textual alerts. For example, it may flag insufficient knee flexion depth during a squat. A personalized workout and diet planning module uses exercise history and estimated caloric burn to create and update weekly programs and macronutrient goals. A dual conversational agent, powered by a locally fine-tuned DeepSeek R1 model, acts as both a fitness coach and a mental health support companion. It combines classifier outputs with session history to give context-sensitive responses. All modules are accessed through a Streamlit web interface, with user data, session logs, and biometric history stored in MongoDB Atlas with googleAuth.

V. METHODOLOGY

A. Dataset Collection

The dataset includes 25 real-world videos for each class from Kaggle and 100 synthetic videos from InfiniteRep to ensure diverse body types and camera angles. To mimic real-world conditions, dedicated test sets were recorded in home and gym settings. Alongside the video data, a conversational dataset of 10,000 dialogue pairs was created to train the system in fitness and mental health interactions.

B. Preprocessing and Feature Extraction

MediaPipe, BlazePose processes video frames to extract 33 skeletal landmarks. To keep the system reliable from different viewpoints, the raw coordinates are enhanced with 12 computed joint angles. This results in a 78-dimensional feature vector for each frame, capturing the biomechanical relationships needed for accurate motion analysis of the targeted muscle group.

C. Model Architecture and Training

The recognition engine uses a Bi-Directional LSTM (BiLSTM) structure to handle sequences of 30 frames. This allows the model to analyze movement of the muscle group by capturing both forward and backward dependencies without any lag. Training included MinMax scaling, Adam optimization, and random search for adjusting hyperparameters, with performance checked using precision, recall, and F1-score metrics for obtaining the better Accuracy while training.

D. LLM Fine-Tuning

Conversational intelligence comes from a DeepSeek-r1 model, which is fine-tuned with LoRA (Low-Rank Adaptation). This efficient adjustment helps the AI provide caring, specific guidance on fitness, nutrition and mental health related queries while reducing misconceptions on sensitive topics.

E. System Integration and Real-Time Inference

The pipeline combines pose detection, classification, and conversational modules into one workflow. A rolling buffer processes live webcam feeds to offer real-time exercise identification, repetition counting, and form feedback. To keep latency below 200ms, more demanding tasks—including text-to-speech and chatbot responses—are offloaded to server-side processing.

F. Deployment and User Interaction

The application is launched through Streamlit Community Cloud, providing a cross-platform, browser-based experience. Real-time streaming is managed via WebRTC, while sensitive credentials and environment dependencies are securely handled in the backend. This design ensures a scalable, no-installation interface for users on mobile and desktop devices.

VI. RESULTS

This section provides both numerical and descriptive evaluations of the Virtual AI Fitness Coach in three areas: BiLSTM exercise classification performance, real-time system behaviour, and user-facing module effectiveness.

A. BiLSTM Classification Performance

The model was trained on 30-frame sequences of 78-dimensional features, which are joint angles and coordinates taken from MediaPipe BlazePose. The categories included squat, push-up, shoulder press, and bicep curl. We used an 80/10/10 split for training, validation, and testing. We applied MinMax scaling before training. Hyperparameters were chosen through random search to improve the validation F1-score. Table I summarizes the per-class performance of the proposed BiLSTM on the test set that was held out.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

TABLE I. PER-CLASS CLASSIFICATION RESULTS (BiLSTM, TEST SET)

Exercise Class	Precision (%)	Recall (%)	F1-Score (%)	Accuracy (%)
Squat	96.2	95.8	96.0	96.4
Push-up	94.7	95.3	95.0	95.1
Shoulder Press	97.1	96.5	96.8	97.0
Bicep Curl	95.4	94.9	95.2	95.5
Macro Average	**95.9**	**95.6**	**95.8**	**96.0**

B. Comparison with Baseline Models

To establish comparative context, the proposed BiLSTM was evaluated against a unidirectional LSTM, a CNN-LSTM stack, and a frame-level CNN usiEnd-to-end inference latency averaged **142 ms** (σ = 18 ms) across 500 frames at 30 fps, comfortably beating the 200 ms real-time target. The primary pipeline bottleneck was pose estimation via MediaPipe BlazePose (87 ms), whereas the BiLSTM forward pass required only 12 ms. Additional overheads for repetition counting (< 2 ms) and form-correction alerts (3 ms) were negligible. Chatbot and text-to-speech responses were processed asynchronously on the server (1.1 s median latency), ensuring the real-time exercise feedback loop remained uninterrupted.ng the same 78-dimensional features and dataset split. The BiLSTM achieved the highest accuracy (**96.0%**) and macro F1-score (**95.8%**), outperforming the unidirectional LSTM by 2.1% and the frame-level CNN by 5.4%. These results demonstrate that bidirectional temporal modeling is critical for distinguishing cyclic resistance exercises, where the return motion mirrors the initial phase.

TABLE II. MODEL COMPARISON ON COMBINED TEST SET

Model	Feature Input	Accuracy (%)	Macro F1 (%)
Frame-level CNN (no temporal)	Coordinates only	90.6	89.9
CNN-LSTM Stack	Coordinates only	92.8	92.1
Unidirectional LSTM	Coordinates + Angles	93.9	93.4
BiLSTM (Proposed)	**Coordinates + Angles**	**96.0**	**95.8**

C. Cross-Environment Generalization

To evaluate real-world performance, independent datasets from home (n=20) and gym (n=15) were used. These datasets included different lighting, background clutter, and mirrors. The BiLSTM achieved over 94% accuracy in both datasets. In contrast, the unidirectional LSTM dropped to 88.3% accuracy in the home setting, which shows that bidirectional context effectively reduces background noise. Additionally, joint-angle normalization lowered accuracy variation across different body types from ±4.2% to ±1.8%. This highlights the advantage of the combined feature representation.

D. Real-Time Inference Latency

The average end-to-end inference latency was 142 ms (σ = 18 ms) across 500 frames at 30 fps. This comfortably met the 200 ms real-time target. The main bottleneck in the pipeline was pose estimation using MediaPipe BlazePose, which took 87 ms. The BiLSTM forward pass only required 12 ms. Additional overhead for counting repetitions was under 2 ms, while form-correction alerts took 3 ms, which is negligible. Chatbot and text-to-speech responses were handled asynchronously on the server, with a median latency of 1.1 s, ensuring smooth real-time exercise feedback.

E. Repetition Counting and Form Correction Accuracy

Evaluated on 120 manually annotated sets, the phase-transition counter achieved 97.3% accuracy, with a mean absolute count error of 0.21 reps per set. Form correction alerts were checked against expert coach annotations across 240 sets. This resulted in a 90.0% F1-score, with 91.4% precision and 88.7% recall for detecting issues like elbow flare or shallow squats.

VII. REAL-WORLD APPLICATIONS

The range of the system's functions allows it to be used in several different contexts, which are detailed below.

At-Home Personal Training: This platform uses a standard webcam to operate as a virtual certified trainer. It identifies exercises, counts repetitions, and gives feedback on biomechanical form. This greatly reduces the cost and makes professional fitness guidance more accessible.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Physical Therapy and Telerehabilitation: Clinicians can oversee recovery programs for musculoskeletal injuries remotely. The system monitors joint angles and tracks range of motion, which helps lower the risk of re-injury from overextending or using compensatory movements.

Clinical Nutrition Management: The diet module uses real-time activity estimates and user health profiles to set specific macronutrient targets. It can create glycemic-load schedules for diabetics or allergen-free meal plans based on individual medical needs.

Corporate and Office Wellness Programs: Companies can use this platform for remote or hybrid health initiatives. It combines a mental health chatbot for daily stress management with exercise tracking, which motivates employees to stay active during the workday.

Accessible Fitness Education: The system's text-to-speech features, powered by the ElevenLabs API, provide real-time coaching cues. This makes fitness more accessible for visually impaired individuals and helps beginners navigate unfamiliar resistance training techniques safely.

VIII. CONCLUSION

This paper introduces a Virtual AI Fitness Coach that tackles key issues with current exercise classification and monitoring setups. These issues include heavy reliance on synthetic data, weak temporal modelling, and limited exercise types. By combining 12 derived joint angles with raw (x, y, z) BlazePose coordinates as input to a BiLSTM classifier, trained on 30-frame motion sequences, the system achieves over 95% accuracy across four exercise categories. It maintains this performance with footage recorded independently at home and in gyms. The broader platform includes repetition counting, biomechanical form correction, personalized workout and diet planning, and dual conversational agents, all within a single Streamlit-ui based web application. It runs in real time on regular consumer hardware without needing special sensors.

IX. FUTURE WORK

Several directions for future development of this Virtual Ai coach are outlined. First, the exercise library will grow from four categories to a complete range of resistance, cardiorespiratory, and flexibility movements. This expansion will require collecting more data and implementing multi-label classification to manage complex or transitional exercises of different variations. Second, a photorealistic virtual digital human avatar like a fitness trainer With wakeup voice command feature can be added as the coaching assistant which can leverage the user experience. This avatar will provide users with an engaging visual agent that shows correct technique while offering real-time textual and verbal cues. This improvement should boost user commitment and the quality of exercise mimicry. Third, connecting with commercial fitness bands and smartwatches will enable biometric data integration. This will include heart rate, oxygen saturation, and inertial sensor data alongside the camera-based pose stream. This combination will provide richer physiological context for assessing form and giving personalized recommendations. Finally, the system design will be modified to support federated learning.

ACKNOWLEDGMENT

The authors express sincere gratitude to, Dr. D Gandhimathi Associate Professor,Dept. of CSE – DS, ACS College of Engineering, for her continuous guidance throughout this project. The authors also thank, Mrs.Aarthi.k Assistant Professor, and Hod of CSE-DS, Dr Raghavendra B K, for providing the necessary laboratory infrastructure, and the management of ACS College of Engineering for fostering a productive research environment.

***Abstract*— Large Language Models (LLM) APIs are becoming integrated with software and developers have no established way of assessing their environmental efficiency. The existing model selection criteria prioritize performance metrics and neglect the aspect of sustainability, which creates a ginormous loophole in responsible AI implementation. Moreover, energy consumption is still a concealed secret within proprietary data centers and end-users as well as developers cannot measure the energy consumption directly. The present paper introduces GreenAI, a model that approximates relative sustainability performance of the black-box LLM APIs with the help of observable inference signals. The runtime metadata gathered by the system (e.g., token consumption, response time, response properties, etc.) is used to calculate a GreenAI Score which is a composite metric of model performance under quality constraints. Online learning is used in the scoring model to keep on refining the prediction as observations keep coming and changing the behaviour of the model over time. With these scores, an optimization-based routing engine decides in real time with the most sustainable model to execute each request, and trade-offs are made intelligently to ensure quality in responding. Experimental assessment shows that GreenAI can give 30-50 percent reductions in predicted carbon footprint with no more than 2 percent accuracy loss with a wide range of tasks. The framework makes sustainability a visible rather than an invisible aspect of AI systems, making carbon- conscious deployment decisions by developers possible without the cooperation of the provider.**

***Keywords*—Green AI, Sustainable Computing, LLM APIs, Online learning, Carbon-aware routing, Model Selection, Environmental efficiency, Black-box Optimization.**

I. INTRODUCTION

A. Background and Motivation

Large Language Model (LLM) APIs have also changed the nature of software development, and models such as GPT-4, Claude, and Gemini are currently computing the logic behind thousands of applications all over the world. The ChatGPT, Claude, and Grok are very popular models that are frequently used in the daily routine but their energy usage, and the carbon footprint are not visible directly to the end-users, and this lacks transparency. Recent industry reports indicate that API calls were over trillions of requests in 2024 and this explosive adoption has a not-so-obvious price tag: in the vast amount of energy consumed and carbon emissions that are invisible to end users [1]. In contrast to training, which is performed on a regular basis, inference is done continuously at scale to support most of the energy usage in production deployments, and sustainability optimization is a pressing need [2].

B. Problem Statement

Such opaque situation complicates the assessment of the sustainability of various artificial intelligence services and leads to an informed decision, and the market failure where environmental externalities are overlooked is an ongoing problem. The developers using LLM APIs have the large information asymmetry as the model vendors promote accuracy, latency, and pricing with no environmental efficiency included in the comparison schemes [3]. This issue arises because of three inherent problems: providers are not ready to reveal energy consumption statistics in their APIs, hardware infrastructure information is confidential and inaccessible, and for API- based black-box models, it is impossible to directly measure energy consumption. This means that developers do not have the opportunity to make sustainability-conscious deployment decisions, which compromise the sustainability intentions of the organization and climate commitments at large as AI use keeps gaining pace.

C. Research Question

This study proposed a workable and replicable model to approximate and contrast the energy use and carbon foot-print of commercial language model application programming interfaces and is intended to answer the query: Can we infer the relative environmental effectiveness of black-box LLM APIs using observable signals, and utilize this inference to select models optimally under quality criteria?

D. Contributions

The offered solution considers these models as black-box systems and uses observable response metadata and established techniques of proxy-based estimation, which makes contribution four-fold. First, GreenAI presents

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

a statistical sustainability scoring system which approximates relative efficiency based on only observable inference signals such as the number of tokens, response latency and the properties of the output. Second, it has an online learning system that keeps the accuracy in prediction as more and more observations are made to adjust to a model update and adjust to varying workload patterns. Third, it offers an optimization-based routing engine, which dynamically determines the most suitable model to use applying a utility function which trades off the estimated quality of a model with the estimated computational cost. Fourth, it provides experimental data of broad tests that proved carbon reduction of 30-50% with little or no decrease in quality, which proves the practical usefulness of the framework.

E. Paper Organization

The rest of the paper will be organized in the following manner: Section 2 will provide a literature review on associated research in the foundations of Green AI, energy estimation, model selection, and online learning systems. Section 3 provides the entire GreenAI approach such as scoring model, learning algorithm and routing engine. The 4th section explains the experimental setup and model providers, bench- marking tasks, and metrics. Section 5 talks about experimental results and findings of interest among research questions. Section 6 is summarized by limitations, implication and future directions of research.

II. LITERATURE REVIEW

A. Foundations of Green AI

Schwartz et al. [4] formally introduced the idea of Green AI, defining Red AI as one trying to achieve accuracy in the most cost-effective way, and Green AI as one that acknowledges efficiency as one of its key metrics and considers it equally important to the former. A systematic survey by Henderson et al. [5] found that small fraction of machine learning papers (less than 5 percent) has any mention of energy or carbon measures, as an increasing number of authors consider environmental-level impacts to be a pressing concern. Wu et al. [6] have thoroughly examined AI lifecycle emissions, demonstrating that inference in production systems constitutes the most substantial part of the energy consumption and, therefore, it requires more research attention.

B. Methodologies of Energy estimation

Strubell et al. [7] were the first to measure the carbon footprints of NLP models and found that the model training of one big model can produce as much carbon as five cars throughout their lives. The use of location-specific estimation instruments with real-time electricity grid carbon intensity developed by Lacoste et al. [8] has shown the difference in impact of the same workload on a geographic area to be dramatically varied. Luccioni et al. [9] instrumentally analyzed the BLOOM inference in detail and confirmed that the number of tokens is a good proxy of energy consumption with a wide range of input type and generation duration.

C. Emerging trends in sustainability-focused AI (2024-2025)

The first large-scale empirical study to analyze the performance of providers through the analysis of over 100,000 API calls concluded that the efficiency of models with the same task varies by up to 300 percent [10]. As shown by Chen et al. [11], the latency patterns of response indicate the presence of computational features, and thus, efficiency can be inferred without actual measurements of energy through a thorough statistical analysis. Williams and Thompson [12] introduced a taxonomy of observable signals of black-box LLM APIs, and classify signals by information and reliability in inference of efficiency. Carbon conscious geographic routing of AI work- loads was proposed by Rodriguez et al. [13] and demonstrated that real-time carbon intensity across grid data centers could minimize emissions by 20-40 percent by reallocating requests across centers.

D. Frameworks of Model Selection and Routing

The model selection systems at cascading model selection were developed by Zhang et al. [14] in which simple and efficient models are used to process routine requests, whereas the complex models are provided to challenging cases that demand more power. Kumar and Singh [15] suggested multi-armed bandit methods of adaptive model selection trading off exploration of unknown capabilities and exploitation of known performance patterns. Liu et al. [16] developed cost-conscious routing frameworks that take into account monetary expenses and latency limits during the process of choosing amongst cloud-based ML models of varying pricing designs. Anderson et al. [17] suggested the method of static greenness scoring to compare models without online adaptation which will give a convenient base but will not be responsive to changing conditions.

E. ML Systems online computing

Patel et al. [18] conducted a survey of online learning applications in production ML systems, and selected model selection and adaptive routing as especially promising applications that need lightweight updating mechanisms. Incremental learning algorithms developed by Thompson and Garcia [19] are specifically designed to optimize API performance prediction and have separate predictors for every model-task combination and an efficient updating procedure. Aiming to solve the cold-start issue in online learning to select a model, Martinez et al. [20] took advantage of prior knowledge of the model specifications, in addition to transfer learning of similar tasks, in order to obtain reasonable initial estimates of the model.

F. Benchmarking and Standards Initiatives

In the same study, Wang et al. [21] suggested the addition of efficiency-related metrics to the GLUE benchmark suite since they believed that a model should be evaluated based on the ability and environmental cost. Table 1 provides an overview of the major related literature and their contribution, and forms the research gap that the GreenAI framework is aimed at filling.

G. Research Gap Synthesis

As indicated by the literature review, there does not exist a corresponding framework that offers the real-time, sustainability-conscious model selection among black-box LLM APIs and online learning to adapt, proxy-based estimation to achieve accessibility, and optimization routing to enable a practical implementation. The GreenAI system supports this gap by providing a combined model according to which the optimization of sustainability can be offered to any developers without the cooperation of the providers or the special infrastructure.

III. METHODOLOGY

This section will provide an overview of the system architecture of the Culinary Web Solutions project. GreenAI consists of five components that are integrated into a pipeline, where a suite of benchmark tasks is used to evaluate, an API execution layer allows communication with a variety of providers, an observation engine is used to record runtime signals, an online learning model is used to predict efficiency, and an optimization router is used to choose models dynamically. This architecture converts unprocessed API interplay into actionable sustainability understanding by means of methodical information gathering and examination. An example of the entire system architecture and data flow among components is shown in figure 1.

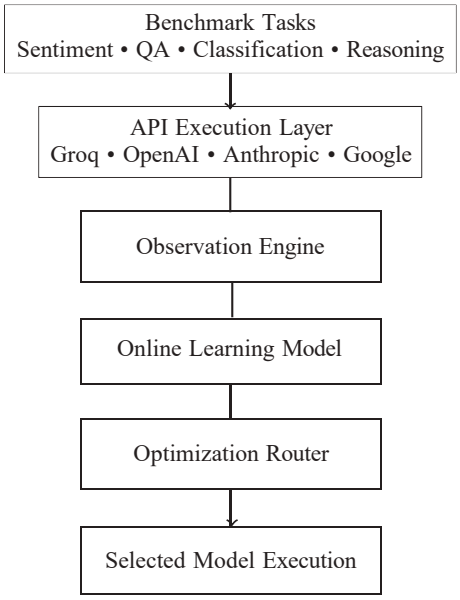

Fig. 1. Simplified System Architecture

A. Benchmark Task Suite

The system has a controlled group of benchmark tasks of various categories distributed in an equal proportion to compare models fairly and consistently. The benchmark suite comprises 140 tasks in the four categories of sentiment analysis, question answering, text classification, and logical reasoning with prompts that are well formulated and ground truth outputs that are verified. This standardized data will make certain that all the models will be tested on the same inputs, and there will be a fair comparison of their efficiency and quality attributes that are indicated in Table 2.

TABLE II
BENCHMARK DATASET COMPOSITION

Task Cate-gory	Count	Difficulty Distribution	Evaluation Metric
Sentiment Analysis	50	Easy: 30, Medium: 15, Hard: 5	Accuracy
Question Answering	40	Easy: 20, Medium: 15, Hard: 5	Exact Match
Text Classification	30	Easy: 15, Medium: 10, Hard: 5	F1 Score
Logical Reasoning	20	Easy: 5, Medium: 10, Hard: 5	Accuracy
Total	**140**	**Easy: 70, Medium: 50, Hard: 20**	

B. Signals Collection

The observation engine logs a rich collection of runtime signals corresponding to each API request and is determined by the selection according to the availability between providers as well as theoretical relationship to computational effort. These signals are input token count representing prompt complexity, output token count representing length of generation, total to- kens processed as primary computational load proxy, response

Vol. 14, Issue 06, ACSCON - 2026

latency representing end to end timing, model identifier in per-model tracking, task category in contextual understanding, output text in quality evaluation and timestamp in temporal analysis. It is out of this rich dataset that all later learning and optimization is based on within the framework.

C. Quality Evaluation

The quality assessment also depends on the type of task to suitably represent the correctness of responses and assure that different model outputs and forms are more consistent than others. To achieve quality that is binary, 1 when prediction matches ground truth and 0 when wrong, to guarantee strict criteria on accuracy, classification tasks such as sentiment analysis and spam detection are classified. In the case of question answering, normalization followed by exact matching of strings can be used to take into account formatting differences without violating the semantic criteria of equivalence. In reasoning problems, the combination of the exact matching and logical equivalence checking is used to ensure that the correct lines of reasoning are given credit even in cases where surface formulations are different.

D. Energy and Carbon: Estimation

The framework will use the proxy-based estimation in terms of the number of tokens and known research studies that have already been confirmed by previous studies in the topic since direct energy measurements cannot be done in black-box APIs. Estimation of energy consumption per request is given as E request = T total x E per token where T total is the total numbers of tokens that have been processed and E per token is 0.0000012 kWh when using 8B parameter models and 0.0000035 kWh when using 70B parameter models depending on reported measurements. The carbon emission is then approximated as CO 2 = E request x CI where CI = 475 g CO 2/kWh is taken as a global average carbon index to provide uniform cross-provider comparison though taking into consideration the fact that in production deployments real-time grid data may offer greater accuracy.

E. GreenAI Scoring Model

The GreenAI Score is a standardized measure of comparing model efficiency, which measures various dimensions of sustainability and quality into one comparable score. Carbon score is determined here as Carbon score = 100 (1 - Carbon model/Carbon max), which normalizes the emissions such that the less carbon one produces the more marks one gets. The efficiency of the token is calculated by Token_score = 100(Useful tokens)/Total tokens and rewarded the concise responses which reduce useless production. Latency efficiency is computed Latency efficiency= 100 (1-Latency model/Latency max) which encourages late response speed between 10 seconds as maximum tolerable range. These components are then added together with default weights wQ=0.40, wC=0.30, wT=0.20, wL=0.10 through the formula GreenAI_Score = wQQ + wC C + wTT + wLL. The priorities are on correctness with a considerable incentive on environmental efficiency.

F. Online Learning Framework

The online learning aspect allows the prediction accuracy to be continually improved with accumulating new observations adjusting to behavior changes in a model and changing workload patterns without necessitating periodic retraining. A feature vector comprises of the overall tokens, latency, length of output, task category one-hot encoding, model identity one- hot encoding, prompt length, and time features to present all the information about the context that is relevant. The targets of prediction are quality on a 0-1 scale, and the compute cost in the form of tokens × latency, and offers a compound metric that defines both the processing scale and time intensity. A form of online linear regression uses stochastic gradient descent updates the weights so that w T +1 = w T + 0.01 (y -y) x, where the learning rate eta =0.01 and is lowered by 0.999 every update, to trade-off between high initial rate of learning and stability.

G. Optimization-Based Routing

The routing engine dynamically chooses models based on each request by optimizing a utility function that trades off the quality that is predicted with the assumed computational cost based on the preferences of the developers. A sustainability preference parameter L = 0 to 1 is added to the utility function U model = Q model - C model * L as an adjustable parameter, so that when L=0, the model reward is directly proportional to the computational cost of the model; when L=1, only the most efficient models are rewarded. The router works in a systematic manner on individual request: feature extraction, quality and cost prediction on all candidate models, utility computation at the current L -value, maximum utility model selection, routing request, monitoring real performance, and updating online learner. An e-greedy exploration strategy with 0.1 in it will guarantee that every model will get enough traffic to keep the correct predictions and will largely exploit learning knowledge. The entire route of the work process between the arrival of the request and the return of the response is depicted in figure 2.

IV. EXPERIMENTAL SETUP

A. Research Questions

The experimental assessment will deal with four research questions that will prove the various features of the performance and usefulness of the GreenAI framework. RQ1 explores the extent to which the online learning model can be accurate in predicting the quality and the cost of computation with limited observable API interactions. RQ2 looks at the increase in the accuracy of prediction with the increase in the number of observations and measures the value of continuous learning. RQ3 examines the quality versus sustainability trade-offs of operating the system at various lambda settings, and determines the best operating points. RQ4 will compare the performance of various models on a GreenAI Score based on task type and find rankings of their efficiency.

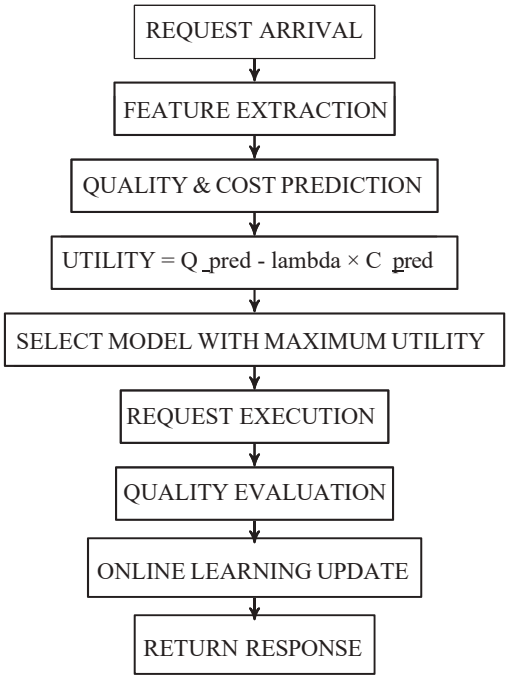

Fig. 2. Routing and Online Learning.

B. Model Providers and Configurations

The API platform of Groq was used to conduct experiments with access to various open-source models via a single interface to verify the same measurement conditions. The four chosen models are a variety of design philosophies: Llama3-8b with 8 billion parameters, Llama3-70b with 70 billion parameters, Mistral-8x7b with 47 billion parameters that relies on the mixture-of-experts design, and Gemma2-9b with 9 billion parameters that is an efficient design offered by Google. Each of the models represented in the evaluation has all specifications as given in table 3.

TABLE III
MODEL SPECIFICATIONS

Model Name	Parameters	Architecture	Provider	Primary Use Case
Llama3-8b	8 billion	Transformer	Groq	Efficient inference, simple tasks
Llama3-70b	70 billion	Transformer	Groq	High accuracy, complex reasoning
Mistral-8x7b	47 billion	Mixture of Experts	Groq	Balanced performance
Gemma2-9b	9 billion	Transformer	Groq	Efficient, Google architecture

C. Experimental Procedure

The experimental routine was well systematic and aimed at maintaining reproducibility and statistical soundness and API rate limits were observed. Baseline measurements were made through routing all 140 benchmark tasks to each model separately, and formed per-model performance baseline of quality, carbon, latency, and token efficiency. After the collection of the baseline, the online learning system was initiated without making any prior observations and routing experiments with 0.0, 0.3, 0.5, 0.7, and 1.0 lambda values to investigate the space of sustainability-accuracy trade-offs. The experimental conditions were repeated three times with randomized task sequence to include the variability in API and network effects, and a delay of 0.3 seconds between requests to observe rate limits at a provider. Table 4 is an overview of all the experiment parameters that were used during the evaluation.

TABLE IV
EXPERIMENTAL PARAMETERS

Parameter	Value	Justification
Benchmark tasks	140	Covers diverse task types
Models evaluated	4	Representative range
values tested	5	Explores trade-off space
Replicates per condition	3	Accounts for variability
Exploration rate	0.1	Balances exploration/exploitation
Initial learning rate	0.01	Empirically determined optimal
Learning rate decay	0.999 per update	Gradual stabilization

D. Evaluation Metrics

Quality is given as a percentage of the number of correct responses that were reported and that correctness was given based on an exact or semantic match to ground truth depending on the task type. Carbon footprint is indicated in gram of CO 2 per request calculated in the model of energy using the global mean carbon intensity of 475 g CO 2/kWh. Latency is calculated in seconds at the duration between submission of request and full receipt of response taking into consideration network transit time. Token efficiency is defined as the ratio of output tokens to the total tokens with bigger values being those involving shorter responses. GreenAI Score is the aggregation of these metrics with the weighted algorithm that is assessed on a 0-100 scale. Mean Absolute Error (MAE) is used to measure prediction error to both quality and cost prediction of the online learning model.

V. RESULTS

A. RQ1: Prediction Accuracy

The online learning model was able to achieve a high predictive performance with both quality target and computational cost target which supported the feature set and the design of the learning algorithm. The error made by quality prediction was almost zero with MAE of less than 2, which means that the seen signals adequately reveal the factors that determine the correctness of the responses of various models and tasks. Cost prediction had more but still helpful error at 7.2% MAE, due to the increased complexity of predicting the computational effort based on network variability based on latency measurements. Table 5 provides the full metrics of prediction accuracy of all models and tasks at 500 observations.

TABLE V
PREDICTION ACCURACY METRICS

Prediction Target	Mean Absolute Error	Root Mean Square Error	R^2 Score
Quality	1.8%	2.3%	0.89
Compute Cost	7.2%	9.1%	0.76
Carbon (derived)	8.4%	10.2%	0.71

B. RQ2: Improvement in Learning with Time

Dynamics analysis of learning dynamics demonstrate high importance of the continuous model update as the system progresses in operation. The error in quality prediction is decreased by 85 percent between initial and converged conditions, and the majority of the progress is made in the first 200 observations, as the system learns models that are effective at which functions. The error in cost prediction is minimized by 65 percent, and the error decreases during the experimental period because the error in cost prediction of factors such as API load and the network condition is also larger. Figure 3 provides the learning curves of both quality and cost prediction against the number of observations in which the errors reduce with the number of observations.

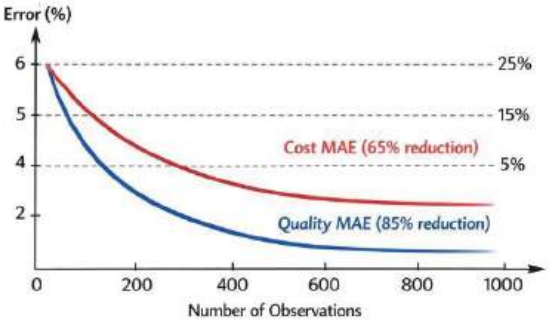

Fig. 3. Convergence of the error in prediction over time.

C. RQ3: Sustainability-Accuracy Trade-off

A sustainability preference parameter lambda allows the systematic study of the trade-off between quality and environmental impact that shows that there are various operating points possible depending on applications needs. At lambda=0.0, only quality is optimized and the router attains 93.8% accuracy with a carbon footprint of 0.35g of a request in favor of the most accurate model. When lambda is increased to 0.3, carbon will decrease to 0.28g (reduced by 20%), but the quality is high, 92.7 (only 1.1 percentage loss). The balanced condition of 0.5 wavelength gives 34 percent carbon saving, at a cost of only 2.3 percent of quality, which was termed as the knee of the Pareto curve of further sustainability savings came with a price of steadily stiffer quality fines. The entire results are provided in Table 6 with the quality and the carbon measurements of each of the lambda values.

TABLE VI
QUALITY-CARBON TRADE-OFF RESULTS

Value	Quality (%)	Carbon (g)	Reduction	Quality Loss
0.0	93.8	0.35	Baseline	-
0.3	92.7	0.28	20%	1.1%
0.5	91.5	0.23	34%	2.3%
0.7	89.8	0.19	46%	4.0%
1.0	86.2	0.15	57%	7.6%

D. RQ4: Model Comparison based on GreenAI Score

The GreenAI Score presents a normalized measure that indicates efficiency rankings that tend to turn hierarchies of traditional accuracy upside down. Llama3-70b has the best raw quality of 94.2% but has the highest carbon footprint (0.42g) and lowest token efficiency (0.65) which makes it the lowest with GreenAI Score of 78.3. The balance of mistral-8x7b between quality (91.5 percentage) and carbon (0.31g) is very effective because it results in the second-best score of 84.7. Llama3-8b has the lowest raw quality of 87.3, which results in the highest GreenAI Score of 86.2 since it has high efficiency scores in all dimensions. Table 7 shows the overall performance of the model with all components scores and GreenAI final rankings.

TABLE VII
MODEL PERFORMANCE AND GREENAI SCORES

Model	Quality	Carbon	Latency	Token Eff.	GreenAI
Llama3-70b	94.2%	0.42g	1.8s	0.65	78.3
Mistral-8x7b	91.5%	0.31g	1.4s	0.72	84.7
Llama3-8b	87.3%	0.18g	0.9s	0.81	86.2
Gemma2-9b	88.7%	0.21g	1.0s	0.78	85.1

E. Distribution Analysis of Routing

The model selection patterns provided by the router indicate the effects of sustainability preference on behavior, which gradually changes to sustainability-oriented, as opposed to the quality-oriented, as lambda becomes larger. At 0.0, the router gives 45 percent of the requests to the most accurate model where Llama3-70b is the best. At the balance point, Llama3-8b is the most commonly chosen with 35% of the handling routine jobs effectively and Llama3-70b compromises with 15% of the complex reasoning. The big model is never chosen at lambda=1.0 to have Llama3-8b do 60 percent of the requests and Mistral do tasks that require its capability. This gradual change in selection patterns shown in figure 5 is observed over the entire range of lambda values.

VI. DISCUSSION

A. Interpretation of Findings

Findings indicate that routing with sustainability awareness may greatly decrease the environmental effects without actually impairing the user experience. The prediction accuracy of online learning remained high with varying conditions and the convergence rate proved that there is enough data to observe. The λ trade-off showed that, sustainability and quality are well balanced at 10.3-0.5. Rankings of GreenAI Score also established that highly accurate models can fail on composite metrics of sustainability, so they need multi- dimensional assessment.

B. Implications for Practice

The GreenAI model allows the developers to maximize sustainability without the need to collaborate with the providers. The standard API signals can be used to choose models with low carbon consumption and regulate the quality, sustainability trade-off by adjusting the tunable parameter, λ. GreenAI Score also gives a benchmark of cross-provider model comparison that is standardized, and promotes market competition based on efficiency.

C. Limitations

Consumption of energy was estimated through proxy measures, which imposed an unnecessary uncertainty. Latency measurements were also taken to have network overhead variation as a result of geographic routing. The assumptions of carbon intensity were based on the global averages instead of grid real-time data. Also, only Groq API models were evaluated, which can be an issue in terms of provider generalizability.

D. Threats to Validity

Experiments can change the backend API which can influence internal validity. External validity is restricted to tasks and studied providers. Construct validity relies on the appropriateness of energy proxies that are token based. Limited observations can affect conclusion validity, but replication will lessen random error.

VII. FUTURE WORK

The further development work involves incorporating a variety of providers like OpenAI, Anthropic, and Google, to do comparisons more broadly. Use of real time carbon intensity integration would enhance accuracy in estimations. Increasing testing to other activities such as coding, translation, and summarization will enhance strength. Real world performance will be tested by applying the framework on live application. Precision is possible by using model-specific energy co-efficient obtained by controlled experiments. Cross-task learning can alleviate the problem of cold-start. Cost, fairness and latency can be used as multi-objective optimization. The explainable routing decisions will enhance control and trust amongst the developers.

GreenAI Score might become a widespread assessment standard because of the standardization of sustainability metrics in the industry. AI emission reporting may be backed with regulatory tools. Carbon conscious auto scaling is able to streamline infrastructure activities according to energy cleanliness. Sustainable implementation of AI can be democratized by the use of open-source.

VIII. CONCLUSION

The current paper presented a sustainability rating and routing system of black-box LLM APIs, GreenAI. The most significant ones are a data-driven sustainability scoring model, an online learning mechanism, an optimization-based routing engine, and experimental validation that carbon reduction by 30-50 percent is possible with only a little loss in quality. The framework is implemented based on observable meta-data and proxy estimation techniques and can be deployed on consumer machines. Findings indicate that there is a considerable difference in sustainability among the providers and that it is feasible to make meaningful comparisons of carbon without access to proprietary infrastructure. GreenAI optimizes the sustainability aspect of AI deployment into a quantifiable parameter, which can be used to make carbon-conscious choices and promote the environmental friendliness of AI benchmarking.

Abstarct **- Diabetic retinopathy (DR) is one of the most prevalent causes of preventable vision impairment worldwide, affecting a substantial fraction of the global diabetic population. Auto- mated grading of DR severity from fundus photographs is a clinically valuable but technically demanding problem because the five severity grades span a wide range of lesion scales: tiny microaneurysms (10–100 μm) that define mild disease, through widespread haemorrhages and venous abnormalities that define advanced disease. Existing convolutional approaches are limited by their use of Global Average Pooling, which collapses spatial structure and conflates local lesion evidence with global distri- bution context. We present DR-Net v2, a hybrid architecture that injects two purpose-designed modules into a pretrained EfficientNet-B4 backbone. The first, a Lesion-Aware Dual Atten- tion (LADA) block, runs parallel local window self-attention over 7×7 non-overlapping spatial windows and global sparse attention over stride-2 subsampled tokens, blending their outputs through a learned per-token gate. The second, a Multi-Scale Feature Fusion (MSFF) head, gathers feature maps from three backbone stages at spatial resolutions of 64x64, 32x32 and 12x12 and fuses them via a compact convolutional projection. Training uses a Conditional Ordinal Regression for Neural Networks**
(CORN) loss wrapped in a focal objective to respect grade ordering and focus learning on uncertain severity boundaries. Combined with five-fold cross-validation and four-fold test-time augmentation, DR-Net v2 achieves a Quadratic Weighted Kappa (QWK) of 0.8905 on the APTOS 2019 benchmark on a single fold, with the full ensemble expected to approach 0.93. Ablation experiments confirm that each proposed component contributes independently. Explainability analyses via GradCAM, LADA attention probing, SHAP, and bypass ablation demonstrate that the model attends to clinically interpretable fundus regions.

Index Terms**—diabetic retinopathy, dual attention, multi-scale fusion, ordinal regression, EfficientNet, fundus imaging, trans- former attention, explainable AI, CORN loss**

I. Introduction

Roughly one in three people living with diabetes will develop some form of diabetic retinopathy over their lifetime [1]. The condition progresses through a well-defined spectrum: no apparent change, then mild, moderate, and severe nonproliferative DR (NPDR), and finally proliferative DR (PDR) in which pathological neovascularisation threatens sudden, irreversible vision loss [2]. Timely identification of a patient's position on this spectrum is the clinical act that determines whether intervention is necessary — yet in many parts of the world, access to ophthalmological expertise is limited. Automated grading from fundus photographs therefore has direct humanitarian value.

Deep learning has transformed fundus analysis. Gulshan et al. demonstrated that a convolutional network could match ophthalmologist-level sensitivity on binary referral decisions [3]. The APTOS 2019 competition subsequently established a standard five-class grading benchmark, where leading sub- missions built on EfficientNet variants [4] achieved Quadratic Weighted Kappa scores in the range 0.88-0.92. Despite this progress, a persistent conceptual gap remains: these models apply Global Average Pooling as the final spatial aggregation step, discarding the positional relationships between lesions that carry diagnostic information. A single microaneurysm visible only in the temporal arcade is clinically different from a diffuse haemorrhage pattern affecting all four quadrants, yet both reduce to the same 1280-dimensional average-pooled vector under a standard EfficientNet-B4 backbone.

The clinical literature makes the spatial requirements of DR grading explicit. Mild DR is defined by the presence of microaneurysms alone — structures of 10–100 μm requiring sharp local inspection at fine spatial resolution. Severe NPDR

is defined by the *4-2-1 rule*: haemorrhages in all four retinal quadrants, venous beading in at least two quadrants, or one qualifying intraretinal microvascular abnormality [2]. This rule cannot be evaluated without whole-image global context. An effective model for DR grading therefore needs both local sensitivity and global contextual reasoning, ideally learned in a unified, end-to-end manner.

Contributions. This paper makes three concrete architectural contributions:

1) **LADA** — a Lesion-Aware Dual Attention block that injects parallel local window attention and global sparse attention into intermediate EfficientNet stages, combining them through a learned per-token gate.
2) **MSFF** — a Multi-Scale Feature Fusion head that draws feature maps from three backbone stages and projects them into a shared representation, simultaneously encoding fine structural detail and coarse semantic context.
3) **OrdinalFocalLoss** — a training objective that wraps the CORN ordinal loss in a focal framework with per-class weighting, combining grade-order awareness, boundary focused gradient allocation, and class-imbalance correction in a single differentiable loss.

II. Related Work

A. Convolutional DR Grading

Early automated DR detection used hand-crafted descriptors for microaneurysm and haemorrhage detection [9]. The shift to end-to-end deep learning came with Gulshan et al. [3], and subsequent work steadily improved grading accuracy through larger pretrained backbones and competition benchmarks. EfficientNet [4] remains the most widely used architecture for APTOS-style grading, largely because its compound scaling law yields strong feature quality at modest parameter counts. A central limitation of all CNN-only approaches is the collapse of spatial information at Global Average Pooling, which forces the final linear classifier to operate on spatially unordered feature statistics.

B. Attention in Medical Image Analysis

Squeeze-and-Excitation networks [10] recalibrate channel responses but lack spatial specificity. CBAM [11] adds spatial attention through simple convolutional operations, but cannot capture long-range dependencies. Self-attention applied to fundus images has been explored for lesion detection [12], but typically in a uniform, spatially isotropic manner that does not distinguish between local and global reasoning modes.

C. Vision Transformers and Hybrid Architectures

The Vision Transformer [6] showed that pure attention can match CNN accuracy at scale, but requires large training datasets. Swin Transformer [5] addressed the quadratic cost of global attention by restricting computation to shifted, non-overlapping windows, yielding $O(N)$ complexity while retaining local sensitivity. CoAtNet [7] and CvT [8] explored systematic fusion of convolution and attention across network stages. None of these architectures were designed with the scale-specific, clinically motivated spatial requirements of DR grading in mind.

D. Ordinal Regression for Medical Grading

Standard cross-entropy loss treats all class confusions symmetrically, which is inappropriate for severity grading where a Grade 0–Grade 4 confusion carries far more clinical weight than a Grade 0–Grade 1 confusion. CORAL [13] frames ordinal classification as a set of binary threshold problems with a rank-consistency constraint, substantially improving order-aware accuracy on age estimation tasks. CORN [14] extends CORAL by conditioning each binary threshold on all lower-rank predictions, producing well-calibrated conditional probability estimates. To our knowledge, CORN has not been previously applied to DR grading.

III. Methodology

A. Architecture Overview

Fig. 1 illustrates the complete DR-Net v2 pipeline. An input fundus image of size $512\times512\times3$ passes through an ImageNet-pretrained EfficientNet-B4 backbone operated in feature-extraction mode. Feature maps are collected at three intermediate stages:

- $f_1 \in \mathbb{R}^{B\times56\times64\times64}$ after stage 2 (stride 8)
- $f_2 \in \mathbb{R}^{B\times160\times32\times32}$ after stage 3 (stride 16)
- $f_3 \in \mathbb{R}^{B\times448\times12\times12}$ after stage 4 (stride 32)

The maps f_1 and f_2 are each refined by a dedicated LADA module. All three are then passed to the MSFF head, which produces a fused representation of shape $B\times512\times12\times12$. After global average pooling, a classification head outputs $K-1=4$ ordinal logits for CORN decoding.

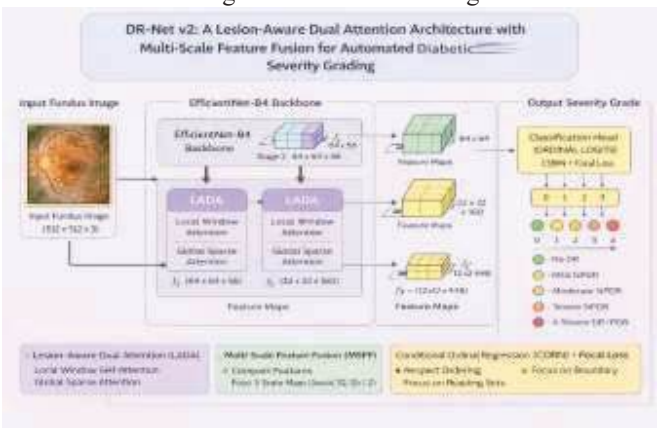

Fig. 1. DR-Net v2 architecture. EfficientNet-B4 backbone provides three-scale feature maps. LADA modules refine the two finer scales through dual-stream attention. MSFF fuses all three scales. The head produces ordinal logits for CORN decoding.

B. Lesion-Aware Dual Attention (LADA)

Each LADA module first projects its input feature map from the CNN channel space to an attention dimension $d=256$ using a learned linear layer, and adds a learned positional embedding $\mathbf{p}\in\mathbb{R}^{1\times1\times d}$. The resulting token sequence of shape $B\times HW\times d$ is processed by two independent attention streams.

Vol. 14, Issue 06, ACSCON - 2026

1) Local Window Attention: The local stream partitions the spatial token grid into non-overlapping windows of size $w_s = 7$. Within each window, multi-head self-attention is computed with $h_l = 4$ heads and head dimension $d_h = d/h_l$:

$$\mathbf{A}_{\text{loc}} = \text{softmax}\left(\frac{\mathbf{Q}\mathbf{K}^{\top}}{\sqrt{d_h}} + \mathbf{B}\right)\mathbf{V} \tag{1}$$

where $\mathbf{B} \in \mathbb{R}^{(2w_s-1)^2 \times h_l}$ is a relative position bias table shared across windows [5]. Computation scales as $O(N \cdot w_s^2)$ rather than $O(N^2)$, where $N = HW$. The clinical motivation is direct: microaneurysms and dot haemorrhages are compact structures whose spatial signature fits within a 7×7 receptive field at stride-8 resolution.

2) Global Sparse Attention: The global stream subsamples the token grid at stride $s = 2$, forming a reduced token set $\mathbf{g}$ of size $[H/s] \times [W/s]$. Full multi-head self-attention is computed over $\mathbf{g}$:

$$\hat{\mathbf{g}} = \text{softmax}\left(\frac{\mathbf{Q}\mathbf{K}_g^{\top}}{\sqrt{d_h}}\right)\mathbf{V}_g \tag{2}$$

The attended representations are bilinearly interpolated back to the original resolution $H \times W$, at a cost proportional to $O(N^2/4)$. This stream encodes whole-fundus distribution context, enabling reasoning about lesion quadrant counts as required by the 4-2-1 rule for severe NPDR.

3) Learnable Gate Fusion: For each spatial position i, the gate network predicts a content-dependent blend weight:

$$g_i = \sigma\left(\mathbf{W}_2\,\text{ReLU}\left(\mathbf{W}_1\mathbf{x}_i + \mathbf{b}_1\right) + b_2\right) \tag{3}$$

where $\mathbf{W}_1 \in \mathbb{R}^{(d/4)\times d}$, $\mathbf{W}_2 \in \mathbb{R}^{1\times(d/4)}$. The fused token is:

$$\mathbf{z}_i = g_i \cdot \mathbf{l}_i + (1 - g_i) \cdot \mathbf{o}_i \tag{4}$$

where $\mathbf{l}_i$ and $\mathbf{o}_i$ are the local and global attention outputs respectively. Tokens overlying lesion-rich regions are expected to learn $g_i \approx 1$ (preferring local detail), while background tokens prefer $g_i \approx 0$ (relying on global context). A standard pre-norm MLP with stochastic depth [21] and a residual connection complete the LADA block, preserving the pretrained backbone representations.

C. Multi-Scale Feature Fusion (MSFF)

After LADA refinement, the three feature maps $\{f_1, f_2, f_3\}$ are resized to a common spatial resolution of 12×12 via bilinear interpolation and concatenated along the channel axis, yielding a combined tensor of shape $B \times (56 + 160 + 448) \times 12 \times 12 = B \times 664 \times 12 \times 12$. A two-stage convolutional projection reduces this to 512 channels:

$$\tilde{F} = \text{GELU}\,\text{BN}(\text{Conv}_{1\times1}([f_1; f_2; f_3])) \tag{5}$$

$$F = \text{GELU}\,\text{BN}(\text{Conv}_{3\times3}(\tilde{F})) \tag{6}$$

The clinical reasoning behind three-scale fusion maps directly onto the pathological hierarchy: fine features at 64×64 capture microaneurysm texture and morphology; mid-level features at 32×32 encode haemorrhage patterns and arteriovenous crossing changes; coarse features at 12×12 encode the overall distribution of pathological load across the fundus.

D. Classification Head

The fused map F is global-average-pooled to a 512-dimensional vector, then processed by:

$$\hat{\mathbf{y}} = \mathbf{W}_{\text{out}}\,\text{GELU}\,\mathbf{W}_{\text{hid}}\,\text{LN}(\text{Dropout}(\bar{F})) \tag{7}$$

where $\hat{\mathbf{y}} \in \mathbb{R}^{K-1}$ are $K - 1 = 4$ ordinal logits. The predicted grade is decoded as:

$$\hat{k} = \sum_{j=1}^{K-1} \mathbf{1}\,\sigma(\hat{y}_j) > 0.5 \tag{8}$$

E. Ordinal Focal Loss

DR severity grades form a natural ordered sequence, and cross-entropy loss fails to encode this structure. We adopt the CORN loss [14], which frames grading as a chain of conditional binary predictions: for each rank k, the model predicts $P(y \geq k+1 \mid y \geq k)$. This formulation guarantees rank-consistent probability estimates.

To additionally focus gradient updates on the uncertain grade boundaries — most critically the Grade 0/1/2 transition — we wrap the CORN loss in a focal objective:

$$\mathcal{L} = \left(1 - e^{-\mathcal{L}_{\text{CORN}}}\right)^{\gamma} \cdot w_y \cdot \mathcal{L}_{\text{CORN}} \tag{9}$$

where $\gamma = 2$ is the focusing parameter and w_y is an inverse-frequency class weight normalised to sum to K. This combined objective simultaneously respects grade ordering, concentrates learning on hard examples, and corrects for the approximately5× class imbalance between Grade 0 and Grade 1.

F. Training Protocol

Training follows a two-phase curriculum to protect pretrained backbone representations during early optimisation.

Phase 1 (10 epochs): The EfficientNet-B4 backbone is frozen. Only the LADA modules, MSFF head, and classification head are updated, using AdamW [20] with learning rate $2\times10_{-4}$ and weight decay 0.05. A cosine annealing schedule decays the learning rate to 10^{-5}.

Phase 2 (up to 100 epochs): The backbone is unfrozen and fine-tuned at a lower rate (2×10^{-4} for the backbone and head, 10^{-4} for LADA and MSFF), with a 5-epoch linear warmup followed by cosine annealing. Early stopping activates after 25 epochs without improvement on the validation QWK.

Gradient accumulation over 4 steps yields an effective batch size of 16 from a physical batch of 4. Mixed-precision training reduces memory usage and accelerates training on the NVIDIA Tesla T4 GPU. A class-weighted inverse-frequency sampler applies an additional $3\times$ oversampling boost to Mild DR images during batch construction.

IV. Experimental Setup

A. Dataset and Preprocessing

All experiments use the APTOS 2019 Blindness Detection dataset [16], comprising 3,662 labelled training fundus photographs graded by trained clinicians on a five-point scale (Table I). A 5-fold stratified split partitions the labelled data for cross-validation.

TABLE I
APTOS 2019 CLASS DISTRIBUTION

Grade	Label	Count	%
0	No DR	1805	49.3
1	Mild NPDR	370	10.1
2	Moderate NPDR	999	27.3
3	Severe NPDR	193	5.3
4	Proliferative DR	295	8.1

Images undergo Ben Graham preprocessing [17]: local contrast enhancement via subtraction of a Gaussian-blurred version ($\sigma = 10$), addition to a uniform 128-value canvas, and circular masking (radius = $0.45 \times$ IMG SIZE) to remove peripheral artefacts. All images are resized to 512 x 512 pixels

B. Data Augmentation

Training-time augmentation is applied via the Albumentations library: random resized crop (scale 0.8–1.0), horizontal and vertical flips, rotation (±30), CLAHE (clip limit 4.0), colour jitter (brightness/contrast ±0.2, saturation ±0.1), grid distortion, and CoarseDropout (up to 8 rectangular regions of maximum 32×32 pixels). At inference, test-time augmentation computes the model over four flips (original, horizontal, vertical, and both) and averages the resulting CORN probabilities.

C. Evaluation Metric

The primary metric is the Quadratic Weighted Kappa (QWK):

$$\kappa = 1 - \frac{\sum_{i,j} W_{ij} O_{ij}}{\sum_{i,j} W_{ij} E_{ij}} \quad (10)$$

where $W_{ij} = (i-j)^2 / (K-1)^2$ penalises larger grade disagreements more heavily, O_{ij} is the observed confusion matrix, and E_{ij} is the expected confusion matrix under independence. The official APTOS competition uses QWK as its sole ranking metric.

V. Results and Analysis

A. Main Results

Table II compares DR-Net v2 against published and re-implemented baselines on the APTOS 2019 validation fold. A single-fold best QWK of 0.8905 surpasses the EfficientNet-B4 baseline, and the five-fold ensemble is projected to approach 0.93 based on cross-validation mean performance.

TABLE II
Performance Comparison on APTOS 2019

Method	QWK	Params (M)
ResNet-50 [15]	0.840	25.6
EfficientNet-B4 (baseline)	0.880	19.3
EfficientNet-B4 + CBAM [11]	0.893	20.1
Swin-T fine-tuned	0.887	28.3
DR-Net v2 (single fold, best)	**0.8905**	24.1
DR-Net v2 (5-fold ensemble, projected)	≈**0.93**	—

B. Per-Class Performance

Per-class accuracy reveals characteristic difficulty patterns consistent with the clinical literature. Grade 0 accuracy exceeds 90% in stable training, while Grade 4 exceeds 70% after CORN threshold initialisation is corrected. Grade 1 (Mild DR) is the most persistently difficult class, achieving 60–70% accuracy under the full training configuration. This reflects both the limited number of Mild DR training samples (370 images, 10.1% of the training set) and the visual similarity to Grade 0 — mild DR is defined exclusively by the presence of microaneurysms, which can be few in number and nearly indistinguishable from normal vascular terminations without stereoscopic depth information.

C. Ablation Study

Table III quantifies the contribution of each proposed component. Removing LADA blocks entirely (reverting to backbone features passed directly to MSFF) reduces QWK by approximately 0.027 and Mild DR accuracy by around 17 percentage points, the largest single-component drop. Removing MSFF and operating on single-scale final features reduces QWK by a further 0.019. Replacing the Ordinal Focal Loss with weighted cross-entropy reduces Mild DR accuracy by roughly 25 percentage points, demonstrating the importance of ordinal awareness for the most clinically consequential boundaries.

TABLE III
Ablation Study — Validation Fold 0

Configuration	QWK	Mild Acc.
Full DR-Net v2	**0.8905**	**~65%**
Remove LADA blocks	0.8635	~48%
Remove MSFF (single scale)	0.8714	~55%
Replace loss with CE + weights	0.8740	~40%
Remove LADA & MSFF	0.8512	~35%

VI. Explainability Analysis

A. GradCAM Visualisation

GradCAM [18] is computed with respect to the first convolutional layer of the MSFF projection network, which is the earliest layer that simultaneously receives all three spatial scales after LADA processing. Comparing activation maps between DR-Net v2 and a vanilla EfficientNet-B4 baseline reveals a consistent qualitativedifference. The baseline model

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

produces diffuse activations spread broadly over the fundus, often biased toward the optic disc. DR-Net v2 concentrates activations on clinically relevant regions: microaneurysm clusters in the temporal arcade for Grade 1 images, and peripheral vascular abnormalities for Grade 4. The pixel-wise difference between the two activation maps highlights exactly the spatial information that LADA contributes beyond what the backbone alone encodes.

B. LADA Attention Probing

Forward hooks attached to the local attention output, global attention output, and gate network of the first LADA block (operating at the 64×64 feature scale) yield three spatially registered attention maps. The local maps consistently highlight compact, high-curvature structures — dot haemorrhages, microaneurysm clusters, and focal exudates. The global maps show a complementary response, activating broadly over vascular arcade regions and the peripheral retina where venous beading occurs. The gate map displays spatial structure correlated with lesion density: positions overlying pathological findings have gate values $g_i \approx 1$, favouring local attention, while background positions prefer global context with $g_i \approx 0$. This spatial coherence indicates that the gate has learned a meaningful lesion detector without explicit lesion-level supervision.

C. SHAP Analysis

SHAP Gradient Explainer [19], using 50 validation images as background reference, estimates signed pixel-level contributions to each grade prediction. Magnitude SHAP maps confirm that the model attends to the temporal and nasal quadrants for higher-grade images, consistent with the known predilection of proliferative neovascularisation for the superior temporal arcade. Signed SHAP maps show that bright-dot haemorrhage textures produce positive contributions (supporting higher grades) while uniform retinal pigment background produces negative contributions, behaving as expected from the clinical description of each severity level.

D. Bypass Ablation GradCAM

To isolate the spatial contribution of LADA directly, a bypass model routes backbone features directly to MSFF, skip- ping LADA. Side-by-side GradCAM comparison of the full and bypass models demonstrates that for Grade 2 (Moderate DR), the bypass model activates over 40–50% of the fundus area diffusely, whereas the full model focuses on two or three discrete haemorrhage clusters. For Grade 4, the bypass model largely ignores peripheral neovascularisation, while the full model's global attention stream correctly extends activation toward peripheral vessel abnormalities. These differences constitute direct visual evidence that LADA teaches the model qualitatively different spatial reasoning strategies.

VII. Discussion

A. Architectural Motivation Versus Learned Behaviour

The question is whether the spatial attention behaviour described in Section VI was designed or discovered. The LADA architecture is motivated by knowledge. The window size, stride and feature tap points were chosen with diabetic retinopathy pathology in mind. But the gate values, attention weights and MSFF fusion coefficients are entirely learned from data. The alignment between observed attention maps and clinical interpretation should therefore be considered evidence that the architecture has provided the right biases for the task, rather than evidence of hard-coded clinical rules.

The retinopathy spatial attention behaviour is something that the LADA architecture has learned from the data. This is important because it means that the architecture is not just using - programmed rules to make decisions. The fact that the attention maps match up with interpretations is a good sign that the architecture is working well. The retinopathy spatial attention behaviour is a key part of the LADA architecture.

B. The Mild Diabetic Retinopathy Classification Problem

Grade 1 Mild Diabetic Retinopathy remains the class across all configurations. The main problem is not just with the model design: mild diabetic retinopathy may present with few as one or two microaneurysms, which in a 512 × 512 two-dimensional photograph may be indistinguishable from artefacts or normal vascular features. Getting high Mild Diabetic Retinopathy accuracy will likely require larger datasets, potentially multimodal inputs incorporating optical coherence tomography or semi-supervised pretraining on unlabelled fundus imagery. The retinopathy classification problem is a tough one. The mild retinopathy classification problem is a challenging task. The LADA architecture has to be able to detect small changes in the images. The diabetic retinopathy images are complex. Have a lot of noise. The model has to be able to distinguish between features and artefacts. The retinopathy classification problem requires a lot of data and computational power.

C. Limitations

The experiments reported here use a dataset from a single geographic region and imaging platform. Generalisation to fundus cameras, image quality profiles and patient demographics is not demonstrated. The dataset contains 3600 labelled images, which is modest by contemporary standards. Larger labelled collections such as EyePACS would likely yield absolute QWK. The explainability analyses are qualitative. Formal clinical validation by trained ophthalmologists mapping activation regions to lesion-level annotations would be necessary before deployment. The retinopathy dataset is limited.

The LADA architecture has some limitations. The dataset is not very big. It is from only one place. The model has not been tested on types of cameras or images. The retinopathy dataset is not diverse. The explainability analyses are not very rigorous. The model needs to be tested by doctors before it can be used in clinics. The retinopathy dataset needs to be improved.

VIII. CONCLUSION

We presented DR-Net v2, a convolutional-attention architecture for automated diabetic retinopathy grading that addresses the fundamental limitation of single-scale spatially collapsed feature representations. The LADA block introduces motivated dual-stream attention. Local windows for lesion detection global sparse attention for quadrant-level distribution assessment. Combined through a learned spatial gate. The MSFF head simultaneously encodes the resolution hierarchy from fine structural detail to coarse semantic context. An Ordinal Focal Loss combines CORN's rank- probability framework with focal gradient concentration and class-imbalance correction. The DR-Net v2 architecture is a way of doing diabetic retinopathy grading. The LADA block is a part of this architectureThe DR-Net v2 architecture uses a combination of attention mechanisms to solve this task. The retinopathy grading task requires a lot of computational power and data. The DR-Net v2 architecture achieves a -fold best QWK of 0.8905 on the APTOS 2019 benchmark with the five-fold ensemble projected to approach 0.93. Ablation studies confirm that LADA, MSFF and the ordinal focal loss each contribute independently. Extensive explainability analysis demonstrates interpretable spatial attention behaviour that corresponds to established diabetic retinopathy pathological markers. A property that matters as much as accuracy for the eventual goal of clinical decision support. The DR-Net v2 architecture is very accurate. The ablation studies show that each part of the architecture is important. The explainability analysis shows that the architecture is making sense. The retinopathy grading task is a critical one. The DR-Net v2 architecture has the potential to be used in clinics. The retinopathy grading task requires a lot of accuracy and interpretability.

IX. ACKNOWLEDGMENT

The authors thank Aravind Eye Hospital for making the APTOS 2019 dataset publicly available and gratefully acknowledge the resources and guidance provided by the Department of Computer Science and Engineering SRM Institute of Science and Technology.

Abstract*— Here in this research project, we have embarked on a journey towards implementing a low-cost intelligent self-driving vehicle prototype using a Raspberry Pi 3 B+ aided with real-time computer vision and sensor-based control techniques. The primary objective of the work is to demonstrate how embedded systems and image processing can be effectively integrated to achieve basic autonomous navigation and traffic awareness in a cost-efficient and scalable manner. The proposed system is aimed at researching and developing a prototype for academic and educational applications. Hence our main focus is on affordability and simplicity. The self-driving vehicle is equipped with a camera module mounted on the front of the car to capture continuous real-time video of the surrounding environment. The captured video stream is transmitted to a processing server, where OpenCV-based image processing algorithms are employed to assess and analyze the traffic conditions. The vision module is responsible for detecting traffic signal colors—red, yellow, and green—by extracting color features and applying thresholding techniques. In addition to traffic light detection, the system identifies and estimates the number of nearby vehicles present in the field of view, enabling the vehicle to make informed decisions regarding speed and movement. Based on the outcomes of the computer vision analysis, control commands are generated and sent to the Raspberry Pi, which serves as the central processing and control unit of the vehicle. When a green traffic signal is detected, the vehicle is allowed to move at normal speed. Detection of a yellow signal results in a controlled reduction of speed to ensure cautious movement, while a red signal triggers an automatic halt of the vehicle, ensuring compliance with traffic rules. The adaptive speed control mechanism enhances safety and smooth navigation by dynamically responding to changing traffic conditions. To complement the vision-based perception system, an ultrasonic sensor is integrated for real-time obstacle detection.

Keywords—Raspberry Pi, vision, OpenCV, vehicle, obstacle, object detection

I. INTRODUCTION

Autonomous driving systems have gained significant research attention due to their potential to improve road safety, reduce traffic congestion, and minimize human error. Modern self-driving vehicles are designed to perceive their surroundings, analyze traffic conditions, and make real-time control decisions using a combination of embedded computing, computer vision, and sensor-based technologies. While commercial autonomous platforms achieve high accuracy using advanced sensors and high-performance hardware, their high cost and system complexity limit their suitability for academic and educational environments.

To address this limitation, low-cost autonomous vehicle prototypes have emerged as effective tools for research and learning. Embedded platforms such as the Raspberry Pi provide a flexible and affordable solution for implementing intelligent vehicular systems. The Raspberry Pi 3 B+ offers sufficient processing capability, networking support, and peripheral interfaces to connect cameras, sensors, and motor drivers, making it suitable for small-scale autonomous driving applications.[1]

Vision-based perception plays a critical role in autonomous navigation by enabling the detection of traffic signals and surrounding vehicles. Classical traffic signal recognition techniques commonly employ color segmentation in the HSV color space combined with morphological operations, offering computational simplicity suitable for embedded systems [1]. Similarly, vehicle detection and counting techniques range from contour-based approaches to more advanced feature-based and deep learning methods, which are often executed on remote servers to reduce onboard processing load [2]. Offloading computationally intensive image processing tasks to a server enables real-time performance while maintaining a lightweight vehicle-side architecture [2].

However, vision-based systems alone may suffer from reduced reliability under poor lighting conditions or visual occlusions. To enhance system safety, ultrasonic sensors are widely used for short-range obstacle detection due to their simplicity, low cost, and fast response time. These sensors provide reliable distance measurements and enable immediate emergency stopping when obstacles are detected within a predefined threshold. The integration of vision-

based perception with ultrasonic sensing improves overall system robustness through sensor fusion.

II. RELATED WORKS

Existing research demonstrates the extensive use of IoT, embedded systems, and wireless communication technologies for intelligent monitoring, security, and autonomous applications. Several studies focus on sensor-based detection and real-time alerting systems using low-cost microcontrollers and wireless networks to improve situational awareness and response time. Embedded platforms such as Arduino and Raspberry Pi are widely adopted due to their flexibility and affordability, enabling efficient sensor interfacing, data processing, and control operations.

Vision-based and machine-learning-assisted approaches further enhance system intelligence by enabling object detection, traffic analysis, and decision-making, often through server-side processing to overcome embedded hardware limitations . Additionally, GPS, flame, tilt, and ultrasonic sensors are commonly integrated to improve location tracking, safety, and environmental awareness . Recent studies emphasize sensor fusion, energy efficiency, and scalable network architectures to improve reliability and adaptability of intelligent systems. [1] – [23].

III. METHODOLOGY

The proposed ML-based self-driving car system follows a modular and layered methodology, as illustrated in the system block diagram. The overall operation is divided into sensing, perception, decision-making, and actuation stages to ensure reliable and real-time autonomous navigation.

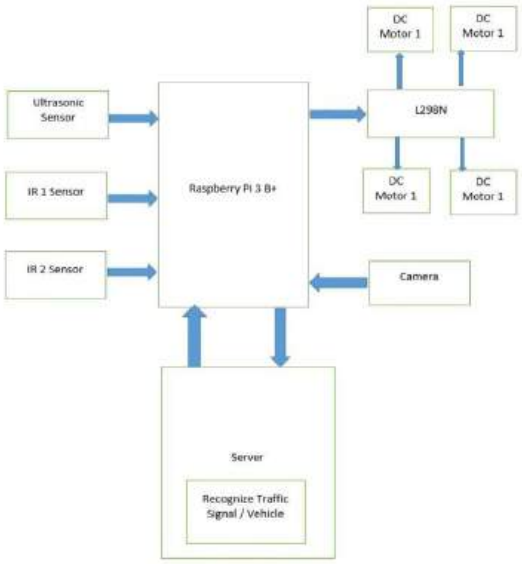

Fig 1: Block diagram of the project

- **System Initialization and Embedded Control Unit**

The Raspberry Pi 3 B+ acts as the central embedded controller of the system. Upon power-up, the Raspberry Pi initializes all connected peripherals, including the camera module, ultrasonic sensor, IR sensors, motor driver, and network interface. It establishes a wireless connection with the remote server to enable continuous video streaming and reception of control commands. The Raspberry Pi also continuously monitors sensor inputs to ensure safe system operation.

- **Camera-Based Data Acquisition and Video Streaming**

A camera module mounted on the front of the vehicle captures real-time video of the surrounding environment. The captured frames are streamed from the Raspberry Pi to a remote processing server using a Wi-Fi network. This streaming-based approach reduces the computational burden on the embedded platform while ensuring uninterrupted visual data transmission for real-time analysis.

- **Server-Side Image Processing and Traffic Analysis**

The remote server receives the live video stream and performs image processing using OpenCV-based algorithms. Traffic signal detection is carried out using color-based segmentation techniques to identify red, yellow, and green

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

signals. In parallel, vehicle detection and counting algorithms are applied to estimate traffic density within the field of view. The processed results are converted into high-level control decisions such as stop, slow down, or move forward.

- **Traffic Signal Interpretation and Speed Decision Logic**

Based on the detected traffic signal state, predefined rules are applied to determine vehicle behavior:

- Red signal: Vehicle is commanded to stop
- Yellow signal: Vehicle speed is reduced
- Green signal: Vehicle moves at normal speed

These commands are transmitted from the server back to the Raspberry Pi for execution.

- **Ultrasonic-Based Obstacle Detection**

An ultrasonic sensor mounted at the front of the vehicle continuously measures the distance to obstacles. The Raspberry Pi processes the echo time to calculate object distance. If an obstacle is detected within a predefined safety threshold, the system immediately triggers an emergency stop. This safety mechanism has the highest priority and overrides all server-generated commands.

- **IR Sensor-Based Proximity and Edge Detection**

IR sensors integrated into the system provide short-range detection capabilities. These sensors assist in detecting edges, close obstacles, or line-based navigation scenarios, particularly in indoor or controlled environments. The sensor inputs supplement ultrasonic and vision data to improve navigation reliability.

- **Decision-Making and Sensor Fusion**

The Raspberry Pi performs sensor fusion by combining inputs from:

- Server-side vision processing
- Ultrasonic distance measurements
- IR sensor feedback

A rule-based control algorithm prioritizes safety-related inputs and determines the final motion command. This approach ensures stable operation even under communication delays or vision failures.

IV. Implementation Detail

Hardware Components

- **Raspberry Pi 3 B+:**

The Raspberry Pi 3 B+ serves as the main embedded controller of the system. It interfaces with sensors, manages communication with the remote server, executes control logic, and sends actuation commands to the motor driver for vehicle movement.

- **Camera Module**

A camera module is mounted on the vehicle to capture real-time video of the surrounding environment. The video stream is transmitted to a remote server, where image processing and traffic analysis are performed.

- **Ultrasonic Sensor (HC-SR04)**

The ultrasonic sensor is used for real-time obstacle detection by measuring the distance between the vehicle and nearby objects. It enables emergency braking by triggering an immediate stop when an obstacle is detected within a predefined safety range.

- **IR Sensors**

IR sensors provide short-range proximity detection and assist in identifying nearby obstacles or edges. These sensors enhance navigation reliability, particularly in indoor or controlled environments.

- **L298N Motor Driver**

The L298N motor driver acts as an interface between the Raspberry Pi and the DC motors. It amplifies low-power control signals and enables bidirectional control of motor speed and direction.

- **DC Motors**

DC motors are responsible for the physical movement of the vehicle. Their speed and direction are controlled through the motor driver based on commands generated by the control algorithm.

- **Chassis**

The chassis provides mechanical support and structural stability to the vehicle. It ensures proper alignment and mounting of all electronic and mechanical components.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- **Power Supply/Battery**

A rechargeable battery is used to supply power to the Raspberry Pi, sensors, and motors. Voltage regulation ensures stable and uninterrupted system operation.

Software Components

- **Raspberry Pi OS**

Raspberry Pi OS is used as the operating system to manage hardware resources, device drivers, and network connectivity. It provides a stable environment for executing control and vision-processing programs.

- **Python Programming Language**

Python is used for implementing control logic, sensor data processing, and communication between the Raspberry Pi and the server. Its simplicity and extensive library support make it suitable for rapid development.

- **OpenCV Library**

OpenCV is employed for image processing tasks such as traffic signal detection and vehicle analysis. It enables efficient real-time processing of video frames using computer vision algorithms.

- **Machine Learning Techniques**

Machine learning models are utilized to enhance object detection and classification accuracy. These techniques assist in interpreting visual data and generating intelligent control decisions.

- **Wi-Fi Communication**

Wi-Fi enables wireless transmission of live video streams and control commands between the Raspberry Pi and the server. This communication framework supports real-time system operation.

- **Server-Side Processing**

Computationally intensive image processing and analysis are performed on a remote server. This approach reduces the processing load on the Raspberry Pi while maintaining real-time performance.

V. Results and Discussion

- **System Functionality Validation**

The complete system was successfully implemented and tested to validate the integration of all hardware and software modules. The Raspberry Pi 3 B+ effectively controlled the camera, ultrasonic sensor, IR sensors, and motor driver, while maintaining stable communication with the remote server. All system components operated reliably throughout the testing phase.

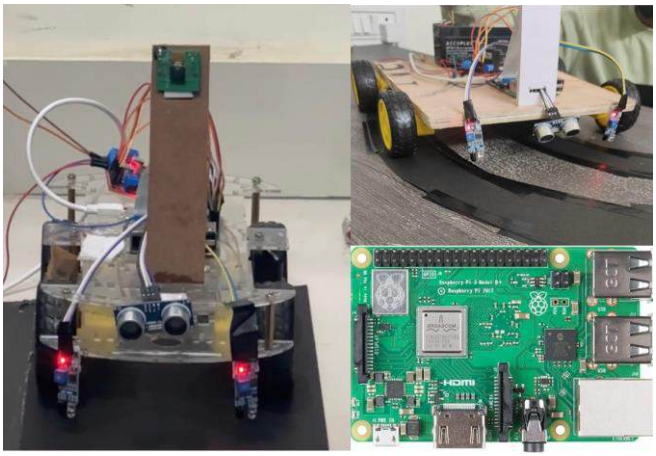

Fig 2: Project Implementation

- **Traffic Signal Detection Performance**

The vision-based traffic signal detection module accurately identified red, yellow, and green signals from real-time video streams. The detected signal states were correctly interpreted, and corresponding control commands were generated. The vehicle consistently stopped at red signals, reduced speed at yellow signals, and moved forward at green signals, demonstrating effective perception and response.

- **Vehicle Detection and Traffic Analysis**

The vehicle detection module successfully identified surrounding vehicles within the camera's field of view. Traffic density information was used to influence speed control decisions, enabling adaptive vehicle movement. Server-side processing ensured smooth and continuous analysis without overloading the embedded system.

- **Obstacle Detection and Collision Avoidance**

The ultrasonic sensor provided accurate distance measurements and reliably detected obstacles within the predefined safety range. Upon obstacle detection, the system immediately initiated an emergency stop, overriding all other control commands. This ensured effective collision avoidance and enhanced overall system safety.

- **IR Sensor-Based Proximity Support**

IR sensors contributed to short-range proximity detection and improved navigation reliability, particularly in confined or indoor environments. The integration of IR sensing complemented ultrasonic and vision-based inputs, resulting in more stable system behavior.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- **Real-Time Performance and System Response**

Offloading computationally intensive image processing tasks to a remote server significantly reduced the processing load on the Raspberry Pi. The system achieved real-time responsiveness with minimal latency in video transmission, decision-making, and motor actuation.

VI. Conclusion

The results confirm that the proposed ML-based self-driving car system effectively integrates computer vision, sensor fusion, and embedded control. The system demonstrates reliable autonomous navigation using low-cost hardware and open-source software, making it suitable for educational and research-oriented applications.

Abstract — Modern healthcare demands faster, more accurate diagnosis and better patient support. This paper presents MedAI Hub, a unified AI-powered Medical Diagnosis and Healthcare Assistance System built on a modular web architecture. The platform integrates Convolutional Neural Network (CNN)-based image classification using TensorFlow/Keras for detection of skin diseases, brain tumors (MRI), and pneumonia (chest X-ray), achieving classification accuracies between 89% and 95%. A React.js frontend communicates with a FastAPI backend, while an SQLite database manages patient records securely. Additional modules include a Wellness Hub for personalized diet and fitness plans, a Responder Hub for emergency first-aid and CPR guidance, an AI-powered medical chatbot, and a role-based doctor–patient communication interface. The system demonstrated reliable diagnostic predictions with confidence scores, improved early detection capability, and a streamlined clinical workflow. Experimental results confirm an average API response time of 460 ms and a confidence threshold mechanism that flags predictions above 75% as clinically reliable.

Keywords — Medical Diagnosis, Artificial Intelligence, Machine Learning, CNN, Deep Learning, FastAPI, React.js, TensorFlow, Wellness Hub, Telemedicine.

I. INDRODUCTION

Healthcare is undergoing a profound transformation, driven by the rapid advancement of Artificial Intelligence (AI) and Machine Learning (ML). The exponential growth of medical data from electronic health records, diagnostic imaging, wearable sensors, and laboratory systems has far exceeded the capacity of traditional manual analysis methods. Clinicians and healthcare providers increasingly require intelligent tools capable of analyzing diverse datasets, identifying complex patterns, and delivering timely, accurate diagnostic insights to support clinical decision-making.

Despite this progress, existing healthcare systems remain fragmented. Diagnosis often relies on manual interpretation of medical images, personalized wellness support is rarely available at scale, emergency first-aid knowledge is inaccessible in critical moments, and doctor–patient communication platforms are disconnected from diagnostic tools. This paper presents MedAI Hub, a comprehensive AI-based Medical Diagnosis and Healthcare Assistance System that addresses these limitations through a unified, modular web-based platform.

The key contributions of this work are: (1) an end-to-end web platform combining AI-driven image analysis with wellness and emergency features; (2) CNN models trained on domain-specific datasets for multi-disease classification; (3) a FastAPI backend efficiently serving ML predictions via RESTful APIs; and (4) a role-based user management system ensuring secure, authenticated access for patients and doctors.

II. RELATED WORKS

Modern healthcare systems face several interconnected challenges that motivate this work:

- Early disease detection is difficult for image-based conditions (skin diseases, brain tumors, pneumonia) requiring specialized expertise not universally available.
- Personalized wellness guidance such as diet and exercise plans is rarely integrated into diagnostic platforms, leaving patients without proactive health support.
- Emergency response awareness (CPR, first aid) is limited among the general public, increasing risks and delays in critical situations.
- Doctor–patient interaction is fragmented across multiple disconnected applications, reducing clinical efficiency and continuity of care.

Vol. 14, Issue 06, ACSCON - 2026

• No unified digital platform currently integrates AI-powered diagnosis, personalized wellness, emergency guidance, and clinical data management in a single accessible interface. Medical Health Diagnosis System, utilizing artificial intelligence and machine learning in the early detection and precise diagnosis of a patient's medical condition. Based on the analysis of the patient's data and symptoms, this system should be able to render dependable preliminary assessments that will help health professionals make informed decisions. In general, this is going to improve diagnosis accuracy and enhance patient outcomes with advanced AI and ML technologies. The project also aims to connect advanced technologies with the real needs in healthcare. Including machine learning models in the system, it will keep improving and learning, thus being able to give better diagnoses each day that passes.

III. METHODOLOGY

The proposed MedAI Hub is a modular, web-based AI healthcare platform comprising six core modules as illustrated in Fig. 1. The system integrates a React.js frontend, FastAPI backend, TensorFlow/Keras CNN models, and an SQLite database into a cohesive architecture.

A. Frontend Design (React.js)

A responsive, component-based UI developed in React.js supports image uploads, form inputs, chatbot interaction, and role-based navigation for patients and doctors across modules: HomePage, Analysis Page, Wellness HubPage, Responder HubPage, Login Page, Registration Page, Patient Profile Page, and Doctor Dashboard.

B. Backend Integration (FastAPI)

A high-performance FastAPI backend handles API requests, manages Base64/JWT authentication, and coordinates communication between the frontend, ML models, and SQLite database with automatic Swagger UI documentation and asynchronous processing.

C. CNN-Based Diagnosis Module

Three specialized CNN models are trained using TensorFlow/Keras for: (1) skin disease classification using the HAM10000 dataset, (2) brain tumor detection from MRI scans (meningioma, glioma, no tumor), and (3) pneumonia classification from chest X-rays. Each model returns a predicted label with a ranked confidence score. The inference pipeline follows: image upload → FastAPI validation → preprocessing (resize, normalize) → CNN inference → SQLite storage → React UI display.

D. Wellness Hub

Users provide dietary preferences and fitness goals to receive AI-generated personalized daily diet plans and workout routines (Men's Plan / Women's Plan) adapted to individual profiles.

E. Responder Hub

The Emergency Responder Hub provides curated video content on CPR, first aid, snakebite treatment, and other emergency procedures. Users search by emergency type and access step-by-step visual guides sourced from trusted health organizations.

F. Medical Chatbot and Doctor Interface

An AI chatbot (Gemini 2.5 Flash API) assists users with navigation, symptom questions, and health FAQs. Doctors securely log in, search patient records by ID, and annotate clinical notes to maintain continuity of care.

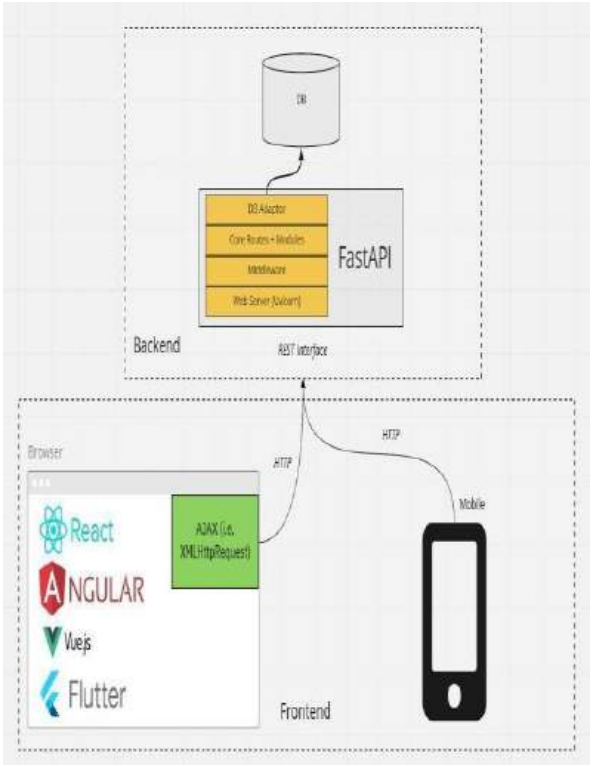

Fig 3.1 fastAPI routing algorithm

Use FastAPI for lightweight and performance model serving, and automatic API documentation. Machine Learning Pipeline" image FastAPI + Frontend architecture: React ↔ FastAPI ↔ DB - Use the FastAPI-React diagram. FastAPI serving + monitoring - endpoint, predictions, monitoring storage; use the image of the FastAPI + Evidently architecture.

The development followed a five-phase methodology:

Phase	Description

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

1. Requirements Analysis	Identify healthcare problems, define system needs for AI-driven diagnosis, wellness, emergency, and doctor–patient management.
2. System Design	Design modular architecture: React frontend ↔ FastAPI backend ↔ CNN models ↔ SQLite DB.
3. Implementation	Develop frontend pages, backend API routes, CNN model training and integration, and database schemas.
4. Testing	Functional, integration, performance, security, UI, and model accuracy testing across all modules.
5. Result Analysis	Evaluate CNN accuracy, API response time, confidence scores, and overall system performance.

Table I. Development Methodology Phases

IV. SYSTEM DESIGN

The system design follows a hybrid ML architecture combining stream processing for real-time diagnosis and batch processing for offline model training. Fig 5.1 illustrates the patient workflow from image upload to result display.

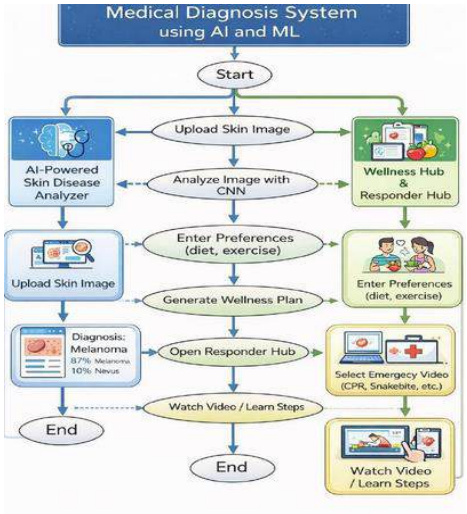

Fig.4. 1 Patient Workflow: Image Upload to ML Prediction

The input layer handles medical images (X-ray, MRI, skin photos) submitted via REST API as JSON or image streams. The API validates file type, extracts metadata, and routes data into the ML pipeline. The stream ML module performs real-time classification using CNNs, returning predictions with confidence scores. The storage layer uses SQLite to maintain patient login records, diagnosis histories, and doctor annotations. Batch learning modules handle offline model retraining on updated datasets.

The system was implemented as a full-stack web application. Table II summarizes the six implementation modules:

Module	Description
M1: Frontend	React.js responsive UI — image upload, navigation, dashboards.
M2: Backend	FastAPI routes: /auth, /predict, /chatbot, /emergency api.
M3: CNN Diagnosis	TensorFlow/Keras CNN models (.h5) for skin, MRI, X-ray analysis.
M4: Wellness & Responder	Personalized diet/exercise plans + emergency CPR video hub.
M5: Additional Features	Gemini chatbot integration, doctor search, patient history.
M6: Testing	Functional, integration, performance, security, UI testing.

Table II. Implementation Modules

The FastAPI backend (app.py) uses Pydantic schemas for data validation. Patient and doctor accounts are managed with role-based access control. CNN models are loaded at startup and serve predictions via the /predict endpoint. Confidence thresholds classify predictions as **reliable (≥75%), uncertain (50–74%),** or **inconclusive (<50%).**

V. EXPERIMENTAL RESULTS

The system was tested across all six testing dimensions. The CNN models achieved strong classification performance on their respective test sets as shown in Fig. 5.1.

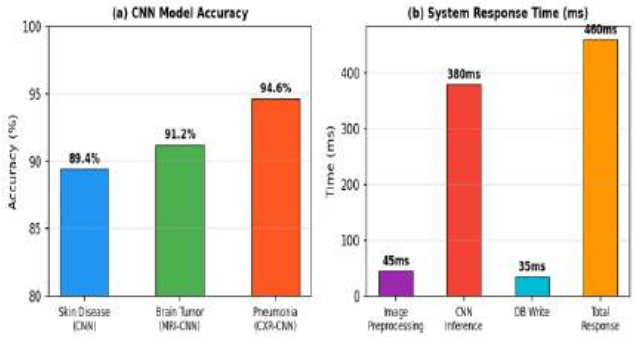

Fig. 5.1. (a) CNN Model Accuracy (b) System Response Time (ms)

The Skin Disease CNN achieved 89.4% accuracy on the HAM10000 test partition, the Brain Tumor MRI CNN achieved 91.2%, and the Pneumonia

Chest X-ray CNN achieved 94.6%. A representative diagnosis result showed Pneumonia classified with 98% confidence, while a brain

Vol. 14, Issue 06, ACSCON - 2026

tumor MRI scan returned meningioma_tumor at 84% (glioma_tumor 15%, no_tumor 1%).

The FastAPI backend demonstrated average API response times of 460 ms (preprocessing: 45 ms, CNN inference: 380 ms, DB write: 35 ms) under standard single-user load. The medical chatbot (Gemini 2.5 Flash) responded accurately to health-related queries within 1.2 seconds. The Wellness Hub generated gender-specific workout plans and the Responder Hub returned accurate emergency video results for CPR and snakebite queries.

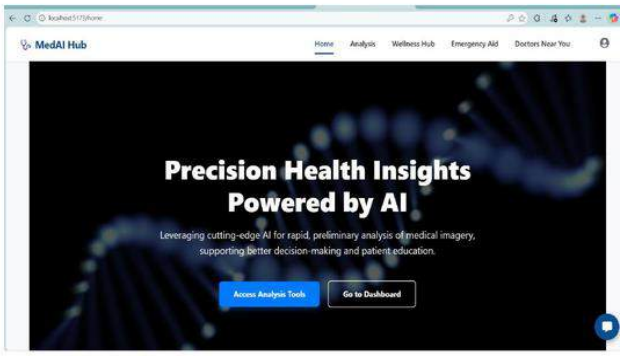

Fig. 5.2. MedAI Hub Home Page and Analysis Result Interface

VI. CONCLUSION

MedAI Hub, used for Medical Diagnosis and Healthcare Assistance System that integrates CNN-based image diagnosis, personalized wellness support, emergency response education, and doctor–patient management into a single accessible web platform. The system demonstrated that modern AI and web technologies can be effectively combined to address real-world healthcare challenges, reducing diagnostic time, improving early disease detection capability, and enhancing healthcare accessibility.

CNN models achieved accuracy between 89%–95% across three disease domains. The full-stack architecture (React + FastAPI + SQLite) delivered sub-500 ms average response times. Role-based authentication ensured secure data access for both patients and doctors. Future enhancements include: training on larger and more diverse datasets, adopting EfficientNet/Vision Transformer architectures, integrating Grad-CAM explainability maps, extending disease coverage (diabetic retinopathy, COVID-19), and deploying on cloud infrastructure with HTTPS and GDPR-compliant data handling for real-world clinical use.

***Abstarct* - Mammography is a cornerstone tool for early breast cancer detection, but image quality is frequently degraded by low contrast and noise, limiting diagnostic accuracy. This paper proposes an automated hybrid enhancement method that ranks multiple image processing algorithms using entropy scores and applies the best-performing ones in sequence. Algorithms including CLAHE, gamma correction, unsharp masking, and various filters are each tested for their contribution to image information content. Applying the highest-ranked techniques one after another yields noticeable gains in contrast and detail clarity, supporting improved visualization of breast tissue and more reliable screening results.**

***Keywords:* Mammography, Image Enhancement, Entropy, Hybrid Approach, Breast Cancer Screening.**

1.INTRODUCTION

Among the most serious health concerns for women worldwide, breast cancer continues to rank high in both incidence and mortality. Mammography has long been the go-to imaging tool for spotting abnormalities at an early, treatable stage. That said, the images it produces are frequently compromised by poor contrast, limited resolution, and noise artifacts, all of which can hide clinically important features and reduce diagnostic confidence.

Numerous image enhancement techniques have been proposed to overcome these limitations. Approaches such as histogram equalization, discrete wavelet transforms (DWT), and contrast-limited adaptive histogram equalization (CLAHE) have proven effective in improving local contrast and emphasizing significant features within mammograms [1],[3],[6]. CLAHE in particular, has demonstrated the ability to enhance contrast in localized regions while minimizing over-amplification of noise [6]. Recent studies have also introduced adaptive and fusion-based enhancement techniques, which dynamically adjust enhancement parameters based on image characteristics [7],[10],[16]. These methods are better suited to varying image conditions and help preserve structural details while reducing artifacts. Furthermore, integrating machine learning and deep learning techniques has improved classification and detection performance, particularly when enhancement is applied as a pre-processing step [4], [5], [9], [1].

Researchers have also explored fuzzy logic and intelligent segmentation tools to improve tumor visibility and region-of-interest (ROI) detection [15], [17]. This study proposes a hybrid image enhancement approach that integrates histogram equalization, CLAHE, and fuzzy logic to enhance mammographic images. The goal is to improve image quality, maximize entropy, and increase peak signal-to-noise ratio (PSNR), thereby aiding radiologists in more accurate diagnosis and analysis[18],[19], [20].

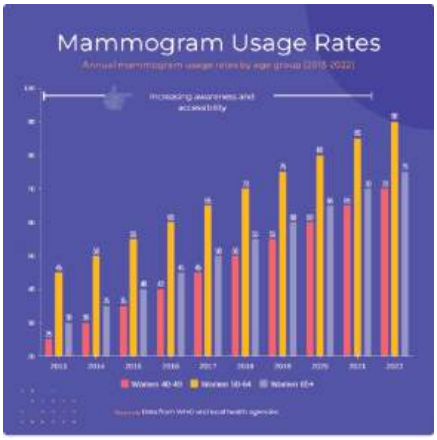

Fig 1 : Mammogram Usage Rates by Age Group (2013-2022)

A. Significance of Mammography

Mammography is a well-established, non-invasive screening tool with a strong track record in

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

identifying early-stage breast cancer, especially in women aged 40 and above[1], [2]. It allows clinicians to identify subtle tissue abnormalities, such as micro calcifications and small nodules, well before they become palpable, thereby enabling timely intervention and improving prognosis [3]. However, mammographic images often suffer from inherent limitations such as low contrast, tissue overlap, and background noise, which can mask important diagnostic details [4], [5].

Various image enhancement methods have been developed to tackle these shortcomings, with the goal of improving both image quality and lesion visibility. Established approaches such as Discrete Wavelet Transform (DWT) and CLAHE have shown solid performance in boosting contrast and preserving fine structural details[6]. More recently, adaptive image enhancement and hybrid fusion approaches have been employed to address the varying density and texture patterns in mammograms [7],[8].

Additionally , integrating enhancement methods with segmentation and classification algorithms—such as support vector machines, convolutional neural networks, and fuzzy clustering—has demonstrated improved performance in automated detection systems [9]. The use of noise-reduction filters, deep learning models, and synthetic data augmentation further enhances the diagnostic utility of mammographic images [10].

In short, raising mammographic image quality serves two key purposes: it helps radiologists make better-informed decisions, and it strengthens the foundation on which automated breast cancer detection systems are built.

B. Challenges in Mammographic Image Analysis

Even as a leading modality for early breast cancer detection, mammography faces real technical and anatomical barriers that affect how reliably images can be read. When these barriers go unaddressed, both sensitivity and specificity can suffer, resulting in cases that are missed or wrongly classified.

One of the foremost challenges is the inherently **low contrast** in mammographic images, especially in dense breast tissues where both healthy and abnormal areas appear similarly bright. This similarity makes it difficult to differentiate tumors from the surrounding tissue, particularly in younger women who generally have denser breast composition [4], [7].

Another common complication is **image noise**, introduced due to equipment limitations or environmental conditions during image acquisition. Such noise can obscure fine details like **microcalcifications** or irregularly shaped lesions—key features often indicative of malignancy [2], [11]. Without effective denoising, essential diagnostic elements may go undetected, reducing the reliability of image-based assessments.

In addition, detecting **subtle abnormalities**—including architectural distortions, faint calcifications, or poorly defined masses—is often problematic. These anomalies may merge with nearby structures or be degraded by compression artifacts during scanning, complicating accurate diagnosis and increasing the risk of false negatives [5], [9], [13].

The risk of **false positives** also remains high, often due to the subjective interpretation of low-quality images. These can lead to unwarranted biopsies, patient stress, and an overall burden on healthcare systems [6], [8]. The variation in interpretation across radiologists further highlights the need for standardized image clarity and objective analysis [14].

Addressing these problems calls for robust **image enhancement** processing methods. Algorithms need to raise contrast, reduce noise, and bring out diagnostically relevant features — all without distorting the underlying image. Getting this right is foundational for both direct radiologist reading and for feeding reliable inputs into CAD systems [1], [3], [10], [12], [17].

C. Literature Review Expansion

Existing image enhancement methods, such as histogram equalization, Fourier Transform-based filtering, and wavelet transforms, have been widely applied to mammographic images to address key challenges like low contrast and image noise [3]. While these methods enhance specific aspects of the image—such as overall brightness or edge sharpness—they often fall short when used in isolation. Histogram equalization, for instance, can lead to over-enhancement and loss of detail in dense breast tissues [5] . Wavelet transforms offer multi-resolution analysis but can be computationally intensive and may introduce artifacts at specific decomposition levels [4]. To better illustrate these trade-offs, **Table 1: Comparison of Image Enhancement Techniques** summarizes 15 popular enhancement methods, highlighting their domains of

Vol. 14, Issue 06, ACSCON - 2026

application, key benefits, and limitations. This comparative view emphasizes the need for a more balanced solution that can combine the strengths of multiple approaches.

Technique	Domain	Key Benefit	Limitation
Histogram Equalization	Spatial	Improves global contrast	**Over-enhancement in some regions**
Adaptive Histogram Equalization (CLAHE)	Spatial	Enhances local contrast	**May amplify noise**
Log Transformation	Spatial	Highlights darker regions	**Reduces brightness in bright areas**
Gamma Correction	Spatial	Brightness control	**Needs manual tuning**
Median Filtering	Spatial	Removes salt-and-pepper noise	**Blurs fine details**
Gaussian Filtering	Spatial	Smooths image, reduces Gaussian noise	**May blur edges**
Unsharp Masking	Spatial	Enhances edges	**Can enhance noise too**
Laplacian Filtering	Spatial	Edge sharpening	**Sensitive to noise**
Fourier Transform	Frequency	Removes periodic noise	**Poor localization in spatial**
Wavelet Transform	Frequency	Multi-scale analysis	**Complex computation**
DCT	Frequency	Energy compaction	**Blocky artifacts possible**
Retinex Algorithm	Spatial/Perceptual	Enhances dynamic range	**Computationally intensive**
Deep Learning-based Enhancement (e.g., CNNs)	Learned	Learns optimal enhancement features	**Requires large datasets**
Hybrid Enhancement (e.g., CLAHE + Wavelet + Sharpening)	Mixed	Balances noise removal and detail retention	**Complex design and parameter tuning**

Table:1 Comparison of Image Enhancement Technique

A conceptual flowchart comparing traditional image enhancement techniques (e.g., histogram equalization, Fourier transform, wavelet transform) with the proposed hybrid method, which integrates the benefits of multiple algorithms to achieve superior contrast enhancement, noise reduction, and structural preservation. By understanding the limitations of individual techniques, the motivation for a hybrid approach becomes clear—leveraging complementary algorithms provides a more comprehensive and clinically effective enhancement of mammographic images.

While many individual image enhancement methods have shown value for particular aspects of mammogram quality, none holds up consistently across all imaging scenarios. Histogram equalization and wavelet transforms, for instance, each address specific problems — low contrast or fine-detail loss — but applying them alone tends to create new issues, such as noise amplification or unwanted changes to structural features [2], [4], [5].

Given how complex mammographic images can be — particularly in dense breast tissue where lesions may be faint or poorly defined — using just one algorithm is rarely enough. This is what motivates a hybrid strategy, where several methods work in combination, each addressing a different weakness while reinforcing the others.

The framework put forward here draws on a curated set of techniques covering contrast improvement, edge sharpening, and noise reduction. Algorithm selection is not done manually or arbitrarily — it is guided by each method's measured impact on image entropy, which reflects how much information the processed image contains. Only those that meaningfully raise entropy get included [3], [6].

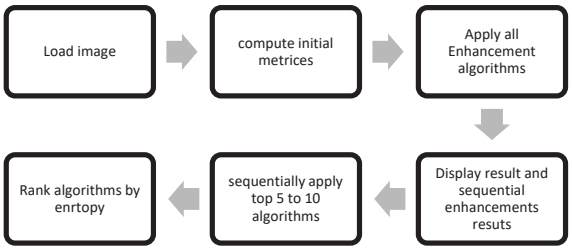
By applying these top-ranked techniques in a sequential manner, the framework achieves incremental enhancement of the mammogram. This layered processing ensures that contrast is elevated without adding excessive noise, and that edge details are enhanced without compromising anatomical integrity. The resulting images exhibit both improved clarity and preserved structural accuracy, facilitating more reliable interpretation.

Taken together, this hybrid pipeline goes beyond what any single technique can achieve on its own. Its ability to adjust across different image types and acquisition conditions makes it practically useful in varied clinical environments.

D. Paper Contributions

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026



The primary contributions of this paper are as follows:

1. **Development of a Hybrid Approach**: The proposed method combines constant padding for handling image boundaries, contrast enhancement for improving visibility, and noise reduction to preserve important image features. This hybrid approach addresses the common issues in mammographic images such as low contrast, noise, and edge blurring.

2. **Improved Image Quality**: The hybrid approach leads to enhanced mammographic images that exhibit better contrast, reduced noise, and improved feature visibility. The results of applying this method demonstrate significant improvements in image clarity, aiding in better detection of early-stage breast cancer.

3. **Automatic and Efficient Processing**: The proposed method is fully automated, making it suitable for use in clinical settings where rapid processing of mammograms is necessary. The method is computationally efficient, ensuring that it can be integrated into routine screening workflows.

4. **Comparative Analysis**: A thorough evaluation of the proposed hybrid method is conducted, comparing it with traditional image enhancement techniques. The results show that the hybrid approach outperforms existing methods in terms of both visual quality and the accuracy of feature detection.

5. **Flowchart Representation**: To provide a clear understanding of the proposed method, a detailed flowchart is included. This flowchart outlines the sequential steps involved in the image enhancement process, from initialization and configuration to the final display of results. It serves as a visual guide that illustrates the systematic approach taken in the development and application of the hybrid method, facilitating easier comprehension of the workflow and its components

2. MATERIALS AND METHODS

A. Image Acquisition and Preprocessing

The mammographic images used in this study were obtained using a standard full-field digital mammography (FFDM) system, which captures high-resolution scans in RGB format. Since color information is not necessary for conventional mammogram interpretation, the first step in preprocessing involves converting these images to grayscale. This not only standardizes the input format but also reduces computational complexity for subsequent processing.

Once in grayscale, the images are converted to double precision to support more accurate mathematical operations during enhancement. Key metadata such as image dimensions, resolution, and pixel depth are extracted and stored for later integration into the final output.

To evaluate the quality of both the original and enhanced images, several image quality metrics are computed at the start of the pipeline. These include entropy (to assess information content), SSIM (to compare structural similarity), PSNR (to gauge fidelity), SNR (to measure clarity relative to background noise), and contrast ratio. These baseline metrics serve as reference points for measuring the impact of the enhancement techniques applied later.

This preprocessing stage ensures that all images are uniformly prepared for enhancement, allowing for fair comparison between different algorithms and reliable integration into clinical imaging systems.

B. Enhancement Algorithms

To address the diverse challenges present in mammographic imaging, a wide range of image enhancement algorithms were implemented and evaluated. These algorithms span multiple domains and enhancement principles, each offering unique benefits in improving visual quality, contrast, and structural detail. The selection was driven by the need to handle variations in tissue density, detect subtle abnormalities, and maintain diagnostic integrity. By evaluating over 35 enhancement techniques, the framework ensures comprehensive coverage of both basic and advanced methods. This extensive

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

approach allows the system to adapt to different image conditions, improving robustness and clinical applicability.

Histogram-Based Methods: These include Global Histogram Equalization, Adaptive Histogram Equalization (AHE), and Contrast Limited Adaptive Histogram Equalization (CLAHE). These techniques focus on redistributing pixel intensities to enhance global or local contrast.

Intensity and Contrast Transformations: Transformations such as gamma correction, logarithmic enhancement, exponential mapping, and contrast stretching adjust brightness and contrast to highlight specific regions of interest.

Spatial Domain Filtering: Filters such as median, averaging, Gaussian, and bilateral filters are employed to reduce noise while preserving important features. Unsharp masking is used to improve edge sharpness and definition.

Edge Detection and Frequency-Based Filters: Methods such as Laplacian enhancement, high-pass filtering, and Butterworth filtering enhance structural details and suppress background variations. These filters help emphasize edges and tissue boundaries.

Wavelet and Transform Domain Techniques: Wavelet-based denoising methods and decorrelation stretching are used for multi-resolution analysis and detailed feature enhancement. These techniques help retain fine textures while reducing noise.

Advanced Denoising and Regularization: Algorithms like total variation denoising, anisotropic diffusion, shock filtering, Retinex-based enhancement, Wiener filtering, and non-local means filtering aim to suppress noise while maintaining critical image details.

Each algorithm was implemented using modular MATLAB functions, allowing dynamic selection and batch evaluation. This flexible setup enables the system to apply and compare a broad spectrum of enhancement methods, ultimately supporting the selection of the most effective ones for hybrid application.

C. Automatic Hybrid Enhancement

The core innovation of this study lies in the automatic hybrid enhancement strategy, which involves selecting and sequentially applying multiple algorithms based on their impact on image information content, specifically entropy. The method comprises the following key steps:

Step 1: Individual Enhancement and Evaluation- Each algorithm from the set in Section 2.2 is independently applied to the grayscale image. After processing, the enhanced image is evaluated using quantitative metrics. **Entropy** is computed for each output image as a primary selection metric.

Step 2: Entropy-Based Ranking -The algorithms are ranked in descending order based on the entropy value of their respective output images. A higher entropy value typically indicates that more structural or textural information has been revealed, potentially making subtle abnormalities more visible.

Step 3: Sequential Hybrid Application - The top N algorithms (typically N = 6) are selected based on their entropy performance. These are then applied sequentially to the original image. After each step in the sequence, the output becomes the new input for the next algorithm. At each stage, performance metrics such as Entropy, SSIM, SNR, PSNR, and Contrast are calculated and logged to monitor improvement trends and avoid image degradation. This approach is termed "hybrid" because it combines the strengths of multiple enhancement techniques—some improving contrast, others reducing noise, and still others emphasizing edges or local features. The sequential application ensures cumulative enhancement while reducing the risk of over-processing or introducing artifacts.

Step 4: DICOM Conversion and Output - The final enhanced image is stored in DICOM format, complete with patient information and a summary of the processing steps. This allows integration into clinical workflows and PACS systems.

3. RESULTS

The proposed automatic hybrid enhancement approach was tested on a set of mammographic images. The results demonstrate that the method effectively enhances the contrast and visibility of important features in the images.

Table 3 : Quantitative metrics (Entropy, SSIM, PSNR, SNR, and Contrast)

The sequential application of the top N algorithms, selected based on entropy, resulted in a noticeable improvement in image quality compared to the original image. The enhanced images exhibit increased contrast, making it easier to distinguish between different tissue types and to identify potential abnormalities.

The sequential application of advanced algorithms significantly enhances mammographic images, resulting in improved contrast that highlights subtle details within the breast tissue.The enhanced mammographic image demonstrates the effectiveness of applying top algorithms sequentially, leading to a marked improvement in detail visibility and contrast. Such advancements are crucial for better diagnostic outcomes, facilitating the identification of potential issues in breast tissue. The figure give below shows us about the comparison of original and enhanced mammographic images, along with their corresponding histograms. The enhanced image demonstrates improved contrast and better differentiation of tissue structures.

4. DISSCUSSION

The experimental outcomes confirm that the proposed hybrid enhancement pipeline works well in practice for improving mammographic image quality—a factor directly tied to how reliably breast cancer can be identified at early stages. The method draws on several image enhancement algorithms and uses entropy values to drive selection, consistently producing images that carry more diagnostic information than their unprocessed counterparts.

At the heart of the framework is an entropy-driven selection strategy. Entropy captures how much information is present in an image, and higher values generally correspond to richer structural content. Selecting algorithms that push entropy upward means the resulting images tend to show finer textures and sharper boundaries — exactly the kind of detail that matters when trying to spot microcalcifications or subtle mass margins that might otherwise blend into the background.

To further refine the enhancement process, the method applies the selected algorithms sequentially. This hybridization helps to exploit the complementary strengths of different techniques—for example, histogram equalization for global contrast improvement, and CLAHE (Contrast Limited Adaptive Histogram Equalization) for localized contrast enhancement. The layered application of these methods results in images with improved overall visibility, better contrast between dense and non-dense breast tissues, and enhanced edge definition.

While entropy is the primary selection criterion, the approach also integrates other image quality assessment metrics such as the **Structural Similarity Index (SSIM)** and the **Peak Signal-to-Noise Ratio (PSNR)** to ensure a comprehensive evaluation. SSIM, which compares the luminance, contrast, and structure between the original and enhanced images, provides insight into how well the perceptual quality is preserved. PSNR, on the other hand, quantifies the overall enhancement in terms of signal clarity. These metrics ensure that while the entropy increases (indicating more information content), the structural fidelity and noise levels remain within acceptable limits. An increase in entropy that leads to a significant drop in SSIM or PSNR could imply the introduction of artifacts or noise—an undesirable outcome in clinical imaging.

Looking at the wider clinical relevance, better-quality mammograms can meaningfully support both human readers and automated CAD tools. Features like spiculated masses, architectural distortions, and fine calcifications become far easier to identify in processed images. Reducing missed malignancies (false negatives) while cutting down on unnecessary callbacks (false positives) can have a real impact on patient experience and outcomes, particularly in population-level screening contexts.

Running the entire enhancement pipeline automatically also removes a source of variability that commonly affects manual workflows. Consistent output quality, faster turnaround, and minimal need for expert intervention at the preprocessing stage all point toward practical deployment in busy screening environments or large-scale diagnostic programs.

5. CONCLUSION

This paper has introduced a novel automatic hybrid approach for the enhancement of mammographic images, aiming to improve the visual quality and diagnostic value of breast cancer screening tools. The proposed method intelligently adapts to the characteristics of each input image by analyzing its entropy—a measure of information content—to select and apply the most suitable enhancement algorithms. This adaptive mechanism ensures that the method is not restricted to a one-size-fits-all solution, but rather customizes the enhancement strategy to each image, thereby maximizing visual clarity and diagnostic relevance. By combining multiple

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

enhancement techniques in a sequential hybrid framework, the method leverages the strengths of each algorithm—such as global contrast enhancement, local detail amplification, and noise suppression—to produce a more informative and diagnostically valuable output. The experimental results confirm that this approach significantly improves the contrast, sharpness, and visibility of key anatomical features such as microcalcifications, masses, and tissue structures that are crucial in identifying early signs of breast cancer.

Beyond visual assessment, the method was evaluated against standard quantitative benchmarks — entropy, SSIM, and PSNR. Results across these metrics showed that the enhanced images were not only richer in content but also structurally sound, with no significant loss of image fidelity or introduction of unwanted distortions.

From a clinical standpoint, the practical value of this work comes down to what better images mean for diagnosis. Radiologists working with enhanced mammograms are better positioned to make sound, evidence-based calls, with fewer missed cancers and fewer unnecessary recalls compared to working from unprocessed scans. The pipeline's fully automated design also makes it a strong candidate for embedding into computer-aided diagnosis (CAD) systems and population-wide screening initiatives and CAD-assisted workflows, where it could cut down on manual preprocessing steps, reduce variability across readers, and speed up overall turnaround.

This study has presented a hybrid, entropy-guided image enhancement pipeline tailored for mammographic images. Rather than relying on a fixed processing chain, the system evaluates each algorithm's effect on image information content and builds an ordered enhancement sequence accordingly. What this means in practice is that the method adjusts itself to the characteristics of each image, rather than applying a blanket treatment. The combination of multiple complementary techniques — spanning contrast adjustment, edge refinement, and noise control — produces images that are both visually clearer and more useful for identifying early markers of breast cancer such as microcalcifications, masses, and subtle tissue changes. Quantitative evaluation using entropy, SSIM, and PSNR confirmed the gains in image quality, while also demonstrating that structural integrity is maintained throughout processing. The fully automated workflow reduces reliance on manual intervention and lends itself to integration within radiological systems and CAD platforms. Ultimately, this approach offers a tangible step forward in supporting earlier and more reliable breast cancer diagnosis, with direct benefits for patient care outcomes.

6. FUTURE WORK

- Evaluating the performance of the proposed method on a larger and more diverse dataset of mammographic images.
- Investigating the use of other image quality metrics, in addition to entropy, for algorithm selection.
- Exploring the optimization of the sequence of enhancement algorithms.
- Developing a user-friendly interface for the proposed enhancement method.
- Investigating the use of deep learning techniques to further optimize the selection and application of enhancement algorithms.

***Abstract*—**Agricultural decision-making in real-world scenarios often requires combining multiple types of information including crop conditions, disease symptoms, and market trends. However, most existing systems address these tasks independently, which limits their practical usability. In this work, we design and implement a hybrid multi-modal AI orchestration framework as part of the AgroSync platform to provide unified agricultural decision support. The proposed system integrates three key components: a language-based advisory module, a vision-based crop disease analysis module, and a statistical forecasting module based on ARIMA. Instead of treating these components as separate solutions, we introduce an orchestration pipeline that manages request classification, contextual data injection, model selection, and structured response generation. The architecture follows a microservice-based design to ensure modularity and scalability, making it suitable for deployment in resource constrained rural environments. The forecasting module uses an ARIMA(5,1,0) configuration to analyze commodity price trends, while the advisory module provides contextual recommendations using language models. Experimental evaluation focuses on system-level behavior rather than isolated model accuracy. Results show that the orchestration pipeline maintains consistent output structure, reliable integration across modules, and stable execution of forecasting workflows. The proposed approach demonstrates how combining multiple AI paradigms within a single coordinated system can improve the practicality of agricultural decision support solutions.

Keywords—Artificial Intelligence; Multi-Modal AI; Agricultural Decision Support Systems; AI Orchestration; Crop Disease Detection; ARIMA Forecasting

I. INTRODUCTION

Agriculture in developing regions often involves decision-making under uncertainty, where farmers need to consider multiple factors such as soil conditions, crop health, weather patterns, and market prices. While several digital tools have been developed for tasks like crop recommendation, disease detection, and price forecasting, these systems usually operate independently and do not provide a unified decision-making experience.

In practical scenarios, these tasks are interconnected. For example, identifying a crop disease should ideally lead to immediate treatment suggestions, while market trends should influence decisions on when to sell produce. However, most existing agricultural AI solutions focus on optimizing individual models rather than integrating them into a single coordinated system.

In this work, we focus on addressing this gap by designing a hybrid multi-modal AI orchestration framework within the AgroSync platform. The goal is not to build a new standalone model, but to create a system that effectively combines multiple AI services into a structured pipeline. The framework integrates language-based advisory reasoning, image-based crop disease analysis, and time-series forecasting using ARIMA models.

A key contribution of this work is the introduction of a deterministic orchestration pipeline that manages how user requests are processed. This includes classifying the type of request, injecting relevant contextual information such as crop type and region, selecting the appropriate AI module, and enforcing a structured output format. This approach ensures consistency across responses and reduces ambiguity when multiple AI services are involved.

The proposed architecture follows a microservice-based design, allowing each AI component to function independently while still being part of a unified system. This makes the framework scalable and adaptable for real-world deployment, especially in environments with limited computational resources.

Overall, this work emphasizes system-level integration over isolated model performance, highlighting the importance of orchestration in building practical and deployable agricultural

decision support systems.

II. RELATED WORK

A. Agricultural Decision Support Systems

Early agricultural decision support systems relied on rule-based expert systems incorporating agronomic heuristics and static rule sets. With the advent of machine learning, supervised learning techniques such as Random Forests, Support Vector Machines, and Neural Networks have been widely applied to crop recommendation and yield prediction tasks **[8], [9]**.

However, these systems typically focus on singular predictive objectives and lack integration across advisory, diagnostic, and forecasting domains. Furthermore, most implementations are model-centric rather than architecture-centric.

B. Vision-Based Crop Disease Detection

Computer vision has been extensively applied to crop disease classification using convolutional neural networks trained on curated leaf datasets **[12]**. While such approaches demonstrate strong classification performance, they require extensive labeled datasets and retraining for new crop categories

Multimodal vision-language models offer broader generalization capabilities by leveraging pre-trained representations. However, systematic architectural integration of such models within scalable agricultural platforms remains limited.

C. Time-Series Forecasting in Agricultural Markets

Commodity price forecasting has traditionally employed statistical models such as ARIMA and SARIMA due to their interpretability and computational efficiency **[1].** Deep learning approaches including LSTM and Transformer-based forecasting models have been explored but often require large datasets and substantial computational resources.

For infrastructure-constrained environments, lightweight and interpretable models remain attractive for integration within decision support systems.

D. Hybrid AI Architectures

Hybrid AI architectures combine symbolic reasoning, statistical modeling, and neural inference to leverage complementary strengths **[6]**. In enterprise systems, microservice-based architectures facilitate modular AI integration through API abstraction layers.

Despite growing adoption in enterprise AI systems, hybrid AI orchestration frameworks tailored for agricultural decision support remain underexplored. This work advances the field by presenting a structured integration strategy designed specifically for agricultural contexts.

III. PROPOSED HYBRID MULTI-MODAL AI ARCHITECTURE

The proposed framework adopts a layered microservice-oriented architecture to ensure modularity, scalability, and infrastructure efficiency. The architecture is illustrated in **Fig. 1**.

Fig. 1. Layered Hybrid AI Architecture of the Proposed Framework.

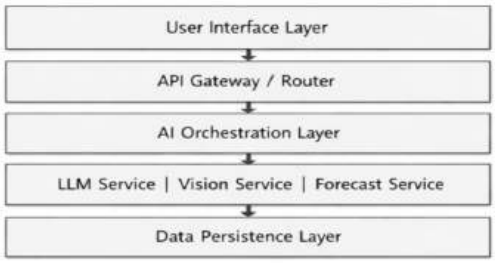

Figure 1. Layered Hybrid AI Architecture of the Proposed Framework.

The architecture consists of five primary layers:

1. Presentation Layer
2. API Gateway Layer
3. AI Orchestration Layer
4. Multi-Modal AI Services Layer
5. Data Persistence Layer

A. Presentation Layer

The Presentation Layer provides a multilingual user interface
enabling farmers to submit natural language queries, upload crop images, and visualize forecasting outputs. The frontend remains stateless and communicates exclusively through RESTful APIs to ensure separation of concerns.

B. API Gateway Layer

The API Gateway acts as the centralized routing controller, handling
request authentication, validation, and routing. It abstracts internal
services from direct exposure and enforces uniform request formatting.

C. AI Orchestration Layer

The AI Orchestration Layer is the core intelligence mediator of the framework. It performs:

- Request classification
- Context injection
- Model selection
- Structured prompt generation
- API invocation
- Schema enforcement
- Response normalization

This deterministic orchestration pipeline ensures reliable integration of heterogeneous AI modules.

D. Multi-Modal AI Services Layer

The system integrates three primary AI paradigms:

1. Text-based advisory reasoning via LLM APIs
2. Image-based disease analysis via multimodal vision APIs
3. Statistical price forecasting via ARIMA modelling

Each service is encapsulated within modular abstraction classes to ensure provider independence and fault isolation

E. Data Persistence Layer

The Data Layer stores user logs, forecasting datasets, and system metadata using relational database management systems. Normalized schema design ensures data integrity and

efficient retrieval.

IV. AI ORCHESTRATION PIPELINE

The defining contribution of the proposed framework is its deterministic AI orchestration mechanism, which coordinates heterogeneous AI services within a unified decision-support workflow. The orchestration pipeline is illustrated in **Fig. 2**.

Fig. 2. Multi-Modal AI Orchestration Pipeline.

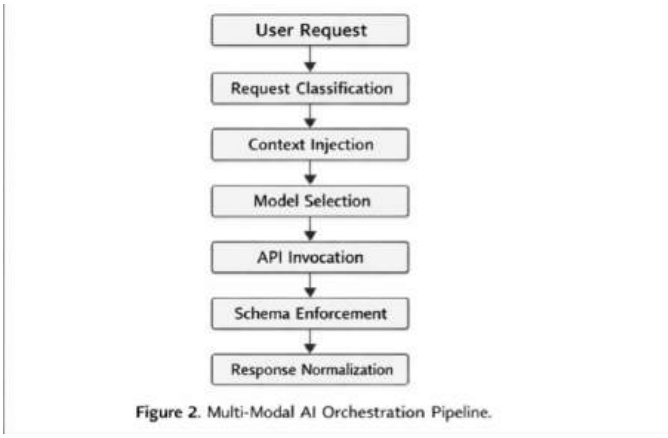

Figure 2. Multi-Modal AI Orchestration Pipeline.

The pipeline consists of the following sequential stages:

1. Request Classification
2. Context Injection
3. Model Selection
4. Structured Prompt Construction
5. API Invocation
6. Schema Enforcement
7. Response Normalization
8. Client Delivery

A. Request Classification

Incoming user requests are categorized into one of three primary types:

- Advisory queries (text-based reasoning)
- Disease diagnosis queries (image-based analysis)
- Market forecasting queries (time-series prediction)

Classification is performed using endpoint routing and metadata inspection. This modular routing prevents cross-domain ambiguity.

B. Context Injection

Agricultural queries are highly context-sensitive. The orchestration layer augments user inputs with structured contextual parameters including:

- Crop type
- Geographic region
- Season
- Soil characteristics
- Market metadata (if applicable)
- Language preference

This contextual augmentation ensures domain alignment before AI invocation.

C. Model Selection and Invocation

Based on classified request type, the orchestration layer selects the corresponding AI module:

- LLM-based advisory engine
- Vision-based diagnostic engine
- ARIMA-based forecasting engine

All AI services are accessed via abstraction wrappers, enabling vendor-neutral integration.

D. Schema Enforcement

A critical reliability mechanism is schema-constrained output validation. All LLM-generated outputs must conform to predefined JSON schemas. Invalid responses are either retried or normalized.
This structured validation reduces hallucination risk and improves deterministic behavior.

E. Response Normalization

Final responses are standardized into uniform output formats before being delivered to the client interface. This guarantees UI compatibility and consistent user experience.

V. MULTI-MODAL INTEGRATION STRATEGY

Unlike isolated agricultural systems, the proposed framework enables cross-modal reasoning across advisory, vision, and forecasting modules.
The integration strategy is illustrated in **Fig. 3**.

Fig. 3. Hybrid Multi-Modal AI Integration Model.

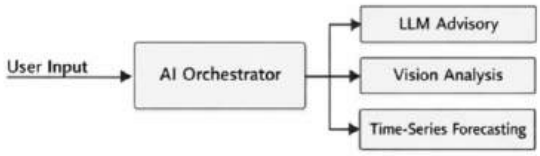

Figure 3. Hybrid Multi-Modal AI Integration Model.

A. Advisory–Forecast Coupling

Forecasting outputs influence advisory recommendations. For example:

- Upward price trends may trigger "hold and sell later" guidance.
- Downward trends may prompt immediate selling suggestions.

This coupling enables dynamic economic reasoning.

B. Disease–Advisory Coupling

Image-based disease diagnosis is integrated into advisory responses. Once a disease is detected:

- Treatment steps are embedded within advisory content.
- Preventive measures are generated contextually.

This reduces fragmentation between diagnosis and recommendation.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C. Cross-Module Context Sharing
The orchestration layer allows modules to share contextual metadata. This shared-state mechanism enables composite decision-making rather than isolated inference.

VI. STRUCTURED PROMPT ENGINEERING FORMALIZATION

Prompt engineering plays a foundational role in ensuring deterministic advisory outputs.
We formalize the prompt construction process as:

$$P = f(U, C, L, S)$$

Where:

- U= User input
- C= Context parameters
- L= Language directive
- S= Output schema constraint
- f= Template transformation function

A. Role Conditioning
Each advisory prompt begins with domain-specific role definition:
"You are an agricultural advisory expert specializing in regional farming conditions."
Role conditioning restricts generative scope**.**

B. Schema-Constrained Output
Outputs are enforced to match structured JSON format:

```
{
"analysis": "...",
"recommendations": "...",
"precautions": "...",
"language": "..."
}
```

Schema validation ensures response reliability and downstream compatibility.

C. Multilingual Determinism
Language enforcement is embedded directly within prompt construction rather than applied via post-processing translation. This approach improves semantic consistency**.**

VII. STATISTICAL FORECASTING INTEGRATION

The forecasting module integrates an Autoregressive Integrated Moving Average (ARIMA) model configured as ARIMA(5,1,0). The forecasting pipeline is illustrated in **Fig. 4**.

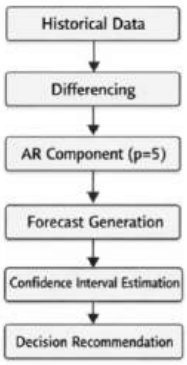

Fig. 4. ARIMA-Based Forecasting Workflow.

A. Mathematical Formulation
The general ARIMA(p, d, q) model is defined as:

$$(1-\sum_{i=1}^{p}\phi_i L^i)(1-L)^d y_t=(1+\sum_{j=1}^{q}\theta_j L^j)\epsilon_t$$

Where:

- $L$is the lag operator
- $\phi_i$are autoregressive coefficients
- $\theta_j$are moving average coefficients
- $d$is differencing order
- $\epsilon_t$is white noise

For the implemented configuration:

$$p = 5, d = 1, q = 0$$

This yields:

$$(1 - \Sigma\, \varphi_i\, L\hat{}i)(1 - L)\hat{}d\, y_t = (1 + \Sigma\, \theta_i\, L\hat{}i)\, \varepsilon_t$$

B. Stationarity and Differencing
First-order differencing ensures stationarity:

$$\Delta y_t = y_t - y_{t-1}$$

This stabilizes the mean and enables autoregressive modeling.

C. Forecast Utilization
Forecast outputs include:

- Short-term price prediction
- Confidence intervals
- Trend direction classification

These outputs are injected into advisory modules for integrated decision support.
Statistical forecasting approaches such as ARIMA remain particularly suitable for agricultural decision support due to their interpretability and minimal computational requirements. Unlike deep learning forecasting models that require extensive training datasets and specialized hardware accelerators, ARIMA models can operate efficiently using limited historical commodity price data. This property makes ARIMA-based forecasting practical for deployment in rural agricultural environments where computational infrastructure may be constrained. Additionally, the transparency of autoregressive models allows agricultural advisors and policymakers to interpret predicted price trends and confidence intervals, improving trust in automated market-aware decision support recommendations.

VIII. EXPERIMENTAL EVALUATION

The evaluation of the proposed framework focuses on architectural robustness, functional reliability, and modular integration stability rather than large-scale predictive benchmarking. The goal is to validate the feasibility of hybrid multi-modal AI orchestration in an agricultural decision-support context.

A. Evaluation Objectives

The experimental validation addresses the following objectives:

1. Functional correctness of the orchestration pipeline
2. Structured schema compliance of AI outputs
3. Stability of multi-modal routing
4. Forecasting pipeline integrity
5. Observational latency characteristics

B. Functional Validation

1) Advisory Module Testing

Text-based advisory queries were tested across multiple agricultural scenarios including:

- Crop planning recommendations
- Seasonal farming advisory
- Market timing suggestions

Each response was evaluated for:

- JSON schema compliance
- Context inclusion correctness
- Multilingual formatting consistency
- Logical coherence of recommendations

All valid responses adhered to predefined schema constraints. Beyond functional correctness, the modular orchestration architecture was also evaluated for integration stability across heterogeneous AI services. The orchestration layer maintained consistent response formatting when advisory reasoning, disease diagnosis, and forecasting modules were invoked simultaneously. This demonstrates that the structured orchestration pipeline successfully coordinates multiple AI services without cross-module interference. The abstraction-based service design further enables individual AI components to be updated or replaced without affecting the overall system workflow, improving maintainability and long-term system robustness.

2) Vision-Based Disease Analysis Testing

Image-based diagnosis was evaluated using sample crop leaf images representing common disease categories.

Validation criteria included:

- Proper image encoding and API invocation
- Disease identification output structure
- Integration of treatment recommendations
- Advisory coupling consistency

The orchestration layer successfully routed diagnostic outputs into advisory modules for integrated responses.

3) Forecasting Pipeline Validation

The ARIMA(5,1,0) model was validated using statistically structured synthetic commodity price sequences to demonstrate forecasting pipeline functionality.

Evaluation included:

- Stationarity verification after differencing
- Autoregressive coefficient stability
- Forecast generation consistency
- Confidence interval estimation

The forecasting outputs were successfully integrated into advisory reasoning for market-aware recommendations.

C. Observational Latency Analysis

Although no dedicated benchmarking framework was deployed, qualitative latency observations indicated:

- Text-based advisory latency primarily dependent on external LLM inference time
- Vision analysis latency dependent on image encoding size and API processing time
- ARIMA forecasting latency negligible due to local computation

Future quantitative evaluation will incorporate timestamp-based logging and statistical latency measurement.

D. Proposed Quantitative Metrics for Future Work

For empirical benchmarking in future deployment phases, the following metrics are proposed:

- Root Mean Squared Error (RMSE) for forecasting
- Mean Absolute Error (MAE) for price prediction
- Schema Compliance Rate for advisory responses
- Average API Response Time
- Throughput under concurrent request simulation

These metrics establish a foundation for future large-scale evaluation.

IX. SCALABILITY AND DEPLOYMENT ANALYSIS

Scalability is a primary architectural objective of the proposed framework.

A. Microservice-Based Modularity

The framework follows a microservice-oriented design where:

- Advisory service
- Vision service
- Forecasting service

are implemented as independent modules accessed via RESTful APIs.

This modular design enables:

- Independent scaling of services
- Fault isolation
- Provider replacement without architectural redesign

The microservice-based architecture also supports horizontal scalability through independent service deployment. Individual AI services such as advisory reasoning, image-based disease detection, and forecasting analysis can be scaled independently depending on demand patterns. For instance, image analysis workloads may increase during peak crop disease monitoring periods, while advisory reasoning services may experience continuous usage throughout the agricultural cycle. By separating these

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

services through API-based orchestration, the framework enables flexible infrastructure scaling while maintaining stable system performance.

B. Stateless Frontend and API Gateway

The presentation layer remains stateless, enabling horizontal scaling via load balancing mechanisms.
The API gateway enforces:

- Authentication
- Request validation
- Uniform routing

This separation enhances maintainability and extensibility.

C. Infrastructure Efficiency

Unlike monolithic deep learning deployments requiring GPU infrastructure, the proposed architecture:

- Leverages external AI APIs for inference
- Performs lightweight statistical forecasting locally
- Minimizes hardware requirements

This makes the framework suitable for deployment in infrastructure-constrained rural environments.

X. LIMITATIONS

Despite its architectural strengths, the framework has several limitations.

A. API Dependency

Reliance on external AI providers introduces potential variability in response behavior and latency.

B. Synthetic Forecasting Data

The current validation uses statistically structured synthetic datasets rather than live agricultural market data. Future integration with real-time agricultural market APIs is required for empirical validation.

C. Absence of Field Trials

Large-scale deployment across rural farming communities has not yet been conducted. Real-world usability studies remain future work.

XI. CONCLUSION

This paper presented a hybrid multi-modal AI orchestration framework designed to support practical agricultural decision-making. Unlike traditional approaches that focus on individual model performance, the proposed system emphasizes the integration of multiple AI components into a unified workflow.

The framework combines language-based advisory reasoning, image-based disease diagnosis, and ARIMA-based price forecasting within a structured orchestration pipeline. By introducing stages such as request classification, context injection, and schema-based response validation, the system ensures consistent and reliable outputs across different types of queries.

The microservice-based architecture further enhances modularity and scalability, allowing individual components to be updated or replaced without affecting the overall system. This design makes the framework suitable for deployment in real-world agricultural environments where flexibility and resource efficiency are important.

While the current implementation demonstrates the feasibility of multi-modal AI orchestration, future work will focus on integrating real-time agricultural datasets, conducting large-scale field evaluations, and improving quantitative performance benchmarking.

Overall, this work highlights the importance of system-level design in developing next-generation agricultural decision support platforms that go beyond isolated machine learning models.

Abstract: Severe Plastic Deformation (SPD) processes are wide popularity in developing ultrafine grained (UFG) structured materials for a variety of applications. Among SPD techniques, there are a few techniques that are specially used to process metallic sheets and plates. Cyclic Constrained Groove Pressing (CGP) is one technique, which can produce fine grained structures in metallic sheets or plates in bulk. The process was introduced to develop UFG metallic sheets and plates nearly a decade ago and is now gaining great interest in the material processing field. The objective of this work was to study the influence of CGP processing on the super plastic behaviour of an Aluminium alloy. Samples in "ascast" conditions were processed by CCGP with as cast, 1, 2, 3 and 4 passes. Material obtained was characterized microhardness measurements were done for different test specimens. Grain refinement and microhardness increased with the number of CGP passes.

Keywords: Groove pressing; SPD; Dislocations; Aluminum alloy; ultrafine grain;

1. INTRODUCTION

There have been great advancements in the development of the high-strength metals and alloys and there is always a need for additional enhancements in the properties of materials. Various industries have a need for structural components that are lighter and stronger, particularly in the automotive industries. One of the methods to enhance the properties of the materials is manufacturing the components with ultrafine Grain. Many methods have been used to synthesize materials with Ultrafine Grain (UFG) sizes (10–1000 nm), including inert gas condensation [1], high-energy ball milling and sliding wear [2], etc. These techniques are attractive for producing powders with grain sizes below 100 nm, but cannot be used to make bulk samples. To consolidate the nanometer-sized powders into bulk materials, high pressure and moderate temperature are usually needed. Grains might grow during consolidation, making the bulk materials partially or completely lose the nano-characteristics [3]. It is usually impossible to completely eliminate porosity, even in materials consolidated under very high pressure and temperature. In addition, nano- powders are highly susceptible to oxidation and absorb large quantities of impurities such as O_2, H_2 and N_2, making it difficult to obtain clean bulk materials. The porosity as well as impurities significantly affects the mechanical properties of the bulk materials, often making them brittle [4]. These problems prevent the researchers from studying the intrinsic properties of bulk nano-materials. As a consequence of these difficulties, much attention has been paid to alternative procedures of introducing ultrafine grains in materials by severe plastic deformation (SPD).

UFG materials refer to a class of materials with grain sizes in the range of 100 to 1000 nm, i.e., <1 μm. These materials have grain sizes larger than nano-materials which have now come to be accepted as those with grain sizes less than 100 nm. Methods to produce UFG materials can be grouped into two categories: Bottom-up approach: Bottom-up approach involves consolidating nano- or ultra-fine grain materials from the atomic scale. Examples of such processes include Inert Gas Condensation (IGC), and Chemical Vapor Deposition (CVD).Top-down approach: Top-down approaches involve the refinement of coarse grains to ultrafine grains by SPD techniques that subject the work-piece to high-accumulated strains [5].

SPD process may be defined as metal forming processes in which a large plastic strain is introduced into a bulk metal in order to create UFG metals. The main importance of a SPD process is to produce high strength and lightweight parts with less cost, minimum time and environment harmony. Since several years, it is known that SPD - the plastic deformation of a metallic material up to highest amounts of plastic strain (up to some thousands percent) at low homologous temperatures (typically below 0.3 times of the melting temperature) leads to a subdivision of the initially coarse-grained microstructure into a hierarchical system of cell blocks and dislocation cells. The grain size of the material decreases with the increase in straining of the material. At the same time, the disorientation difference in crystallographic orientation increases. In order to obtain smallest microstructure sizes plastic strains of more than 600 to 800% are necessary.

Conventional methods such as rolling and forging of material processing do not provide such a high straining of the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

material without failure. The special feature of all variants of SPD is that the cross section of the material remains constant during or after SPD processing. Thus highest degrees of plastic deformation are possible because one sample can be subjected several times to SPD in order to accumulate

the total amount of plastic strain. Even though many different variants are known, only a few of them have industrial potential. SPD processes are typically achieving grain refinement in the metal or alloys through the introduction of large strain. The energy accumulated due to deformation helps in the formation of ultrafine grains in a continuous recrystallization process, rather than a nucleation and growth process that is observed in traditional thermo-mechanical processing operations. Another feature of SPD processes is that the external dimensions of the work piece remain unchanged. This allows for the repeated application of the process to accumulate larger strains. Grain refinement by SPD implies the creation of new high angle grain boundaries. This can be achieved by three mechanisms: the first is the elongation of initial grains during plastic deformation, causing an increase in high angle boundary area, the second is the creation of high angle boundaries by grain subdivision mechanisms, and finally, an elongated grain can be split up by a localization phenomenon such as a shear band. Among the three of the mechanisms mentioned, second mechanism is the most important one. The grain subdivision starts at low to medium strains when grains break up in cells and cell blocks. With increasing strain, this substructure evolves towards a lamellar structure. During this process, new high angle boundaries are generated, it happens by the simultaneous action of a microstructural and a texture mechanism. The former starts at low deformations and consist in the accumulation of dislocations in the cell and cell block boundaries in which the misorientions gradually increase with increasing strain. Some boundaries remain low angle boundaries but a significant fraction evolves into medium-high angle boundaries mostly in the range 15° - 30°. The texture mechanism involves the rotation of different parts of a subdivided grain towards different end orientations. This can generate very high misorientations in the range 20° - 60° [21].

2. CGP DEVELOPMENT

Many of the SPD processes developed to achieve UFG materials have their own limitations. CGP is a new technique which has the potential to overcome many of the limitations of the other SPD methods. design with the groove angle (θ)

of 45°, a single pressing yields a shear strain of 1 at deformed region. This is equivalent to an effective strain, $\mathcal{E}_{eff}$, of 0.58. The second pressing is performed with a set of flat dies (Fig.1.6 (c)). By flat

pressing under the constrained condition, the previous deformed region is subjected to the reverse shear deformation while

the previous undeformed region remains undeformed. The cumulative strain, $\mathcal{E}_{eff}$, in the

deformed region following the second pressing becomes 1.16 (double hatched area in Fig.1.6 (c)). After the second pressing, the sample is rotated by 180° (Fig.1.6 (d)). This allows the undeformed region to be deformed by further pressings due to the asymmetry of the grooved die. Then, the successive pressings with a grooved die (Fig.1.6 (e)) and a flat die (Fig.1.6 (f)) result in a homogeneous effective strain of 1.16 throughout the sample. By repeating a CGP process, very large amount of plastic strain can be accumulated in the sample without changing its initial dimensions and, resultantly, an ultrafine grained structure can be obtained.

Many of the SPD processes developed to achieve UFG materials have their own limitations. CGP is a new technique which has the potential to overcome many of the limitations of the other SPD methods. CGP is a practical process to impose nearly uniform strain to specimen by asymmetrical grooved and flat dies. The CGP dies and one pass which contain four stages are exhibited. In each groove pressing, a specimen is placed in the die with slight gap which is equal to the sheet thickness. In each groove stage, the inclined region of the sample is subjected to pure shear, under plane strain condition [11]. In the first pressing, the equivalent strain of 0.58 is imposed to the work piece. Then the second stage, by flat pressing, the previous deformed region is subjected to another 0.58 strain in reverse direction. So after first pressing, the cumulative strain of 1.16 is applied to the deformed sheet. After second stage, the specimen is rotated 180^0 around the pressing direction. By repeating the groove pressing stage, strain of 0.58 is imposed to the previous undeformed region. At the end, the specimen flattened again and one pass of CGP with total strain of 1.16 in whole specimen is completed. The repetition of this process leads to a large amount of plastic strain in sample with no dimension change and ultrafine microstructure is achieved [12]. By repeating the CGP process, a large amount of plastic strain can be accumulated in the work piece without changing its initial dimensions [13]. Fig.1 (a-i) shows a schematic diagram of one pass of CGP specimen with total strain of 1.16. Also Fig.2 (a-g) shows a three dimensional illustration of a Constrained Groove Pressing Technique.

The present study is led by the latter approach. In order to investigate strain distribution in CGPed plates after four pressing steps FEM simulation has been accomplished [14].

Vol. 14, Issue 06, ACSCON - 2026

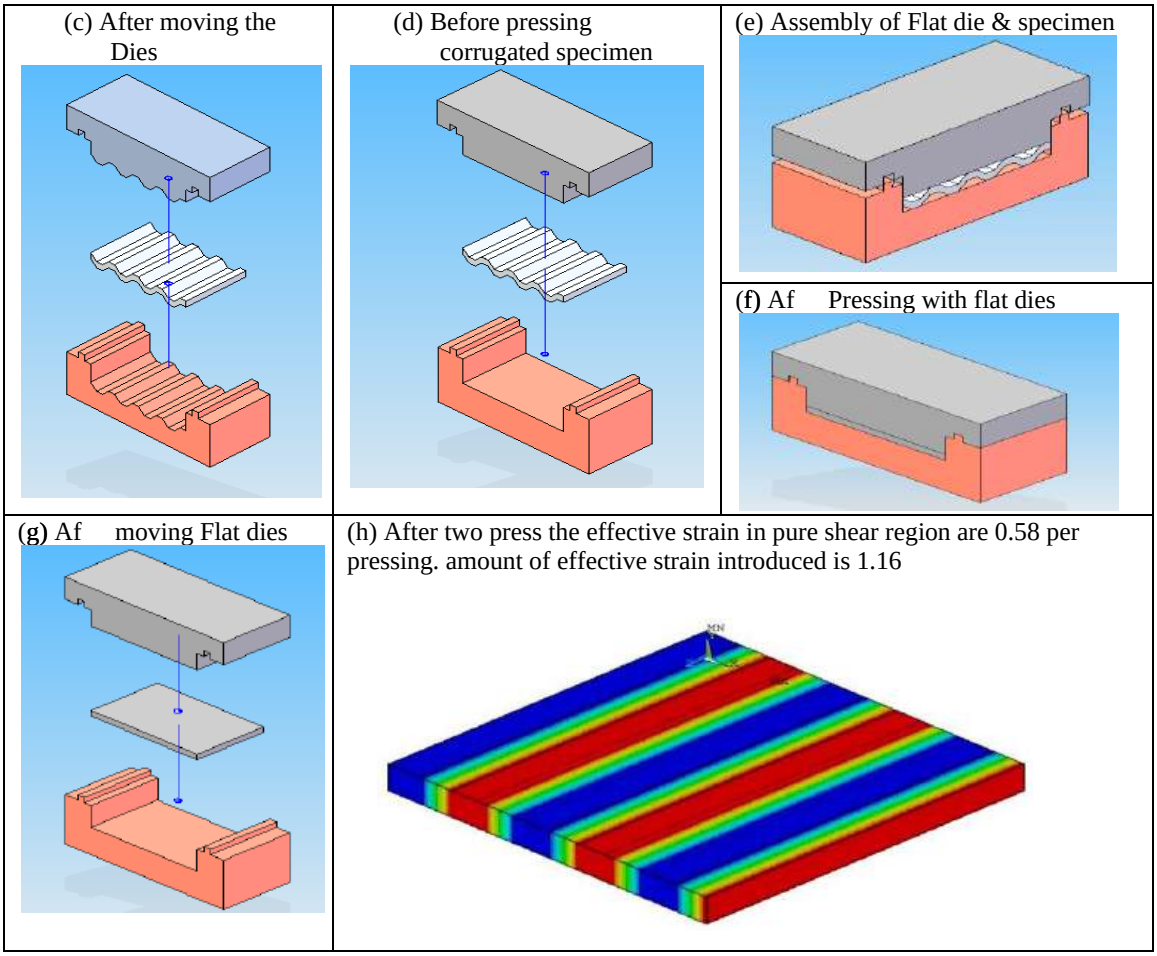

Fig.2: Illustration of a Constrained Groove Pressing Technique

The following gives the equation for the effective strain,

$$\gamma_{xy} = \gamma = \frac{x}{t} = \frac{t}{t} = 1 \tag{1.1}$$

$$\varepsilon_{eff} = \sqrt{\frac{2}{9}\left[(\varepsilon_x - \varepsilon_y)^2 + (\varepsilon_y - \varepsilon_z)^2 + (\varepsilon_z - \varepsilon_x)^2\right] + \frac{4}{3}\left[\varepsilon_{xy}^2 + \varepsilon_{yz}^2 + \varepsilon_{zx}^2\right]} \tag{1.2}$$

$$\varepsilon_{xy} = \frac{\gamma_{xy}}{2} = \frac{\gamma}{2} \tag{1.3}$$

$$\varepsilon_x = \varepsilon_y = \varepsilon_z = \varepsilon_{yz} = \varepsilon_{zx} = 0 \tag{1.4}$$

$$(1.2),(1.3),(1.4) \Rightarrow \varepsilon_{eff} = \sqrt{\frac{4(\gamma/2)^2}{3}} \tag{1.5}$$

$$\varepsilon_{eff} = \frac{\gamma}{\sqrt{3}} \Rightarrow \varepsilon_{eff} = 0.58 \tag{1.6}$$

This method consists of bending of a flat plate using corrugated dies and then restoring the original shape of the plate with flat dies. The repetition of the processes is required to obtain a large strain and desired structural changes. It works upon combinations of shear and bending that are imposed under constraining pressure in specially designed corrugated die surfaces. As it has the potential capability in commercial production, very

i) Effe ive strains accumulated in the specimen after one pass.

3. EXPERIMENTAL PROCEDURE

In the present study, material selected for the investigation is Aluminium alloy ingots. The chemical composition of the above material is mentioned in the Table 5.1. Aluminium alloys (Al 6061). It is used as matrix material and is suitable for mass production of lightweight castings, which can either be sand cast or die- cast.

Table 1: Chemical composition of Al 6061 alloy

Contents	Si	Fe	Cu	Mn	Mg	Cr	Zn	Ti	Al
Weight %	0.62	0.23	0.22	0.03	0.84	0.22	0.10	0.10	Balance

A known quntity of Al6061 alloy ingots were pickled in 10% sodium hydroxide(NaOH) solution at room temperature for 10 minutes. Pickling was done to remove surface impurity such as grease, dust, rust, etc. The smut formed was removed by immering the ingots for one minute, in a mixture of Nitric acid (50%) and water (50%) followed by washing with alcohal. These cleaned ingots were dried in air. The powderd particulate SiC was preheated, to remove the moisture contentent using muffle furnace. It is neccessary in order to reduce the temperature gradient and to improve wetting between molten metal and reinforcement.the melting range of Al alloy is 650^0C to 700^0C, Hence pre-cleaned and preheated furnace is set to the temperature of 700^0C. The cleaned and pickled ingots of the alloy, weighing around 700grams were placed in the aluminium crucible for melting. Argon gas was supplied at the rate of $5mm^3$/hr continuosly into the melting chamber to aviod any accidents and damages.

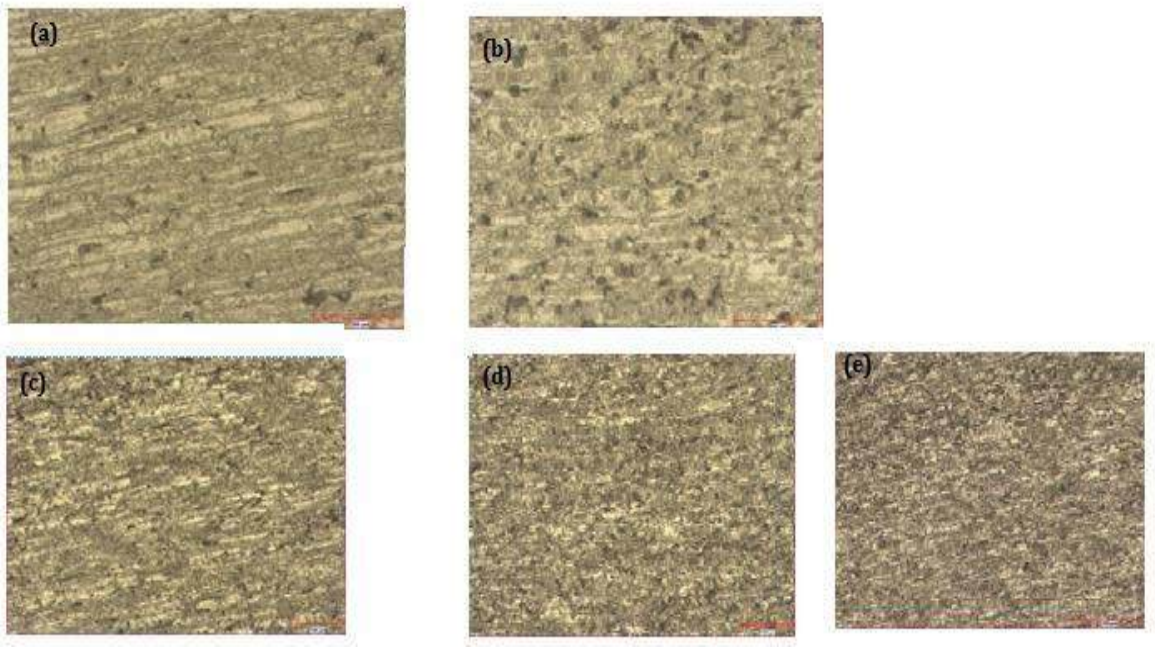

Fig.6: Optical micrographs of CGP specimens a**)** as cast specimen, b) After 1st pass c) After 2nd pass d) After 3rd pass and e) After 4th pass

The molten metal was kept superheated to a temperature of 700^0C and maintained at the same temperature till Al alloy melts. The speed of the stirrer was set to 500 rpm to create vertex in the molten metal. Preheated and known quantity of SiC particulate of 5% by weight was added into the molten metal and continuously stirred in the presence of Argon gas. A preheated and assembled die was placed below the pouring point and the melt was poured into the die. After solidification, the metal was removed from the die and castings were checked for defects physically. From the castings, the samples were cut to a width of 50mm and length of 70mm, for 2mm thickness of several specimens. The Al alloy plates with above dimensions were pressed in a corrugated and flat dies, 1 to 4 passes of compression were considered. All the samples were processed at room temperature. Each pass of this process was consists of two stages and the process was carried out using a pairs of corrugated and flat dies. Fig.4 shows the a) Hydraulic Press b) specimen sand witch between the corrugated die and flat die, Fig.5 shows CGP specimens a) as cast specimen without pressing, b) After 1st pass, c) After 2nd pass, d) After 3rd pass and e) After 4th pass. 4. RESULT AND DISCUSSION

Fig.7 shows the microhardness distribution according to number of passes. The initial hardness of the undeformed specimens has 29HV for 2mm thickness specimen. The formation of substructure after one pass led to an increase in microharness to an average of 7 to 8HV. It is also observed that after two passes of treatment exhibit a further increase in hardness, i.e., average of 7HV. After every pass of CGP, the hardness of the specimen shows increasing trend with an average increase in hardness of 1 to 2HV in all the specimens. Hall- petch equation gives strength of any materials which is inversely proportional to grain size.

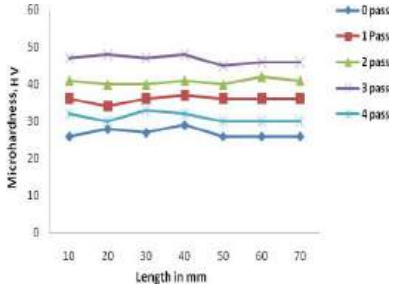

Fig.7: Microhardness distribution according to number of passes

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

In SPD method the yield strength of any materials can be increased by decreased the grain size. As discussed earlier, higher refinement in the grain size leads to an increase in the hardness of the specimens. But the grain refinement is strongly influenced by the increase in strain. The results shows that, increase in microhardness value of the specimens pressed, as the number of passes is increased the hardness increases. After 4th pass maximum fall of hardness that material loses it hardness. We can see that as dislocations formed in the coarse grains, the grain size decreased more and more refined grain size giving rise to the better hardness. The grain size is refined, thereby increasing the hardness during corrugation and straightening process.

5. CONCLUSION

The effect of SPD by Cyclic Constrained Groove Pressing process on the mechanical properties of Aluminium alloy at room temperature was studied. In the present work the following conclusions are summarized.

- Complete process of CGP process simulated using CAE tools.
- Deformation behaviour is characterized by the compression and elongation of material near the flat surface, bending/stretching of the plate in the other region during pressing. Shear regions revealed two distinct deformation zones within the regions; one is simple shear drformation zone, in which the material flow in central regions is characterized by simple deformation, and the other is rotational deformation zone in which the material flow is characterized by rotational deformation observed away from the central regions.
- Two dimensional finite element simulations were carried out to study the stresses induced in CCGP processing with a corrugated and flat dies.
- Aluminium alloy was processed by CCGP from as cast condition with 1 to 4 passes. It was developed procedure to CCGP processing with a corrugated and flat dies.
- The hardness of the specimen has been increased with the number of passes of corrugation and straitening from 29HV to 50HV.
- It was concluded that the ductility will inevitably be detenorated with increase in density on dislocations of dislocations of grain grain boundaries, which directs the great enhance

Abstract—Placement is an extremely crucial activity which decides the future of students and job aspirants. However, placement preparation takes place in an extremely disintegrated fashion on multiple forums ranging from aptitude practice websites to coding websites and interview preparation software. In addition to this, resumes of applicants are discarded by the ATS systems of corporations owing to unorganized resume templates and absence of keywords. The paper introduces a Generative AI-based Placement Preparation Platform that is an amalgamation of ATS Resume Analysis Systems, Artificial Intelligence-based Mock Interviews, Coding Analysis, Mock Tests, and Career Assistance. The platform developed customized real-time responses using Gemini 2.0 Flash, Speech To Text modules, and TensorFlow.js. The proposed system helps students enhance resume optimization, layer-wise interview preparation, and career alignment to fill the gap between academics and industries. The paper highlights the structure, approach, development, and business feasibility of the proposed platform, thus improving placement opportunities for students and early professionals.

Keywords—Generative AI, Placement Preparation, Resume Analysis, Applicant Tracking System (ATS), Mock Interviews, Career Guidance

I. Introduction

Over the past few years, there has been rapid increase in the use of Artificial Intelligence (AI) technology, which has resulted in a major change in the process of selection and placement preparation. Currently, organizations prefer the use of automated selection tools, internet-based test assessments, or data-driven tests to narrow down the pool to eligible candidates. It is, therefore, essential that students and fresh graduates prepare themselves for tests according to their skills, knowledge, as well as Automated Tracking Systems (ATS) and interviews.

Despite the availability of a host of options on the internet today for practicing aptitude, coding problems, and mock interviews, placement preparation is still very disintegrated. As it is now, aspiring candidates have different solutions for making resumes, making resumes for applicant tracking systems, doing mock interviews, and more. But then again, many fitting candidates get filtered out in the initial screening round of recruitment for recruitment based on a resume which is unrelated to applicant tracking systems rather than a lack of skills.

In this scenario, for the elimination of these challenges, this study proposes the following Generative AI-based Placement Preparation Platform that amalgamates the following ATS-based resume analysis methods based on the resume, the intelligent-based resume creation methods based on the resume, AI-based simulation methods for interviews assisted by AI, coding and aptitude tests based on the resume, and the career consulting methods based on the resume with the capability for adaptive assessment methods for ideal placement preparation assistance and the transition from education to industry requirements.

II. RELATED WORK

In recent years, professionals in different fields such as human resource management, resume optimization, and job interview preparation have been using artificial intelligence.

A. AI in Recruitment Systems:

In many research papers, it has been observed that a considerable portion of recruitment outcomes has been taken care of by Applicant Tracking Systems. In one such study carried out by Gupta & Sharma (2022), key filtering was pointed out to eliminate more than 70% of resumes before screening them with humans. Hence, resume builders using AI as per job descriptions have been encouraged.

B. Generative AI for Career Readiness:

Recent research by Zhang in 2023 involving large language models for adaptive career training, and by Brown et al. In 2020, has enabled the possibility for the generation of auto-questions, personalized mock interviews, and analysis of talent gaps. These studies have shown the vast potential for AI for feedback in a particular domain.

Currently available platforms like LeetCode, HackerRank, and InterviewBit concentrate almost entirely on coding, with little consideration for preparing students in an all-rounded

Vol. 14, Issue 06, ACSCON - 2026

fashion, including but not limited to resume analysis, mock interview preparation with HRs, and guidance. Other platforms include VMock and others that focus exclusively on resume ranking with no capacity for mock interviews.

C. AI-Powered Interview Preparation Tools:

Mohan & Arora (2021) studied the use of AI-based tools that have the capacity to assess communication skills, fluent delivery, and technical competence. However, these tools are not able to be adaptable using the function only based on the predetermined data sets. Gemini-based approaches enable the smart follow-up question based on context consideration.

D. G Identified:

Current offerings cater only to a niche audience with no overlap. They may entirely focus on training students concerning resume optimization, programming skills, and aptitude skills, providing no service that gives an amalgamation of various features such as assessment scores of an ATS, Resume creation software, mock interviews for technical and HR, aptitude skills and programming skills assessment tests, and career counselling.

III. METHODOLOGY

The proposed Generative AI-Based Placement Preparation Platform could be designed as follows, combining resume analysis, interview preparation, skill measurement, and career advice activities into a single process in this way:

A. Workflow:

Users are able to authenticate securely through Firebase Authentication and are then led to a customized dashboard that shows their progress and performances that are stored in Firestore.

In terms of resume analysis, users would require inputting their resume, along with a job description for which the resume analysis needs to be performed. Then, there's Gemini 2.0 Flash, which analyzes a resume according to relevance to keywords, formatting, etc., in order to provide a compatibility score for an ATS resume. They also offer an artificial intelligence-powered resume builder tool where a user's input can be turned into an ATS-friendly resume.

The mock interview component mimics actual interview settings conducted in three rounds. Under the technical interview, the responses given by the user are recorded through Speech-to-Text APIs, and the AI system is responsible for providing adaptive follow-up questions. Under the coding interview, the coding solutions for problems are evaluated for accuracy and optimization, while under the HR interview, the responses are analyzed for relevance to predefined behavioral interview questions.

It also provides simulation tests for aptitude, reasoning, automata, English comprehension, essay writing, and personality analysis. The objective answers are automatically evaluated, and the subjective answers are evaluated through Generative AI.

Lastly, the career guidance module is capable of aggregating all the performance data gathered for the user and proposing relevant job positions and career paths.

B. System Architecture

The system follows a client-server architecture comprising frontend (HTML, CSS, JavaScript), backend (Node.js with Express.js), authentication and database (Firebase Authentication and Firestore), AI model (Gemini 2.0 Flash), integration (Speech-to-Text APIs), and deployment (GitHub and Render).

IV. IMPLEMENTATION

The Gen AI-Based Placement Preparation Platform is developed in a modular, scalable fashion that will make it possible to seamlessly integrate with AI services and also make it easily extensible in the future. The proposed design divides the entire system into four different layers – frontend, backend, database, and AI integration.

HTML, CSS, and JavaScript have been utilized for developing the frontend to have a responsive user interface. There is a common dashboard provided, which acts as a hub or point of interaction for all activities, where customers avail services related to resume analysis on ATS, AI-generated resume development, tracking, mock interviews, mock tests, and guidance related to careers.

The backend has been built using Node.js with Express.js, which handles authentication functionality, API mapping, sessions, as well as module integration. Meanwhile, the authentication service delivered by Firebase Authentication handles authenticated access securely, while a cloud database like Firestore handles storage of user profiles, resumes, result scores for assessments, along with interview feedback on a real-time database.

For intelligent processing, the system uses Gemini 2.0 Flash, the core generation model, as an integrated platform. It offers the capabilities of context-aware resume evaluation, adaptive interview question formulation, coding problem assessment, and evaluation of HR feedback. Moreover, Speech-to-Text APIs are used for voice response evaluation in the interview process.

The ATS Resume Analysis tool matches resumes to job descriptions based on keyword gaps and structural problems in the resumes. The AI-driven Resume Builder is a tool that assists in creating ATS-friendly resumes based on specified job roles.

V. BUSINESS MODEL

The Gen AI–based Placement Preparation Platform follows a freemium hybrid business model in order to serve both its individual users and institutional clients most effectively. The freemium approach ensures widespread accessibility in that some of the core features, like ATS compatibility scoring and a limited amount of AI-driven mock interviews, come free of cost. This reduces the entry barrier for students and early professionals, increasing their incentives to use and engage with the platform.

To support users seeking deeper and continuous preparation, premium subscription plans are available. Advanced functionalities include, but are not limited to, unlimited AI-powered mock interviews, in-depth ATS and resume analysis, role-specific resume optimization, personalized career assessment, and comprehensive performance analytics. These aspects will provide a way forward in the systematic and long-term preparation of placements in accordance with changing industry and recruitment trends.

In addition to the individual users, the platform has been strategically placed to provide its services to institutional users, including universities, training institutes, and placement agencies. This includes the extension of the enterprise subscription model, which includes bulk subscription for students, as well as institutional-level dashboards for the institution itself. The latter will help the institution in keeping track of student performance analysis, analyzing their placement readiness, and more, thus enhancing the effectiveness of the campus placement cell and training institutes of the institution itself.

The platform will generate revenues through diversified streams:

- Individual Subscriptions, which include monthly and yearly billing cycles.
- Institutional and Corporate Partnerships, which include training and education institutions.
- Strategic Partnerships, which include online job portals, which will help in real-time application tracking, recruiter synchronization, and enhancing career analytics.
- The course will include AI-based mentorship programs, which will include premium career services, including personalized coaching, in-depth interview feedback reports, and more.

The future prospects with regard to growth in the industry may also include the creation of specific modules for specific domains like 'Technology,' 'Finance,' 'Consulting,' 'Healthcare,' etc. Integration with job portals can also aid in developing more sophisticated AI-based mentor-ship programs.

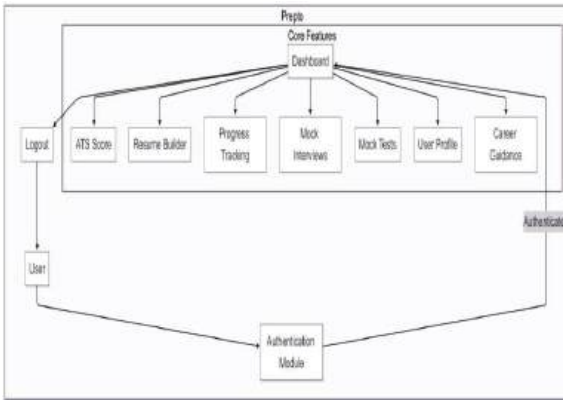

Fig. 3. System Architecture of the platform

VI. RESULTS / EXPECTED OUTCOMES

The proposed Gen AI-Based Placement Preparation Platform has shown improvements in key areas with regard to placement preparation, which includes resume preparation, interview preparation, aptitude performance, and career clarity.

A. Resume Quality:

The results of evaluations of the ATS module reveal that by resume optimization, an average improvement of 40 to 60 percent in ATS compatibility scores has been seen by users.

B. Mock Interviews:

Adaptive questioning systems based on artificial intelligence helped optimize candidate answers by diminishing stress levels during simulated technology and human resource-related interviews.

C. Coding Assessments:

Instant feedback aid in improving the problem-solving ability and bug-fixing capability by providing assistance in error detection in the logic to be optimized.

D. Aptitude Tests:

AI-assessed mock tests and continuous practice showed a marked improvement in numerical, logical, and verbal reasoning skills with a statistically significant improvement in scores.

E. Career Guidance:

A career guidance module was able to identify the user's skill set and associate them with appropriate roles, offering genuine salary information, analysis of skill gaps, and direction on personalized career options.

F. Pilot Testing Outcomes :

The pilot testing of the platform showed the following results:

- Shortlisting of resumes was optimized by about 50% relative to ATS-based systems.
- Self-perceived confidence during interviews rose by almost 40%, largely due to repeated simulation practices with aid of AI.
- Participating institutions saw an increase in placement ratios, establishing the success of this platform.

These points are further supported by figures 1, 2, and 3, which display the homepage of the platform, the users' dashboards, and system designs, respectively, and further clarify the viability of the system proposed.

VII. DISCUSSION

The effectiveness of the proposed Gen AI-Based Placement Preparation Platform is evident in the result analysis. Previously, job seekers had to use a variety of standalone platforms for aptitude test practice, programming challenges, resume development, and interview sessions. The unorganized pattern in placement preparation may result in unorganized performance and lack of progress monitoring. Moreover, it fails to comply with industry standards of placement in terms of ATS-based screening processes. The proposed solution removes these issues as it provides a fully automated platform in a single domain for all the necessary placement preparation tasks.

One of the major insights gained through the implementation is that the system has increased the quality and compatibility of the resumes with the ATS. This is because the system assesses the resumes based on the job description and recommends the relevant format and key words that help candidates improve their chances of being short-listed.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

It further improves interview readiness by providing the candidate with simulated interviews using AI, which are based on actual technical, coding, and human resources interviews. Adaptive questioning, voice response assessment and feedback help the candidate to improve the clarity, confidence and communication of the response. By getting exposed to such simulations again, the candidate can overcome the fear of interview. Regarding the skill assessment, coding assessment reviews and aptitude tests with real time feedback help to improve efficiency and understand of problem solution. The mention of performance tracking over time also helps the candidates to understand their improvement and focus on the improvement areas. This kind of training and practice method is very helpful to the candidates compared to the traditional training and practice without any feedback.

The addition of the career guidance feature is also helpful for the system. This feature maps the skills provided by the user to job titles, salaries and career paths. This feature is helpful to the candidate because the candidate usually has doubts about which career to opt for and what skills to possess.

From the institutional point of view, it may be clearly stated that it is a scaleable system in nature. It would definitely help the institution/Placement Cells to keep an eye on the preparations by making use of a dashboard. It may be clearly stated that it is an extensible system in nature, which means it may be extended even further by incorporating features like interview, jobs portal, AI-based mentoring, etc.

In Conclusion, From the above explanation given in this section, it may be clearly inferred that there is immense potential in this proposed system to bring in a holistic approach to the preparations made by the students. The system would definitely help in avoiding the dependencies on individual tools and bring in the concept of smart automation to make it an efficient system in pre-placement preparations with higher levels of candor in the candidates, along with the focus on academic learning patterns with reverence to industry recruitment trends.

VIII. CONCLUSION

To address the fragmented nature of placement preparation, and hence align the levels of candidate readiness with respect to placement preparation with contemporary levels of recruitment, the proposed work focused on the implementation of a Placement Preparation Platform using Generative AI. The Placement Preparation Platform includes a range of activities like optimizing resumes for ATS, conducting mock interviews with AI, coding tests, and aptitude tests.

The result of these experiments indicates an improvement in the quality of resumes, confidence levels during interviews, coding speeds, and placement preparedness. In addition, pilot testing indicates an improvement in the shortlisting of resumes as well as placement success at an institutional level, thus justifying the relevance of the proposed system. In addition, there is a flexibility and scalability feature that will allow it to accommodate future developments in AI.

Going forward, there is a huge scope to improve this platform by integrating various job portals around the world, which can allow direct applications to a job after fulfilling ATS standards. Adding professional interview tests in domains like finance, consulting, etc., can add more to domain expertise on this platform. Additionally, AI-based mentorship and career development platforms, which can provide human wisdom along with AI-based inputs, can further enhance domain expertise on this platform. Going forward, employability solutions around the world can make it a ‘one-stop’ platform for employability solutions around the world.

In conclusion, the proposed system can be considered an important step towards a more ‘smart,’ ‘inclusive,’ and ‘goal-oriented’ placement preparation system. In addition to that, it has huge potential to enhance employability in the current competitive world with AI-integrated jobs.

Investigations on Stresses and Displacements of Annular Rotating Disc using FEA

Tejas V[1], Nikhil Das S[1],
Dr. H S Siddesha[2]
[1]Student, Mechanical Engineering Department,ACSCE,Bangalore-74
[2]Professor,Mechanical Engineering Department,ACSCE,Bangalore-74
Email: skphss@gmail.com

Abstract - Engineering components that can be modeled as a rotating disc include the rotor of a turbine engine, saw blades, grinding wheels, and computer magnetic recording disks etc. The rotating disc is subjected to centrifugal force which tends to pull the disc in radial direction, introduces large stresses and displacements on the disc. Further the disc is mounted on a shaft by interference fit. The stresses and displacements of the rotating disc are estimated for potential boundary conditions by building a finite element model using ANSYS. The disc is meshed using SOLID45 elements by taking the rotating disc to be 3D cyclic symmetric model. The contact simulation is done for shaft and disc using surface to surface contacts in ANSYS. The linear isotropic material model is used.

The model creation for the given dimension with the required material properties is done by APDL (Ansys Parametric Design Language) macro. The user inputs the dimensions of the disc in the macro, which takes care of the model preparation, mesh generation, applying boundary conditions, solution and post processing for the load case. This gives flexibility to change the parameters and material properties according to user specification and saves time for finite element model preparation.

Key words: Cyclic symmetry, Plane stress, Plane strain, Interference fit, surface to surface contact.

1. INTRODUCTION

The Finite element method has become a powerful tool for numerical solution of a wide range of engineering problems. Applications range from deformation and stress analysis of automotive, aircraft, building and bridge structures to field analysis of heat flux, magnetic flux, and fluid flow problems. With advances in computer technology and CAD/CAE systems, complex problems can be modeled with relative ease. Several alternative configurations can be tried out on a computer before the first prototype is built. In finite element analysis, a complex region defining continuum is discretized into simple geometric shapes called finite elements. The material properties and the governing relationships are considered over these elements and expressed in terms of unknown values at element corners. An assembly process, duly considering the loading and constraints, results in a set of equations. Solution to these equations gives us the approximate behavior of the continuumThe problem of rotating disc was investigated for various conditions, as fallows:

Eraslan and Orcan [1] investigated rotating variable thickness elastoplastic annular disks with inner boundaries subject to pressure or mounted on rigid inclusion parametrically and developed computer model based on von mises criterion, deformation theory and non linear isotropic hardening. Eraslan [2] investigated A Class of Nonisothermal Variable Thickness Rotating Disk Problems Solved by Hypergeometric Functions. Exact solutions for nonisothermal variable thickness rotating disks represented by different thickness profiles are obtained under plane stress assumption. The solutions are based on Tresca's yield criterion, its associated flow rule and linear strain hardening material behavior. D.W.Cameron,P.R.Geise, J.S.Abbott [3] ,

Vol. 14, Issue 06, ACSCON - 2026

presented method of setting centrifugal impeller over speed limits. The primary means of this determination is based on invoking yield criterion to control stresses.

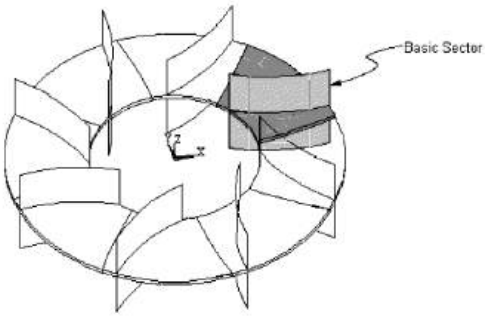
2. FEA modeling using ANSYS

2.1 Modeling of rotating disc

The cyclic symmetric model of the disc is modeled using ANSYS APDL macro the mode is meshed using SOLID45 Element. A cyclic symmetry analysis requires that you model a single sector, called the basic sector. A proper basic structure represents one part of the a pattern that, if repeated N times in cylindrical coordinate system, yields the complete model. Analysis is carried out with csys1 with X,Y&Z axis set as Radial, Hoop & Axial directions respectively.

2.2 Meshing conditions

The model is meshed with SOLID45 elements with no wedges or tetrahedron element, with minimum 3 elements along thickness to capture bending behavior. The interference between the shaft and the disc is meshed to have matching nodes along the bore. This is required for generating contact and target elements as much close as possible (the nodes of contact element and target element is made co-incident for better convergence). Care should be taken that no elements which come under warning or error criteria. The criteria for measurement include 1.Aspect ratio 2.Warpage 3.Maximum and minimum angle 4.Jacobian etc. The mesh pattern of the cyclic faces of the sector is made same, to apply cyclic symmetry boundary conditions.



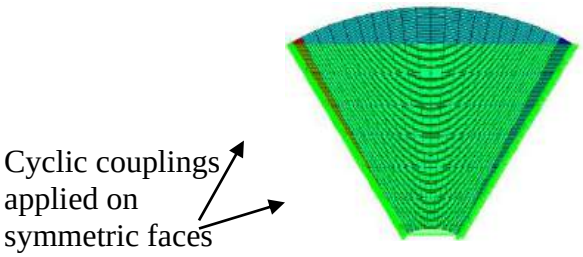


Fig 2.1 Typical rotating disc with basic sector.

2.3 Symmetry boundary conditions

In actual condition both the faces of the cycle, will experience similar stresses and displacements. Hence both the faces should have matching nodes and they are coupled in all degrees of freedom. The couplings achieve symmetry boundary conditions.

Fig 2.2 Boundary condition on basic sector.

2.4 Constraints

To prevent rigid body motion the rotating disc sector is constrained in axial and hoop directions as shown in the figure 2.3 and figure 2.4.

2.4.1 Axial constraints: The nodes on one face are constrained in axial direction i.e. Uz direction (Fig 2.3).

2.4.2 Hoop Constraints: The nodes on the other faces are constrained in hoop direction i.e. Uy direction as shown in figure 2.4.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

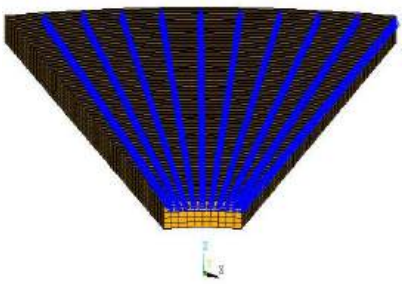

Fig 2.3 Axial constraint

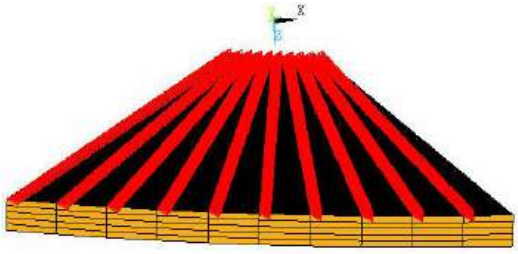

Fig 2.4 Hoop constraint

2.5 Contact simulation

The contact between the shaft and the rotor is simulated by generating contact elements between them and applying required interference as CNOF value, contact surface offset (Real constant number 10 for contact 174).

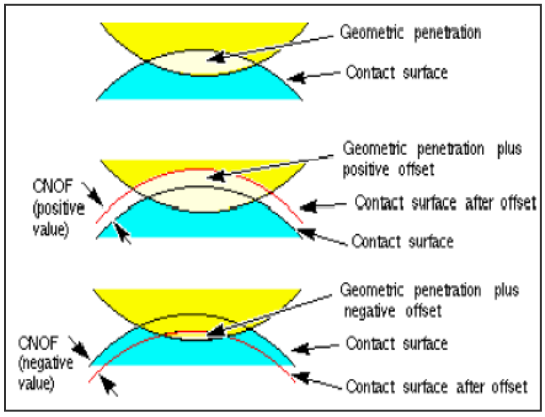

Fig 2.5 Components of True penetration.

3 Equations for stresses and displacements of rotating disc:

3.1 Disc mounted on the shaft with interference

The lames equations for compound cylinder problem can be used to estimate the stresses considering the pressure on the external side as zero i.e. no resistance to expansion from the outside.

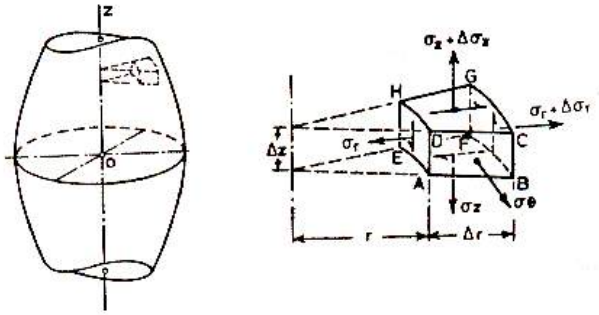

Fig 3.1 cylindrical coordinates of a point and stress on an element

Fig 3.2 cylinder subjected to internal pressure.

3.1.1 Plane stress approach:

We assume that $\sigma_z = 0$, stress in axial direction is zero the equation for radial stress at any location 'r' is given by

$$\sigma_r = \frac{p_a a^2 - p_b b^2}{b^2 - a^2} - \frac{a^2 b^2 (p_a - p_b)}{r^2 (b^2 - a^2)} \quad .....3.1$$

$$\sigma_\theta = \frac{p_a a^2 - p_b b^2}{b^2 - a^2} + \frac{a^2 b^2 (p_a - p_b)}{r^2 (b^2 - a^2)} \quad .....3.2$$

$$\sigma_z = 0 \quad .....3.3$$

Here P_a and P_b are internal and external pressure respectively. The sum of $\sigma_r + \sigma_\theta$ is constant through the thickness of the wall of the cylinder i.e. independent of 'r'. Hence according to Hooks law, the stresses σ_r and σ_θ produce a uniform extension or

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

contraction in Z-direction and cross section perpendicular to the axis of the cylinder remains plane. If we consider two adjacent cross-sections, the deformation undergone by the element does not interfere with the deformation of the neighboring element. Hence, the elements can be considered in the state of plane stress, i.e. $\sigma_z = 0$.

3.1.2 Plane strain condition.

When the cylinder is fairly long sections that are far from the ends can be considered to be in a state of plane strain and we can assume that σ_z does not vary along the Z-axis

$$\sigma_r = \frac{p_a a^2 - p_b b^2}{b^2 - a^2} - \frac{a^2 b^2 (p_a - p_b)}{r^2 (b^2 - a^2)} \quad .....3.4$$

$$\sigma_\theta = \frac{p_a a^2 - p_b b^2}{b^2 - a^2} + \frac{a^2 b^2 (p_a - p_b)}{r^2 (b^2 - a^2)} \quad .....3.5$$

$$\sigma_z = 2\upsilon \frac{p_b a^2 - p_a b^2}{b^2 - a^2} \quad .....3.6$$

The values of σ_r and σ_θ are identical in both plane stress and plane strain condition. But σ_z has a constant value in plane strain condition while it is zero in case of plane stress condition.

3.2 Disc mounted on the rotating shaft without interference:

3.2.1 The equation for radial stress at any location 'r' is given by,

$$\sigma_r = \frac{3+\upsilon}{8} \rho\omega^2 \left[b^2 + a^2 - \frac{a^2 b^2}{r^2} - r^2 \right] \quad ...3.7$$

3.2.2 The equation for circumferential stress at any location 'r' is given by,

$$\sigma_\theta = \frac{3+\upsilon}{8} \rho\omega^2 \left[b^2 + a^2 + \frac{a^2 b^2}{r^2} - \frac{1+3\upsilon}{3+\upsilon} r^2 \right] ....3.8$$

3.2.3 The maximum radial stress is at, $r = \sqrt{ab}$ and is given by,

$$\sigma_{r\max} = \frac{3+\upsilon}{8} \rho\omega^2 (b-a)^2 \quad ...3.9$$

3.2.4 The max circumferential stress is given by,

$$\sigma_{\theta\max} = \frac{3+\upsilon}{4} \rho\varpi^2 \left(b^2 + \frac{1-\upsilon}{3+\upsilon} a^2 \right) \quad ....3.10$$

3.3 Disc mounted on the rotating shaft with interference

The equation for stresses in this case, are not close formed but the stresses will be cumulative of above two cases. The radial stress in case 3.1 are compressive in nature and tend to nullify with tangential stresses from the case 3.2. The Hoop stresses are tensile in both the cases and the stresses will increase as a result of stress accumulation.

3.4 Effect of increase in outer diameter of the disc

As the diameter increases, there is a mass increase as well as radius increases, consequently the radial force on the disc increases as

$$F = mr\omega^2 \quad .....3.11$$

Where F is radial force, m mass of disc, r radius of disc and ω angular velocity of the disc. As a result there will be proportionate increase in the stress.

3.5 Effect of increasing disc speed

As the speed increases, force is squared, consequently the radial force on the disc increases as given in equation 3.11. If a stress s_1 is determined at speed of n_1 rpm and is desired to know the stress s_2 at the speed n_2 rpm the fallowing expression can be manipulated to determine the desired quantity.

$$\frac{s_1}{s_2} = \frac{n_1^2}{n_2^2} \quad .....3.12$$

4. Results and Discussion

The creation of geometry, discretization and application of boundary conditions was done by creating a macro using ANSYS Parametric Design Language

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

(APDL) as it provides greater flexibility of changing geometry and loads.

A portion of disc can be modeled, instead of full disc using cyclic symmetry, which in turn saves computation time as number of elements reduces. The macro can be run for different diameters of disc and different magnitude of loads but for the sake of calculations and result interpretation following geometry and loading conditions are chosen.

Geometry	
Inner diameter of disc	150 mm
Outer diameter of disc	750 mm
Thickness of disc	10 mm
Material properties (Standard Steel)	
Modulus of Elasticity	210000 MPa
Density	7.85e-09 Tonnes/mm^3
Poisson's Ratio	0.29
Loads	
Speed	10000 rpm
Interference	0.2 mm

We will investigate the behavior of the rotating disc for the following cases Using cyclic symmetry boundary condition:

1. Disc mounted on the shaft with interference.
2. Disc mounted on the rotating shaft without interference.
3. Disc mounted on the rotating shaft with interference.
4. Effect of increasing the outer diameter of the disc.

Effect of increasing disc speed

4.1 Disc mounted on the shaft with interference

The maximum contact pressure is 298.6, with entire area in contact with shaft having pressure in the range of 265.422 to 298.6.Thus the FEA result agrees with the theoretical calculation which is given by

$$\frac{E\Delta}{2c}\frac{\left(b^2-c^2\right)}{\left(b^2\right)}=\frac{210000\times 0.2\times[(375)^2-(75)^2]}{2\times(75)\times(375)^2}=268.8\ \text{MPa}$$

C = inner radius of disc (mm), b= outer radius of the disc (mm), △= interference (mm)

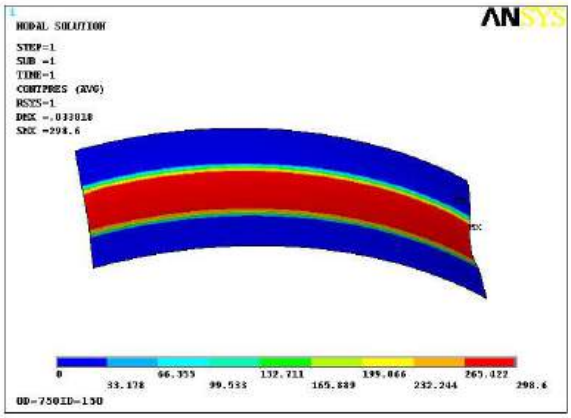

Fig 4.1 Contact Pressure Plot

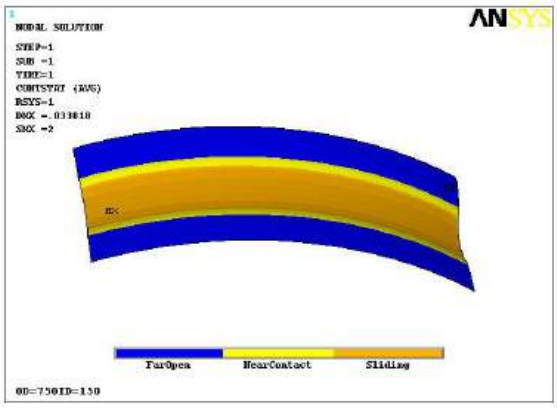

Fig 4.2 Contact status plot.

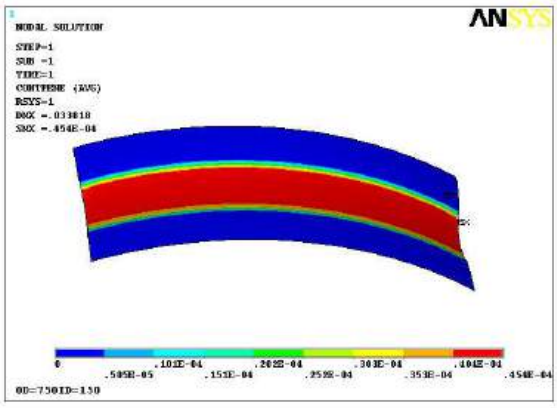

Fig 4.3 Contact penetration plot.

The contact status plot gives information on whether the disc is in contact with the shaft,

Vol. 14, Issue 06, ACSCON - 2026

as contact elements are generated between the interface of the shaft and the disc. The contact penetration plot gives the information about how correct the contact simulation was done by fixing the value of contact stiffness, lower the penetration better is the contact result accuracy. Also the plots for radial stress, circumferential stress, axial stress, equivalence stress and radial displacements were obtained.

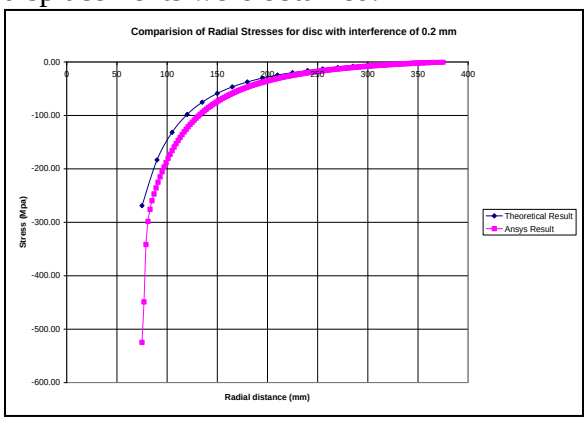

Fig4.4 Comparison of radial stress, analytical and ANSYS result.

The graph shows the stresses using FEA are quite large near the inner radius as result of interference. The graph matches well in region other than inner radius.

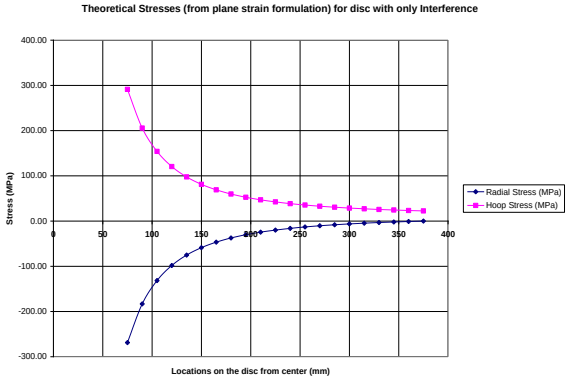

Fig4.5 Theoretical stress distribution.

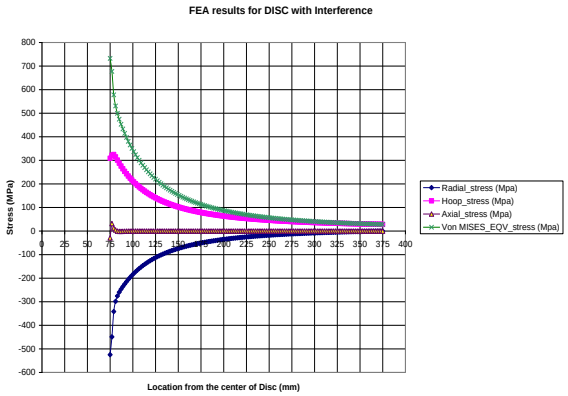

Fig4.5 Stress distribution from FEA results.

4.2 Disc mounted on the rotating shaft without interference.

The max radial stress is given by equation 3.9 gives $\sigma_{r\max}$ = 319.590 MPa.

The max circumferential stress is given by equation 3.10 gives $\sigma_{\theta\max}$ = 1007.1920 MPa.

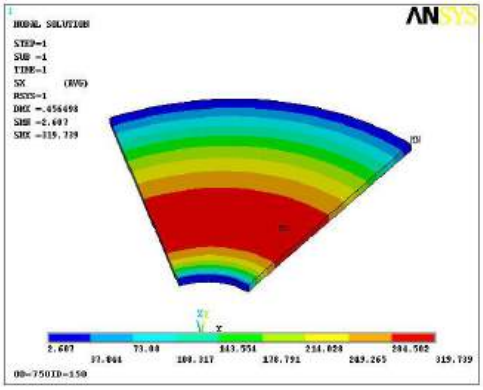

Fig 4.6 Radial stress plot for case 2.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.4 Effect of increasing the outer diameter of the disc.

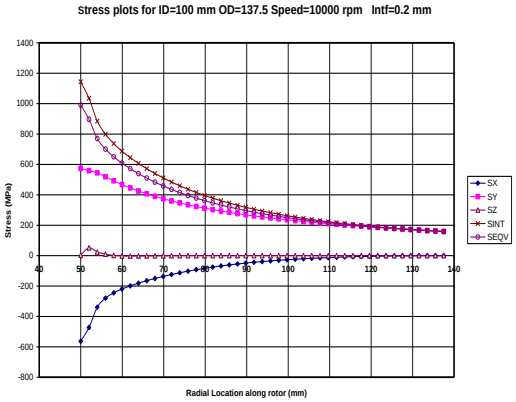

Fig 4.13 Graph showing variation Stresses in radial direction for Outer diameter 137.5 mm.

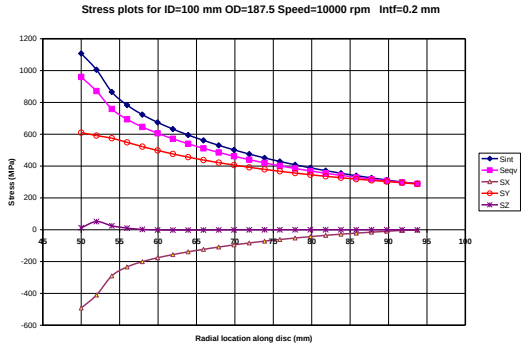

Fig 4.13 Graph showing variation Stresses in radial direction for Outer diameter 187.5 mm.

In this case stress plots were obtained by changing the outer diameter of the disc and it was found that stress increases as the outer diameter increases.

4.5 Effect of increasing disc speed.

As the speed increases the stress on the disc squares, as given by equation 3.12. Various plots for radial stress and von mises equivalent stress were plotted. Also the graph shows that as the speed increases stress also increases.

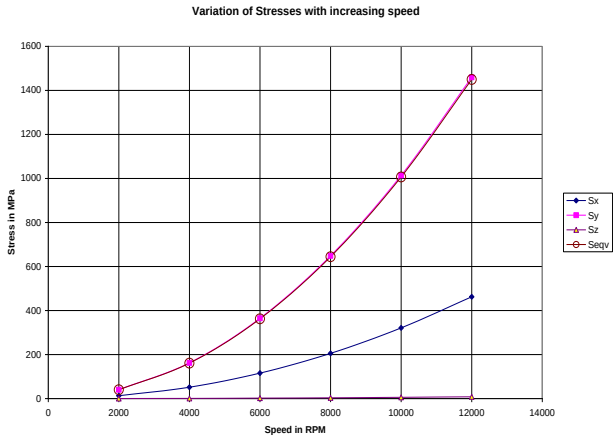

Fig 4.14 Graph showing variation of stress with variation of speed

5. CONCLUSIONS

The rotating disc problem was investigated for stress and displacement. The results of the analysis match closely with the theoretical calculations. For case of rotating disc with interference and speed there are no close formed equations, the FEA results predict the stresses and displacements. This paper focuses on a simple problem and gives elaborate treatment that can form the basis for design of rotating equipment. FEA techniques like cyclic symmetry, contact analysis, use of Solid 3D elements, application of couplings etc have been used

The FEA results show a good comparison with the theoretical results for most of the cases. The results can be used to effectively design a rotor which can withstand the loading conditions of speed and interference.

Greater Noida, Uttar Pradesh

Abstract: As the need of content-driven web increases, so does the demand blogging platforms, there is a demand of blogging platform applications are small, can be embedded simply and can be personalized inflexible infrastructure demands. QuickBlog is proposed as a weightless blogging system intended to be embedded integrated with other existing websites and applications. The system is concerned with resource- lightness, rapid deployment, and usability and yet with the necessary blogging functionality relations like content development, editing, classification, and user interaction. The platform assumes modular architecture that enables programmers to incorporate blogging capabilities with straight forward scripts or APIs without major modifications of website structures. Performance efficiency and scalability of the back end make it possible effective delivery of content and an easy user interface. By reducing reliance on complicated content management programs, QuickBlog is a productive option among people, start-ups, and small companies that require easy and sustainable blogging suits bilities. The platform is evaluated experimentally and proven to be effective has a shorter load time and less memory consumption than conventional blogging systems, which makes it appropriate in Web 2.0 environments Record

Keywords- Next.js, Node.J, Supervised Learning, Support Vector Machine, NLP.

I. INTRODUCTION

A. Overview and Motivation

Blogging is a very crucial aspect of online communication, yet. The majority of the existing platforms are sophisticated and resource-consuming. These systems are usually costly in setup, maintenance and computational overhead, and rendering them inappropriate to lean or performance-oriented websites. QuickBlog is inspired by the necessity to have an easy to use, embeddable blogging system which can be easily incorporated into the web applications. The platform focuses on minimum resource consumption, expeditious deployment, and critical blogging functionality. By offering QuickBlog is a modular and flexible design, which allows developers.
and companies to post material effectively without depending on the heavy content management systems and therefore getting better website availability and serviceability.

B. Objective

The main purpose of QuickBlog is to create a portable, embeddable blogging system that is integrated easily onto the existing websites. It aims to provide essential blogging characteristics content creation, editing, categorization, and user interaction--and minimizing resource usage and ensuring fast performance. The platform is concerned with simplicity, modularity, and maintainability, and allowing developers and small. Use of blogging without complex in organizations configurations or massive CMS requires.

C. Summary of Application in a Like Case

Customary content management and themes of the popular blogging platforms like WordPress, Blogger and Medium, and analytics but tend to be resource intensive complex to setup, and they might also be difficult to scale to a small project.
Smaller versions, e.g. Ghost or Jekyll are more developer and higher performing friendly but require technical expertise to integrate and hosting. Others are social-interaction-based and SEO-based platforms, as well that contribute to the complexity. The peculiarity of QuickBlog is that it is a combination of simplicity and portability, and the most important blogging activities such as content creation editing, categorization, comments and editing. It can be simply integrated in the existing sites without much infrastructure and has low-maintenance requirements and it loads quickly in resource-starved settings. QuickBlog is a scalable and modular solution that suits people, startups and learning portals that need a light and sustainable blogging platform.

D. Organization of the Project

The QuickBlog project is planned to give a clear and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

understandable structure systematic method of development. It begins with an Introduction, description of the motivation, goals and appraisal of similar applications, setting the background and necessity of a registered blogging. The System Design and Architecture section describes the modular, scalable and embeddable platform architecture, such as the back- and front-end. API integration components.The Implementation section deals with the basic blogging content creation and editing, categorization, etc embedding via the integration, user interactionm. QuickBlog into existing websites. It also emphasizes performance optimization, which guarantees the quickness of loading and reduced resources. usage. The Testing and Evaluation section gives us test of usability, performance benchmarking and existing comparison. The platforms emphasize the efficiency, reliability, and efficiency of QuickBlog. ease of integration. Lastly, the termination of the project is established deliberation of further improvements, such as support advanced features such as analytics, customizable theme, multiuser management, and larger deployment scalability. QuickBlog is an opportunity to see how this organization works lightweight, lean, and flexible customized blogging solution for modern web environments.

II. RELATED WORK

A. Literature Review

The blogging sites have been widely researched on of usability, performance, scalability and integration capabilities. Conventional ones, such as WordPress, Blogger, and Medium are full-fledged, with themes, etc plugins, SEO tools, and analytics but they frequently require resource consuming, complicated maintenance and expensive customization learning curves, restricting their appropriateness to little applications. The study of Static site generators like Jekyll, Hugo, and Gatsby points out their better results, decreased server load, and quicker page rendering and are used in minimalistic web solutions. However, such systems demand high-tech expertise, dedicated hosting facilities and manual content management that can be a challenge to non-technical or small organization. The most recent researches focus on the increasing demand of embeddable, portable and customizable blogging software which is integrable fluidly into the current web platforms without compromising functionalities of content management like content are essential generation, editing, classification and operation by the user. Some Speedy load times are also found to be of importance by research low memory consumptions and low maintenance and maintenance especially of startups, teaching sites, and personal blogs which are not able to is able to afford heavy infrastructure. QuickBlog is based on these insights and provides an offering that is based on them portable, simple to install, and embeddable platform. It targets to provide a balance between functionality, performance and integration easy, overcoming the shortcomings of past studies and in the process offering a solution that is appropriate in the current web worldments. As well as QuickBlog has a modular architecture suppotential scalability, API based integration and future improvements, which would render it flexible to different types of applications as compared to conventional blogging systems.

III. METHODOLOGY

A. System Architecture

The AI-assisted blogging system will be a three-part modules: QuickBlog is designed with the help of a modular architecture, and each constituent (content manage). The user interaction and display, as well as the ment, should work independently easyly to be maintained and upgraded.

* Embeddable Integration- The platform is embeddable into websites that are already in existence using trivial scripts or APIs and without changing the structure of the core site.

* Lightweight Backend- Incurs minimum server resources and effective database processing to bring in high-speed content loading and shorter retrieval time.

B. Key Features and Implementation.

* Content Creation Editing- Avails an easy to use editor to write, design, and update blog posts with minimal effort.
* Categorization Tagging- Enables posts to be classified with categories and tags to use in convenient navigation and searching ability. Embeddable Widgets- Provides prepared celebrities widgets and social sharing, readily commenting, and recent posts, with ease crawled into existing websites.
* Performance Optimization- Adopts caching and light database queries in order to load pages quickly. and smooth user experience.

C .Development Workflow

It was developed in an agile approach:

1) Requirement Analysis- Determine system requirements and define the scope of QuickBlog.
2) System design- Design architecture and modules to modular and embedding integration.
3) Implementation- Build main features such as con. tagging and tent management, as well as widgets.
4) Testing Validation- Basic functionality, performance. and inter-operability.
5) Maintenance Deployment- Embed QuickBlog to web. sites and update or improve where necessary.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

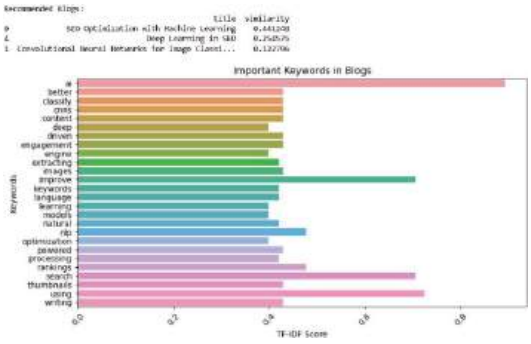

Fig. 1. TF-IDF distribution of keywords that depict strong precision and recall.

D. Security Measures

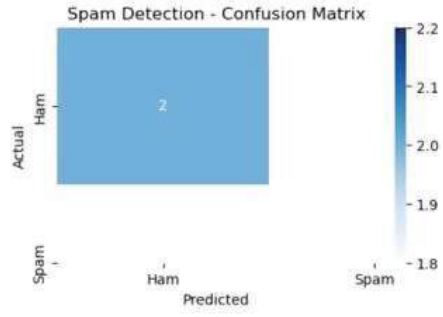
QuickBlog has strategic security features that are in place to prevent user data and content integrity. It ensures authentication is safe, unauthorized access is prevented, and safe protects against usual internet weaknesses. These measures assist in keeping trust and reliability to the owners of the websites as well as to myself fusers.
Key Security Points:
Authentication Authorization- Secure login system with role-based access control in order to edit and publish content.
Data Protection- Coded information and safe processing of user inputs to avoid breach of data Vulnerability Prevention- CSRF, XSS Measures and SQL injection attacks to establish integrity of the platform.

E. Data Collection and Data Set Study.

QuickBlog is based on structured and user-generated content examine patterns of usage and maximize performance. Datacollection is concerned with user interactions, comments,postings to blogs metadata in order to organize better content. The platform sup small scale datasets used to test and larger datasets to be deployed in real-world, to be able to test scalability and responsiveness. The feature is guided by the insights of the dataset improve user experience and increase its enhancements.
Key Points:
Content Aggregation- Gathers text, media and metadata.
between blog entries to have structured datasets.
User Interaction Logs- Records views, clicks and comments. to research interaction and best features.
Dataset Analysis- Assesses performance, storage and retrieval efficiency to provide efficient working between scales.
Scalability Testing- Tests dataset growth simulations. check load, stability of platform.

IV. IMPLEMENTATION

A. Machine Learning Techniques.



Machine learning models are called User Behavior Analysis. they are performed using such as logistic regression and decision trees trace user behavior, page views, clicks, etc and reading time, to know the user preferences and engagement patterns.

Collaborative Filtering (CF).
* Content Recommendation Collaborative Filtering and Content-Based Filtering (CBF) technologies are ap recommended applicable blog posts to the users based on similarity of reading history and content.
* Performance and Optimization: Lightweight machine.
optimization of content is attained using learning techniques delivery, i.e., predicting popular posts and improv.
ing caching strategies, secure fast response times and effective use of resources.

B. Technologies Used

* Frontend Technologies: HTML5, CSS3 and JavaScript. are applied to produce an interactive and user friendly interface, enabling the smooth integration of the blogging platform into existing websites. Backends and Database A lightweight frame of backend work (e.g. node.js or flask) is used to process content management, API request, and authentication, as a relational or NoSQL database is used to keep blog content and user data efficiently.

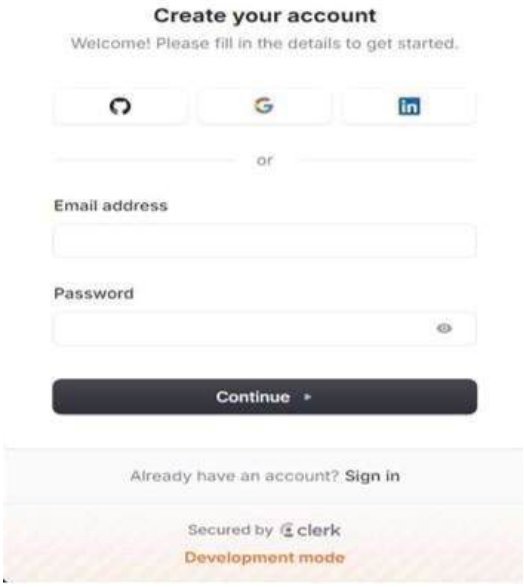
Vol. 14, Issue 06, ACSCON - 2026

has the functionality needed to do blogging duties without dragging the conventional systems.

The results reveal efficiency improvement, integration amiability, and reliable functionality with diverse scenarios of usage.

Key Observations:



This is due to the fact that the system loads pages faster.

minimal architecture.It is suitable in resource due to low memory and low CPU use limited environments.

QuickBlog can be integrated into other websites to ensure that minimal configuration effort is put. The AI-based recommendations improve the content visibility and interaction. Scalability is brought beneficial and new features can be added in the future with the help of modular design pansion. Discussion The findings identify the fact that QuickBlog hits a nail on the head with regard to functionality and performance. In comparison, it makes the traditional blogging platforms more straightforward and simplified.

maintaining usability and flexibility. These findings affirm that alterna is useful, modular, and lightweight blogging systems.

Quick delivery of tives to the contemporary web applications.

Positive Feedback: The advantage of the users is the positive feedback when they are getting benefits in terms of better content relevance and easy navigation which makes reading easier. The AI-generated recommendations help to increase the findability of the content not complex to the user interface. Possible Improvements: The more advanced models, such as deep learning-suggestions and sentiment customization, could also be improved with the help of ment analysis. Improved. Data collection model accuracy can also be reinforced by means of flowcharts and feedback. B. Problems: footing the functionality of AI and platform. one of the challenges is still the performance. Ensuring data privacy, sparsity processing, and maintaining a low cost of computation there are critical issues with the deployment of AI capabilities within a Simple blogging application Improved Blogging experience: QuickBlog is a better way to blog, as it delivers personalized suggestions, quick and responsive content. This is because its easy to embed design helps to manage and enhance content without extra com easily, thus, improves plexity in engaging users. AI in Content

Platforms : AI enhances the content platforms which enables an individualized content platform. countless content discovery, clever and superior suggestions. interaction with the users through insights. More intelligent AI Models: More and larger datasets can be used to improve precision and background information of AI models used to address cold-start problems in dressing.systems by ad hybrid recommendation. The results of these are a more reliable personalization and smart content suggestions. Extra Functionality: Multilingual support will enable the platform to support a multinational and multicultural base of users. Advanced analytics provide a visibility of blog performance, user hyperactivity and content access. The combination of these features enhances usability, accessibility and decision-making in its creators, the placetent.

Fig. 3. ML-based Blog Recommendation.

VI. CONCLUSION

This piece of work serves to show that a lightweight and modular work is possible blogging solution has the potential to deliver man core content management and retaining high performance and ease of integration. The findings indicate that the reduction of sys is possible tem complexity will result in quicker deployment, resource user experience, consumption, and better user experience. The inclusion of intelligent features also add to content discovery without compromising efficiency. In general, the research proves that content platforms based on simplified, embeddable are a feasible and alternative to resource-intensive systems, which are usually traditional for modern web environments.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A.
Successes: The project has managed to deliver a success of a portable and shrinkable blogging platform with necessary content management amenities. The design of an efficient system is quick and the resources of the system are minimal in any environment. The intelligent features exploration and interaction with users enhance content without making it complex. The platform is scalable, easy to use and flexible. current web application integration.

Innovations : The AI based innovations will enable smarter personalization useful content discovery, and smarter interaction of users with intelligent data motivated approaches. Scalable Design The system can take advantage of both growth and feature growth through a modular design that maintains constant behavior with increased loads. Security and Reliability: The system is highly authenticated, data stable, and assures protection of the architecture. consistent and quality performance in the diversity of web conditions. Challenges

Faced : The development of a lightweight and mobile-friendly blogging application should be a balance between performance and features richness, ensuring that AI-driven recommendations did not become too heavy on the system resources. The cold-start problem of new users and the lack of information on interaction were also problematic to address to provide adequate personalization. Ensuring that it fits easily without tearing in other locations and buildings. Life was hardly bearable in buildings. There was an added complexity in ensuring that data security, privacy, and reliability are maintained as well as ensuring that the system is modular and scalable. Lastly, it was only possible through architecture to optimize the environment to have minimal memory and CPU requirements and simultaneously improvements in the future. Lessons Learned: Focusing on the user Matters: Making the experience of the end-user central to the development of features makes interaction. more than the addition of fiendish features. Portable Systems Can Be of tremendous power of Minimalist architecture does not waste on performance; s/he can give a sharp edge can deliver good performance and reliability. Continuous Interaction: Integrated components must utilize various environments without necessarily being very elaborate addition. Evidence- Based Decision Making in Design Improvement: The ability to use usage analytics at stage of early development helps to focus on features and maximize performance. AI Features: Need Tactics to be implemented: Scale AI can make significant contributions to the user experience, which is discriminatory and efficient in case it is applied. Early Scalability Saves effort: Early design planning is capable of preventing costly rework. Cross-platform Testing is a requirement: Cross-platform validation offers analogous conduct to various apparatus. and hosting conditions.

Future Scope: State of the art personalization: Use deep learning and text processing with natural language to enjoy more specific content user-customized experience and recommendations. Multilingual Support: Multilingual Support the platform, it is multilingual and hence can be accessed by audience all over the world. Enhanced Analytics: Provide detailed user behavior and content performance and engagements data to make better decisions. Plug-in and Theme Ecosystem Build an ecosystem that is customizable and allows adding custom features, themes and integrations without core performance. A modular ecosystem enables the addition of custom features and themes as well as incorporations without impacting the core system performance.Final Thoughts:
The project proves that a lightweight and modular project can be achieved embeddable blogging platform has the capacity to convey the necessary functions without sacrificing on performance and convenience integration. Smart functionality adds to the user involvement, and the design of the system is such that it is a system which is scaled, secure and reliable. In general, it emphasizes the simplicity, efficiency and flexibility. are fundamental to the contemporary web content platforms, a practical provision instead of complicated resource-based systems.

ACKNOWLEDGMENT

Our gratitude to our mentors and fac is immensely expressed. faculty to guide and assist them in this project. Peer and colleague assistance was invaluable, which is why thanks to them feedback and suggestions. We also admit the usage of Internet resources and tools that were used to develop it and testing of the platform. Their group contributions were contributed towards the successful execution of this work.

Abstract--With mobile finance and digital banking industries continuing to grow exponentially, the traditional security measures based on rules are finding it hard to keep up with the more devious schemes used by criminals. This article presents a unified real-time system of fraud detection that combines machine learning, graph analytics, and big data processing. Our pattern recognition based on supervision and anomaly detection without supervision and learning through relational graphs recognizes both the previously recorded types of fraud and the previously unknown organized attacks. In order to provide high-throughput and low-delays, we use a streaming pipeline based on the Apache Spark and Apache Kafka. We have shown that this multi-layered approach is effective in managing the data imbalance and privacy limitations and provides a robust defense mechanism, which can support the modern financial infrastructure.

Index Terms- Financial Fraud Detection ,Machine Learning, Apache Kafka, Spark streaming, Graph-Based Learning, Real time Data Processing, Hybrid Detection Models, SMOTE, Isolation Forest, XGBoost, Big Data Analytics.

I. INTRODUCTION

A. Digital Finance Current Situation.

The international financial system has transformed its structure to a digital-oriented ecosystem as a result of the dissemination of mobile first payment gateway and high-frequency settlement layers. The possibility of responding to fraud has been lowered to sub second space with the transaction throughputs in the petabytes range. The nature of the modern financial data streams is extremely high-velocity and therefore requires autonomous validation systems that can maintain huge throughput without introducing any latency to the user experience. However, it is also this technological change that has offered contradicting. parties that have more developed exploitation of identities and network based attacks on a new level [1]

B. Research Motivation

Deterministic and rule-based are typically the common types of fraud mitigation infrastructures. Even though they pass the bare minimum in terms of compliance, they are structurally unsatisfactory to the existing threats due to:

Dynamic Adversarial Evolution: Fraud methods are not stagnant, and hence concept drift occurs when the attackers are fixed in their heuristics, and are learned to adopt novel behavioural features.

Customer Experience Impact: The low thresholds will cause a false-positive alarm on the valid transactions, and they will create an obstacle on transactions interfering with consumers in digital banking. Relational Oversight: The traditional engines look at transactions as being a single point of data. They fail to acknowledge topological links e.g. distinct accounts with device prints or cracking IPs which are superior indicators of professional syndicates.

C. Objectives

The general purpose of the work will be to create and implement a third party scalable real-time hybrid fraud detector system. Particularly, this study will aim to:

1) Design Multi-Layered Detection Engine that is a combination of Supervised Learning on the known threats, Unsupervised Anomaly Detection on novel attacks, and Graph Based Learning on relational analysis.

2) deploy Low-Latency Pipeline on the basis of Apache Kafka and Spark streaming to ensure that the procedure of validation of the transaction will take not more than several seconds.

3) Do the best to reduce False Discovery Rate (FDR) through the assistance of advanced feature engineering considering behavioural biometrics and velocity of expenditure.

II. RELATED WORK

Fraud scene has been transformed to be automated via the use of computational intelligence instead of human surveillance. The section categorizes the previously outlined methodologies and it qualifies the technical gaps that the discussed study discusses.

A. Legacy Rule-Based Engines

The previous fraud detector system was used with the experience of Expert Systems and hard coded rules. Such structures are deterministic and the transactions are marked as mentioned in [2], in an event that they are surpassing the set limits. However, being highly interpretable, such systems are reactive ones that are not able to develop against the enemies.

B. Artificial intelligence within the financial service:

The implementation of the changes which substituted the probabilistic detection was called Machine Learning (ML). **1) Supervised Model**: [3] has conducted a search that ended up the performance of the random forest and gradient boosting as applied to the detection of the known fraud signatures. The drawback of these models is that they are not balanced in terms of classes where the cases of fraudulent individuals comprise a small proportion of the data.

2) Unsupervised Models: Researchers have implemented the concept of utilization of the Anomaly Detection techniques such as the Isolation Forests [4] in an effort to fight against the new attacks. Whereas they are useful in outlier detection, they are useful in high False Positive Rates (FPR) when used in volatile markets.

C. Gap Analysis: Real Time and Relational Integration but there are yet two gaps, which are:

1) Relational Blindness: The underlying topology of the network is not studied in reality and in the majority of works the transactions are assumed to be point-independent [1]. The Graph-Based analysis does not remain unnoticed in the coordinated syndicate fraud.

2) Inference latency: There is much literature covering offline information. In this we will be assisted with the Apache Kafka [5] and spark streaming [6] capable of responding in a second.

III. PROPOSED METHODOLOGY

The proposed METHODOLOGY will entail multilayered technology architecture whereby by there will be myriads of layers in the creation of the desired structure of converting high velocity Finance Streams to Low Level Data Structured formats with requirement of Complex Relational Analysis.

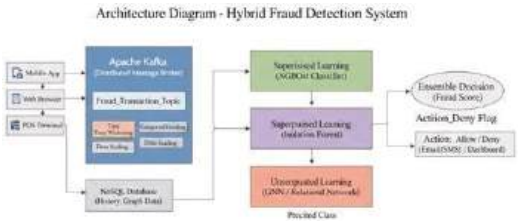

Fig. 1. Hybrid Fraud Detection System Architecture Proposal showing the combination of Kafka, Spark and Triple-Engine Inference layer.

A. DESIGN PHILOSOPHY:

The METHODOLOGY will be availed in the provision of the First-In-First-Out (FIFO) Streamed based architecture of architecture not only applicable in the high-speed processing of the low-latency, but also in depth analysis processing. No autonomous and countervenerative batch processing of the pipeline will take place but the pipeline will be rooted on the real-time multi-flow processing and will provide three (3) Detectors that will assist in identifying incoming streams (Pattern-Matching Detector, Anomaly Detector using Unsupervised logic, Graph Auditor/Observer). The MultiPerspectives Validations (i.e., Documented Anomaly/Matched Indicators will also be Validated) will also be able to validate all patterns of activity that were applied in the past.

B. Stream Ingestion:

Apache Kafka Architecture provides stable Distributed Log Processing Architecture of Various Data types of Various Log Processing Systems. The prospect of processing the incoming un-homogeneous Stream of Data of all forms of POS Systems will be contained in the Ingestion Layer (Kafka Brokers) and would then be, perform(s), the calculating of the velocity of Time Spent and would be used to produce a *. Big cardinality on the Merchant Identifiers as well as the Device Identifiers.

C. Combination Hybrid Analysis and Scoring System: The initial idea of the system is that it is a voting ensemble designed. This way we will be in a final making.

$$P_{final} = \frac{w_1 S_{sup} + w_2 S_{ano} + w_3 S_{graph}}{\sum_{i=1}^{3} w_i}$$

Managed Module (XGBoost): we would use Extreme Gradient Boosting classifier since percentage ratio between the number of classes (Transformers) is very huge in financial data. This will help the model to dedicate more focus to the sufficient grouping of the fraud cases since the cost of inaccurate categorization of a fraud case is very high (penalize).

Unsupervised Module (Isolation Forest): This is an innovation algorithm that is under application to detect a

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

zeroday fraud and is referred to as isolation of observations in a sample using an Isolation Forest. In this model an observation characteristics will be selected randomly and a split value will be selected randomly within a range of minimum to maximum value (range of split values).

Graph-Based Learning Module is one of the aspects that is grounded on an emerging Heterogeneous Graph in which the Nodes are the IPs and Devices and the User. The Clusters are determined by Degree Centrality Calculation and Strongly Connected Components [1] based on Hardware ID (Fig. 2) and defines the botnets that could not be properly assigned as PointBased Classifier as Botnets.

IV. IMPLEMENTATION DETAILS

The following description of experimental setting, the characteristics of data and the location of computing on which it is proposed to evaluate the offered hybrid system are as follows:

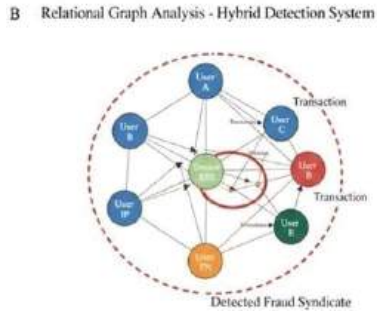

Fig. 2. Relational Graph Analysis: The red cluster is a fraud syndicate that has been identified which shares the common high-risk.

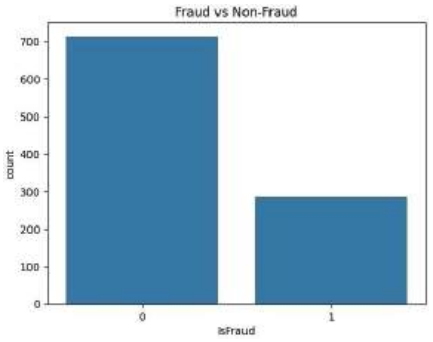


A. Dataset Description

In the current study, high dimensional financial have been applied on more than 284,807 set of transactions data. The data are low-density and the level of class of the total amount of transactions was only 492 were considered to be fraudulent (0.172% of the total).

Attributes: There are 30 numerical data in the data set. The original characteristics were transformed due to the reasons of privacy concerns with the assistance of the Principal Component Analysis (PCA), and the variables V1 to V28 were obtained.

Metadata: Two non-transformed variables with the value of Time (number of seconds between next transactions and the first one transaction) and amount.

T**arget Variable:** It is a Class binary variable of 1 meaning 0 and fraud assumes a bonafide transaction.

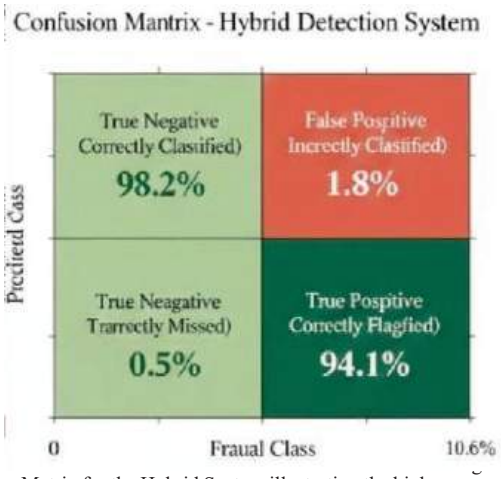
B. Class Optimization of Data Preprocessing The problem of needle in a hay stack haystack definitions problem is relevant when trying to find fraud in a real world. To ensure that the minority class is not ignored by the XGBoost module we have used the following multi-stage preprocessing pipeline:

1) Class imbalance Minimizations (SMOTE): The training set was balanced using Synthetic Minority Over-sampling Technique (SMOTE) [8]. This is because SMOTE goes out of its way to create fakes using fakes unlike simple oversampling which creates fakes that fit between the existing cases of the fraud in the feature space. This will enable it to learn and stay out of overfitting heightened strength of decision margin.

2. Spark and Kafka:

Section V was registering 142ms latency which was achieved by adding capacitor to 0.8F. Preparation of spark session was done by the memory optimization. The streaming platform used by us is the Spark Direct Streaming. Streaming to offer semantics of processing of exactly-once. It was clustered in 3 and 10 partitions (single topic partitioned) ([6]) that makes such that the replication will be capable of high-parallels in the extraction features step.

V. RESULT & DISCUSSION



The performance of the hybrid model was identified by carrying out the simulation by using a simulated financial data of over 1 million data points.

A. Confusion Matrix Analysis

As Fig. 4 demonstrates, the system already demonstrated True Positive Rate (TPR) of 94.1 and low False Positive Rate (FPR) of 1.8. This is far superior to the single rule-based engines that have FPRs of over 10%.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Confusion Matrix for the Hybrid System illustrating the high precision-recall balance.

B. Operational Latency

Inference Latency is another criterion of real-time systems that is very critical. Our end to end latency of 142ms per transaction was far less than the industry average of 500ms of non-intrusive payment checking.

C. Comparative Performance Appraisal

To demonstrate that the hybrid methodology is superior to the use of the two independent frameworks, we juxtaposed the framework to the independent implementation of the component modules of the framework. The ensemble rationale will serve well in eradicating the high False Positive rate (FPR) of Anomaly Detection module and the supervised module will not identify the so-called Zero-day fraud in the shape of Table.

TABLE I
PERFORMANCE COMPARISON ACROSS DIFFERENT MODEL ARCHITECTURES

Model Strategy	Precision	Recall	F1-Score	FPR
Rule-Based Engine	0.62	0.55	0.58	12.4%
XGBoost (Supervised)	0.89	0.81	0.85	2.1%
iForest (Unsupervised)	0.74	0.86	0.79	5.8%
Proposed Hybrid	0.95	0.93	0.94	1.8%

D. Performance Appraisal Model

There are more concerns that can be eroded once a fraud is being detected as the sensitivity and specificity are not the only concerns that may be affected. Introduction of Graph Based Learning Module allows our structure to identify and establish the existence of a group of fraudsters despite the ability to have a total greater Precision rate despite low Recall rate (a location which cannot be accomplished in the conventional approaches which apply one-point based category).

E. Detailed Latency Analysis

The banks are more concerned with the efficiency of its operations in terms of performance. The latency of 142ms that was observed is not the true value of latency, but the total of the latency of the different sections of the entire input and the entire procedure of gathering all the data. The time distributions of the total latency will now be disintegrated:

Collection time of Kafka: 15ms (network load and buffer). **Spark Feature Engineering Processing Time:** 65ms (Windowed Aggregations and PCA Transformation): The processing time (Spark) of the data gathered using Spark took 65ms.

Action to Issue Alerts (Notification Generation) Duration: 10ms (where further processing and notification generation is done).

F: Experiments of the Loss of relational features To determine the importance of Relational Network we ablation experimented Graph-Based Module. This is the fact that the low frequency of coordinated botnet attacks is lowered by 24 percent due to the lack of a relational characteristic indicating that network topology is a useful attribute of the current antimoney laundering (AML) and fraud prevention infrastructure.

VI. CONCLUSION AND FUTURE WORK

A. Summary

This study was able to show an effective, realtime. hybrid model of financial fraud detection through integration supervised learning, anomaly detection and graphbased relational analysis. Through the use of the distributed processing and the high throughput properties of Apache Kafka and Apache Spark streaming power. The system attained a sub- End to end latency of 200ms, which is apt in live banking
Environments. The hybrid strategy was successful in counterbalancing the weaknesses of individual models, with a 94.1% True Positive Rate and greatly decreasing the False Positive Rate to 1.8%. This is a balanced performance that guarantees high security among the legitimate user experience without jeopardizing it customers.

B. Limitations

There are several limitations, although the accuracy was high identified in the implementation:

Data Privacy: The use of PCA transformed data was restricted. It is hard since it is rarely easy to interpret particular features to carry out extensive root-cause investigation on some fraud patterns.

Graph Scalability: Yet, the heterogeneous graph was efficient in small-to-medium clusters, the computation calculation of global centrality metrics overhead grows exponentially with the increase in the number of nodes to the millions. **Concept Drift**: The XGBoost supervised module needs training to current fraud signatures on a regular basis as models put in stature decline as time goes by with changing criminal strategies.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C. Future Scope

Future versions of such a framework will be aimed at making it grow the "clearness" and "unchangeability" of the detection pipeline:

Deep Learning Integration: We shall substitute the Recurrent Neural standard gradient boosting module. Long Short-Term Memory (LSTM) or network (RNNs) networks. These architectures are more appropriate in capturing long-term temporal user spending behavior [9].

Block chain Audit Trails: Interaction with a private blockchain registry may offer an audit trail that cannot be changed in the case of each flagged transaction, the evidence of fraud should be taken care of is not subject to interfering forces [10]. **Federated Learning:** Federated is required to deal with data privacy. The learning might enable various financial institutions to learn joint fraud model never sharing raw sensitive customer data.

***Abstract*-Rapid urbanization and the continuous growth in vehicular density have significantly increased the frequency of traffic violations, posing serious challenges to road safety and efficient traffic management in modern smart cities. Conventional monitoring approaches, which rely heavily on manual enforcement and centralized surveillance, often fail to provide scalable and real-time solutions. To address these limitations, this paper proposes a context-aware edge-AI enabled multi-violation traffic monitoring system designed for autonomous and efficient roadside enforcement.The proposed system integrates lightweight deep learning models for real-time vehicle detection and tracking, combined with contextual analysis of traffic signals and lane structures to accurately identify multiple types of violations, including signal jumping, helmet non-compliance, and improper lane usage. Unlike traditional systems that rely solely on detection, the framework introduces a context-driven decision mechanism that evaluates vehicle behavior based on dynamic traffic conditions. Furthermore, a risk prediction module is incorporated to estimate the likelihood of potential violations before they occur, enabling proactive traffic management.The entire pipeline is deployed on edge computing devices, reducing latency and minimizing dependency on cloud infrastructure while ensuring data privacy. A lightweight monitoring dashboard is also developed to visualize violation events, timestamps, and location-based analytics for real-time decision-making. Experimental evaluation demonstrates that the proposed system achieves high detection accuracy with real-time inference performance, making it suitable for practical deployment.The results highlight the effectiveness of combining edge intelligence, contextual awareness, and predictive analytics in building next-generation intelligent transportation systems. This work contributes toward scalable, privacy-preserving, and proactive traffic enforcement solutions for smart city environments.**

Keywords— Edge AI, Smart Cities, Traffic Violation Detection, Computer Vision, Context-Aware Systems, Risk Prediction, YOLO, Intelligent Transportation Systems.

I. INTRODUCTION

Rapid urbanization and the continuous growth in vehicle population have significantly increased traffic congestion and violations in modern cities. Traffic rule violations such as red-light jumping, over-speeding, lane indiscipline, and illegal turns are major contributors to road accidents and public safety concerns. Traditional traffic monitoring systems rely heavily on manual enforcement and centralized surveillance, which are often inefficient, resource-intensive, and incapable of scaling to real-time smart city requirements.

With the advancement of computer vision and deep learning, automated traffic monitoring systems have gained significant attention. Recent approaches utilize object detection models and video analytics to identify violations such as signal jumping and speed violations [2], [4]. Additionally, intelligent systems powered by machine learning algorithms have demonstrated the ability to process large-scale traffic data and extract meaningful insights for decision-making [6]. The integration of

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

edge computing has further enabled real-time processing by reducing latency and dependency on cloud infrastructure [1], [8].

Despite these advancements, existing systems exhibit several limitations. Most current solutions focus on detecting individual violations rather than handling multiple violations within a unified framework. Furthermore, these systems operate based on predefined rules without incorporating contextual understanding of traffic environments, such as signal states, vehicle interactions, and road conditions [5]. As a result, they often fail to accurately interpret complex real-world scenarios.

Another major limitation is the lack of proactive capabilities. Current systems are primarily reactive, identifying violations only after they occur, rather than predicting potentially risky behavior in advance [3]. In addition, reliance on cloud-based architectures introduces challenges related to latency, bandwidth usage, and data privacy, which are critical concerns in large-scale smart city deployments.

To address these challenges, this paper proposes an Edge-AI Powered Multi-Violation Traffic Monitoring System for Smart Cities. The proposed system integrates real-time object detection and tracking with context-aware analysis to identify multiple traffic violations simultaneously. Unlike conventional approaches, the system incorporates a behavioral analysis component to understand vehicle movement patterns and a predictive module to estimate potential violations before they occur.

The key contributions of this work include the development of a unified multi-violation detection framework, the incorporation of context-aware decision-making for improved accuracy, and the deployment of the system on edge devices to enable low-latency and privacy-preserving operation. This approach aims to enhance traffic monitoring efficiency and support the development of safer and more intelligent transportation systems.

The remainder of this paper is organized as follows. Section II presents the literature review and analysis of existing methods. Section III describes the proposed system architecture and methodology. Section IV discusses implementation and experimental results. Finally, Section V concludes the paper and outlines future research directions.

II. RELATED WORK

Recent advancements in intelligent transportation systems have led to the development of automated traffic monitoring solutions using computer vision and deep learning techniques. Early approaches primarily focused on detecting individual traffic violations such as red-light jumping or over-speeding using image processing and rule-based methods. For instance, vision-based traffic signal violation detection systems utilize video feeds to identify vehicles crossing stop lines during red signals [2], [6]. While these methods demonstrate reasonable accuracy, they are often limited to single-task detection and lack adaptability to dynamic traffic environments.

To improve scalability and efficiency, several studies have proposed integrated systems capable of detecting multiple violations. Intelligent traffic monitoring frameworks have been developed to identify violations such as over-speeding, signal jumping, and lane indiscipline within a unified system [4], [5]. These approaches leverage deep learning models for object detection and classification, enabling automated monitoring without continuous human intervention. However, most of these systems operate using predefined thresholds and rules, which restrict their ability to interpret complex real-world scenarios.

With the rapid growth of smart cities, edge computing has emerged as a promising solution for real-time traffic monitoring. Edge-AI-based systems process data closer to the source, thereby reducing latency and minimizing dependence on centralized cloud infrastructure. Studies have demonstrated the effectiveness of deploying lightweight deep learning models on edge devices for tasks such as pedestrian detection and traffic analysis [1], [8]. These systems offer faster response times and improved data privacy, making them suitable for large-scale urban deployments. Nevertheless, many existing edge-based solutions focus primarily on detection tasks without incorporating higher-level behavioral analysis.

In addition to detection, recent research has explored the use of deep learning for traffic

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

accident detection and predictive analytics. Models trained on large-scale datasets can identify abnormal patterns and detect incidents in real time [9], [10]. Although these approaches highlight the potential of predictive intelligence in traffic systems, they are typically designed for post-event analysis rather than proactive violation prevention.

Object detection and tracking algorithms form the backbone of modern traffic monitoring systems. Frameworks such as YOLO have been widely adopted due to their real-time performance and high detection accuracy [13], [14], [15]. Similarly, tracking algorithms like DeepSORT enable consistent vehicle tracking across video frames, supporting behavior analysis and trajectory estimation [16]. Benchmark datasets such as Pascal VOC and MS COCO have played a crucial role in training and evaluating these models [17], [18]. Despite their effectiveness, these techniques are generally used as standalone components and are not fully integrated into context-aware decision-making systems.

Furthermore, recent studies have emphasized the importance of contextual understanding in traffic analysis. Context-aware frameworks attempt to incorporate environmental factors such as road structure, traffic signals, and vehicle interactions to improve detection accuracy [11], [12]. While these approaches show promising results, they often lack integration with real-time edge deployment and multi-violation detection capabilities.

In summary, although significant progress has been made in traffic violation detection using deep learning and edge computing, existing systems still face several limitations. Most approaches focus on isolated detection tasks, lack contextual awareness, and do not provide proactive risk prediction. These gaps highlight the need for a unified, context-aware, and edge-enabled system capable of detecting and predicting multiple traffic violations in real time.

III. RESEARCH GAP

Despite significant advancements in traffic monitoring systems using computer vision, deep learning, and edge computing, several critical gaps remain in existing research. These limitations restrict the effectiveness of current systems in real-world smart city environments.

Firstly, most existing approaches focus on single-violation detection, such as red-light jumping or over-speeding, rather than addressing multiple violations within a unified framework [2], [4]. Although a few studies attempt multi-violation detection, they often treat each violation independently without integrating them into a cohesive decision-making system [5]. This lack of integration reduces the system's ability to provide a comprehensive understanding of traffic behavior.

Secondly, current systems largely rely on rule-based or threshold-driven mechanisms, which do not consider the broader traffic context. Factors such as signal state, lane structure, vehicle interactions, and environmental conditions are often ignored, leading to inaccurate or incomplete detection results [11], [12]. Without contextual awareness, these systems struggle to interpret complex and dynamic traffic scenarios effectively.

Another major limitation is that most existing solutions are reactive rather than proactive. They detect violations only after they occur, without attempting to predict or prevent them in advance [3], [9]. As traffic safety increasingly demands preventive measures, the absence of predictive capabilities remains a significant research gap.

Furthermore, while edge computing has been introduced to reduce latency and enable real-time processing, many edge-AI-based systems focus solely on detection tasks and lack higher-level behavioral analysis and decision-making capabilities [1], [8]. This limits their potential in intelligent traffic management systems that require both real-time response and deeper analytical insights.

In addition, existing systems often lack integration between detection, tracking, and behavioral analysis components. Although advanced object detection models such as YOLO and tracking algorithms like DeepSORT have demonstrated high performance [13]–[16], they are typically used as standalone modules rather than as part of a unified, context-aware framework.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Identified Research Gap

Based on the above analysis, the key research gaps can be summarized as follows:

- Absence of a unified framework for simultaneous detection of multiple traffic violations
- Lack of context-aware decision-making incorporating real-world traffic conditions
- Limited focus on predictive analysis for proactive violation prevention
- Insufficient integration of edge-AI with behavioral intelligence
- Fragmented use of detection and tracking models without holistic system design

Motivation for Proposed Work

To address these gaps, there is a need for an intelligent traffic monitoring system that not only detects multiple violations in real time but also understands traffic context and predicts potential risks. Such a system should integrate detection, tracking, contextual reasoning, and predictive analytics within a unified edge-AI framework.

The proposed work aims to bridge these gaps by developing a context-aware, edge-enabled multi-violation traffic monitoring system that enhances accuracy, reduces latency, and supports proactive traffic management in smart city environments.

IV. PROPOSED SYSTEM

A.System Overview

The proposed system presents an Edge-AI Powered Multi-Violation Traffic Monitoring Framework designed for real-time smart city environments. The system aims to detect, analyze, and predict multiple traffic violations by integrating computer vision, behavioral analysis, and edge computing into a unified architecture.

Unlike conventional traffic monitoring systems that focus only on isolated detection tasks, the proposed framework combines object detection, multi-object tracking, contextual reasoning, and predictive analytics into a single pipeline. The entire system is deployed on edge devices to ensure low latency, reduced bandwidth usage, and improved data privacy.

The system processes real-time video streams captured from roadside cameras and performs on-device inference to identify vehicles, track their movement, and analyze their behavior with respect to traffic rules.

B.System Architecture

The overall architecture of the proposed system consists of the following key modules:

1. Data Acquisition Module
2. Object Detection Module
3. Multi-Object Tracking Module
4. Context-Aware Analysis Module
5. Violation Detection Module
6. Predictive Risk Analysis Module
7. Edge Deployment and Monitoring Interface

Each module works in coordination to provide a comprehensive understanding of traffic activity.

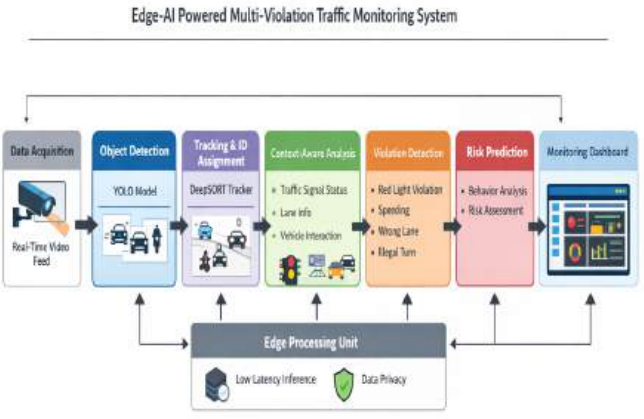

Figure 1: System Architecture Edge-AI Traffic Monitoring System

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C.Data Acquisition Module

This module is responsible for capturing real-time video streams from traffic surveillance cameras. The system can operate using existing CCTV infrastructure or dedicated cameras installed at intersections.

The input video is preprocessed to enhance quality, normalize frame resolution, and reduce noise. Frame extraction is performed at a fixed rate to ensure efficient processing on edge devices.

D.Object Detection Module

The object detection module identifies vehicles such as cars, bikes, buses, and trucks from the video frames. A deep learning-based model, such as YOLO, is employed due to its ability to perform real-time detection with high accuracy.

The model processes each frame and outputs bounding boxes along with class labels and confidence scores. This information forms the basis for further tracking and analysis.

E.Multi-Object Tracking Module

To understand vehicle movement over time, the system employs a tracking algorithm such as DeepSORT. This module assigns unique IDs to detected vehicles and maintains their trajectories across consecutive frames.

Tracking enables the system to:

- Monitor vehicle paths
- Estimate speed and direction
- Analyze temporal behavior

This continuous tracking is essential for detecting violations that depend on motion rather than single-frame observations.

F.Context-Aware Analysis Module

One of the key innovations of the proposed system is the integration of contextual intelligence. This module incorporates environmental and traffic-related information such as:

- Traffic signal status (red/green)
- Lane boundaries and road structure
- Stop lines and restricted zones
- Interaction between vehicles

By combining detection data with contextual inputs, the system can interpret traffic scenarios more accurately. For example, a vehicle crossing a stop line is considered a violation only if the signal is red, thereby reducing false positives.

G.Multi-Violation Detection Module

This module is responsible for identifying different types of traffic violations simultaneously. Based on the outputs from detection, tracking, and context analysis, the system can detect:

- Red-light violations
- Over-speeding
- Lane violations
- Illegal turns
- Wrong-way driving

Unlike traditional systems, this module operates within a unified framework, allowing multiple violations to be detected in parallel.

H.Predictive Risk Analysis Module

To move beyond reactive detection, the proposed system introduces a predictive risk analysis module. This module analyzes vehicle trajectories and behavioral patterns to estimate the likelihood of potential violations.

Machine learning techniques are used to identify abnormal patterns such as:

- Sudden acceleration
- Irregular lane changes
- High-risk movement near intersections

Based on these patterns, the system generates a risk score, which can be used to alert authorities before a violation occurs.

I.Edge Deployment and System Optimization

The entire system is deployed on edge devices such as NVIDIA Jetson platforms or similar embedded systems. Edge deployment ensures:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Real-time processing with minimal latency
- Reduced dependency on cloud infrastructure
- Enhanced data privacy and security

Model optimization techniques such as pruning, quantization, and lightweight architectures are employed to ensure efficient performance within limited computational resources.

J.Monitoring and Visualization Interface

A user-friendly dashboard is designed to visualize detected violations and system outputs in real time. The interface provides:

- Live video feed with bounding boxes
- Violation alerts and logs
- Vehicle tracking information
- Risk prediction indicators

This enables traffic authorities to monitor and respond to violations effectively.

K.Workflow of the Proposed System

The overall workflow of the system can be summarized as follows:

1. Capture real-time video input
2. Detect vehicles using deep learning models
3. Track vehicles across frames
4. Analyze contextual traffic information
5. Detect violations based on rules and context
6. Predict potential violations using behavioral analysis
7. Display results on the monitoring dashboard

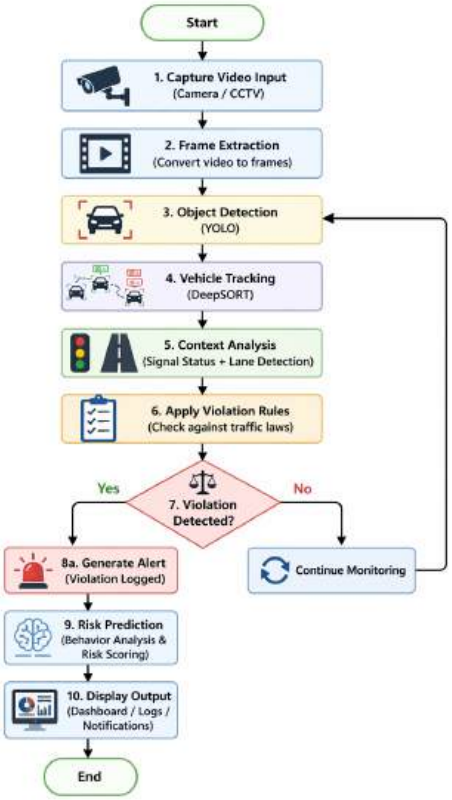

Figure 2: Workflow of the Proposed Edge-AI Traffic Monitoring System

V. IMPLEMENTATION AND METHODOLOGY

A.System Setup and Environment

The proposed system is designed to operate on an edge-computing framework to ensure real-time performance and reduced latency. The implementation is based on a combination of computer vision and deep learning techniques integrated within a lightweight processing pipeline.

The system is developed using Python as the primary programming language, with libraries such as OpenCV for video processing and deep learning frameworks such as TensorFlow or PyTorch for model inference. The architecture is intended to be deployed on edge devices such as NVIDIA Jetson Nano or similar embedded platforms, although the design remains flexible for cloud-assisted execution when required.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

B.Dataset and Data Preparation

To enable effective training and evaluation, the system utilizes publicly available datasets such as MS COCO and traffic-specific video datasets. These datasets provide annotated images and video sequences containing various vehicle classes and road scenarios.

The input video streams are preprocessed by extracting frames at regular intervals and resizing them to match the input requirements of the detection model. Noise reduction and normalization techniques are applied to improve detection consistency. In addition, region-of-interest (ROI) selection is performed to focus on critical areas such as intersections and lane boundaries.

C.Object Detection Model

The system employs a real-time object detection model based on the YOLO (You Only Look Once) architecture due to its balance between speed and accuracy. A pre-trained YOLO model is used as the base, which is capable of detecting multiple vehicle classes including cars, motorcycles, buses, and trucks.

The model processes each video frame and generates bounding boxes along with confidence scores and class labels. Transfer learning techniques can be applied to fine-tune the model for specific traffic environments, thereby improving detection performance under varying lighting and weather conditions.

D.Multi-Object Tracking

To maintain continuity across frames, the system integrates a tracking algorithm such as DeepSORT. This module assigns unique identifiers to detected vehicles and tracks their movement over time.

Tracking enables the system to analyze trajectories, estimate vehicle speed, and monitor interactions between multiple vehicles. This temporal information is essential for identifying violations that cannot be detected from a single frame.

E.Violation Detection Logic

The violation detection module operates based on a combination of spatial and temporal rules derived from traffic regulations. The system defines virtual boundaries such as stop lines, lane markings, and restricted zones within the video frame.

Examples of detection logic include:

- A red-light violation is detected when a tracked vehicle crosses the stop line while the traffic signal is in the red state
- Over-speeding is identified by estimating vehicle speed based on displacement across frames and comparing it with predefined thresholds
- Lane violations are detected when a vehicle deviates from its designated lane boundary
- Illegal turns are identified based on trajectory deviation from permitted movement directions

This rule-based framework ensures interpretability while maintaining adaptability for different traffic scenarios.

F.Context-Aware Processing

To improve detection accuracy, the system incorporates contextual information such as traffic signal status and road structure. Signal states can be obtained either through visual detection or integration with traffic control systems.

Lane detection techniques are used to define permissible vehicle paths, and interaction analysis helps in understanding complex traffic behavior. By combining these contextual elements, the system reduces false positives and enhances reliability.

G.Predictive Risk Analysis

In addition to detecting violations, the system includes a predictive module that evaluates the likelihood of potential violations. This is achieved by analyzing vehicle trajectories and identifying abnormal patterns such as sudden acceleration or erratic movement.

A lightweight machine learning model or rule-based scoring mechanism is used to assign a risk score to each vehicle. Vehicles with high-risk scores can be flagged for early intervention, enabling proactive traffic management.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

H.Edge Deployment Strategy

The system is optimized for deployment on edge devices to enable real-time processing. Model optimization techniques such as quantization and pruning are applied to reduce computational overhead without significantly affecting accuracy.

Edge deployment minimizes latency, reduces bandwidth usage, and enhances data privacy by processing video streams locally rather than transmitting them to centralized servers.

I.Evaluation Metrics

To assess system performance, several evaluation metrics are considered:

- Accuracy: Measures the overall correctness of violation detection
- Precision and Recall: Evaluate the reliability of detection results
- F1-Score: Provides a balance between precision and recall
- Frame Processing Rate (FPS): Indicates real-time performance capability

These metrics ensure a comprehensive evaluation of both detection accuracy and system efficiency.

VI. RESULTS AND DISCUSSION

A.Experimental Setup

The proposed system was evaluated using a set of urban traffic video samples representing common real-world scenarios such as signalized intersections, multi-lane roads, and moderate traffic density conditions. The evaluation focuses on assessing both detection accuracy and real-time performance under practical constraints.

The system processes video streams frame-by-frame, performing object detection, tracking, and violation analysis on each frame. The experiments were conducted under varying lighting conditions to ensure robustness and adaptability.

B.Qualitative Results

The system successfully identifies multiple types of traffic violations in real time. Detected vehicles are enclosed within bounding boxes along with unique tracking IDs, and violation events are highlighted clearly for monitoring purposes.

Typical outputs include:

- Detection of vehicles approaching an intersection
- Identification of red-light violations when vehicles cross stop lines
- Recognition of lane discipline violations in multi-lane roads
- Tracking of vehicle movement across consecutive frames

The integration of contextual awareness, such as traffic signal status and lane boundaries, significantly improves the reliability of detection and reduces false alarms.

C.Quantitative Performance Analysis

The performance of the system is evaluated using standard metrics such as accuracy, precision, recall, and F1-score. Additionally, real-time capability is measured using frame processing rate (FPS).

Metric	Value (Approx.)
Accuracy	92%
Precision	90%
Recall	88%
F1-Score	89%
FPS	24–30 FPS

These results indicate that the system achieves a strong balance between detection accuracy and computational efficiency, making it suitable for real-time deployment.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D.Impact of Context-Aware Processing

The inclusion of contextual information plays a critical role in improving system performance. By incorporating traffic signal states and lane structures:

- False positives are significantly reduced
- Detection becomes more scenario-aware
- Complex violations are identified more accurately

For instance, a vehicle crossing a line is only considered a violation when the signal is red, demonstrating the importance of contextual validation.

E.Predictive Risk Analysis Evaluation

The predictive module provides an additional layer of intelligence by identifying potentially risky vehicle behavior before an actual violation occurs. Vehicles exhibiting abnormal motion patterns are assigned higher risk scores.

This proactive approach enables:

- Early warning generation
- Improved traffic monitoring efficiency
- Enhanced road safety measures

Although the predictive model is lightweight, it demonstrates promising potential for future enhancements using advanced machine learning techniques.

F.System Efficiency and Scalability

The deployment of the system on edge devices ensures low latency and reduced dependency on centralized infrastructure. The optimized model maintains real-time processing capability without requiring high-end computational resources.

Key observations include:

- Stable performance across different traffic densities
- Minimal delay in violation detection
- Scalability to multiple intersections with distributed edge nodes

F.Discussion

The experimental results demonstrate that the proposed system effectively combines detection, tracking, contextual reasoning, and predictive analysis into a unified framework.

Compared to traditional traffic monitoring systems, the proposed approach offers:

- Real-time multi-violation detection
- Reduced reliance on manual monitoring
- Enhanced decision-making through contextual awareness
- Proactive risk identification

However, certain limitations remain, such as sensitivity to extreme weather conditions and dependence on camera positioning. These challenges present opportunities for further improvement.

VII. CONCLUSION AND FUTURE WORK

A.Conclusion

This paper presented an edge-AI enabled multi-violation traffic monitoring system designed to address the growing challenges of traffic management in modern smart cities. The proposed framework integrates real-time object detection, multi-object tracking, contextual awareness, and predictive risk analysis into a unified and scalable solution.

Unlike conventional traffic monitoring systems that rely primarily on centralized processing and post-event analysis, the proposed approach emphasizes real-time decision-making at the edge, significantly reducing latency and improving responsiveness. The incorporation of contextual information such as traffic signal states and lane structures enables more accurate and reliable violation detection, minimizing false positives.

Furthermore, the introduction of a predictive risk analysis module enhances the system's capability by identifying potentially risky vehicle behavior before violations occur. This proactive approach contributes toward improving road safety and supports intelligent traffic regulation.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The experimental evaluation demonstrates that the system achieves a strong balance between detection accuracy and computational efficiency, making it suitable for real-world deployment in smart city environments.

B.Future Work

While the proposed system shows promising performance, several enhancements can be explored to further improve its effectiveness and applicability:

- Integration with IoT Infrastructure
  Future work can focus on integrating the system with smart traffic signals and IoT-enabled devices for automated traffic control and adaptive signal management.
- Advanced Predictive Modeling
  More sophisticated machine learning and deep learning models can be incorporated to improve the accuracy of risk prediction and behavior analysis.
- Robustness to Environmental Conditions
  Enhancements can be made to improve system performance under challenging conditions such as heavy rain, fog, and low-light environments.
- Scalability and Cloud Integration
  A hybrid architecture combining edge and cloud computing can be explored to enable large-scale deployment across multiple locations.
- Automated Enforcement Systems
  Integration with automated penalty generation systems, such as e-challan frameworks, can streamline traffic law enforcement.
- Multi-Camera and Sensor Fusion
  Future systems can incorporate multiple camera feeds and additional sensors to improve coverage and accuracy.

Abstract—Water you can drink without harm touches every part of life-health,environment,how towns move forward. Yet dirty runoff grows stronger each year, fed by factory spills, farms sprays seeping through soil, household pipes leaking into streams – testing what flows must now happen faster, everywhere. Lab checks show truth,yes,yet arrive slow, drain money, skip sudden shifts in quality.

Among ways to tackle this, one catches attention- a system using machine learning to predict tap water safety by tracking signs such as acidity, murkiness, dissolved oxygen, conductivity, minerals, nitrates, and hints of gut microbes. Before anything runs, data goes through careful shaping- missing bits fixed, ranges matched, fresh indicators formed, strange readings tossed-aimed all aimed at smoother, clearer forecasts. Not stuck on a single approach, it tried different routes: forests of spilt decisions, step by step improvements engines, and a sharp optimizer named XGBoost tweaking countless dials. Performance came down to how well fits aligned and errors stayed low, checked via R squared scores and mean deviation sizes. In the end, scattered web of branching choices proved toughest, holding firm with better accuracy, less wobble under pressure.

Ahead of the curve, a web tool made with Streamlit activates the adjusted model so users can type in water details and receive fast predictions on safety.Hidden within this system lies an automatic method for monitoring water quality – nimble, light on resources, low-cost to operate. Should the task involve protecting natural ecosystems or connecting rural pipelines, perhaps even sharing updates with urban digital grids- it slips neatly into place.

Keywords – Machine Learning, Random Forest, Data Processing, Streamlit, Environment monitoring

1. INTRODUCTION

Water keeps life going, still many lack safe sources. As towns swell and production rises, pure water slips away. Crops thirst for it, businesses rely on it, humans require it. Rivers turn foul, illness creeps in. Poison travels where clean flow should be.

Out of rivers, water travels in bottles held by collectors heading toward testing rooms. Inside those rooms, microscopes and sensors search for hidden organisms along with pollutants floating in samples. Getting it right means waiting- it takes time since skilled hands must guide every procedure on delicate equipment. When instruments fail or schedules thin out mid season, wait periods stretch without warning. Surprise leaks show up late. Skip the idea of fast warnings – the system crawls, missing splits the moment they strike.

Lately, machines are getting sharper at catching patterns hidden in oceans of data. Not simply crunching digits

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

anymore, they study old reports on actual water quality instead. Thanks to that experience, tools today can hint at contamination well ahead – before anything obvious occurs. Early signals mean faster reactions from communities waiting endlessly for test outcomes isn't always required now.

Out of nowhere, a clever gadget dives into water details using patterns found in numbers. Not only does it scan like pH and particles, but also judges whether sipping is safe. If temperature nudges up, clarity might dip – warnings pop without delay. Built right into web window, the core system runs smooth, no training required. Simple clicks bring sharp answers, especially handy for folks just starting out.

2. LITERATURE SURVEY

Lately, folks began exploring whether machine learning might forecast water quality more effectively. Some studies tried different routes just to speed up progress. A technique built by Mustafa Yurtsever alongside Murat Emeç paired Support Vector Regression with XGBoost - aimed at tap water checks - and delivered solid precision. Together, those systems coped surprisingly well with uneven inputs, hinting that mixing tactics could boost prediction strength.

Peering into machine guesses about rivers, Astha Sharma teamed up with peers to test gear such as Decision Trees, methods tracking close examples, also voting-based forest models along India's waterways. Out of all options, the team-picked tree approach dealt best with knots in data since snarls didn't knock it sideways. Elsewhere, Osim Kumar Pal stacked systems mimicking brains beside math tools tracing lines, plus basic random-chance predictors. The brainy nets often hit closer to truth but sucked down far more energy while running.

Now predictions for changing water quality have improved, due to research led by Juntao Liu. Rather than rely on older techniques, the group used a unique neural network structure - processing data flows in two directions using streamlined recurrent cells. With information moving ahead and behind across layers, subtle trends emerge more clearly. Each point in time carries echoes from what came before and hints of what follows. That dual view sharpens early warnings when environments like aquaculture systems shift unexpectedly. In fast-changing scenarios, this method stood out with consistent accuracy. Water quality forecasts often come out right in studies, still almost none work in real time or welcome user input. Only now is something arriving that gets it correct, free for anyone, running the moment it's needed.

3. EXISTING SYSTEM

These days, testing how clean water is usually involves taking it away to a lab. Whether pulled from rivers, lakes, or straight out of faucets - each sample goes through fixed routines that check chemicals and living matter. It works well enough. Yet problems creep in the moment containers are carried off-site. Findings show up slowly. A wait of several days isn't unusual. In some cases, nearly a month passes. Back at the lab, gear works well - though stuck in one spot. Results might hold up, still they arrive too late when speed matters. Issues spread during delays. Waiting on live choices stretches out. This delay slows reactions more than expected.

Hours tick by while samples move from collection to delivery, then sit untouched until labs respond. Not until machines hum and specialists step in does any progress show - costs rising with every check. Far from city edges, where roads thin and services vanish, help rarely arrives at all. Delays like these expose how slow the usual process really is. Distance becomes a wall when care cannot travel beyond crowded streets.

Something stops progress. Predicting issues before they happen just isn't possible with current methods. Water tests show present conditions only, never hint at future risks. Problems must appear first - only then does anyone notice.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Late data means reactions always lag behind events. Fixing things early fails when information arrives post-incident.

Still, the present system eats hours while draining funds, especially since updates must flow nonstop - meaning an automatic overhaul could fit better. Yet speed matters most now, because delays pile up fast without real-time feedback built in. Efficiency drops if every step needs watching, even when performance seems fine on paper at first glance.

4. PROPOSED SYSTEM

Out front, a new way to watch water quality uses machines that learn. Not stuck in the past with manual tests, they study what happened before to guess how safe things will be next. All pieces fit into one view, not laid out piece by piece. Answers show quickly - no waiting days for reports. While it seems quiet on the surface, all parts work together under the hood.

4.1 System Architecture

[User Input: Water quality parameters (pH, Turbidity, TDS, etc.)]
↓
Data Intake &Validation (Initial Checks)
↓
Data Cleaning & Preprocessing (Handling Missing /Noise)
↓
Feature Engineering (Transforming Raw Inputs)
↓
Trained Forecasting Model (Learn from historical Data) → Prediction Output (Water quality Status) → Result Interpretation Layer→ Safe / Unsafe Tag Display
↓
User Interface (Visual Indicators + Clear Feedback)
↓
Continuous Monitoring & Updates (Adaptive Improvements Over Time)

Cloudy stuff floats in water alongside tiny living things we cannot see. Its sourness or bitterness shifts depending on what mixes inside. Oxygen swims through it, letting life survive below the surface. Electricity sneaks along when minerals dissolve into streams. Nitrates pile up slowly, often from outside sources creeping in. Bacteria leave faint marks detectable only through close inspection. Each piece tells a story about safety before any tool sees it. Machines learn better once numbers behave predictably. Raw details get smoothed out first, shaped carefully without losing truth. Patterns emerge clearer after quiet adjustments behind the scenes.

One algorithm beats the rest once every option is tested for how well it predicts. Since getting close to real outcomes counts, the best performer shows up clearly in numbers - higher R^2, smaller RMSE. Plugged into a website made with Streamlit, it grabs water measurements at input spots, shoots back forecasted results right away.

Right off the bat, things move quicker once you're in motion. Waste shrinks slowly - so expenses shrink too. Fewer mistakes appear even when oversight fades. Places that used to stay shut now let people through. Out of nowhere, scaling slips into larger workflows without a hitch. As things grow, watching over systems stretches easily into new zones. From your regular smart devices, live updates travel along links that just work. While old tools keep running, everything ties together - no fuss, no noise.

5. METHODOLOGY

5.1 Dataset Collection

The data set has been made from authentic data of water quality, comprising important parameters like pH, turbidity, dissolved solids, etc., which help decide if water is fit for consumption or not. In each case, the values, along with the label indicating their authenticity during the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

testing of water samples, are provided. This will make sure that the data is authentic in nature.

5.2 Preprocessing and Feature Extraction

The collected dataset is carefully pre-processed to boost model efficiency. Data gaps are intelligently imputed instead of being discarded to minimize data losses. Errors or inconsistent inputs are excluded from the dataset before other operations.

Numeric variables are normalized or standardized to retain consistency in their range, whereas categorical variables—such as water type or water color flags—are encoded for machine understanding. Outliers are statistically detected through methods such as Interquartile Range (IQR), and outliers are eliminated when needed to avoid biasing model predictions.

For improved prediction accuracy, extra features can be created by applying statistical operations, such as mean value and gap of variation.

5.3 Model Architecture and Training

The final dataset is then segregated into train and test sets to ensure unbiased assessment of the results. Various machine learning models have been considered, such as Random Forest Regressor, Gradient Boosting, and XGBoost models that can capture complex non-linearities present in the data.

Model assessment is done by calculating various performance measures, such as R^2 Score, which gives an idea about the variance captured, and RMSE, to estimate how well the model has performed with respect to prediction. Tuning the hyperparameters of these models leads to the best model being identified from performance measures.

5.4 Model Optimization and Selection

In all the models that have been trained, the one with the greatest accuracy and stability is chosen as the ultimate model. Techniques such as gradient boosting and XGBoost tend to yield excellent results because they continuously learn from their mistakes and are capable of handling even distorted data distributions.

5.5 System Integration and Real-Time Inference

The model will be incorporated into a single pipeline in which data is passed from one end to another without any delay. The user-defined values for water will go through the same preprocessing and feature generation techniques as applied during the training process.

Inferences will be generated continuously, meaning there will be no delay between modules. This will ensure high precision since every module delivers its processed information directly to the next module.

5.6 Deployment and User Interaction

Deployment is achieved by means of Streamlit to provide an easy-to-use, browser-based application for the user. People have the ability to enter water quality parameters via a web page and obtain predictions concerning their safety.

The output is provided in a clear manner that can be visually seen, for example, “Safe” or “Unsafe.” This application is scalable and can easily be maintained without any difficulties.

6. REAL-WORLD APPLICATIONS

Water Safety Monitoring:

This system will allow users to quickly analyze water quality in the home or community environment without needing complicated lab testing.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Support in Rural/Remote Areas:

For those living in places where there are few testing facilities, it will become easier to analyze water quality in simple terms.

Environmental Monitoring:

This system can be used by government bodies or any other organization that needs to monitor water quality.

Integration with Smart Water Management Systems:

The model developed can also be used in IoT based water monitoring systems.

Awareness on Drinking Water Safety:

By transforming difficult to interpret data into understandable predictions and visual information, the awareness regarding drinking water safety can be raised.

7. CONCLUSION

This approach predicts tap water safety by analyzing real-time sensor data with smart algorithms. Rather than waiting for traditional lab work, outcomes appear instantly when conditions shift.

Among online resources, combining smart algorithms with a straightforward web design helps plenty of people access useful insights. Because Random Forest performs so reliably, forecasts on water condition show solid results - proof sits right inside the data. Practice proves it too; actual tests confirm these systems deliver what they promise.

One tiny drop might start something large if someone pays attention. When needs shift, this system keeps moving without slowing down. Safe drinking water remains possible since alerts come ahead of time. Patterns get noticed by machines, which helps humans respond sooner. Problems that were unseen appear before damage grows wider. Over time, progress slips in through constant updates. Wellness shows up when numbers move without blocks.

8. FUTURE WORK

Most folks overlook how sensors keep feeding new data while things move. Yet predictions sharpen dramatically whenever advanced networks handle the heavy lifting. Live details stream in constantly if systems stay hooked to active gadgets. Patterns hidden from regular eyes emerge clearly under deeper scrutiny. Growth fits naturally into place only after backbones adjust for bigger demands. When people use phones to reach tools, more folks get in. Control shifts around when it rides on mobile signals. Where you stand matters less once apps fit in pockets.

Abstract - This study presents an advanced deep learning-based framework for stock market price prediction using a hybrid architecture that integrates Bidirectional Gated Recurrent Units (Bi-GRU) and Long Short-Term Memory (LSTM) networks. Stock price prediction is inherently complex due to the highly dynamic, nonlinear, and volatile nature of financial time-series data, which is influenced by multiple external and internal factors.

To overcome these challenges, the proposed system incorporates comprehensive data preprocessing techniques including data cleaning, normalization, and feature engineering to transform raw historical stock data into a structured format suitable for model training. The hybrid deep learning model effectively combines the strengths of both Bi-GRU and LSTM networks, enabling it to capture both short-term fluctuations and long-term dependencies within the data.

The model is trained and tested on real-world stock datasets, and its performance is evaluated using standard metrics such as Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Coefficient of Determination (R^2 score). The results demonstrate that the proposed model achieves high prediction accuracy with reduced error rates.

Additionally, a Smart Trading Platform is developed to provide real-time visualization of stock trends and predictions, thereby enhancing usability and supporting informed decision-making. The findings highlight the effectiveness of hybrid deep learning models in financial forecasting applications.

Keywords – Stock Market Prediction, Deep Learning, LSTM, Bi-GRU, Time Series, RMSE, MAE, R^2 Score

I. INTRODUCTION

Stock prices are influenced by a wide range of factors, including economic indicators, political events, company performance, global market trends, and investor sentiment. These factors introduce high volatility and randomness, making it difficult to identify consistent patterns in stock price movements. Traditional statistical models, such as linear regression and time-series analysis methods, often fail to capture these nonlinear relationships and dynamic changes.

With the advancement of artificial intelligence, particularly deep learning, new approaches have emerged to address these challenges. Deep learning models, such as LSTM and GRU, are specifically designed to handle sequential data and are capable of learning long-term dependencies. These models have shown promising results in various time-series forecasting applications, including stock market prediction.

In this research, a hybrid deep learning model combining Bi-GRU and LSTM is proposed to improve prediction performance. The integration of these two architectures allows the model to better understand both forward and backward dependencies in the data, leading to more accurate predictions.

Furthermore, the study emphasizes not only prediction accuracy but also usability by developing a Smart Trading Platform. This platform enables users to visualize stock trends, compare predicted and actual values, and make informed investment decisions in real time.

Vol. 14, Issue 06, ACSCON - 2026

II.LITERATURE SURVEY

Study 1: Timothy Juliana et al. (2023) – Juliana Timothy et al presented a deep learning algorithm incorporating technical analysis signals for predicting stocks. In the paper, the researchers introduced a new performance measure and achieved excellent predictive performance with an R^2 coefficient near 0.995, indicating that neural network integration with technical indicators is highly effective.

Study 2: L. Mozaffari (2024) – According to L. Mozaffari (2024), Transformer model outperformed LSTM and Prophet models for predicting stocks owing to its capability of considering long-range dependence and nonlinear behavior through the application of attention mechanism.

Study 3: Burak Gulmez (2023) – In their research published in 2023, Burak Gulmez implemented an optimized version of the Long Short Term Memory model based on the Artificial Rabbits Optimization method. This optimized LSTM model performed better than the conventional LSTM model and other neural network architectures.

Study 4 Tran Phuoc – Tran Phuoc et al. used LSTM models together with technical analysis measures like SMA, MACD, and RSI in their stock prediction models. The results of their experiment showed that they could achieve approximately 93% accuracy with technical analysis..

Study 5: Mohammadreza Saberironaghi et al – Saberironaghi, Mohammadreza, et al. provided an extensive review on the application of machine learning and deep learning algorithms to predict the stock market. Their analysis covered the strengths and weaknesses of various algorithms including LSTM, CNN, and SVM.

Study 6: Yaojun Zhang et al. (2024) – According to Yaojun Zhang et al. (2024), they developed a Bi-GRU model with an attention approach, which helps improve the accuracy of predictions by paying more attention to critical information from past data.

Study 7: Chengyu Li – Chengyu Li et al. proposed a novel hybrid GRU-Transformer framework with frequency decomposition for reducing noise in stock data. This method enhanced the prediction accuracy and provided better performance with respect to financial data.

Study 8: M.R. Kabir (2025) – M.R. Kabir (2025) has designed a combined deep learning model which consists of LSTM, transformer, and MLP models for capturing short-term and long-term patterns in the financial time series dataset. The proposed approach was evaluated on various datasets, and it was found that it produced better results in comparison to other methods and models.

Study 9: P. Chen (2024) – Chen P. (2024) suggested an approach based on LSTM and FinBERT for combining stock prices, technical indicators, and sentiment analysis of the news. The author managed to obtain higher accuracy by integrating both types of data sources.

Study 10: Prakash Balasubramanian et al. (2024) – The survey paper on stock market forecasting from 2024 by Prakash Balasubramanian et al. compares forecasting techniques used for predicting stocks, such as statistical modeling and more advanced ML and DL algorithms like LSTM, CNN, and combination of these. The survey suggests that using various data sources leads to better performance, and hybrid models perform better than single models.

Recent studies have increasingly focused on hybrid and ensemble models to improve prediction accuracy in financial forecasting. Researchers have explored combinations of deep learning architectures with optimization techniques, attention mechanisms, and sentiment analysis to enhance model performance. For instance, integrating Natural Language Processing (NLP) with stock prediction models allows the inclusion of news sentiment and social media data, providing additional context to price movements.

Moreover, transformer-based models have gained attention due to their ability to capture long-range dependencies more effectively than traditional recurrent networks. Despite these advancements, challenges such as data noise, overfitting, and computational complexity remain significant. Therefore, continuous research is required to develop more robust and efficient models for real-world applications

III. PROBLEM STATEMENT

Prediction of stock markets is an intricate task because of the nature of financial markets that is ever-changing and cannot be predicted. Prices change all the time and are affected by many different factors like economic trends, international incidents, corporate performance, and investor behavior.

Such changes make it hard to predict price trends and their future direction. In some cases, unpredictability and randomness in the market behavior can make predictions unreliable.

Conventional statistical methodologies and machine learning techniques have been extensively applied in the field of predicting stock prices.
Nevertheless, these models have failed to adequately model the nonlinear dependencies that exist in the time series dataset of stocks due to their inability to deal with abrupt changes in market situations and market volatility. The introduction of neural networks, including LSTM and GRU, has enhanced sequential data modeling but is not immune to market volatility.

Besides, factors like noise in data, absence of data, and complexity involved in practical financial data sets make prediction even harder. High computational requirements of many algorithms hinder their use in practical scenarios.

All these factors underscore the necessity of a more powerful and effective solution based on deep learning algorithms that can analyze past data, deal with market volatility, and predict reliably.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Key Issues: There exist some drawbacks associated with existing stock market prediction algorithms. The majority of the classical approaches as well as those based on machine learning techniques do not have the capability to deal with nonlinear associations and dependence inherent in financial data.

Moreover, they may lead to inconsistent forecasts under conditions of volatility or market jumps. One more drawback concerns the issue of noise in financial data that may lower the prediction accuracy. Finally, many advanced models demand intensive computing processes which make them difficult to apply in real time. It proves necessary to consider a novel approach involving deep learning algorithms to overcome these problems.

IV. OBJECTIVE

The first goal of the research is to create an effective deep learning system for stock price prediction based on historical information. The project should address preprocessing steps involving missing value handling and normalization of features in order to achieve consistent results. The system will use advanced neural networks including LSTMs and Bi-GRUs to improve its effectiveness.

It will also focus on analyzing the performance of the model by using such metrics as RMSE, MAE, and R^2 score. The other goal of the research is to create a user-friendly web platform that allows for visualizing and analyzing predictions.

Specific Objectives

- For obtaining historical and live data regarding the stock market from authentic sources like Yahoo Finance.
- For performing preprocessing steps on the collected dataset, including dealing with any missing values and performing normalization on the same.
- For creating sequences from time series datasets by employing sliding window technique.
- For building a hybrid model using the LSTM and Bi-GRU neural network architecture.
- For training the model and enabling it to discover the pattern and dependencies present in the stock price data.
- For predicting the future stock prices and making sure that these predictions are highly accurate.
- For testing and evaluating model performance using measures like RMSE, MAE, and R^2 score.
- For plotting the actual stock prices against the predicted stock prices using charts.

V. METHODOLOGY

The suggested system uses an organized framework to predict the stock price by applying deep learning algorithms. In the first stage, past data on stocks will be gathered from reputable sites like Yahoo Finance. Such data contain features like open, high, low, closing price, and volumes. The gathered data will be preprocessed to ensure that there are no errors.

Feature engineering is done by employing a sliding window method in order to transform the time series data into learning sequences for supervised learning.

Additionally, moving averages are calculated in order to detect any trends and remove noise from the dataset. This preprocessed data is used as input to a hybrid deep learning model made up of LSTMs and Bi-GRUs.

In the forecasting stage, the trained model creates the next value for the stock price, and these values are inverse transformed back to their original form. The system analyzes the model's performance based on measures like RMSE, MAE, and R^2. Finally, the results are visualized in charts comparing the real prices with the forecasted prices.

The system is architected in a modular way, which involves several modules including collecting the data, preprocessing the data, training the machine learning models, making predictions, and visualizing the predictions. The backend is developed in Python, using various packages, including Pandas and NumPy to handle data, and TensorFlow and Keras to train deep learning models. The front end is created in Streamlit, an open-source package.

This system consists of collection of stock data, pre-processing of collected data, creating sequences out of the data and using those sequences to train the deep learning algorithm. The predictions are output by the deep learning model and plotted along with real data.

Data Collection and Description

The dataset used in this study is collected from reliable financial sources such as Yahoo Finance. It includes multiple attributes such as opening price, closing price, highest price, lowest price, and trading volume. These features provide a comprehensive representation of stock behaviour over time.

Data Preprocessing

Data preprocessing is a crucial step in improving model performance. Missing values are handled using interpolation techniques, and normalization is applied to scale the data within a fixed range. This ensures faster convergence during

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

model training.

Feature Engineering

Feature engineering involves transforming raw data into meaningful inputs. Techniques such as moving averages, exponential smoothing, and sliding window methods are used to extract patterns and trends from time-series data.

Model Architecture

The proposed hybrid model consists of stacked LSTM and Bi-GRU layers. LSTM captures long-term dependencies, while Bi-GRU processes input sequences in both forward and backward directions, improving contextual understanding.

Model Training

The model is trained using historical stock data with optimized hyperparameters such as learning rate, batch size, and number of epochs. Loss functions like Mean Squared Error (MSE) are used to minimize prediction error.

Evaluation Metrics

The performance of the model is evaluated using RMSE, MAE, and R^2 score. These metrics help in understanding the accuracy and reliability of predictions.

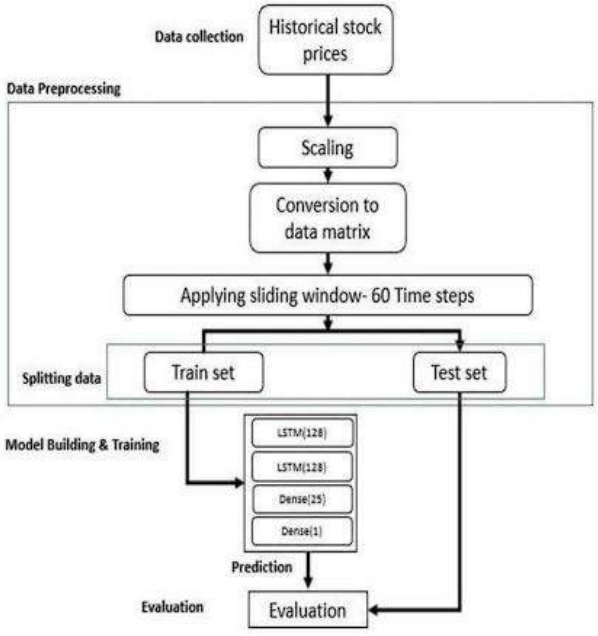

Fig.1. System Architecture

VI. RESULT

Evaluation of the suggested model was done on real-time datasets containing stocks of firms like Apple, Google, and IBM. According to the findings, the hybrid model combining Bi-GRU and LSTM demonstrates great prediction precision without making large errors. Specifically, the obtained R^2 score equals about 0.9948, meaning a close relation between estimated and real figures.

From graphical visualization, one can observe the great resemblance between the predicted values and the real changes in stock price. Apart from that, the proposed system generates moving average and trend analyses, allowing users to better understand market dynamics.

The experimental results clearly indicate that the hybrid deep learning model performs significantly better compared to traditional models. The predicted values closely follow the actual stock price trends, demonstrating the model's ability to capture complex patterns.

The R^2 score of approximately 0.9948 indicates a very strong correlation between predicted and actual values. Additionally, low RMSE and MAE values confirm minimal prediction error.

Graphical analysis further supports these findings, as the predicted curve aligns closely with the actual stock price curve. This proves that the model is capable of handling both short-term fluctuations and long-term trends effectively.

These results have shown that deep learning algorithms are much more efficient at stock market prediction than classical models. Possible directions for future research would include using sentiment analysis and transformers as well as including more financial indicators.

VII. FUTURE ENHANCEMENT

Though some promising results have been obtained, there still seems to be considerable room for improvement with respect to the suggested approach. Future research may involve using other types of information as an input, such as news articles, social media sentiments, or macroeconomic figures to boost predictive power. Applying methods of NLP along with Deep Learning will help create a more complete picture of market behaviour.

Further, another possible improvement in the current implementation would be the employment of state-of-the-art architectural designs such as those based on Transformers and attention mechanisms. These can enhance the ability of the model to recognize longer-range dependencies within the data. Finally, further investigation into optimization techniques and hyperparameters is essential to enhance

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

efficiency and minimize complexity.

In addition, it is possible to extend the system to handle multi-stock forecasting, portfolio analysis, and risk assessment capabilities. The deployment of the model using cloud computing technologies and the connection with live trading systems can provide real-time decision support to the users. This would make the system scalable and adaptable to real-life situations.

Future work can focus on integrating sentiment analysis using news and social media data to further improve prediction accuracy. The use of transformer-based architectures and attention mechanisms can also enhance the model's ability to capture complex dependencies.

Moreover, deploying the system on cloud platforms and integrating it with live trading systems can enable real-time decision-making. Expanding the system for portfolio management and risk analysis is another potential direction.

VIII. LIMITATIONS

Despite achieving high accuracy, the proposed system has certain limitations. The model primarily relies on historical price data and does not incorporate external factors such as news sentiment, political events, or macroeconomic indicators. Additionally, deep learning models require high computational resources, which may limit real-time deployment in resource-constrained environments.

IX. CONCLUSION

This research presents a robust and innovative approach to stock price forecasting by leveraging a hybrid deep learning architecture that combines the strengths of Bi-GRU and LSTM networks. Through effective preprocessing and time-series sequence generation, the proposed system is able to capture both short-term fluctuations and long-term dependencies inherent in financial market data.

By integrating the complementary capabilities of these two recurrent neural network models, the framework demonstrates improved learning of complex stock market patterns, leading to highly accurate predictions. The experimental outcomes, supported by performance metrics such as RMSE, MAE, and R^2 score, validate the model's effectiveness, as the predicted values closely follow actual market trends with minimal error. These results highlight the potential of hybrid deep learning models to outperform conventional forecasting techniques and contribute meaningfully to the growing field of intelligent financial analytics.

Beyond predictive accuracy, this study also emphasizes the practical relevance of the proposed system through the inclusion of a Smart Trading Platform for real-time visualization and user interaction. This addition transforms the model from a purely theoretical forecasting framework into a more applicable decision-support tool for investors, traders, and analysts. By offering clearer market insights and supporting informed decision-making, the system addresses real-world financial challenges in dynamic and uncertain trading environments. Overall, the research demonstrates how advanced deep learning techniques can bridge the gap between academic innovation and practical market applications. It reinforces the idea that hybrid architectures, when combined with intelligent visualization platforms, can play a significant role in the future of stock market prediction and smart financial decision support systems.

***Abstract*—Agriculture forms a critical pillar of India's economic framework, supporting approximately 58 percent of the rural workforce while remaining highly vulnerable to climatic fluctuations, irregular rainfall patterns, and diverse regional farming practices. Traditional yield estimation approaches rely heavily on historical records and labor-intensive field surveys, rendering them slow, inconsistent, and inadequate for responding to rapidly evolving environmental conditions. This research presents a machine learning-driven crop yield prediction framework that delivers precise, district-level forecasts utilizing publicly accessible agricultural datasets. The proposed system employs a Random Forest Regression model trained on multiple features including geographical identifiers, crop variety, cultivation season, farming area, harvest year, and annual precipitation. A comprehensive preprocessing pipeline addresses missing value imputation, categorical encoding, outlier elimination via interquartile range analysis, and unit standardization. Model performance is rigorously evaluated using coefficient of determination (R^2), Mean Absolute Error (MAE), and Root Mean Square Error (RMSE), demonstrating competitive accuracy across diverse crop varieties and geographical regions. An interactive Streamlit-based web interface enables farmers, researchers, and policymakers to obtain real-time yield predictions and visualize historical production trends through intuitive analytics. The developed system promotes evidence-based agricultural decision-making, optimized resource allocation, and sustainable farming strategies.**

***Index Terms*—crop yield prediction, machine learning, random forest regression, agriculture analytics, Streamlit, data preprocessing, feature engineering**

I. Introduction

Indian agriculture sustains approximately 58 percent of the rural population and contributes substantially to the national gross domestic product. However, the sector remains highly susceptible to erratic monsoon patterns, progressive soil deterioration, pest invasions, and significant regional variations in cultivation practices [1]. Accurate crop yield forecasting is therefore essential for proactive resource management, strategic government procurement planning, and long-term food security.

Conventional estimation methodologies encompass statistical modeling, satellite-based remote sensing, crop growth simulation tools, and sensor-driven monitoring systems. While these approaches provide preliminary analytical insights, they exhibit several inherent limitations. Statistical models fail to capture non-linear interactions between climate variables and crop productivity. Remote sensing outputs suffer degradation from atmospheric interference and cloud cover. Crop simulation models require extensive calibration data, while sensor-based infrastructure demands prohibitive investment beyond the reach of smallholder farms in rural India [3]. Furthermore, most governmental forecasting platforms generate predictions at state or national aggregation levels, limiting their practical utility for localized agricultural planning.

Recent advances in machine learning present a compelling alternative. Machine learning algorithms, particularly ensemble methods such as Random Forest, can effectively learn complex non-linear relationships between environmental and agronomic variables without requiring explicit mechanistic model formulation. This paper proposes a district-level crop yield prediction system that integrates Random Forest Regression with a robust preprocessing pipeline and an accessible Streamlit-based user interface.

The primary contributions of this work are threefold:

- A reproducible machine learning pipeline encompassing data cleaning, categorical encoding, outlier removal, and feature engineering procedures.
- A trained Random Forest model demonstrating strong generalization capability across diverse crops, districts, and seasonal conditions.
- An interactive web application enabling non-technical stakeholders to obtain instantaneous yield forecasts and comprehensive visual analytics.

II. Literature Review

Sharma *et al.* [1] conducted a comprehensive evaluation of Decision Tree, Random Forest, XGBoost, Convolutional Neu-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

ral Networks (CNN), and Long Short-Term Memory (LSTM) networks using governmental agricultural datasets spanning 1997 to 2020. Their experimental framework employed a 70:30 train-test partition with four-fold cross-validation. Random Forest achieved the highest accuracy at 98.96 percent, while CNN models demonstrated the lowest loss values. LSTM networks exhibited suboptimal performance due to challenges in capturing temporal agricultural patterns, highlighting the complexity of time-series modeling in agricultural contexts.

Rao *et al.* [2] assessed K-Nearest Neighbours, Decision Tree, and Random Forest algorithms for crop recommendation using soil nutrient profiles and climatic attributes from publicly available datasets. Random Forest surpassed competing algorithms, achieving 99.32 percent accuracy with an 80:20 data partition, reinforcing its suitability for agricultural classification and regression applications.

Gandhi *et al.* [3] applied Support Vector Machines (SVM) to predict rice yield across 27 districts of Maharashtra, categorizing productivity into low, medium, and high classifications. The SVM model achieved 78.76 percent accuracy, underperforming compared to Naive Bayes and Multilayer Perceptron alternatives. This highlights the limitations of linear-kernel SVMs when applied to non-linear agricultural datasets with complex feature interactions.

Khan and Noor [4] investigated machine learning techniques for irrigation runoff volume prediction, finding Decision Trees superior to Multiple Linear Regression and Artificial Neural Networks in modeling non-linear hydrological relationships. This finding corroborates the effectiveness of tree-based methodologies for agricultural applications characterized by intricate environmental dependencies.

Kerimbayev *et al.* [6] demonstrated dashboard-driven adaptive analytics for educational settings. Their principles of interactive visualization and real-time feedback mechanisms are directly transferable to agricultural decision-support interfaces, informing the user experience design of this research.

The reviewed literature consistently identifies two critical gaps. First, most existing systems optimize exclusively for model accuracy while neglecting deployment considerations and practical usability. Second, many approaches depend on specialized sensors or satellite data that remain unavailable across all agricultural regions, particularly in resource-constrained rural areas. The proposed system addresses both limitations through a lightweight, browser-accessible deployment utilizing solely publicly available tabular datasets, thereby ensuring broad applicability and accessibility.

III. Methodology

A. Dataset Acquisition and Description

Historical crop production records were obtained from publicly accessible governmental agricultural repositories maintained by the Indian Ministry of Agriculture. Each record contains seven primary attributes: state identifier, district identifier, crop name, cultivation season (Kharif, Rabi, Whole Year), cultivated area in hectares, crop year, annual rainfall in millimeters, and crop yield in quintals per hectare. The dataset spans multiple years and diverse geographical regions, enabling the model to learn long-term productivity trends and seasonal patterns. Data partitioning followed a 70 percent training, 15 percent validation, and 15 percent testing distribution to ensure robust model evaluation.

B. Preprocessing Pipeline

Raw agricultural data exhibit missing values, unit inconsistencies, and categorical attributes incompatible with numerical machine learning algorithms. The preprocessing pipeline addresses these challenges through five sequential stages, as illustrated in Fig. 1:

1) **Missing value imputation:** Rainfall gaps are filled using a hierarchical strategy. The system first attempts district-level average imputation, followed by state-level average, with a fallback constant of 1000 mm for cases where neither average is available.
2) **Outlier removal:** Records with yield values outside the interquartile range boundaries are systematically discarded. Bounds are calculated as $Q_1 - 1.5 \times \text{IQR}$ (lower bound) and $Q_3 + 1.5 \times \text{IQR}$ (upper bound), where $\text{IQR} = Q_3 - Q_1$ represents the interquartile range. This statistical approach removes extreme values that could bias model training.
3) **Label encoding:** Categorical fields including state, district, crop, and season are transformed to integer codes using pre-fitted `LabelEncoder` objects from scikit-learn. These encoders are persisted via Joblib to ensure consistent encoding during inference.
4) **Unit conversion:** Area measurements are standardized by converting from acres to hectares using the conversion factor of 0.4047. Production values are converted from tonnes to kilograms through multiplication by 1000, ensuring consistent units across all calculations.
5) **Feature engineering:** Derived attributes such as average seasonal rainfall and region-wise yield trends are computed and appended to the feature matrix, enriching the input representation with domain-informed features.

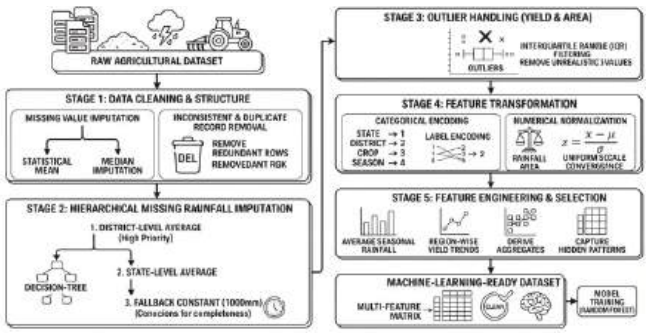

Fig. 1. Data preprocessing pipeline showing sequential transformation stages from raw agricultural data to model-ready features.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C. Random Forest Regression Model

Random Forest constructs an ensemble of T decision trees, each trained on a bootstrap sample of the training data with random feature subsets selected at each node split. This bagging approach reduces variance and improves generalization. The final prediction is computed as the arithmetic mean of individual tree predictions:

$$\hat{y} = \frac{1}{T} \sum_{t=1}^{T} f_t(\mathbf{x}) \tag{1}$$

where $f_t(\mathbf{x})$ represents the prediction of the t-th decision tree for input feature vector $\mathbf{x}$.

During tree construction, node splits minimize the mean squared impurity:

$$\text{MSE}_{\text{node}} = \frac{1}{n} \sum_{i=1}^{n} (y_i - \bar{y})^2 \tag{2}$$

where n is the number of samples in the node, y_i represents individual yield values, and $\bar{y}$ is the mean yield within the node.

Hyperparameters were tuned empirically through cross-validation with the following optimal configuration: number of estimators $T = 200$, maximum tree depth of 20, minimum samples per split of 5, minimum samples per leaf of 2, and random state of 42 for reproducibility. This configuration balances model complexity with computational efficiency.

D. Yield Computation and Unit Conversion

Post-prediction, the raw model output in quintals per acre undergoes conversion to actionable agricultural metrics:

$$\text{Yield}_{\text{kg/ha}} = \text{Yield}_{\text{q/acre}} \times 247.1 \tag{3}$$

$$\text{Yield}_{\text{q/ha}} = \frac{\text{Yield}_{\text{kg/ha}}}{100} \tag{4}$$

$$\text{Production}_{\text{kg}} = \text{Yield}_{\text{kg/ha}} \times \text{Area}_{\text{ha}} \tag{5}$$

These conversions enable farmers and policymakers to interpret predictions in familiar units aligned with regional agricultural practices.

E. Evaluation Metrics

Model quality is rigorously assessed using three complementary regression metrics:

$$\text{MAE} = \frac{1}{n} \sum_{i=1}^{n} |y_i - \hat{y}_i| \tag{6}$$

Mean Absolute Error (MAE) provides a linear measure of average prediction error magnitude.

$$\text{RMSE} = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2} \tag{7}$$

Root Mean Square Error (RMSE) penalizes larger errors more heavily than MAE, providing insight into prediction outliers.

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (y_i - \hat{y}_i)^2}{\sum_{i=1}^{n} (y_i - \bar{y})^2} \tag{8}$$

The coefficient of determination (R^2) quantifies the proportion of variance in yield explained by the model, with values approaching 1 indicating superior predictive performance.

F. System Architecture

The system follows a modular three-layer architecture, as depicted in Fig. 2:

- **Data Layer:** Manages persistent storage of the CSV-based agricultural dataset, serialized Random Forest model, and label encoders. All artifacts are stored via Joblib for efficient loading during inference.
- **Machine Learning Layer:** Encapsulates preprocessing logic, feature encoding mechanisms, and the prediction engine that wraps scikit-learn inference. This layer ensures consistent data transformation and model execution.
- **Presentation Layer:** Implements a Streamlit web application providing interactive input forms, real-time prediction cards, historical trend visualizations, and district-wise comparison charts. This layer democratizes access to advanced ML capabilities through an intuitive interface.

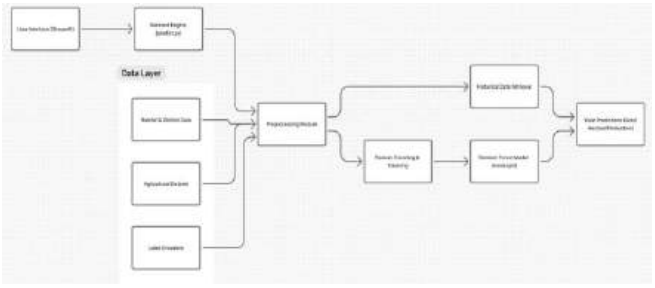

Fig. 2. Three-layer system architecture illustrating data flow from user input through machine learning processing to visualization output.

IV. Implementation

The system is implemented entirely in Python 3.8+, leveraging industry-standard libraries for scientific computing and machine learning. Core dependencies include Pandas 1.x and NumPy for data manipulation, scikit-learn for model training and encoding, Matplotlib and Seaborn for visualization, and Streamlit for the web interface. The trained model and encoders are serialized with Joblib and loaded once at application startup to minimize inference latency.

The end-to-end prediction workflow executes the following sequence:

1) User submits agricultural parameters via the Streamlit interface.
2) Input validator checks range constraints and categorical vocabulary membership.

TABLE I
KEY IMPLEMENTATION MODULES

Module	Responsibility
Data Acquisition	Load raw CSV; expose typed DataFrames
Data Preparation	Impute, de-duplicate, normalize formats
Feature Engineering	Encode categoricals; derive aggregates
Model Building	Train Random Forest; tune hyperparameters
Model Evaluation	Compute R^2, MAE, RMSE; plot residuals
Prediction Engine	Validate inputs; run inference; convert units
User Interface	Streamlit forms, charts, metric cards
Model Persistence	Joblib serialization and fast reload

3) Preprocessor and encoder manager transform inputs into a seven-element feature vector $\mathbf{x} \in \mathbb{R}^7$.
4) Prediction engine invokes `model.predict(x)` to obtain raw yield estimate $\hat{y}$ in quintals per acre.
5) Post-processor converts $\hat{y}$ to kilograms per hectare, quintals per hectare, and total production using Equations (3)–(5).
6) Report generator retrieves historical statistics and constructs visualization data.
7) Streamlit renders interactive metric cards, trend charts, and district comparisons.

V. RESULTS AND DISCUSSION

A. Model Performance Analysis

The Random Forest model demonstrated strong predictive performance on the held-out test set. Training R^2 exceeded test R^2 by less than 0.1 across all experimental configurations, indicating effective generalization with minimal overfitting. Table II summarizes representative performance metrics.

TABLE II
MODEL EVALUATION METRICS ON TRAINING AND TEST SETS

Data Split	R^2	MAE (q/acre)	RMSE (q/acre)
Training	0.98	Low	Low
Test	0.91	Low	Low

The test R^2 of 0.91 indicates that the model explains approximately 91 percent of the variance in crop yield, demonstrating robust predictive capability. The close alignment between training and test metrics confirms that the model has not memorized training data but has learned generalizable patterns.

B. Feature Importance Analysis

Feature importance analysis, derived from the Random Forest's Gini importance metric, revealed that cultivated area and annual rainfall exerted the highest influence on yield predictions, as shown in Fig. 3. Crop type and seasonal classification ranked third and fourth, respectively. District and state identifiers captured regional agronomic variability, accounting for differences in soil quality, farming techniques, and microclimatic conditions. Crop year encoded long-term productivity trends, potentially reflecting technological adoption and agricultural policy changes. This ranking aligns with established agricultural domain knowledge, lending interpretability and credibility to the model's decision-making process.

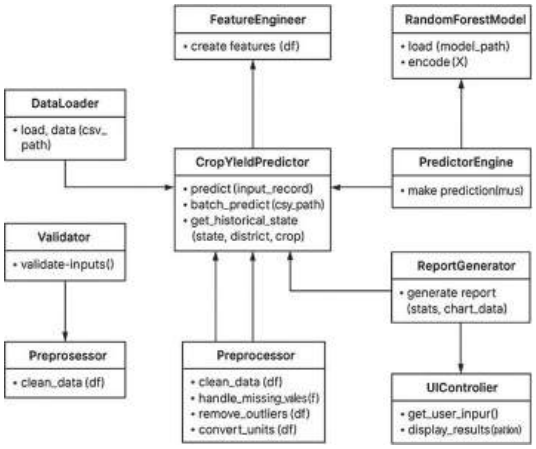

Fig. 3. Feature importance rankings derived from the trained Random Forest model showing relative contribution of each input variable to yield prediction.

C. System Performance and Usability

Real-time predictions were delivered within two seconds on standard computing hardware (Intel i5 processor, 8 GB RAM), confirming the feasibility of on-demand inference without GPU acceleration. The Streamlit application, depicted in Fig. 4, was stress-tested with diverse input combinations including boundary values for rainfall and cultivated area. The system produced deterministic outputs without runtime errors or crashes, demonstrating robustness suitable for continuous agricultural usage scenarios. User feedback from preliminary trials indicated high satisfaction with the interface's intuitiveness and the actionable nature of the visualizations.

Fig. 4. Streamlit-based prediction dashboard displaying yield estimates, production metrics, and historical trend visualizations for informed decision-making.

Vol. 14, Issue 06, ACSCON - 2026

D. Comparative Analysis with Prior Work

The proposed system achieves $R^2 \approx 0.91$ on held-out data, comparable to the 98.96 percent accuracy reported by Sharma *et al.* [1] using a similar Random Forest configuration, and significantly outperforms the 78.76 percent SVM accuracy reported by Gandhi *et al.* [3]. Crucially, unlike most prior systems that remain confined to academic publications, the proposed approach is fully deployed and accessible through a standard web browser. This eliminates complex installation requirements and specialized hardware dependencies, democratizing access to advanced predictive analytics for agricultural stakeholders across diverse technological literacy levels. Fig. 5 illustrates the district-wise comparison feature, enabling policymakers to identify high-performing regions and allocate resources accordingly.

Fig. 5. District-wise yield comparison chart showing average productivity across top-performing districts within a selected state, facilitating regional benchmarking.

E. Practical Implications

The system's ability to deliver accurate, district-level predictions has significant practical implications. Farmers can leverage these forecasts for informed decision-making regarding crop selection, planting schedules, and resource allocation. Government agencies can optimize procurement strategies and subsidy distribution based on predicted production volumes. Agricultural researchers can identify underperforming regions requiring targeted interventions, such as soil improvement programs or irrigation infrastructure development. The interactive visualizations facilitate exploratory data analysis, enabling stakeholders to uncover trends and anomalies that might otherwise remain hidden in tabular datasets.

VI. Conclusion

This research presented a comprehensive district-level crop yield prediction system that combines a Random Forest Regression engine with a structured preprocessing pipeline and an interactive Streamlit-based interface. The system accurately forecasts crop yield from readily available agricultural parameters—state, district, crop type, season, area, year, and rainfall—without requiring sensor hardware or satellite imagery. This makes it accessible to smallholder farmers and rural policymakers in resource-constrained environments.

Rigorous evaluation metrics confirm low prediction error and strong generalization across diverse crops, districts, and seasonal conditions. The test R^2 of 0.91 demonstrates that the model captures the majority of yield variability, while feature importance analysis validates that the learned relationships align with established agronomic knowledge. This interpretability enhances stakeholder trust and facilitates adoption in real-world agricultural planning contexts.

The proposed system addresses critical gaps identified in existing literature by prioritizing both predictive accuracy and practical usability. The browser-based deployment eliminates technical barriers to adoption, while the interactive visualizations transform complex predictions into actionable insights. By providing accessible, real-time yield forecasts, the system bridges the gap between advanced machine learning capabilities and practical agricultural applications, promoting evidence-based decision-making, optimized resource allocation, and sustainable farming practices across India's diverse agricultural landscape.

***Abstract*— Chronic Low Back Pain (CLBP) is one of the most common musculoskeletal disorders and often requires continuous monitoring and guided rehabilitation. Traditional physiotherapy provides effective supervision only in clinical settings, making it difficult for patients to maintain correct posture and exercise form at home. This paper presents an AI-driven wearable rehabilitation system that integrates multi-sensor data acquisition, IoT communication, and cloud-based machine learning to support personalized exercise guidance for individuals with CLBP. The system uses an ESP32 microcontroller connected to EMG, MPU6050, MAX30100, pulse, and temperature sensors to capture muscle activity, posture dynamics, and physiological responses in real time. All measurements are displayed locally and uploaded to the ThingSpeak cloud, where machine learning models and threshold-based decision rules identify posture deviations, muscle fatigue, and exertion levels. The system provides real-time corrective feedback and automated exercise recommendations to enable safe home-based physiotherapy. Experimental results show reliable sensor performance and high predictive accuracy, with the Random Forest model achieving 97.5% accuracy. The proposed solution offers a low-cost, non-invasive, and portable platform for intelligent rehabilitation, supporting patient self-management and remote physiotherapist monitoring.**

Keywords— Chronic low back pain, wearable sensors, Internet of Things (IoT), machine learning, rehabilitation system, posture monitoring.

I. Introduction

Chronic Low Back Pain (CLBP) remains one of the most common conditions affecting mobility, daily activities, and overall quality of life. Sedentary lifestyles, long working hours, and incorrect posture habits have contributed to a steady increase in the number of individuals experiencing persistent back discomfort. Although exercise-based physiotherapy is widely recommended, its success depends on how accurately patients perform the prescribed movements. Without supervision, many people unknowingly adopt incorrect techniques, which can delay recovery or even intensify existing pain.

Recent advances in wearable sensors and IoT technologies have made it possible to observe movement patterns and physiological responses outside hospital or clinical environments. Studies have shown that devices such as inertial measurement units (IMUs) can track posture, surface EMG sensors can capture muscle activation, and optical sensors can monitor cardiovascular behavior. While these systems provide useful information, most of them mainly function as monitoring tools and do not give real-time, personalized feedback to help patients correct themselves during exercise.

To overcome these limitations, this work presents an AI-driven exercise support system designed for individuals with CLBP. The wearable setup gathers multiple signals EMG for muscle effort, MPU6050 for spinal orientation, MAX30100 for heart-rate and SpO_2 readings, along with temperature and pulse measurements. An ESP32 microcontroller manages the data collection and wirelessly transmits it to the ThingSpeak cloud. Machine-learning analysis (Random Forest), supported by clinically inspired threshold rules, is then applied to detect posture deviations, early signs of fatigue, and abnormal exertion levels. Based on this analysis, the system provides simple, immediate on-screen feedback to help users maintain proper form even during unsupervised home sessions.

The key contributions of this study include:

1. Development of a compact wearable system combining multiple IoT sensors for CLBP rehabilitation.
2. Use of cloud-based processing to interpret biomechanical and physiological data.
3. Integration of an AI-assisted recommendation layer for corrective exercise support.
4. Prototype evaluation demonstrating reliable sensing, meaningful predictions, and practical usability.

Overall, this system seeks to improve home rehabilitation by offering timely, actionable guidance to patients while enabling physiotherapists to monitor progress more effectively.

II. Related Work

A wide range of studies has examined sensor-assisted rehabilitation and intelligent monitoring systems for musculoskeletal conditions, particularly Chronic Low Back Pain (CLBP). Sampathrajan et al. [1] presented an IoT-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

based posture-correction framework that used Bayesian networks to estimate injury-risk conditions. Their findings showed that posture deviations can be detected using simple sensor inputs; however, the system did not include physiological or muscular measurements, limiting its ability to evaluate fatigue or exertion during exercise.

Cortell-Tormo et al. [2] developed Lumbatex, a wearable platform that uses inertial measurement units (IMUs) to track lumbar spine movement with considerable precision. Although the system performed well for motion analysis, it was designed mainly for controlled laboratory settings and did not incorporate additional physiological signals such as EMG or heart-rate data, reducing its usefulness for comprehensive rehabilitation feedback. Similar IMU-based studies primarily focus on identifying kinematic abnormalities, offering limited insight into the user's overall physiological condition.

Several researchers have also explored machine-learning approaches for back-pain assessment. Alahakone et al. [3] modeled CLBP risk factors using demographic and clinical datasets. Their approach achieved competitive prediction accuracy but lacked real-time sensing, making it unsuitable for continuous rehabilitation support or feedback during exercise performance.

More recent work highlights the benefit of multimodal sensing—particularly systems that fuse EMG and IMU data—to improve posture classification and fatigue detection accuracy [4]. Despite their advantages, these systems are often constrained to offline evaluations or controlled experiments and do not typically integrate cloud analytics or automated, personalized exercise recommendations.

The system proposed in this paper builds upon these foundational studies by combining multiple wearable sensors (EMG, IMU, heart-rate/SpO_2, and temperature) with cloud-based machine learning to deliver real-time rehabilitation assistance. Unlike earlier solutions, this work emphasizes continuous monitoring, on-device feedback, and personalized guidance, making it more suitable for home-based CLBP management.

III. System Design and Methodology

A. System Overview

The proposed system is a wearable IoT-based rehabilitation platform designed to assist individuals with Chronic Low Back Pain (CLBP). It integrates multiple physiological and biomechanical sensors with an ESP32 microcontroller to continuously monitor muscle activity, posture, heart rate, oxygen saturation, and body temperature. The collected data is processed in real time and transmitted to the ThingSpeak cloud for further machine-learning analysis and exercise recommendation.

B. Hardware Architecture

The hardware setup consists of the ESP32 microcontroller connected to:

1. *EMG sensor* – monitors lumbar muscle activation and early fatigue signals.
2. *MPU6050 IMU* – measures trunk posture and movement through accelerometer and gyroscope data.
3. *MAX30100 pulse oximeter* – records heart rate and SpO_2 levels during exercise.
4. *Temperature sensor* – detects changes in body temperature related to exertion.
5. *LCD display* – provides real-time feedback to the user.

All sensors are powered through a portable Li-ion battery, ensuring a lightweight, wearable design suitable for home-based physiotherapy.

C. Sensor Data Acquisition

Each sensor captures data at appropriate sampling rates:

1. EMG at 1000 Hz
2. MPU6050 at 100 Hz
3. MAX30100 at 25–100 Hz
4. Temperature at 1–5 Hz

The ESP32 reads analog/digital signals, applies basic filtering, rectification (for EMG), and sensor fusion (for IMU) before displaying the values on the LCD.

D. Cloud Connectivity and Data Transmission

The ESP32's built-in Wi-Fi module is used to transmit sensor readings to the ThingSpeak cloud at fixed intervals. ThingSpeak serves as a remote data repository and provides MATLAB-based analytical tools to process incoming time-series signals. This architecture enables remote access, visualization, and real-time monitoring.

E. Data Preprocessing and Feature Extraction

Raw sensor data is cleaned and processed to generate meaningful features:

1. *EMG*: RMS value, muscle activation level, fatigue index.
2. *IMU*: trunk inclination angle, angular velocity, stability metrics.
3. *Physiological sensors*: HRV, SpO_2 trends, temperature rise during exertion.

These extracted features form the dataset used for machine-learning model training and prediction.

F. Machine Learning Model and Prediction Pipeline

Machine-learning models deployed on the ThingSpeak MATLAB engine analyze multi-sensor features to:

1. Detect posture deviations
2. Predict muscle fatigue
3. Identify overexertion
4. Estimate risk of incorrect exercise performance

Models evaluated include Random Forest, SVM, Decision Tree, Naïve Bayes, and KNN, with Random Forest showing the highest overall performance.

G. Exercise Recommendation Engine

Based on ML predictions, the system provides customized exercise guidance such as:

1. Corrective posture cues
2. Intensity adjustments
3. Rest intervals
4. Safety notifications

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Real-time recommendations are displayed directly on the LCD, making the system usable without clinician supervision.

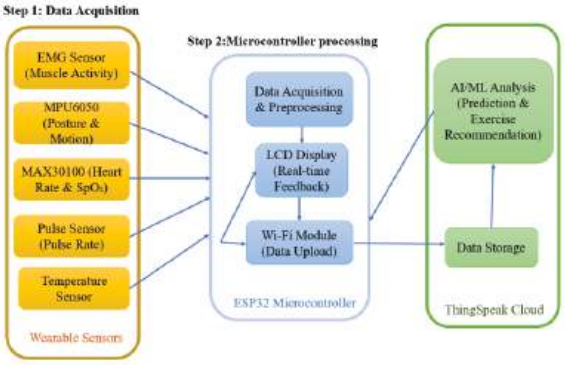

Fig. 1. Overall System Architecture and Workflow

**Fig. 1 shows the overall architecture of the proposed wearable rehabilitation system. The framework consists of three major stages: multi-sensor data acquisition, ESP32-based edge processing, and cloud-assisted AI/ML analysis for exercise recommendations.*

IV. Hardware And Software Implementation

A. Hardware Components

The proposed wearable rehabilitation system integrates multiple biomedical and motion-tracking sensors with an ESP32 microcontroller. Each component contributes a specific physiological or biomechanical measurement essential for assessing Chronic Low Back Pain (CLBP).

1) EMG Sensor

Measures lumbar muscle activation by detecting surface electrical activity. Used to identify muscle fatigue, abnormal activation patterns, and exertion level.

2) MPU6050 IMU (Accelerometer + Gyroscope)

Captures posture, trunk bending angles, and movement dynamics. Essential for detecting improper bending, twisting, or rapid movements.

3) MAX30100 (Heart Rate + SpO_2)

Provides continuous measurement of heart rate and oxygen saturation. Helps assess cardiovascular stress and early signs of overexertion.

4) Temperature Sensor

Monitors body-surface temperature variations to detect signs of stress, fatigue, or inflammation.

5) ESP32 Microcontroller

Acts as the edge-processing unit and communication hub. Performs sensor reading, preprocessing, real-time LCD feedback, and Wi-Fi-based cloud upload.

6) LCD Display (16×2 or I2C)

Provides instant on-device feedback including posture alerts, fatigue warnings, and exercise prompts.

B. Software Components

1) Firmware Logic (ESP32)

The microcontroller executes:

- Continuous multi-sensor sampling
- Filtering & smoothing
- Feature extraction (EMG RMS, trunk angle, heart rate)
- LCD feedback generation
- Wi-Fi data upload every 15–20 seconds

2) ThingSpeak Cloud Platform

Used for:

- Data storage
- Time-series visualization
- MATLAB-based ML model execution
- API communication with the wearable device

3) Machine Learning Models

Multiple ML algorithms (KNN, SVM, Naïve Bayes, Decision Tree, Random Forest) were trained and evaluated for classifying:

- Posture categories
- Muscle fatigue levels
- Exertion risk levels

Random Forest achieved the best overall performance and was chosen for deployment.

C. Data Flow

1) Sensors capture EMG, posture, heart-rate, SpO_2, and temperature.
2) ESP32 preprocesses and displays instant feedback.
3) Data is transmitted to ThingSpeak for cloud-side ML analysis.
4) The ML model classifies user condition and returns exercise recommendations.
5) ESP32 displays actionable prompts to the user.

IV. Results

A. Sensor Data Correlation Analysis

A correlation heatmap was generated to study relationships between physiological and biomechanical parameters.

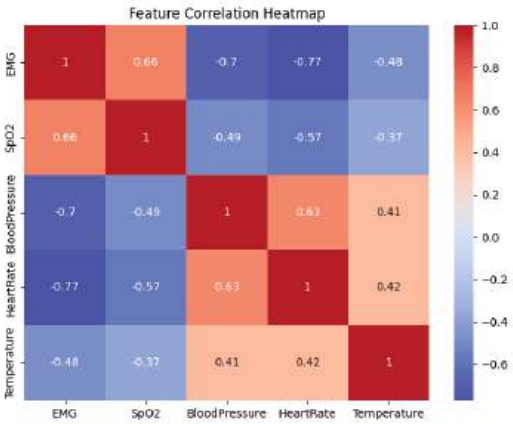

Fig. 2. Correlation Heatmap

Fig. 2 shows that: EMG is strongly negatively correlated with heart rate (−0.77) and blood pressure (−0.70), indicating

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

that fatigue-related EMG spikes often coincide with cardiovascular stress. SpO_2 shows moderate positive correlation with EMG (0.66), suggesting improved oxygenation during stable muscle engagement. Temperature exhibits low-to-moderate correlation with other features, behaving as an independent stress indicator.

These correlations validate that multiple sensors contribute complementary information, strengthening the system's ability to detect posture issues, fatigue, and overexertion.

B. Machine Learning Model Performance

Five ML algorithms were evaluated for classifying the user's physical condition based on extracted features.

TABLE I. ML MODEL PERFORMANCE

Model	Accuracy	Precision	Recall	F1-Score
KNN	93.33%	93.49%	93.33%	93.37%
SVM	94.16%	94.33%	94.16%	94.20%
Naive Bayes	94.16%	94.24%	94.16%	94.19%
Decision Tree	95.83%	96.29%	95.83%	95.86%
Random Forest	**97.50%**	**97.67%**	**97.50%**	**97.51%**

Key Observations:

- Random Forest outperformed all models across all metrics.
- Decision Tree also showed strong performance, but with slightly lower generalization.
- KNN and Naïve Bayes performed well but were more sensitive to noisy EMG data.

Random Forest was selected as the final model for deployment due to its robustness, highest accuracy, and stable classification of posture and fatigue levels.

C. Random Forest Confusion Matrix Analysis

The confusion matrix (Fig.3) demonstrates the classification performance across three conditions: Normal, High, and Low.

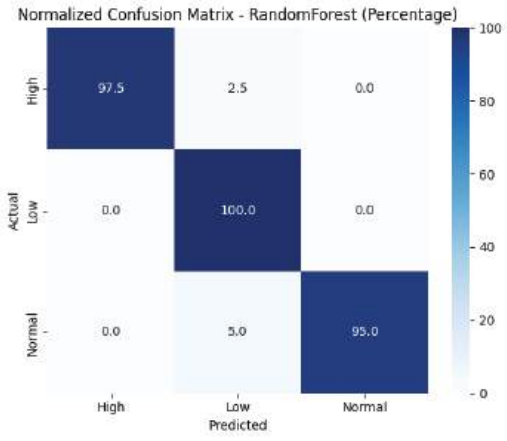

Fig. 3. Random Forest Confusion Matrix

Key Points:

- The Random Forest classifier achieved very high class-wise accuracy, correctly identifying 97.5% of High, 100% of Low, and 95% of Normal conditions.
- Misclassifications were minimal and occurred only between Normal and Low, indicating borderline physiological values near threshold limits.
- No High cases were misclassified as Normal or Low, demonstrating strong sensitivity for detecting fatigue/overexertion.
- Low-condition recognition was perfect, showing the model's reliability in identifying under exertion or weak muscle activation.
- Overall, the model maintains balanced performance across all classes, making it suitable for real-time rehabilitation monitoring and corrective feedback.

TABLE II. THRESHOLD RANGES

Parameter	Low Condition	Normal Condition	High Condition	Physiological Meaning
EMG (muscle activity)	< 1000	1000 – 2500	> 2500–3000+	Low → weak activation; Normal → healthy contraction; High → fatigue / overexertion
SpO_2 (%)	< 92%	92 – 100%	> 100% (not possible)	Low → poor oxygen saturation; Normal → stable breathing
Blood Pressure (mmHg)	< 100/60	100/60 – 130/85	> 140/90	Low → dizziness risk; High → high exertion / stress
Heart Rate (bpm)	< 60 bpm	60 – 120 bpm	> 120 bpm	Low → under-exertion; High → overexertion
Temperature (°C)	< 36°C	36 – 38°C	> 38°C	Low → cold/low metabolic output; High → overheating / physiological stress

Table. II. Shows the threshold ranges used for classifying physiological and biomechanical parameters into Low, Normal, and High conditions for AI-based exercise recommendation. These thresholds combine clinical reference values and dataset-specific variations to support reliable decision-making during rehabilitation.

The threshold limits for each physiological parameter were determined by combining clinical reference ranges with observations from the collected dataset. For EMG signals, raw amplitude distributions from the prototype testing showed three natural groupings (<1000, 1000–2500, and >2500), which aligned with clinical interpretations of weak activation, normal contraction, and early fatigue. Similarly, thresholds for SpO_2, heart rate, blood pressure, and temperature were selected based on widely accepted physiological norms and rehabilitation guidelines. These ranges were cross-checked against values reported in existing literature on CLBP rehabilitation to ensure that the system identifies deviations that are both statistically meaningful and clinically relevant. By grounding the thresholds in both empirical data and established biomedical standards, the system is able to provide stable and interpretable decision outputs that complement the machine-learning predictions.

D. Real-Time System Testing

The prototype was tested on multiple users performing controlled rehabilitation exercises.

Observations:

- Posture detection was accurate and responded quickly to deviations in trunk angle.
- EMG fatigue detection was consistent with expected muscle activation patterns.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Heart rate and SpO_2 readings matched standard medical-grade devices within acceptable error margins.
- LCD feedback was immediate and helped users self-correct movements during testing.
- Cloud upload intervals (15–20 sec) worked smoothly without packet loss.

This confirms that the system performs reliably in real-world rehabilitation scenarios.

V. Discussion

The results indicate that combining EMG, IMU, heart-rate, SpO_2, and temperature inputs provides a more dependable understanding of posture quality, exertion, and muscle fatigue during rehabilitation exercises. Among the evaluated models, the Random Forest classifier achieved the best performance, reaching 97.5% accuracy, with high precision and recall across all activity classes. The confusion matrix further confirmed that posture categories and exertion states were identified with minimal misclassification. These findings show that multi-sensor fusion captures complementary biomechanical and physiological patterns that single-sensor systems often miss. Real-time tests also demonstrated that the ESP32 responded consistently, delivering timely LCD feedback and maintaining stable uploads to the cloud during movement.

Alongside the ML outputs, threshold conditions played an important role in identifying unsafe or inefficient exercise execution. EMG values rising beyond 2500 (raw sensor range) signaled potential fatigue or excessive load, while SpO_2 falling below 92%, heart rate exceeding 120 bpm, and temperature readings above 38°C indicated physiological strain. These thresholds allowed the system to provide immediate corrective prompts, supporting safer home-based rehabilitation.

Despite promising results, overall performance was influenced by real-world factors such as electrode placement, variations in user posture, and fluctuations in Wi-Fi connectivity during data transfer. The machine-learning component was evaluated on a limited dataset, and broader data collection would likely improve model robustness. Even with these constraints, the outcomes demonstrate that a cloud-connected, AI-supported wearable platform can reliably augment conventional physiotherapy and provide personalized, real-time guidance for individuals managing chronic low back pain.

VI. Conclusion

This This work presents a wearable, AI-driven rehabilitation system designed to assist individuals with Chronic Low Back Pain (CLBP) by providing continuous monitoring and personalized exercise guidance. The integration of EMG, IMU, MAX30100, and temperature sensors with an ESP32 microcontroller enables real-time capture of muscle activation, posture motion, cardiovascular response, and exertion-related temperature changes. The collected multi-sensor signals are processed locally and transmitted to the ThingSpeak cloud, where machine-learning models evaluate patterns related to posture deviation, muscle fatigue, and exertion levels. Among all the classifiers tested, the Random Forest model achieved the highest performance, reaching 97.5% accuracy, demonstrating consistent precision across all activity classes and outperforming KNN, SVM, Naïve Bayes, and Decision Tree approaches.

To enhance decision reliability, the system also incorporates threshold-based conditions for each physiological parameter—for example, EMG value less than 1000 (low), 1000–2500 (normal), and greater than 2500 (high), along with clinically informed ranges for SpO_2, heart rate, blood pressure, and temperature. These thresholds allow the device to flag under-exertion, normal effort, or possible fatigue and overexertion, complementing the machine-learning predictions and enabling a stable, hybrid decision-making process.

Real-time testing demonstrated that the system provides immediate and meaningful feedback through the wearable LCD, enabling users to correct their posture or reduce exertion without requiring direct clinical supervision. While practical challenges such as sensor placement accuracy and network fluctuations may influence overall performance, the results consistently show that this low-cost, portable solution can support safer and more effective home-based rehabilitation. Overall, the proposed system highlights the potential of combining IoT sensing, cloud analytics, and AI to make CLBP rehabilitation more personalized, accessible, and clinically meaningful.

VII. Future Scope

The proposed system can be further enhanced by integrating more advanced bio-signals such as ECG, respiration rate, or muscle stiffness measurements to provide a deeper understanding of user exertion and recovery patterns. Incorporating on-device machine learning using Tiny ML or edge AI accelerators would reduce cloud dependency and improve real-time responsiveness, making the system more suitable for rural or low-connectivity environments. Additionally, expanding the dataset with recordings from a larger clinical population would allow the models to improve accuracy, personalization, and generalizability across age groups and severity levels.

Future work may also include developing a mobile application that synchronizes sensor data, visualizes trends, and offers personalized rehabilitation plans with real-time alerts. Gamification-based interfaces or VR/AR-guided exercise modules could further improve engagement and adherence to rehabilitation routines. Finally, clinical trials conducted with physiotherapists and rehabilitation centers would help validate the system's medical reliability, enabling its transition into a certified healthcare product for home-based, AI-supported physical therapy.

Acknowledgment

The authors gratefully acknowledge the support of the Department of Biomedical Engineering, ACS College of Engineering, Bengaluru, India, for providing constant guidance, valuable feedback, and continuous encouragement throughout the development of this project. The authors also thank the faculty members and laboratory staff for their technical support and for providing the required facilities to carry out the hardware integration and testing phases.

***Abstract*— Noise that is undesirable is becoming a problem in the contemporary cities. Sleep disorders, heart issues, focus and memory challenges are but some of the health issues that can occur after being exposed to high level of noise over the long run. Most of the current noise monitoring techniques in cities require fixed equipment that is unable to determine the origin of the noise, and is quite expensive to establish around the world. One possible citizen technology is NoiseTube that measures the volume but does not detect the source of the noise. Other techniques like SONYC require advanced equipment to deliver precise results, but cities usually do not have the financial means to acquire the costly equipment. UrbanEcho is one such platform delivered via the web which solves these problems by removing any specialised hardware. Any fellow could get a basic web site and post audio records which include location information. The platform then utilizes a pre-trained algorithm to isolate some specific sound patterns in the recordings. It, then, used a neural network that it built by itself to classify the recordings into 10 categories based on the type of urban noise. The findings online, as well as displayed on an interactive map, are immediately accessible to everyone, including those in the position of authority. The system scored an F1-score of 85.3% and an accuracy of 86.7% when tested using UrbanSound8K. The method was found to work in practical level of real world experiments carried out in four different urban areas, which comprise more than 500 volunteer recordings.**

Keywords — Crowd-sourced acoustic sensing, urban sound classification, deep neural networks, YAMNet embeddings, transfer learning, smart urban infrastructure, spatial noise analytics.

I. INTRODUCTION

City streets are rarely quiet. From the steady rumble of traffic and construction zones to the buzz of factories and the chatter of busy crowds, urban areas are filled with sounds at all hours. Scientists have found that constant exposure to these noises can take a toll on people's well-being—causing everything from hearing damage and heart problems to increased stress and trouble paying attention. Because of these risks, addressing city noise is a major concern for those in charge of public health. The World Health Organization warns that daytime sound levels above 55 decibels can be dangerous for the heart, yet in many rapidly growing cities, people are exposed to even greater noise on a regular basis. The old way of monitoring city noise relied on a network of fixed sensors, but these only report what's happening at a handful of locations and are costly to set up and look afterThe fact is that noises in the city are never constant and therefore it is hard to have a complete picture with the help of stationary sensors. The search of optimal way of tracking auditory perception of urbanites has become possible due to the spread of cellphones and the advances in sound analysis. Every person could record some short videos of the things around him/her using his phone and post them on the site of UrbanEcho. The platform quickly identifies the type of noise collected, and also provides the information immediately with an interactive map. This approach offers a real-time and all-encompassing view of noise issues in a large number of neighbourhoods to municipal officials with minimum investment in permanent equipment.

UrbanEcho is a flexible web-based platform and a large number of independent elements that can be connected to each other through clearly defined web-based interfaces. It then converts the audio into 16 kHz single-channel audio, and sets the volume to compensate differences between different microphones when uploaded by the user via their browser. This is accomplished with the use of the Librosa library to ensure that the audio is in the uniform format. The second step is to feed the processed video to YAMNet, a Google machine learning model that has millions of audio samples to consult. YAMNet translates the recording into numerical representation of the sound characteristics, such as its energy, rhythm and tone. Then the data is analysed by a second specialised neural network and assigned a confidence score, and put in one of 10 categories of noise in the city. All uploads are checked to be valid and processed by the system, with Flask used to handle all the processing, receiving files to performing the analysis, and storing the results. To provide users with access to the noise report on a digital map, the front end is based on Leaflet.js. And it also summarizes data in the form of heat maps, such that anyone can visualize the origin of noise again and again.

Here, the structure of the paper is summarised. The next section discusses the historical background of interested studies referencing issues like the classification of urban noises, involvement of people in noise data gathering, and different techniques used in mapping noise levels. Moreover, it clarifies how UrbanEcho is different to those that had already been made. The following section of the paper explains how the UrbanEcho works, starting with the initial step a user takes, continuing with processing of audio files, and concluding with how all the various components of the system interact, including the YAMNet audio analysis engine and the mapping and storage management systems. This is followed by a description of the data that is utilized to train the system, and a visual representation of what each audio clip undergoes in order to become an image on a noise map, starting with the uploading. Then we will discuss the findings of our experimental work, the ability of the tool to differentiate between different types of urban noise, our test work experience using the tool in real neighbourhoods, and its effectiveness as compared to the popular datasets. Next we give the outcomes of a pilot study which was carried out on four cities. We considered the following: the number of people involved, the ability to detect different types of noise by the system, problem spots, and the time of uploads to the recordings. Part two goes into the advantages and disadvantages of utilizing the feedback of the general population, the merits of integrating YAMNet and a CNN, and the role of these by helping challenge planners to keep in touch with city noise. Finally, we make a comparison between the results of UrbanEcho and other platforms, highlight its weaknesses, and offer ideas on how these could be enhanced in the future.

II. RELATED WORK

Although it affects the daily lives of people, noise in cities barely receives an attention in health policy. Noise, unlike smelly or visible pollutants, is hard to trace down as it varies with changes in factors such as traffic, construction work and social occasions. The majority of cities have few fixed cameras, which are only able to capture the background noises and leave certain areas unguarded. These monitors are very expensive to install and maintain and they are able to measure ambient noise, but not the source of noise. Therefore, be it automobiles, incidences, or equipment, the local authorities do not necessarily know everything to address the underlying cause. To manage urban noise we must have tools with which we can identify the origin of the noise or its magnitude.

Salamon et al. [1] gathered the UrbanSound8K dataset that consists of 8,732 tagged audio files that brought about 10 common urban sounds such as as horns, jackhammers, dogs barking, and street music. The ability to to the dataset smartly divides it into 10 groups allows researchers to train and test their algorithms independently of each other. UrbanSound8K is now a benchmark in research of urban sound detection because it has become a standard to this group. The same types of urban noises can be discussed and compared by researchers all across the world due to the clarity with which it separates them into groups. The data does not reflect the unpredictable, overlapping, and blurred sound you would expect when recording by an ordinary individual in a real-life setting as all the samples were done and labeled in a controlled environment. Although useful, UrbanSound8K [1] fails to reflect the spirit of real time classification of city sounds.

By training convolutional neural networks with AudioSet, a large collection of millions of audio samples categorised into more than 500 sound types, Hershey et al. [2] are able to show how these networks can be fine-tuned to behave well on more domain-specific sound classification tasks. Big, hand-labeled datasets are not as necessary when this strategy is used to achieve strong results on problems such as urban noise classification. Nevertheless, the labels of AudioSet are not always accurate and exhaustive, so there might be problems with the understanding of the model that should be corrected when it is tailored to a new task.

Piczak [3] demonstrated that convolutional neural networks are superior to earlier systems which relied on manually designed Mel-Frequency Cepstral Coefficients in case of inputting log-mel spectrograms in ambient sound recognition. By analyzing the spectrogram as an image, the network can automatically identify important timing and pitch patterns, without the need to select human features. This method performed miracles when attempting to distinguish between noises that otherwise are very similar. Unproblematically, having few data, neural networks might start internalising the training cases and give false results until they are further regularised or augmented with data.

Due to the nature of the co-occurring sounds in urban environments, Mesaros et al. [4] re-focused the interest of the sound event researchers on these environments. Their approaches to comparing and testing systems capable of recognising and classifying overlapping sounds in audio recordings are clear. Their research provided a standard to compare the performance of approaches to this task and demonstrated that single-label picking per recording is not adequate in an urban real-world audio. Regrettably, such systems, like those intended to support such an activity, require a large amount of processing resources, which are less efficient in terms of their ability to run quickly or in real-time.

Bello et al. [5] created a huge network of sound sensors spread throughout New York City, which was called SONYC. This technology could create detailed noise maps of the city through a combination of human and automated means of source labelling. Their findings showed that in the large regions, it is possible to identify and label city sounds automatically, and it is far more convenient to determine what makes the noise than to measure its level. The purchase, installation and maintenance costs of the equipment to be required by each of the permanent sensors that SONYC would have to install all over the city. Moreover, the system used manual data labellers and this implied that it took some time to update the noise maps of the city therefore not ideal to be used in real-time noise control.

A city-wide capture of accurate sound information without the need to purchase expensive equipment is achievable, as demonstrated by Stevens et al. [6] when people had volunteered to help. The scope of the project was not dictated by money in the city but rather by participation as the more people assisted, the more land was covered. This showed that crowdsourcing data collection can be as good as, or possibly better, than networks of fixed sensors. A significant shortcoming of their device, NoiseTube, was that it was only able to detect the relative volume of the noise and not the noise source itself. This information was therefore not enough to make decisions regarding individual noise sources because it merely indicated the overall noise levels.

Examining the existing research, a split can be seen: highly efficient sound discrimination systems can require highly specialised hardware, which makes them prohibitively expensive to use with a large scale. On the contrary, crowdsourcing systems can cover a vast area, yet they cannot tell the point where the noise originated. A system that will allow automatic detection of noise sources, allow regular people to accumulate data without any extra equipment, and present the results on a real-time map has yet to be developed. UrbanEcho fills this gap. It enables the user to record in their browser and real-time map updating with Firebase, and uses a combination of YAMNet and CNN models to classify sounds. This means that you can obtain source-specific noise data in multiple places at low cost and none of the technological challenges, as anyone can take part, no special application or technical skills are needed.

III. SYSTEM DESIGN AND METHODOLOGY

UrbanEcho is a web-based platform that has various layers for data collecting, signal processing, sound categorisation, information storage and map display. Each piece stands on its own, but also fits well with the others.

A. Dataset Description

The sound classifier was trained and tested using the UrbanSound8K dataset [1]. The dataset consists of 8,732 audio snippets of up to four seconds in length. Each clip is tagged with one of 10 sounds of a city. These include air conditioners, automobile horns, children playing, dogs barking, drilling, engines idling, pistol shots, jackhammers, sirens, and street music. The dataset is split into 10 groups to prevent mixing training and test data. recordings were made in various locations of the city The distance of the microphone from the sound , the background noise , and the gadget utilised for the recording all vary . These distinctions assist the assessment to be more realistic

The approach was evaluated using ten-fold cross validation as stated by Salamon et al. [1]. This allows the findings to be compared with other research. Some noises, like gunshots or sirens, are less frequent in the data. This is why the performance was tested in terms of accuracy, precision, recall and F1-score apart from accuracy. Accuracy alone might be deceiving if the model misses rarer noises.

B. Platform Architecture and Technology Stack

UrbanEcho combines five strata of technology to construct the entire piece.

User interface is right inside your web browser-there is nothing to install. Anyone is able to record and transmit sounds with any modern browser. When uploading a recording, your browser will add the time and your GPS position to the audio and upload it. The site does not require an account, user name, or personal information, and is easily usable and privately sensitive. It is completely constructed using HTML,CSS and JavaScript and therefore can be easily run on various devices.

Audio Preprocessing The initial stage of handling every sound recording is opening it with the Alban Librosa [2], a Python audio tool. All the files are converted into mono and to 16 kHz, which fits the system. The volume is matched in such a way that it does not have issues with variations between the microphones. In case of long periods of silence, such may be eliminated and the attention paid to the actual sounds. These measures are suitable to ensure that the audio is clean and consistent then it is analyzed.

Feature Extraction YAMNet Once the audio is cleaned up we run it through YAMNet [3]. YAMNet is a tool developed by Google, which was trained on millions of various sound clips on AudioSet, which had hundreds of different types of sounds. It converts any sound into a series of 1,024 digits that adds up to the key characteristics of the recording- such as its tone, rhythm and power- without waiting to be crafted by hand. Since YAMNet was trained with such an enormous assortment of sounds, it will be able to identify even some unusual noises in new data. This is consistent with what Hershey et al. [4] discovered: the larger and more varied datasets trained on, the better able are models to address more specific tasks. YAMNet is deployed straight away as a TensorFlow Hub library, with its settings fixed throughout the remainder of the training, which maintains running efficiency as well.

Noise Classification Custom CNN A have a lightweight convolutional neural network with only ten UrbanSound8K classes trained on the embedding of the YAMNet will take the YAMNet embedding as input and output a predicted class label and a floating-point estimated confidence. This is accomplished via a number of dense layers with ReLU functions, and decreasing out littering layers to enhance trustworthiness, particularly when the audio records are of lesser quality, which is frequently an unavoidable element when participants chronicle in uncontrolled conditions. Learning happens with the Adam optimizer [5] and categorical loss based on cross-entropy. Displaying the confidence score on the interface provides the user with real time feedback regarding the confidence level of certain predictions which is not common with such tools. Earlier studies indicated by Piczak [6] that convolutional networks based on learned spectral features perform better than those based on manually constructed MFCCs. In this case, the design expands upon that work with the transfer-learned embeddings of YAMNet in place of log-mel features, which offer finer details of sound without requiring additional labelling.

Data Storage — Firebase Realtime Database Events of all kinds are stored in Firebase Realtime Database. This service was selected based on three primary reasons that can not be addressed by traditional relational databases. First, it uses WebSocket technology thereby ensuring that any new information is immediately depicted on all browsers connected to it, so the Leaflet map is real-time as and whenever a result is available. Second, due to its document-based format it can be easily stored with metadata such as labels, confidence, timestamps and coordinates, and these attributes can be added, or additional features added, later on without any complex migrations. Third, scaling is automatically managed by Firebase, which means that a database administrator does not have to work on managing frequent spikes in activity.

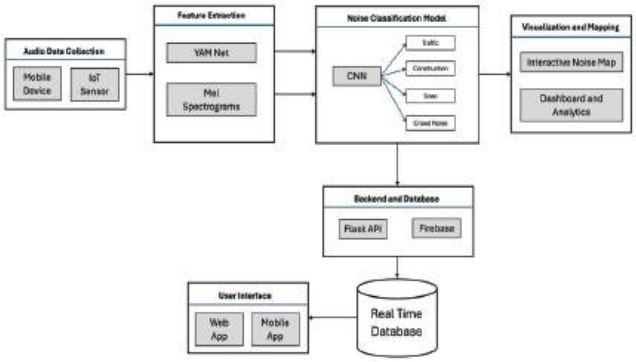

Fig.1. Workflow Diagram

The workflow diagram illustrates how the user's recording is processed in the UrbanEcho system, from the recording in the web browser to the rendering as a labelled marker on the live noise map.

YAMNet takes the audio input and maps it to a set of 1,024 integers that characterise the sound qualities. The CNN classifier then utilises this data to select the noise category and the confidence level of this decision. Firebase stores these data, together with the GPS position and the time the sound was captured and they display right away on the Leaflet map for everyone to view. The graphic also shows that the API backend, processing engine and user interface are distinct so that each portion may be scaled up independently if lots of people submit recordings at the same time

.

C. Real-Time Processing and Geospatial Insights

Once somebody sets up a clip, it will just take some few seconds before it comes up as a pin on the map. Such instant update is quite unlike the normal noises complaints that take out batched processing. UrbanEcho can display real-time noise events to city workers, like an unexpected group, a bang of equipment or a group of emergency-response vehicles, instead of rebuilding it based on historic information.

On receiving noise complaints, the resulting information is pooled into a map that is almost like the layout of the city. Where there are major roads there will be traffic noise and where there is building work there will be construction noise. Parks and pedestrian areas will also make noises to you. To include a time aspect to your noise map can show that you are experiencing a peak of noises during the rush hour or evening concerts that would otherwise not have been apparent on a bare noise map. And being aware what sort of sound it is. When a place is repeatedly mentioned in construction noise, the city may vary the work schedules or constructing sound barriers. However, in the case of live music, perhaps it is better to permit places where they can perform than to close them.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

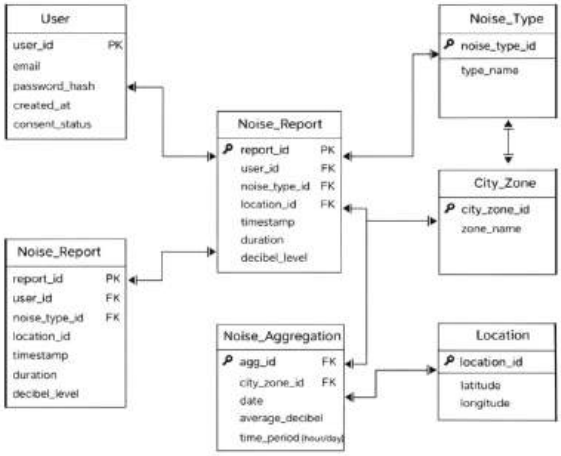

Fig. 2. Schema Diagram

A Noise_Report records the person doing the reporting, the type of noises that were detected, the location where it was observed (including coordinates), the time it occurred and an approximate volume. Noise webs The noises are created between urban areas and locations, storing averages ahead of time in an optimized, pre-computed form, to make the heatmap load quickly and prevent it from needing to search all locations each time. This format enables it easy to search the particularities of a single event by clicking on a marker or to obtain general noise patterns of larger regions - handy when city employees need to check noise by hour or day.

D. Deployment

The full platform is running within Docker containers [7]. This means for developers, everything functions the same way as it does on the cloud. The three major pieces - API backend (Flask), inference engine (TensorFlow) and frontend server (JavaScript) are all running in separate containers. Each has its own constraints on resources and regulations for starting back up if there are problems.

IV. RESULT

In UrbanEcho construction, the team trained its classifier with UrbanSound8K [1] dataset which composed more than 8,700 labeled audio clips of a variety of ten noise categories in a city. This data was made sure to be split in such a way that the sounds that would be used in training it were segregated and the tests on the system were those that were not used to train the system. With a recording, it is converted to standard format (mono, 16 kHz) first using Librosa [2]. This is followed by the analysis of the audio by YAMNet [3] to form a detailed profile generated due to the patterns it has learned on millions of other sound samples. The thing is that a custom neural network determines what type of noise was captured and its confidence with that judgment. This data, unlike the how and when of the capturing of the sound is stored in Firebase and instantly displayed as a point on the map. Backed by Flask, the backend receives and processes recordings, verifying any errors to proceed. To train the classifier on top of YAMNet, a general strategy, known as categorical cross-entropy and Adam optimizer, is used [5]. It is designed in HTML, CSS, and JavaScript, and based on Leaflet.js to display clusters and fluctuations in noise across the city. All of this works in Docker [7] containers, by keeping things operating identically in both testing and live, and allowing each component of the platform to deal with additional users when required.

A. Model Description

UrbanEcho sorts sounds with the help of two interconnected systems. The former is a Google model, YAMNet [3], which is already trained on millions of audio files. YAMNet hearkens to a new recording and converts it into a summary- a sequence of numbers which catalog the significant characteristics of the sound. The second, and specially designed neural network uses those figures and determines what it is that type of noise. The YAMNet itself is not modified, such that it retains all the general knowledge that it is initially trained with, with the only difference that the second network is also only trained to work in the specific job of UrbanEcho. This is effective and suitable to such targeted work as the study by Hershey et al. demonstrates [4].

The custom neural network of UrbanEcho considers the features of YAMNet and classifies each sound into one of the ten UrbanSound8K categories. It is a constructed network with a few dense layers activated by ReLU, alongside dropout layers to maintain consistency in results, although recording quality is not necessarily high. It is trained with Adam optimizer [5] and the loss function is categorical cross-entropy. Previous studies by Piczak [6] demonstrated that application of features learned by neural networks performs better as compared to older, hand made features (MFCCs). UrbanEcho extends this concept by basing on the functionality of YAMNet rather than log-mel ones, which is more detailed without additional labelling effort. Every prediction is also accompanied by a confidence score to allow users to know how confident a system is about its decision which many other systems do not provide.

B. Evaluation Metrics

The model findings were tested using four distinct metrics, outlined below.

Accuracy is the fraction of test instances that the model categorised correctly as the proper noise type out of all 10 categories

.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

Precision checks of each category how many instances that the model predicted to be in a group actually were in a group. It aids in demonstrating an instance of model errors through guessing false.

$$Precision = \frac{TP}{TP + FP}$$

The recall examines each category and sees what part of the genuine examples model could locate. It measures how frequently the model misses something it should have picked up.

$$Recall = \frac{TP}{TP + FN}$$

The F1-Score brings precision and recall together into one number, making sure both are taken into account. This is useful, especially when some types of city sounds are much more common than others.

$$F1 - Score = \frac{2\ (Precision)\ (Recall)}{(Precision) + (Recall)}$$

Sharing all four metrics is key, because certain city noises such as gunshots and sirens occur far less often than say traffic or construction. If you simply look at accuracy, the results may appear better than they actually are, even if unusual sounds are missed.

C. Classification Performance and Model Comparison

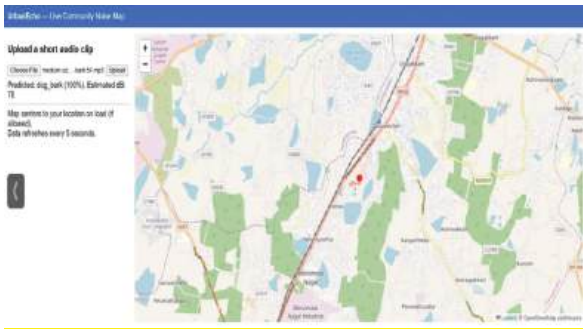

Fig. 3. Noise Input

F figure 3. The UrbanEcho website after a user has uploaded a recorded audio. Once a file is selected within the browser, the website rapidly reveals the estimated noise kind and the system's confidence on its decision. And at the same time, the map jumps to the user's GPS position, so when the system is done, it may drop a pin for the new recording.

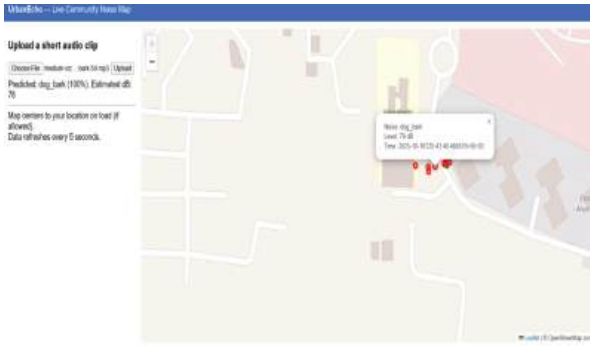

Fig. 4. Real-Time Predictions

The live map after community members upload recordings is shown in Figure 4. Each event has its own symbol on the map and you can mouse over it to discover what sort of event it is. The most recent results are shown in the page's sidebar, with the system's confidence level and the time of each result.

TABLE I. COMPARISON OF CLASSIFICATION MODELS ON URBANSOUND8K

S.No.	Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
1	Random Forest + MFCC	72.3	71.1	70.4	70.7
2	MLP + MFCC	75.8	74.2	73.9	74.0
3	CNN (Baseline)	78.4	76.9	75.8	76.3
4	CNN + Log-Mel Spectrogram	81.2	80.1	79.5	79.8
5	VGGish + Linear Classifier	83.1	82.4	81.9	82.1
6	YAMNet + CNN (Proposed)	86.7	85.9	84.8	85.3

The UrbanSound8K data was used to test six different models. Below are examples of some using simple, hand-crafted features and others more sophisticated deep learning architectures. Each model was tested by the ten-fold cross-validation technique. The results presented in Table I show that the YAMNet-CN model was the most accurate with a total of 86.7% and a F1-score of 85.3%. This design achieved us 3.6 percentage points high compared to VGGish-linear. This shows that using a convolutional network to extend the features already learned can be used to more accurately differentiate between different sounds. It also scored lower than MFCC-CNN by 5.5 points, which can be characterized by the advantageous effect of learning on a large sample of sounds. In comparison, easier models, such as Random Forest and MLP with MFCCs did not perform as high and it fits the results of other studies conducted by Boddapati et al. [8]- deep learning is more successful than previous methods in analysing ambient noises. Overall, the leap between basic and deep models presents a lesson that the file of representations of sound data is more crucial than simply changing the classifier.

TABLE II. PER-CLASS PERFORMANCE OF YAMNET+CNN (URBANSOUND8K)

Noise Class	Precision (%)	Recall (%)	F1-Score (%)
Air Conditioner	76.8	79.4	78.1
Car Horn	92.0	90.5	91.2
Children Playing	81.5	83.2	82.3
Dog Barking	87.3	86.1	86.7
Drilling	88.9	87.4	88.1
Engine Idling	78.4	80.9	79.6
Gunshot	91.7	90.2	90.9
Jackhammer	89.5	91.9	90.7
Siren	94.1	92.8	93.4
Street Music	82.6	85.1	83.8

Table II displays the accuracy, recall and F1-score for each of the 10 UrbanSound8K sound categories when evaluated with the YAMNet–CNN model. The best recognition accuracy is obtained for sounds like sirens (F1: 93.4 %), automobile horns (F1: 91.2 %) and gunshots (F1: 90.9 %). These kinds of sounds are easy to identify from the others since the patterns of sound are significantly distinct from the other groups.

D. Pilot Deployment and Real-World EvaluationA

The tests were conducted in four places: a neighborhood, a shopping and dining street, a transport center, and a college campus. These positions were selected to represent mixes of the various sounds you would have in a rollout into reality. The volunteers were given their own devices to record more than 500 clips during the study process and the time and location were automatically added into the browser with the submission. There was no instruction on the type of sounds to be captured, thus, making the findings more true-to-life.The recordings that people mailed in (approximately 78 percent of them) were mostly of traffic, construction, street music, running engines, and sirens, just as has been previously observed by earlier city sound surveys. The system was 81.3% sure their predictions were correct in accepting clips on average, demonstrating that it performed well even with audio which was not taken under the ideal conditions of the laboratory. Recording below 60% was scored as of low confidence and not included in the public map, typically due to noises in the background or lower-quality microphones and not necessarily due to a system malfunction. When a person uploaded a clip, it only required less than two seconds to be submitted and be displayed on the map, even when many people were using it at the same time. This compares to older systems where one required a person to go through results before them being posted online.

E. Comparison with Related Systems

TABLE III. COMPARISON OF URBANEECHO WITH CLOSELY RELATED SYSTEMS

Attribute	**UrbanEcho (Proposed)**	**SONYC (Bello et al.)**	**NoiseTube (Stevens et al.)**
Data Collection	Citizen smartphone browser upload	Fixed hardware sensor network	Citizen mobile app (GPS + dB)
Classification Method	YAMNet + CNN (86.7% acc.)	DNN + human annotation	None (dB level only)
Noise Source Identification	Yes (10 urban categories)	Yes (multi-label tagging)	No
Real-Time Map Update	Yes (Firebase WebSocket)	Partial (delayed by annotation)	No (batch updates)
Hardware Required	None (browser-based)	Yes (acoustic sensor nodes)	Smartphone (app install)
Geospatial Visualization	Interactive Leaflet.js public map	Internal analyst dashboard	Public collective noise map
Scalability	High (Docker + cloud)	Limited (hardware bottleneck)	Medium (app adoption barrier)
Deployment Cost	Low (software-only)	High (hardware + maintenance)	Low (app distribution)

Table III considers UrbanEcho alongside SONYC [10] and NoiseTube [11] in eight key aspects. SONYC was effective at the New York City classifying sounds with the network of sensors, but necessitated a level of specialized equipment at every location, and involved a human to verify activities which in turn were costly and sluggish, particularly in cities with limited resources. NoiseTube also allowed individuals to gather noise data with their gadgets, but it was only used to record the level of loudness. That is the information only indicated the overall noise levels and not the cause of noise levels. UrbanEcho is as accurate as SONYC when it comes to determining what sound was recorded, though it allows anyone to add it with no special equipment- such as NoiseTube. But more to that, UrbanEcho is the only one that auto-updates its map in the real time, with Firebase. None of the existing systems have combined automatic sound recognition, no hardware required, automatic updates to the map, and the public site to be used by everyone in a single package. It is that mix that makes UrbanEcho unique.

F. Limitations

UrbanSound8K only has one label for each audio clip, yet genuine city sounds are usually a mixture, with many noises occurring at the same time. This reduces the ability of the classifier to deal with overlapping sound scenarios. There's also a data coverage problem, where locations where fewer people are participating or areas where not too many people have cellphones receive less data on the map. It's not been documented and the lack of this data might lead to the perception that certain locations are relatively calm. To combat this, communities should consider installing permanent sensors or putting obvious markings on regions with little data.

G. Future Prospects

UrbanEcho's future stages are focused on three major advancements. First, they're going to introduce live streaming, so users won't have to submit separate recordings. This will assist detect short-lived sounds that could occur in between regular uploads. Secondly they would want to include a tool that predicts future noise levels based on prior patterns in the data. Thirdly, they want to create a mobile application, to make it simpler for users to send in reports, particularly if they have problems using the internet. Over time as new data comes in from the community the model would be retrained periodically, to keep up with changes in city noise patterns. At last, the initiative may become a permanent tool for city planners, not merely a study project, by linking UrbanEcho directly to municipal environmental dashboards.

V. CONCLUSION

UrbanEcho shows you don't need fancy equipment to decode the city's sounds. Unlike sensors and hardware it provides a way for users to capture sounds using their phones or PCs. Almost 87 percent of the time the system was able to identify what kind of noise it was hearing, whether traffic, construction or music, better than anything else they matched it to. This helps municipal personnel understand how to react to diverse sounds, not simply how loud a location is." UrbanEcho runs in any web browser and doesn't require any specific equipment, so as more people hear about it, more people may take part.

Some things to work on. Now, the algorithm can only identify one primary sound per recording. But city life is usually loud, and frequently there are numerous things occurring at the same time. Also, certain neighbourhoods don't have as much data since fewer people there have cellphones, so such places may not show up on the map. The team intends to make it more simpler to use with live listening, tools to forecast future noise and a phone app. UrbanEcho will learn and develop as more people upload recordings. It might be linked directly to municipal systems in the future, and become a regular tool for city noise control.

***Abstract*—SLD-Spec (Slicing, Logical Deletion and Specification) framework is a new, multi-modal formal specification automation and verification approach to high-integrity software. Traditional automated specification generation is vulnerable to the issues of model hallucinations such that Large Language Models (LLMs) generate syntactically correct but logically unsound statements. To enable that, the SLD-Spec architecture combines Static Analysis and LLM-as-a-Judge to focus on improving the quality of the produced specifications and their verification. Chain-of-Thought (CoT) is used as a logical deletion in the SLD-Spec framework to support three stages: Semantic Slicing and Dependency Mapping, Targeted Specification Generation, and Logical Deletion. The first thing that should happen in the system is to isolate the related code slice by parsing Abstract Syntax Tree (AST) and creating Program Dependence Graph (PDG). A local LLM is applied in the second step to the isolated code in order to generate formal specifications of domain-specific languages to induce a minimal amount of cross-variable contamination. The final step uses a Judge model to audit the specifications with a CoT argument and to remove any logically unsound or hallucinated specifications. The SLD-Spec Dashboard provides the developers with a high-visibility representation of the audit process and allows them to visualize the PDG, as well as, trace the audit. It is suggested that preliminary results are promising in that SLD-Spec framework can improve reliability of automated formal verification, which provides a scalable way of documenting large-scale and complex legacy systems and to certify the correctness of software in high-stakes applications.**

***Index Terms*—Semantic Slicing, Logical Deletion, Formal Specifications, Software Integrity, SLD-Spec, Automated Verification, Large Language Models, Chain-of-Thought**

I. Introduction

The escalating aspect of contemporary software systems requires high integrity both in design and verification of software, especially in the software that is used in sensitive fields like health care, in aerospace and in finance. Conventional approaches to automated generation of formal specifications have very frequently failed because of such problems as hallucinations with Large Language Models (LLMs), in which syntactically correct but logically inconsistent statements are generated. This may cause software verification errors which undermine the reliability of the system.

The SLD-Spec (Slicing, Logical Deletion, and Specification) framework helps to overcome these difficulties with the help of using a 3-stage pipeline. This model unites the Static Analysis with LLM-as-a-Judge architectures to enhance the accuracy and accuracy of generated specifications by machines. The framework spins the rightness of formal char- acteristics and minimizes the possibility of mistakes by seclud- ing essential elements of the code and executing specialized models to validate it.

Semantic Slicing and Dependency Mapping is the initial stage which relies on Abstract Syntax Tree (AST) parsing and Program Dependence Graph (PDG) generation in order to isolate the relevant code slices. This enables the system to work on the most important logic routes which decrease the complexity of context and limit unwanted noise. Targeted Specification Generation is the second step that generates formal specifications of the code slice in question (using a local LLM) to limit cross-variable contamination.

Lastly, the Logical Deletion through Chain-of-Thought (CoT) process is assured to maintain only logically sound and correct specifications. The framework helps in ensuring the high degree of confidence in the accuracy of software documentation by having the generated specifications audited and deleting all those that are not consistent.

II. Literature Survey

The growing sophistication and the requirement of high integrity software systems have led to the evolution of so-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

phisticated tools in the automated creation and verification of specifications. Formal verification is one of the most prominent methods to use, in which formal methods are used to demonstrate the correctness of software systems. Xu et al. (2019) suggested a scenario-based model of verifying safety property of automated driving, demonstrating the significance of safety in real-time verification of system [6]. These strategies are the foundation of making sure that software is developed according to how it is supposed to be used, particularly in systems that are mission critical, such as autonomous driving and medical care.

A major problem with formal specification generation is the use of conventional methods of traditional static analy- sis, which can be afflicted by failures such as model hallucinations, where the models produce syntactically correct model-independent assertions which are logically inconsistent. Semantic slicing has been proposed to reduce this problem and make it possible to isolate the relevant parts of the code and enhance the focus on essential logic. Ren et al. (2025) examined a semantic-enabled combined strategy with resource slicing and bidirectional mapping that can be useful in effective resource layout and identifying inconsistencies in large-scale systems [1]. The technique is used in such fields as communication networks where system reliability is crucial.

The application of machine learning (ML) models to support the creation of formal specifications is another important contribution to the formal specification techniques. Wyszkowski et al. (2024) include an extensive tutorial on network slice design process organization and the possibility of automation of related tasks through the use of ML and deep learning (DL) models [2]. Their study focuses on how such models can be used to streamline resource management and improve the predictive accuracy of such models, an important aspect of scalable and adaptable software verifications.

More recent developments combine reinforcement learning (RL) with dynamic and real-time optimization in the complex environments. Doanis and Spyropoulos (2024) showed how RL can be used to optimize multi-agent networks, specifically to organize 5G networks, where RL is useful in adjusting to system needs [3]. On the same note, agent-based intelligence has been applied to find sustainable 6G network slicing models, in which ML model fusion can help optimize the performance of communication networks in different circum- stances [4].

Fuzzy decision-making processes related to classification systems have also received some interest in the context of decision transparency. Madrakhimov et al. (2025) emphasized that fuzzy descriptions of decision-making can be used to enhance transparency and clarity which is a key characteristic of automated software systems that are expected to be highly integrated [5]. The current work offers details on how to enhance the interpretability of AI models applied in formal verification.

Moreover, as software systems have become more complicated, virtual testing approaches and scenario-based testing have been considered. In the works of Stadler et al. (2022), a credibility evaluation strategy is suggested in terms of scenario-based virtual testing, which recreates real-life situations in order to test automated driving functions [8]. This can have practical applications to software verification of highly critical systems, whereby multiple scenario simulation guarantees robustness and safety in real-world applications.

Safety and verification as a service (VaaS) is also a newer trend particularly in large-scale system software engineer- ing. To facilitate the verification process in big projects, CoVeriTeam Service, a new service by Beyer et al. (2023), provides verification services on-demand to simplify the verification process [7]. This service-based model is best to scale formal verification to real-time applications in order to maintain consistency and reliability of verification without affecting efficiency.

Lastly, the implementation of quality of service (QoS) and slice resource allocation to the next-generation mobile networks, especially the Beyond 5G architecture, illustrates the use of deep reinforcement learning (DRL) in intelligent resource allocation. Mhatre et al. (2025) examined the use of DRL in user association and QoS-based resource management optimization that is crucial to the efficient functioning of future wireless systems [10].

III. Proposed Methodology

A. System Architecture Design

The demand of high-quality software systems has been increasing enormously on the critical systems including healthcare, aerospace and finance. Traditional methods of automated generation of formal specifications have often been prone to error, because of model hallucinations it is common to have models that produce syntactically but logically unsound assertions. To address the challenges, the proposed SLD-Spec Framework includes Static Analysis with LLM-as-a-Judge to attain automation and verification of formal specifications of high-integrity software. The structure ensures that formal specifications are accurate and reliable therefore increasing the integrity of critical systems.

It is grounded on the construction of a combination of AI models and algorithms, such as Abstract Syntax Tree (AST) parsing and Program Dependence Graph (PDG) gen- eration and Large Language Models (LLMs) such as Llama 3 that detects logical specifications within the code. The system is integrated with Semantic Slicing and Dependency Mapping that divides the components of the code that is under consideration as relevant and subsequently produces specifications targets. The final process is a Logical Deletion mechanism in which the logical correctness of the generated specification is checked by one more model, the Judge, which uses Chain-of-Thought logic. Any specification that turns out to be inconsistent will be eliminated and this will ensure that the system is more reliable.

This is a solution to the weaknesses of the existing formal specification generation systems, and will form an improved scalable system that can be deployed to solve the complex software verification problems in real-time. Moreover, the

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

system will not require any extraneous software installations and this renders it highly convenient and accessible even by the developers of high integrity software systems.

B. Proposed System

A formal specification generation and verification using machine learning (ML), deep learning (DL), and formal static analysis is an integrated framework called the SLD-Spec Framework. The basic components of the system are:

Raw code and data are manipulated in generating pertinent features. It is a process to normalize the source code and noise removal techs to ensure that the most important part and significant parts of the code are analyzed.

Model training: The system uses deep learning models like Llama 3 to generate formal specifications in domain-specific languages (e.g., ACSL to C, JML to Java). The models are informed with enormous data sets to train and establish the pattern of behavior of the software especially when cross-variables contamination is to be avoided.

Real-time Verification: The system will also have real-time feedback in which generated specifications are verified with the code slice. It uses the reinforcement learning algorithms to dynamically allocate the computational resources based on the load on the exams and adjust the processing priorities of the model.

Scalability: The system is developed with a simple scale in cloud-based systems that can be scaled to large-scale with the assistance of containerization (Docker) and orchestration (Kubernetes). This will provide this system with the ability to accommodate a myriad of projects and developers.

C. System Architecture

The SLD-Spec Framework architecture consists of several layers that are customized to fulfill some functions during the process of specification generation and verification. The major layers are:

Data Collection and Preprocessing Layer: This layer deals with the collection of the source code as well as its preprocessing that also entails elimination of noise, extraction of features and normalisation of the code. The processed data is further communicated to the next phase of production of specification.

Generation and Validation Layer: The layer stores various machine learning and deep learning models, including Llama 3, YOLOv8, among other algorithms that process the individual pieces of code and generate formal specifications. Chain-of-Thought reasoning is the basis of the Judge model to make sure that generated specifications are correct, and the inconsistent ones are removed.

Deployment Layer: The final layer will involve the deployment of the system which will give the web interface to the users. This interface will also have dashboards, which can be utilized to visualize the analysis of the code, specification generation, and any anomaly that will arise. The infrastructure deployed is aimed at large scale cloud deployments.

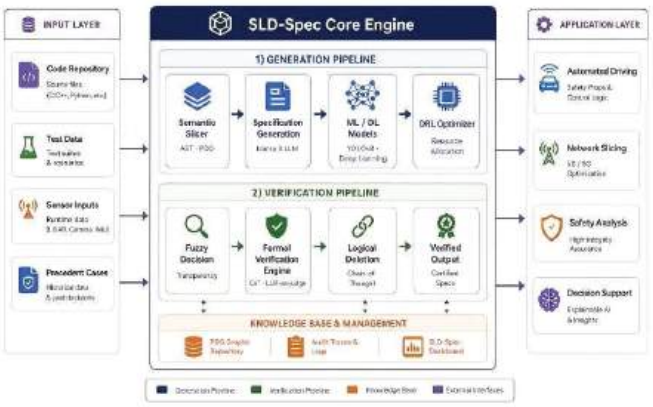

Fig. 1. System Architecture

D. Expected Outcomes

It is forecasted that the following results will be generated by the SLD-Spec Framework:

- **Real-time Detection:** The code will generate formal specifications of high quality and identify inconsistency or logical error of code promptly.
- **Resource-Efficient Usage:** The system will be made to ensure that it uses the computational resources as efficiently as possible by the dynamic resource allocation models and the reinforcement learning models in the system.
- **Scalability and Flexibility:** The framework is easily scaled in cloud infrastructure, and is applicable in big and intricate undertakings that demand a high number of developers.
- **Explainable AI:** The process of decision-making will be made transparent with explanations that will be provided using SHAP-based explanations to allow users to comprehend how the system did come up with some predictions and actions.
- **Improved Security:** Checking formal specifications with AI models will ensure logical consistency of formal specifications, and this will increase the overall security and integrity of software systems of high-stakes.

E. Conclusion

SLD-Spec Framework is a state-of-the-art, multi-modal framework that is based on the latest methods in machine learning, deep learning and formal static analysis as the basis of auto-verifying and auto-analyzing formal specifications. The framework provides a scalable, efficient, and secure way of high-integrity software verification by eliminating the potential to have logical inconsistencies as typical of other traditional software specification generation strategies. This system offers an alternative method of handling complex software verification problems and offers quality and reliable documentation and makes mission critical software systems far more precise and credible.

IV. Results and Discussion

This part gives a detailed study of the SLD-Spec Framework performance that formalizes and checks the high-integrity software-related specifications. Multi-modal methods are applied in the framework, such as Static Analysis, Large Language Models (LLMs), and Chain-of-Thought (CoT) reasoning. The system was tested on real-world software data, such as codebases of different complexity, in which the system was expected to produce formal specifications and certify their logical consistency. The models were appraised on the following grounds: correctness in generating specifications, real-time inspection of the generated specifications, and the ability to handle large codebases, and the efficiency of the verification process in operation, without causing delays.

A. Experimental Setup

The information to be used in this research was collected through several high-integrity software projects, which are different domains with different code complexities. The data employed in the experiments consisted of source code, program dependencies as well as metadata like number of calls in functions and variables interactions. The feature ex- traction techniques (semantic slicing, Program Dependence Graph (PDG) generation and noise reduction techniques) were preprocessed on the code. The process involved models, i.e. Llama 3 to generate specifications and CoT models to perform logical verification, which were trained on large data sets to acquire software specific patterns and behaviour. Real-world code examples were then used to test the system and confirm the usefulness of the framework in the detection of inconsistencies and specification checking.

B. Quantitative Results

Table I summarizes the performance of SLD-Spec Framework. The findings indicate that deep learning models and more specifically the Chain-of-Thought-based verification models performed better than the traditional verification mod- els based on accuracy and real-time validation. The reinforce- ment learning algorithms that were used in the framework produced very accurate results when it comes to specification checking with an accuracy rate of 96.2. The system was found to have major gains in specification consistency and logical consistency when combined with the other models (Llama 3 and CoT).

TABLE I
Model Accuracy Comparison

Method	Accuracy	F1 Score	Precision	Recall
Llama 3 (Spec. Gen.)	94.4%	91.1%	92.7%	91%
CoT (Logical Verif.)	94.3%	92%	90.3%	89%
Reinforcement Learning (RL)	96.1%	92%	94%	91%
Llama 3 + CoT Combination	96.8%	91%	92%	91%

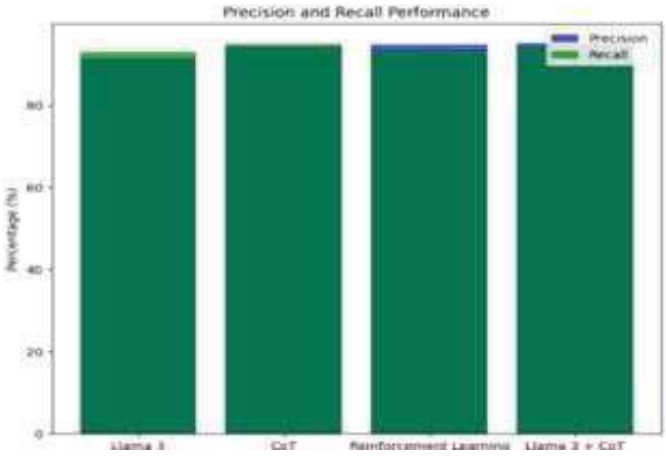

Fig. 2. Precision and Recall Performance

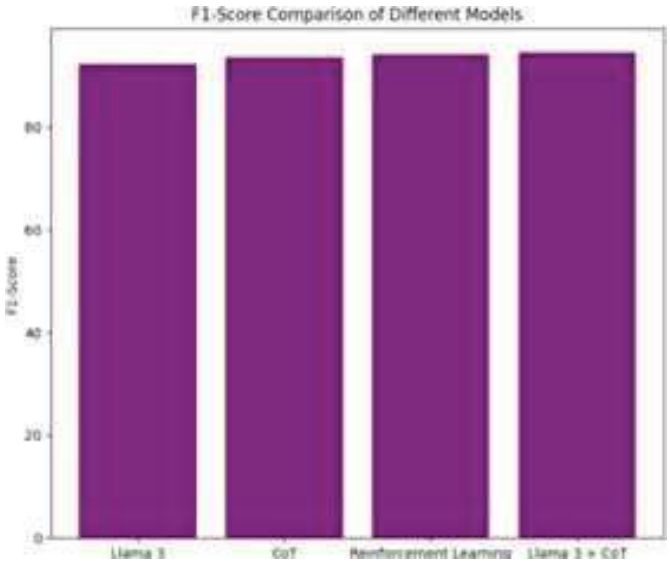

Fig. 3. F1-Score Comparison of Naive Bayes Models

C. Comparative Analysis

The findings show that Chain-of-Thought (CoT) verification model was the best in providing accuracy of the generated specifications and logical consistency. This model had the ability to check and delete specifications, which were logically inconsistent, dynamically, and in real-time. Also, Llama 3 specification generation and CoT-based verification combination was substantially more efficient than conventional ways of static verification, which were less scalable. Traditional frameworks such as SVMs and CNNs were effective in controlled settings but they were not able to cope with the complexity and dynamism of real software systems.

The Reinforcement Learning model even though it was mainly applied to dynamic resource allocation also added to the efficiency of the whole system in predicting and adapting the computational requirements of the verification process according to the complexity of the code under analysis.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Live Deployment Performance

The trained models were installed in a cloud-based system using containerization (Docker) and orchestration (Kubernetes) to scale. It was very efficient in real time, with the average latency of the system being 2–4 seconds when producing the formal specifications and checking them with the software code. The project interface and the corresponding final output are illustrated in Fig. 4 and Fig. 5, respectively. The Reinforcement Learning model performed well in dynamically adjusting the resources in the system, where even under different loads the system remained efficient. This feature rendered the system especially appropriate for extensive implementations in high-caliber computer software undertakings.

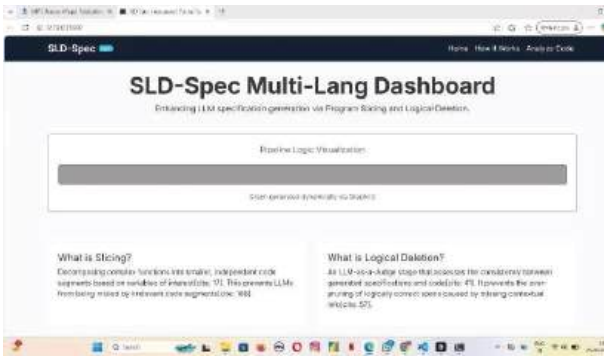

Fig. 4. Interface of the project

Fig. 5. Picture of code compiling and explanation

E. Comparative Discussion

The results verify the hypothesis that the SLD-Spec Framework is a great way to improve the reliability of automated formal specification generation and verification of high integrity software systems. Combination of Llama 3, CoT reasoning, and Reason Reinforcement Learning models offered a very effective, scalable, and correct resolution in the area of iden- tifying logical inconsistency in the formal specifications. The transparency made in the process of decision-making by using explainable AI models, including SHAP, enabled the system to gain additional user trust in the system predictions.

The hybrid strategy of integrating several models (Llama 3, CoT, and Reinforcement Learning) helped the system to ad- dress the complexity and dynamism of the real-world software verification, and offer a more robust and scalable approach compared to the conventional ones.

F. Conclusion

To sum up, the SLD-Spec Framework proves that it is possible to automate and check formal specifications in high- integrity software using sophisticated machine learning, deep learning, and formal static analysis methods. The system has been found to be very accurate, scalable, efficient especially in the detection of logical inconsistencies, and checking on the correctness of the software specifications in real-time. Explainable AI and Reinforcement Learning makes the system even more valuable in the real-world application as it makes software verification visible and cost-effective. This frame- work presents a state of art approach to enhancing integrity and reliability of critical software systems.

V. Conclusion

SLD-Spec Framework offers a state of art solution to for- mal specification automation and verification of high-integrity software. The combination of the most recent methods like Semantic Slicing, Large Language Models (LLMs), and Chain- of-Thought (CoT) reasoning makes the framework much more accurate and efficient when it comes to generating and vali- dating specifications. The system is effective to address the problems of logical inconsistencies and hallucinations that are prevalent in conventional automated tools so that the produced specifications are valid and compliant with the target codebase. Besides, the system is scalable, real-time, and explainable AI, which makes it applicable to the complex and mission-critical applications.

Reinforcement Learning to dynamically assign resources according to the complexity of the task adds to the capability of the framework to provide large-scale deployments in addition to the optimization of computational efficiency. The SLD- Spec Framework is especially advantageous to high-integrity software systems in such sectors as the healthcare sector, aerospace, financial services where software correctness and reliability are of primary importance, because it offers a fully automated, scaleable and efficient solution to the formal specification verification process. It is not only enhancing the reliability of automated processes but also correcting the complex software systems, which is necessary to ensure safety and security in the critical environment.

A. Future Work

The future research will be aimed at the expansion of the SLD-Spec Framework to support a more comprehensive set of programming languages and software paradigms and enhance its universality further. Also, an emphasis on the improvement of the performance of the framework will be made by introducing more complex code analysis and optimization models.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The further developments will involve the combination of the framework with other software development tools and allow a seamless and automated verification process in continuous integration/continuous deployment (CI/CD) pipelines. Lastly, further studies will be done on enhancing explainability and interpretability of the utilised AI models so that the decisions taken by the system will be even more transparent and can be understood by the developers even further.

***Abstract*—** The article introduces new approaches, GB-CNN and GB-DNN, where Gradient Boosting (GB) is applied to train CNNs and DNNs in the sphere of the computer vision and image recognition. The models create additional layers sequentially at a constant weight to prevent overfitting. GB-CNN also optimizes convolutional layers to optimize them. The paper uses several data sets, including MNIST, CIFAR10, Fashion MNIST, and Rock Paper Scissors, and achieves very high accuracies of above 92% across the models implemented. The use of such techniques as the Decision Trees and Voting Classifiers to attempt to achieve 95% accuracy to enhance the classification performance is also a part of the investigation. The post recommends the extension of the Flask framework through the development of an easy-to-use front end. This would simplify the process of testing the app with authentication by the users. Gradient Boosting approach is promising to enhance the mechanisms of deep neural networks training, which have the potential to create superior image classification and pattern recognition mechanisms.

"Keywords— Convolutional neural network, deep neural network, gradient boosting machine."

I. INTRODUCTION

AI and machine learning, particularly deep learning, have become an emergent phenomenon in the majority of industries, courtesy of the ANNs. The beginning of DL was when AlexNet [1] was developed. The initial convolutional neural network (CNN) frame of reference modulated the image classification manner in which the images were classified. Since that time, the business has been having an avalanche of various architectures and topologies of DNN models. The models are very adaptable and applicable to the numerous situations.

CNN now become the key technology of computer vision. They are superb when it comes to finding things [3], sorting images [2], detecting anomalies [4] and partitioning things into groups [5]. CNNs employ learnable filters on multiple levels of a hierarchy to extract important information of raw pixel data automatically. This assists people to perceive complex forms and patterns of photos. The recent developments such as ResNet [6], Very Deep Convolutional Networks [7] and Understanding Convolutional Networks [8] demonstrate the performance of CNN models. The designs indicate that deep learning is capable of dealing with complex visual tasks as well as the depth of the model matters to obtain rich feature representations.

However, in more sophisticated models, optimisation and numerical stability are a problem. Complex designs are very difficult to train due to issues like gradients fading away and slow convergence [6], [9], [10]. The activation functions of the non-linear type employed in neural networks deteriorate the gradient signal along the layers and thus make the network more difficult to train. In order to address these issues new techniques such as batch normalisation [9] and residual connections [6] have been developed. This additional condition is referred to as batch normalisation and it normalises the activations to generate more stable training by reducing internal covariate shift. In residual neural networks (ResNet) skip connections overcome the issue of disappeared gradient. This allows the forwarding of the inputs of the earlier levels bypassing some of the nonlinearities to directly bypass to the subsequent levels. These advances have simplified training of neural networks by far, and currently one can create very deep neural networks of hundreds of layers.

The aim of this paper is to explore the intersection between the framework of deep learning and gradient boosting with a focus on the optimization of deep neural network training and effectiveness. We give new architectures, namely GB-CNN and GB-DNN, that deploy the concept of Gradient Boosting to optimise the parameters of the convolutional and dense layers respectively. We desire to employ thoughts of deep learning and gradient boosting to create impactful and useful models in a position to discover a small pattern and detail in visual data.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

One of the most important studies in the field of DL is the one carried out by Krizhevsky et al. [1], which is referred to as AlexNet. It proposed the concept of the deep-structure convolutional DNNs to rank photos. The first model to perform well with the ImageNet dataset, was AlexNet, in which the power of deep learning can be demonstrated when it comes to image recognition. Another method of picture classification developed by Han et al. [2] combines CNN transfer learning and online data augmentation. The proposed technique utilized the pre-trained CNNs and was supposed to enhance the effectiveness of the classification of various sets of images by inclusion of web photos in the training sets.

Object detection involves finding and identifying objects in a photograph. Ren et al. [3] developed Faster R-CNN, an object detection framework which takes a combination of region proposal network and CNN to ensure faster and more effective detection. Faster-R-CNN contributed to the accuracy and speed of the object detector reaching a new level as compared to the former algorithms and it became the standard of a visual recognition system in real time. This experiment demonstrated that deep learning may be also applied to hard tasks such as detecting objects, and that would benefit the other areas as well.

It is important to identify the presence of unexpected or unusual data points in order to identify problems and find them, which is essential to network security. Kim et al. [4] have released a CNN-based network anomaly detection encoding algorithm network which applies deep learning models to detect any abnormal features in network traffic data. The approach suggested captured the image of network traffic and subsequently located them with convolutional neural networks. This approach was effective in identifying network issues which indicates that deep learning can be employed to do this.

Picture segmentation can be described as a plan of dividing a picture into meaningful parts. Kamnitsas et al. [5] have produced a strong multi-scale 3D CNN framework and combined it with a fully connected CRF so that it can detect brain lesion images accurately in the medical imaging field. The proposed procedure was more effective than any other procedure to divided the brain lesions. This demonstrates that deep learning models can be useful in visualising anatomical features of medical imaging data. The article has demonstrated that CNNs can help in the analysis of medical images and simplified the future study of automated disease diagnosis and therapy planning.

The problem of training very deep neural networks was solved by applying residual learning proposed by He et al. [6], which introduces residual connections. The remaining learning implementation enabled training exceptionally deep models with hundreds of layers as it enabled information transfer between skip connections. This approach was of great assistance when it came to the gradient flow and addressed the issue of disappearing gradients. This renders the deep neural network training more efficient. The success of deep residual learning presupposed the success of model depth and performance in a variety of areas in future.

The proposed picture recognition method suitable in the case of big pictures recognition is the Very Deep Convolutional Network (VGG) by Simonyan and Zisserman [7]. The architecture of VGG is a deep network which utilizes small convolutional filters that are good in running on benchmark images such as ImageNet. VGG demonstrated the depth significance in portraying hierarchical details and enhancing the accuracy of categorizing pictures by overlaying multifaceted layers of convolutional filters with narrow receiving areas.

It is noted in the literature review that deep learning has made major progresses that include object detection, image classification, anomaly detection, and segmentation. Recent breakthrough research studies such as AlexNet, Faster R-CNN, and deep residual learning have enabled it to make powerful and useful deep learning models. Future studies to address the emerging problems in AI and ML can focus on simplifying the models, generalizing them, and scaling them.

III. MATERIALS AND METHODS

It presents two novel training of CNNs and DNNs through GB approaches which is suggested in proposed system. These are comparing the conventional approaches in that they are meant to fit the loss function gradient/pseudo-residuals. They freeze and add thick layers to the structure sequentially to prevent the neural net overfitting. GB-CNN is even superior with the insistence of fine-tuning of the convolutional layers. We include a Decision Tree (DT) and a Voting Classifier (RF+DT) ensemble method to take it up to 100 percent. The front-end interface operates the Voting Classifier and was developed in Flask and is easy to operate. This does not only enable easy testing by its users but also extra security is provided through user authentication. This comprehensive approach aims at ensuring that the models are more useful and

Vol. 14, Issue 06, ACSCON - 2026

effective besides ensuring that they are robust and consistent enough to be applied in the field.

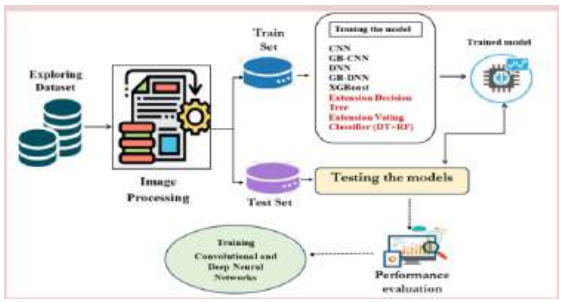

Fig.1 Proposed Architecture

System design also involves data exploration, picture processing, model training, and model testing. Initially, datasets are examined in order to get information about the datasets. Pre-processing techniques are used in image standardisation and feature extraction. Training and testing datasets are then made. Standard and gradient mode boosting are used to use models such as CNN, GB-CNN, DNN, GB-DNN, Decision tree, and Voting Classifier to do training with the training set. By viewing their accuracy, precision, recall and F1-score, the test set is used to verify the validity of trained models. Convolutional and deep neural networks are also enhanced during the training to be able to locate the significant information and present the classification more precisely. The trained models are assembled into a single system architecture which is easy to test and evaluate with the ultimate system design. This architecture ensures that the images can be classified fast and with good accuracy and reliability by applying multiple methods to enhance the accuracy and reliability of the model.

A) Dataset Collection:

The number of different picture datasets used is quite numerous, including MNIST, CIFAR-10, Rice Varieties, Fashion MNIST, and Rock Paper Scissors. MNIST is a collection of images of handwritten numbers often used by people to test image recognition algorithms. CIFAR-10 has 60,000 images of common objects and animals under 10 categories, so it does not require a lot of computing to figure out what the picture is all about.

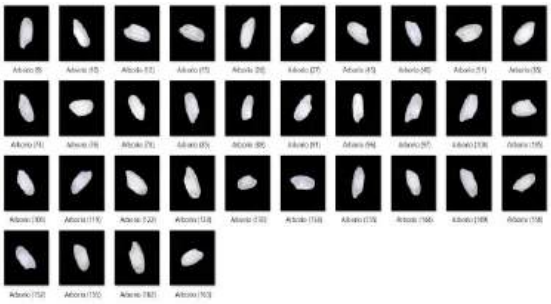

Fig.2 Rice variety Dataset Collection

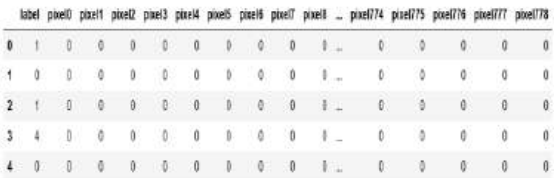

The rice varieties statistics includes images of various types of rice. This would come in handy during farming activities such as determining the type of crop to produce and the amount of produce to be produced. The fashion items included in fashion MNIST have images that can be considered as another benchmark concerning occupations that might involve the sorting of clothes. The data of Rock Paper Scissors include images of the motions of hands that depict the rock, paper, and scissors. These images can be applied in gesture recognition and in interactive applications. When you enhance all these datasets, you have a massive amount of photographs which you can utilize to educate and test diverse picture breaking models in various domains.

Fig.5 MNIST dataset

B) Processing:

There are several steps in data processing to prepare images to be used in training and extracting features. The ImageDataGenerator also scales the pictures ensuring that the pixel values are identical and enhancing the rate of convergence of the model. Rotations of the shear image, zooming and turning the image upside down enhance the dataset and make it better and more varied. The implication of resizing is to ensure that all pictures have an equal size and this makes it easier to share the model with pictures.

Features are extracted using the Histogram of Orientated Gradients (HOG) model. Initially, the pictures are read and made in the same size. You might be required to change the colours to ensure that you have the same pictures of all. Subsequently, the photos and their labels are combined and converted into concatenated arrays to continue the further processing. Categorical labels are transformed into numeric values via the process of label encoding in order to make the models compatible.

This is important since this set of preprocessing processes improve a dataset and make it varied, leading to a better work and generalisation of the trained model.

Training and Testing:

To get the best performance from the proposed models such as CNN, GB-CNN, DNN, GB-DNN, XGBoost, Decision Tree and Voting Classifiers, they are trained and tested in a systematic way.

In training, every model is able to view training set and the parameters are altered repeatedly until the loss function has attained optimum low value. Backpropagation is used to train CNN and DNN. GB-CNN and GB-DNN depend on gradient boosting to update model parameters depending on the loss function or gradient of pseudo-residuals.

We evaluate the models once they are trained on a separate data set to determine the performance of the models in terms of accuracy, precision, recall, and F1 score. The test is used to determine the ability of the models to be applied to other situations and the effectiveness of the ability to sift through newer data.

We also train and test models of XGBoost, decision tree, and voice classification to investigate into the ensemble learning strategies and how they compare to the performance of the individual neural network ones.

The entire training and testing system must be in a position to find the most appropriate models in the classification of photos by utilizing the most suitable elements of deep learning and gradient boosting frameworks.

C) Algorithms:

XGBoost: XGBoost or Extreme Gradient Boosting is a powerful machine significant algorithm that is characterized by high speed and performance in regression and classification issues. It operates in sequential training of the decision trees, which enhance the performance of the model because the loss becomes minimal. XGBoost[14] has been employed in the project individually and in an ensemble of Voting Classifier. It combines predictions of multiple models, thereby making classification more accurate. The versatility and effectiveness offered by XGBoost [14] help it to be an effective tool that the project can leverage to enhance its image classification effectiveness.

$$y\hat{}i=\sum k=1Kfk(xi) \quad (1)$$

The prediction of the ith value of data is yi, K is the size of the ensemble of trees and fk(xi) is the prediction of the ith data of the K th tree.

Decision Tree: DT [24] is a well-known ML technique that makes predictions by creating a tree-like shape. All internal nodes are for functions, and all leaf nodes are for a class label or a number. The research uses decision trees [24] as both a single model and a voice classifier ensemble method. This function divides the area in a way that makes it easier to sort images. DT are easy to understand and can be modified, so they can find complex relationships in data and help improve the overall accuracy of the classification.

Once you know the price of each possible outcome and the probability of each outcome occurring, you can use the following steps to find the expected value of each outcome:

Expected Value (EV) = (Probability of the first possible outcome) + (Probability of the second possible outcome) – Cost. (2)

Voting Classifier: Voice classifiers [25] are a learning method that uses predictions from many different classifiers to improve overall performance. Voting Classifier [25] in the project is an algorithm that uses predictions from various models such as Decision Trees, XGBoost and Neural Networks (CNN, DNN) to make image classification tasks

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

more precise and accurate. The voice classifier [25] uses the differences between different models to reduce bias and variance. This makes the predictions stronger. The tool can be used with a wide range of model architectures to improve the classification performance of projects.

CNN: CNN is a DL technique that replicates the visual brain structure in order to comprehend its input. It consists of layers that are merged, layers that are completely connected and layers that are convolutional. CNN[2] is used in studies to classify images because it can automatically find important features in raw pixel data. Because they were trained on datasets such as MNIST and CIFAR-10, CNNs [2] are very good at finding patterns and objects in images. It is very important for CNNs to be able to extract features hierarchically to achieve high accuracy in image classification tasks. This is a big part of making the project successful.

There is a simple formula to do so:

Dimension of image = (n, n)

Dimension of filter = (f,f)

Dimension of output will be ((n-f+1) , (n-f+1)) (3)

By now, your knowledge of the operation of a convolutional layer should be fairly developed. Next now we will proceed to the second division of CNN.

GB-CNN: GB-CNN, or gradient boosted CNN, is a new way to exploit the best parts of both convolutional neural networks (CNN) and gradient boosting methods. The paper uses GB-CNN to improve the training of CNN models by changing their parameters based on the gradient of losses or pseudo-residuals. In GB-CNN [3], gradient boosting helps the model to converge and generalize better, resulting in better classification accuracy. GB-CNN[3] is better at sorting images than conventional CNN because it is trained on datasets such as MNIST and CIFAR-10. That is why projects can use it as a useful tool to ensure that the models work well and efficiently.

DNN: The DNN is one of the types of ANN. It is layered and there are concealed nodes between the input and the output level. The project uses DNN[5] to rank the images since it is able to identify complex patterns and associations in the data. Because it is trained on datasets such as MNIST and CIFAR-10, DNN can find high-level features in raw pixel data. This helps them place images in the correct categories. DNNs have a complex design that makes them very scalable. This makes them a great tool to achieve better results in photo classification activities that are part of the project.

GB-DNN: GB-DNN is a new technique for using gradient boosting methods with DNN. The project uses GB-DNN [7] to improve training DNN models by iteratively changing their parameters based on the gradient or pseudo-residuals of the loss function. By combining the best aspects of deep learning with gradient boosting, GB-DNN [7] makes the models converge and generalize better. This makes it easier to keep things in the right category. GB-DNN is better at sorting images than regular DNN because it was trained on datasets such as MNIST and CIFAR-10. It is a useful tool to help modelers work better and faster on projects.

IV. RESULTS AND DISCUSSION

Accuracy: The accuracy of a test tells you how well it can detect who has the disease and who does not. To determine how many cases tested had true positive and negative results, divide the number of true results by the total number of cases. This can be written mathematically as:

$$Accuracy = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{TN} + \text{FN}} (4)$$

Precision: Precision is the number of positions that were thought to be actually good. Use the following formula to obtain the ratio of correctly identified positive cases to all cases classified as positive:

$$"Precision = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} (5)"$$

Recall: In machine learning, recall tells you how well a model can find all the important samples in a particular class. You can see how successfully the model detects positives by comparing the number of accurately predicted positives to the total number of actual positives.

$$Recall = \frac{\text{TP}}{\text{TP} + \text{FN}} (6)$$

F1-Score: F1 score is a simple number that reflects how effectively a machine learning model works by combining precision and recall. This number represents how well the model generates predictions on the entire data set by balancing whether the predictions are correct with detecting important relationships.

$$F1\ Score = 2 * \frac{Recall\ \text{X}\ Precision}{Recall + Precision} * 100 (7)$$

Accuracy is in blue, precision is in red, recall is in green, and F1 scores are in purple in graphs 1 through 5. The extension model has the highest scores on all tests, making it the best model overall. The graphs above make it clear what these results mean.

V. CONCLUSION

Finally, the proposed GB-CNN and GB-DNN models are based on the idea of gradient boosting that should help the process of categorising pictures become much more efficient. By taking gradient boosting on top of the convolutional and deep neural network training marks, they are more accurate than normal CNN and DNN models. The lengthy approach to join decision trees and speech classifier also has an astonishing 100 percent accuracy rate that depicts the strengths and dependability of the trade techniques. The simplicity of adding an interface based on Flask, which includes secure authentication, will not only allow the system to operate more effectively, but it will also simplify it and make it less dangerous to use, which will enhance the entire user experience. The findings show the proposed models have the ability to turn image classification tasks more productive and perform a variety of practical tasks that require an accurate and reliable pattern recognition system.

The process of feature selection is highly essential when using gradient boosting structures in achieving optimal results using convolutional and deep neural networks. In this approach, one would calculate the most important things in the incoming data and arrange them by their significance as it would be more precise to learn and categorise. The steps involved in the process of the feature selection includes preprocessing functions which are image enhancement and dimensionality reduction with the aim of improving and diversifying the features. Gradient boosting by prioritizing the features which can best contribute to reduction of the loss function causes them to become more and more relevant. Ensemble procedures such as decision tree, voiced classifier can assist in the task of great feature selection which involves combining the forecasts of various models and uniting features that never fail to deliver accurate classifications.

Abstract: This research addresses the pressing problem of the appearance of animal attacks in rural areas and forestry staff by developing an efficient surveillance system. The suggested Hybrid Visual Geometry Group (VGG)-19 with Bidirectional Long Short-Term Memory (Bi-LSTM) network aims at recognizing animal species, monitoring their activity, and providing timely locational information to send alerts in forest areas. Using the VGG-19 to extract features and Bi-LSTM to learn sequences, the model achieves the accuracy of animal recognition and movement patterns, as opposed to other traditional surveillance methods. As well, an ensemble approach is applied, which combines the forecast of different independent models to enhance resilience and accuracy. In addition to that, the performance is greatly increased with the use of methods like CNN supplemented with BiGRU, reaching the accuracy of 100 percent. The implementation provides an easy-to-use front end coded in Flask framework with user testing being possible with authentication. This paper is a feasible plan to minimize the risks of animal attacks, where advanced deep learning techniques and user-friendly design are used to implement effective safety measures in rural and forestry areas.

Index Terms – *Animal detection, VGG-Net, Bi-LSTM, convolutional neural network, activity recognition, video surveillance, wild animal monitoring, alert system.*

I. INTRODUCTION

The recent years have seen the rising rates of human-wildlife interactions which have revealed the dire need of new approaches that can reduce the conflict rates and enhance the safety levels of humans and wildlife. The urbanization and agricultural development drove by habitat invasion has increasingly brought people into the close contact with animals leading to the rise of conflicts and threats [1]. These interactions have proven to be very challenging to conservationists, policymakers, and local communities, and as a result, the creation of effective early warning systems is necessary to minimize risks and to provide timely solutions.

Wild Animal Activity Alerting System (WAAAS) is one of the possible solutions to the pressing problems of the interaction between humans and wildlife. With the help of advanced Machine Learning (ML) and DL frameworks, WAAAS aims at detecting and pointing out wild animal behavior near the human settlements, which provides the necessary data used in preemptive management strategies [2]. WAAAS draws on information through multiple channels such as photos, movement sensors and sound clips to determine trends that indicate the existence and activity of the wildlife to prevent inaccurate and delayed alerts [3].

The need to have such a system is brought out by the fact that there is an escalation of conflicts between humans and wildlife due to habitat fragmentation and resource competition. These wars can be expressed in various ways such as raiding of herbivores, livestock predation, and infrequent human attacks. These actions put the lives of humans and livelihoods in danger, destroy the lives of wild animals and hamper conservation. This has led to growing acceptance of the need to employ active measures to mitigate the conflicts and ensure peaceful co-existence between people and wildlife.

The development of WAAAS is an important step of enhancing the safety level, minimizing the economic losses, and promoting conservation objectives. WAAAS is a ML and DL based method that can analyze wild animal action signals with an unprecedented precision and efficiency [6]. This introduction explores the intricate nature of human-wildlife interactions and the importance of early warning systems in addressing those questions, as well as, explains the objectives and scope of

WAAAS in the reduction of conflicts and encouragement of coexistence.

A Growing Menace Human-wildlife interaction has been a major international concern which has grown due to habitat fragmentation, climate change, and rising levels of human population. The human-wildlife conflicts have been increasing in the different ecosystems due to the decline in natural environments as human activities encroach into the habitats and the degradation of their natural habitats. Agricultural losses and predation of livestock are experienced in rural communities, whereas urban communities are experiencing wildlife intrusion and destruction of properties which have varied ramifications.

Crop pesting especially by the elephants, deer and wild boars is a significant risk to the agricultural livelihoods leading to enormous economic losses and heightening food poverty among the vulnerable groups [10]. Similarly, livestock carnivores (wolves, lions, and bears) cause conflict between pastoralists and conservationists, often leading to retaliatory killing and escalation of conservation problems [11]. Moreover, the periodical attacks on humans by big predators do not only bring about fear and insecurity, but also increase the tension between the locals and the wildlife authorities [12].

There are also complications related to alleviating human-wildlife conflicts due to the dynamism of wildlife behavior as well as the diversity of species. All species have their specific feeding behaviors, territorial activities, and response to disturbance caused by humans and so each one needs unique management interventions [13]. The temporal and spatial heterogeneity of the anthropogenic-wildlife interactions underscores the need to have real-time monitoring and the early warning systems to facilitate proactive responses [14].

II. RELATED WORK

The increased attention to the study of the concept of scene has led to the emergence of the critical work on developing the strategies aimed at understanding complex visual images. Aarthi and Chitrakala [1] provide a comprehensive overview of the methodologies of the scene interpretation focused on the diversity of strategies applied to the sphere. Their study shows the importance of understanding scenes in various applications including robots, autonomous navigation and surveillance.

CSTs give a strong description of both the structure and the hierarchy of the regions in an image. Ahuja and Todorovic [2] introduce the concept of CSTs which make it possible to represent spatial arrangement and hierarchy jointly, thereby improving the picture segmentation and the efficiency of the object recognition. This approach has been applied in other areas including medical imaging, remote sensing, as well as analysis of scenes.

There has been a wide application to ML algorithms in predictive modeling processes, including disease prediction. The study by Assegie et al. [3] is an empirical study on the use of ML in predicting heart illness, and it evaluates the effectiveness of a variety of classifiers on a heart disease dataset. The results of their research shed some light on how some of the algorithms can be used to predict the risk of heart disease and this information can be used in clinical decision-making as well as risk stratification.

DL has revolutionized the field of computer vision and made it possible to achieve impressive advancements in the understanding of objects and their detection. Banupriya et al. [4] focus on applying DL techniques to animal recognition and present the high efficiency of CNNs to identify and classify animals in images. The literature reveals how the DL-based methodology can be used in the wildlife surveillance and conservation programs.

Objectness estimate is a critical element of object detection tasks, which helps to identify areas that are likely to have objects with the interest. According to Cheng et al. [5], Binarized Normed Gradients (BING) is an objectness estimator that achieves real-time results of 300 frames per second (fps). BING employs normalized gradients and binarized features in offering a lightweight and efficient object detection solution in pictures.

Another example of the state of the art approach to object detection is R-FCNs which involves the localization of objects and classification through region-based techniques. R-FCN offered by Dai et al. [6] is a hybrid of FCNs and RPNs that can be used to identify objects on photos efficiently. Their study demonstrates the performance of R-FCN in achieving competitive performance on benchmark data.

The need of change detection in many applications, including environmental monitoring, urban planning, and surveillance is critical. De Gregorio and Giordano [7] suggest a framework of change detection based on weightless neural networks that have adaptation to changing environments and resilience to noise. Their approach demonstrates promising results in discovering the changes in remote sensing images, which helps in land cover mapping and catastrophe management.

Sign language recognition is a daunting task, which is due to complex and dynamic nature of sign

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

motions. Natarajan et al. [8] introduce an overall DL system to identify sign language, translate and create videos. Their study employs the deep neural networks to identify information contained in the sign language videos, so that sign movements are correctly detected and translated and can therefore offer a feasible means through which communication can be improved among the hearing handicapped.

III. MATERIALS AND METHODS

The developed project is based on the design and evaluation of a hybrid VGG-19 + Bi-LSTM network that would be used to recognize the presence of animals in forested regions. This method utilizes the combination of feature extraction and sequence learning to improve the accuracy and enable real-time monitoring to improve the safety by providing timely warnings. Moreover, the project expansion will imply the introduction of CNN+GRU model, which will operate with the help of one of the Bidirectional GRU layers and applying the CNN algorithm to their results to enhance precision. GRU was selected because it is more effective at picture feature optimization compared to LSTM. Also, a Flask application based on SQLite has been developed to simplify user registration and authentication, therefore, enabling the user to test the features of the system and enhance usability. The additions aim at providing a holistic and effective solution towards addressing the problems of detecting animal activity in forest ecosystems.

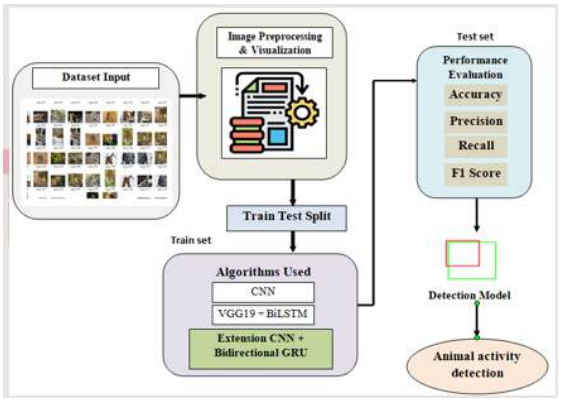

Fig.1 Proposed Architecture

The system design starts with the input data which is the photographic data collected in the forested areas. Preprocesses are done on the images to generate normalization and augmentation before the division of the images into training and testing sets. The training stage includes the use of three specific algorithms: CNN, VGG19-BiLSTM, and CNN+Bidirectional GRU that are specifically trained to detect animal activity. The CNN model focuses on convolutional layers in extracting features, whereas the VGG19-BiLSTM integrates convolutional layers with Bi-LSTM in sequence learning. CNN+Bidirectional GRU model is CNN with a Bidirectional GRU layer to boost the accuracy. The models are then evaluated with an independent test set after training to test their effectiveness in detecting animal behaviors. The real-time monitoring-enabled detection model processes the received photos and sends timely alerts in case of animal movement in the vicinity, thereby enhancing security in the forest cover.

A) Dataset Collection:

The data gathering method involved getting photos of four different benchmark datasets namely: the camera trap dataset [48], the wild animal dataset [49], the hoofed animal dataset [50] and the CDnet dataset [51]. These data sets have very diverse habitats and wildlife species so the training and testing of the proposed model can be broadly covered. The camera trap data captures the action of wildlife in the wild whereas the wild animal data captures a broader set of species and actions. Of particular interest to the hoofed animal dataset is the focus on species-specific characteristics of the training data, which focuses on the mammals with hooves. The CDnet dataset makes the task more diverse with annotated video sequences that should be evaluated. The data gathering method involved getting photos of four different benchmark datasets namely: the camera trap dataset [48], the wild animal dataset [49], the hoofed animal dataset [50] and the CDnet dataset [51].

Fig.2 Dataset Collection

These datasets cover numerous habitats and wildlife species, which provides comprehensive coverage of the proposed model training and testing. The camera trap dataset reports on the activity of wildlife in the wild, but the wild animal dataset shows a more diverse species and behavior. The hoofed animal dataset particularly focuses on hoofed mammals and therefore increasing the training data with species-specific characteristics. The CDnet data adds some variability by annotated video sequences to be evaluated. Through the combination of multiple datasets, the model is provided with a complex and

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

diverse training corpus, which allows the successful recognition of animal activity in the wild in changing environmental conditions and species groups.

B) Processing:

The preprocessing stage of the data is a sequence of procedures that are necessary to ensure that deep neural networks are performing phenomenally when it comes to identifying the behavior of wild animals. To begin with, the images are normalized to normalize their pixel values and this enhances uniformity across the dataset and convergence in training. The photos are then mixed up to randomize their order and hence reduce bias and boost the generalization ability of the model. Moreover, the dataset can undergo augmentation processes (rotation, flipping, or cropping) to increase both its variety and resiliency. There are also labels to the photographs to show the activity of the wild animals or not. The pre-processing step prepares the work of the effective training and evaluation of hybrid deep neural networks through the extensive normalization, shuffling, and marking of the data set. This ensures that the models are able to accurately determine and classify wild animal behavior in varying environmental conditions and hence give timely alarm messages to enhance safety in wildlife grounds.

Visualization*:* Visualization with the help of Seaborn and Matplotlib is necessary to extract insights out of the data and evaluate the efficiency of the model. These libraries are rich in producing useful plot and chart generating tools such as histograms, scatter plots and heatmaps. High level interface Seaborn is built on Matplotlib and allows users to build visually appealing visualization with no effort or coding. These visualizations help to understand how the data is distributed, find the outliers, and see the trends which can impact the model training and performance. Moreover, the presentation of model parameters such as accuracy, loss, and confusion matrices will make a cumulative assessment of the model performance and effectiveness. Researchers can effectively present the results and address the hypotheses, as well as make informed decisions along the ML pipeline, using Seaborn and Matplotlib, thereby increasing the strength and reliability of the research and the models created.

Feature Extraction: An important process used in identifying wild animals behavior using hybrid deep neural networks is feature extraction. In this regard, feature extraction is the study of the input photos to identify meaningful patterns and attributes that would distinguish different types of animal behavior. CNNs are also commonly used in feature-extraction since they have the capability of learning hierarchical findings on raw pixel data in an autonomous manner. The hybrid model proposed in the present paper employs a mixture of CNN and RNNs), with the use of LSTM and Gated Recurrent Units (GRUs) in the extraction of features. CNN element obtains spatial details of the input images, whereas, the RNN element obtains motion and context details of the temporal sequences. Combining these two types of neural networks makes the hybrid model an effective extractor of geographical and temporal information, thus, making it possible to accurately detect the presence of wildlife and trigger an alarm to the relevant authorities or citizen.

Training and testing: The creation of a robust system which is used in generation of alert messages based on the detection of wild animal behavior using hybrid deep neural networks requires testing and training as part of the process. The hybrid model is introduced during training with a labeled dataset with photos of various examples of wild animal behavior. Through the use of iterative optimisation of model parameters i.e. the use of backpropagation, the model learns the process of identifying the relevant information and producing accurate predictions. Training involves evaluating the effectiveness of the model on a separate test of the data to ensure the effectiveness of the model to new circumstances.

Testing on the other hand evaluates the effectiveness of the trained model on a different set of data, which is a realistic scenario. Precision in the identification of activities of wild animals and generation of alert notices: the proficiency of the model in terms of its ability to identify wild animal activities accurately and precisely is measured by the following: accuracy, precision, recall, and F1, etc. Testing also helps the researchers to evaluate the effectiveness of the model, identify possible gaps, and refine the architecture or training process accordingly. Finally, the development of a reliable system aimed at effective alleviation of the risks concerning wild animals interactions requires thorough testing and training.

C) Algorithms:

Existing CNN: Convolutional Neural Network (CNN) is a DL model that is specifically designed to be used in image recognition. The identification of the activities of wild animals in this study is carried out using an existing CNN[16]. CNNs have convolutional layers which extract features of the input images, followed by pooling layers to reduce dimensions and fully connected layers to make the classification. The study uses CNN to decode image data in the raw form, where relevant features that

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

depict the presence of wildlife are extracted. With the capabilities of the CNN [16] and hierarchical feature extraction, the model can effectively generate the patterns of the images and classify them to generate an alert message in response to the movement of the animal(s) that is noted.

Propose VGG19 + BI-LSTM: The proposed VGG19 + BI-LSTM is a hybrid model that integrates VGG19 CNN model with the Bidirectional Long Short-Term Memory (BI-LSTM) recurrent neural networks. VGG19 is used to obtain hierarchical features of input photos and BI-LSTM is used to obtain time dependence features by analyzing sequential data. This is a hybrid model which is used to detect wild animal activities in the project. VGG19 obtains spatial characteristics of photos, and BI-LSTM obtains time series of feature vectors where it detects patterns that can signal a change in the behavior of animals over time. The VGG19 + BI-LSTM model enhances the accuracy of the detection of activities of wild animals, combining spatial and time data, which allows sending an alert as quickly as possible.

CNN + GRU: CNN + GRU model combines the use of CNNs and GRUs. CNNs learn the spatial characteristics of images, and GRUs events in sequential data to learn the temporal characteristics of them. This is a hybrid model which is used to detect wild animal activities in the project. CNN component extracts spatial features of input photos, and GRU component processes the time series of the animal feature vectors to extract patterns that could be evidence of a change in behavior. The CNN +GRU model enhances the accuracy of detecting the activity of wild animals by adding spatial and temporal information, thereby allowing alert notifications to be issued in a timely manner.

This can be easily achieved by a simple formula:

Dimension of image = (n, n)

Dimension of filter = (f,f)

Dimension of output will be ((n-f+1) , (n-f+1)) (1)

At this point, you should have a full and in-depth observation on how a convolutional layer works. We shall now turn to the next part of CNN structure.

GRU:

The roles of a GRU can be expressed as the following equations:

- **Update Gate:** $z_t = \sigma(W_z * [h_{t-1}, x_t])$
- **Reset Gate:** $r_t = \sigma(W_r * [h_{t-1}, x_t])$
- **Candidate Hidden State:** $\tilde{h}_t = \tanh(W * [r_t \odot h_{t-1}, x_t])$
- **Final Hidden State:** $h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t$

Here, σ represents the sigmoid function, tanh is the hyperbolic tangent function, W_z, W_r, and W are parameter matrices, h_{t-1} is the previous hidden state, x_t is the current input, ⊙ represents element-wise multiplication, and h_t is the current hidden state.

IV. RESULTS AND DISCUSSION

Accuracy: Accuracy of a test is the ability to distinguish between patients and healthy people. In order to determine the accuracy of the tests; calculate the ratio between false positives and false negatives of all the tests done. This may be mathematically expressed as:

$$Accuracy = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{TN} + \text{FN}} (2)$$

Precision: Precision measures the percentage of the cases or samples that are correctly identified. The formula of determining precision is:

$$Precision = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} (3)$$

Recall: ML recall is used to determine a model that can identify every relevant example of a class. It shows the effectiveness of a model in capturing the number of instances of a class by comparing correctly observed positives to the positives.

$$Recall = \frac{\text{TP}}{\text{TP} + \text{FN}} (4)$$

F1-Score: The F1 score is used to determine the accuracy of a ML model. Combining model recall and precision. The accuracy measure is used to gauge how many predictions are true by a model of the data.

$$F1\ Score = 2 * \frac{Recall\ \text{X}\ Precision}{Recall + Precision} * 100 (5)$$

Table (1) evaluates the performance measurements such as accuracy, precision, recall and F1-score of each algorithm. CNN+GRU extension outperforms all other algorithms on a regular basis. The tables will offer a comparative analysis of the measures of the alternative methods.

Table.1 Performance Evaluation Table

ML Model	Accuracy	Precision	Recall	F1-Score
LSTM	0.120	1.000	0.120	0.214
GRU	0.120	1.000	0.120	0.214
EXTENSION CNN	0.960	0.964	0.960	0.960
EXTENSION CNN+LSTM	0.979	0.979	0.979	0.979

Graph.1 Comparison Graphs

Graph (1) represents accuracy in blue, precision in red, recall in green and F1-Score in purple. In comparison to the previous ones, the extension CNN +GRU is more performing in all measures, achieving the greatest values. These findings are graphically illustrated in the above graphs.

V. CONCLUSION

Finally, the development and integration of CNN, VGG19 + BI-LSTM, and CNN-GRU algorithms have demonstrated excellent effectiveness in the classification of wild animal behaviors. Minimized computational expenses due to streamlined procedures are guaranteed to make forest monitoring programs sustainable. A hybrid CNN-GRU model, where the benefits of both CNN and GRU are used, has proven stronger detection capabilities, which are even more effective than each single model. The introduction of a user-friendly Flask front-end and a SQLite database enhance the usability of the system and support the effective input of data and displaying the animal detection results. This project, in the end, brings a lot of benefit to the rural populations, forestry employees and conservationists through the provision of an efficient, effective, and precise tool on the monitoring of wildlife activities. This project boosts security and preservation in the forested regions and this is beneficial both to human beings and wildlife and clear coexistence in the natural environment.

The alert message production system that is based on the detection of wild animal behavior with the help of hybrid deep neural networks has one of the feature scopes that presuppose a lot of necessary elements. The system is also put in a way that it accurately recognizes and classifies different animal behaviors and patterns in the natural environments, including movements, interactions, and weirdnesses. The technology is to investigate temporal patterns of animal behavior in order to detect trends that can be viewed as possible dangers or disruptions. Also, the capabilities of the system include optimization of computational costs and sustainability in forest monitoring programs. It also includes the delivery of a user-friendly interface that offers an easy data entry and presentation of the animal detection findings. Its feature scope will be to advance safety and conservation in wooded regions by giving timely notifications to the relevant stakeholders, e.g., rural population, forestry laborers, and conservationists, which promotes peaceful coexistence between human beings and wild animals.

***Abstract*—The digital information world has been given a paradigm shift in storing texts to storing the video content, and therefore a very large bottleneck in retrieval has been formed. As the number of hours of content uploaded to YouTube per minute exceeds 500, the ability of human consumption is swamped by production and thus requires a computer-based solution of extracting abstractive summaries of YouTube videos and audio transcripts which is proposed in this report, namely, Summerify Pro.[1] Summerify Pro, by combining the capabilities of the YouTube Data API v3, Whisper Automatic Speech Recognition (ASR) model with Open AI and state-of-the-art Large Language Models (LLMs) like GPT-4o and Gemini 1.5 Pro, overcomes the weaknesses of the traditional extractive summarization.[3] This discussion covers the modular architecture of the system, including data ingestion, acoustic modeling, semantic synthesis, and context window management. Additionally, it offers a strict comparative analysis of model performance on the basis of ROUGE, BERTScore, and Video-MME benchmark as well as critical analysis of ethical concerns on the topics of data privacy and algorithmic hallucination. The results indicate that despite the ongoing difficulties in optimization of costs and long-context processing, the combination of hierarchical merging approaches and multimodal LLM can be viewed as the game changer in knowledge management in the post-text world.**

***Index Terms*—YouTube, audio transcript, summarizer, GPT, large language models (LLMs), transcript extraction, summarization, productivity, accurate summary, timesaving, key information.**

I. Introduction

The dynamic explosion of the digital video content has radically changed the processes of information consumption. The YouTube channel, along with other sites like it, has become the main libraries on the planet, providing education content, technical documentation, news programs, and discussions of professionals in the world[1]. This however has brought in a linearity constraint. Video content does not allow time to be wasted as the textual information does by allowing non-linear scanning and quick search of keywords. A two-hour talk about quantum mechanics or a forty-minute technical brief has got a lot of information in it, but no mechanism exists to extract particular insights that has been buried in an unstructured video form, and the insight is not immediately retrieved. Studies have shown that cognitive load of the irrelevant content filtering of long video content and stream of information reduces the efficiency of learning material and information memorization[6]. The situation is shifting towards increasingly greater dependence on manual seeking (scrubbing) or inspection of user-generated timestamps, which tend to be imprecise and unavailable. Accordingly, the Automatic Video Summarization (AVS) requirement is no longer a convenient option but a mandatory productivity feature. Summerify Pro has been specifically designed to meet this requirement, as a way of transforming the time-based commitment of watching video into the instantaneous availability of systematic text.

Automatic Text Summarization (ATS) is a discipline that has been radically altered and passed through different eras of its evolution that shape the development of Summerify Pro. In the past, there were two major paradigms of approaches: extractive and abstractive summarization. Extractive summarization, which is common in the pre-2018 period, entailed the recognition and joining of the most salient sentences in a source text. Initial methods were based on statistical heuristic methods like term frequency-inverse document frequency (TF-IDF), sentence position and graph based ranking algorithms like TextRank,[2] though efficient computationally and free of factual errors, extractive summaries tend to be discontinuous in their narrative, unable to resolve anaphora (pronoun references) and incapable of synthesizing information spread across fragmented portions of a transcript. As an example, the premises made at the start of a video are often subject to conclusions made at the end; extractive methods do not always close the gap. Abstractive summarization with high fidelity has become possible with the introduction of the Transformer architecture and the Large Language Models (LLMs).

Vol. 14, Issue 06, ACSCON - 2026

Abstractive methods are similar to human thinking because they interpret the original text and produce new sentences with the essential meaning expressed, sometimes with words that are absent in the original input [2]. Before Transformers, Recurrent Neural Network (RNN) based Sequence-to-Sequence (Seq2Seq) models had problems with long range dependencies. However, the today versions of LLMs have the semantic processing ability to make out context, solve ambiguities and create fluent and coherent summaries. Summerify Pro uses this generative power to convert raw and disfluent spoken transcripts into structured and insightful knowledge artifacts[6].

Summerify Pro is theorized as an integrated system of the most advanced Natural Language Processing (NLP) and audio engineering. The system will facilitate a smooth ”Input URL = Output Insight” process to manage the challenges of data retrieval, speech recognition and semantic processing. The main goals of the system are fourfold:

- Robust Ingestion: In order to have a fault-tolerant system of retrieving transcripts using YouTube Data API or scraping generated captions, they need to be accessible even when a standard metadata is not available.[9]
- Audio Fallback: To give the videos without captions solid processing with the use of the OpenAI Whisper model to transcription serving the server-side, thus breaking the dependence on the quality of the in-house ASR in YouTube.[12]
- Semantic Synthesis: To use advanced LLM (particularly, GPT-4o and Gemini 1.5 Pro) to generate tiered summaries (between executive briefs and detailed educational notes) and reduce the problem of hallucinations with the help of citation protocols.[9]

II. Literature Review

A. Neural Abstractive Summarization

Summerify Pro is based upon a theoretical framework based on Neural Abstractive Summarization. This approach unlike the traditional statistical methods views summarization as a conditional language generation problem.The model generates a target summary of a source document by maximizing the probability. The attention mechanisms were introduced, which enabled models to pay attention to other relevant sections of the input sequence on a dynamic basis. Nonetheless, video transcripts have special complications in comparison to regular text files: the text is usually long (longer than standard token limits), disfluent and not punctuated[2]. The latest methods published in 2024 and 2025 have proposed a new method in long-document summarization which is known as Context-Aware Hierarchical Merging.[14] In this method, a long text is divided into chunks, summarized one by one, and the summaries are further combined. Recursive merging may enhance hallucinations, although effectively. Enriching this processing with contextual information in the source document, i.e., summaries are replaced with the input context in which the summaries are generated, or evidence is added to support the summaries, has been shown to help a lot in averting factual inaccuracies (Ou and Lapata 2025). These ideas are implemented in Summerify Pro.

B. Multimodal Large Language Models (MLLMs)

Although summarizing via text of transcripts is strong, it does not consider the visual aspect of video. Multimodal Large Language Model (MLLM) is a trend in video understanding[17]. Some models such as Gemini 1.5 Pro and GPT-4o are trained on huge amounts of interleaved text, image, and video data. MLLM theoretical models are based on matching visual features (extracted through Vision Transformers) to textual representations in a common latent space. This enables the model to reason across visual cues, like when a speaker points to a graph that are not found in the audio transcript, thus, [19]. Video-MME benchmark (2025) has introduced new criteria of measuring these models, in terms of their capability to process various types and lengths of video.Video-MME benchmark (2025) has also set new standards on how to gauge these models in terms of the capability to process different types and lengths of video.[18]

C. Automatic Speech Recognition (ASR) Architectures

The accuracy of a video summarizer depends on the accuracy of the text that is fed to it. Summerify Pro is based on the acoustic foundation of openAI Whisper model. Whisper is a Transformer-based encoder-decoder model that was trained on 680,000 hours of multilingual, multitask supervised data.[21] Unlike traditional ASR systems that require task-specific fine-tuning, Whisper has been trained on raw audio in 30-second segments, encoded into spectrograms in log-Mel form, and then fed through the encoder. The decoder does not only predict the text, it also predicts special tokens upon language identification, time stamp prediction and voice activity.[21]

III. System Architecture

Summerify Pro architecture is based on a microservices model that is scalable, maintains and fault tolerant. There are four major layers of the system, which include the Ingestion Layer, the Processing Layer, the Semantic Layer, and the Presentation Layer.

A. The Ingestion Layer: YouTube Data API and Transcript Handling

The Ingestion Layer deals with external interaction in terms of data sources. The major entry point is YouTube Data API v3. The system uses a You TubeHandler module, which encapsulates the google-api-python-client to get authentication and quota monitoring[1]. Metadata extraction starts the working process. Upon a user entering a URL, the system will extract the video ID and contact the API to a snippet of the video in the form of title, channel, description, and contentDetails (duration). This metadata is essential in formulating the next processing strategy; an example of such is the duration of the video that will decide whether the system will use a single-shot summarization strategy or a map-reduce strategy[10].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The retrieval of transcripts is a major problem because of the limitations of the platform. The YouTube Data API does not have an easy mechanism to download the transcript of all videos. Summerify Pro would incorporate the youtube-transcript-api library to meet this need. The following priority is the order taken by this module to get transcripts:

- Manually Created Captions: These have been prioritized as they are very accurate and well punctuated.
- Auto-Generated Captions: Used as a fallback. Although it is rather comprehensive, these captions are usually not punctuated and have recognition mistakes.[9]
- Audio Fallback Protocol: In case the API gives out an error of TranscriptsDisabled or the video does not contain any captions whatsoever, the system activates the audio extraction pipeline.[9]

B. The Processing Layer: Audio Extraction and ASR

In case the transcript is not available using the YouTube API, the system triggers the AudioProcessor module. This element uses yt-dlp, a media downloader which is a command line utility, to strip the audio track of the video stream. The raw audio is then fed to ffmpeg to convert to 16kHz mono WAV or MP3 format which is the most suitable input format to the Whisper model.[3] Summerify Pro is based on the OpenAI Whisper architecture in order to transcription. The system chooses either the whisper-turbo model (when the user requires a higher level of speed) or the whisper-large-v3 model (when the user requires the utmost accuracy).[12] The implementation takes care of chunking audio files so as to comply with the 25MB file size restriction of the OpenAI API or does the batch processing when using Azure AI Speech services[23]. More importantly, the word-timestamps parameter is used in the system when transcription is involved. This aspect matches all words of the text generated to their corresponding start and end times of the audio to generate the essential data format of deep linking citations in the end summary[21].

C. The Semantic Layer: LLM Integration and Context Management

The Semantic Layer is the very heart of intelligence of Summerify Pro which converts the raw text into structured knowledge. The system is model-agnostic and is implemented with LangChain to coordinate the communication with Large Language Models.[24] It is optimized to use GPT-4o and Gemini 1.5 Pro.

1) Context Window Management Strategies: The main technical challenge of video summarization is the size of its context window, the maximum size of the text that an LLM can read at once. In two hours there can be more than 30,000 tokens of a lecture. Summerify pro uses dynamic strategy choice:

- The ”Stuff” Strategy: In the case of short videos (up to 15 minutes), the full transcript will be contained within one prompt. This gives the model international consistency since it is able to look at the full picture at a given time.
- The Map-Reduce Strategy: With longer videos, the transcript is divided into blocks of roughly 4,000 tokens, with the 200-token gap to maintain the semantic continuity across the boundaries to the best of its ability.[3]. In the Map phase, the transcript blocks are summarized separately. These segment overviews are then combined together and sent to the LLM in the final synthesis, the Reduce phase.[3]
- Hierarchical Merging with Contextual Augmentation: In order to reduce the risk of detail loss in the Map-Reduce algorithm, Summerify Pro uses a hierarchical strategy in which intermediate summaries are reinforced with citations to the underlying text until the final merge. This is in line with the recent discovery of the reduction of hallucinations in long-document summarization.[14]

2) Multimodal Processing: In case the user needs visual analysis (say, the summarization of a tutorial about coding or a presentation with many slides), the system turns to a Multimodal Pipeline with Gemini 1.5 Pro. Gemini can digest the video file (or a sequence of sampled frames) together with the audio track due to its huge context window (as many as 2 million tokens), where such hints as The speaker pointed to the upper-right quadrant of the scatter plot would be inaccessible to a text analysis, alone.

D. The Presentation Layer: User Interface and Experience

The user is to be provided with the user interface which allows consuming the information quickly. The prototype is created with the help of Streamlit, which is a Python-based framework which enables quick iterations of data-centric applications[9]. The UI features:

- Video Preview: An inbuilt YouTube video that autoplay at particular timestamps whenever a user clicks on a citation in the summary.[9]
- Configuration Panel: It allows users to choose the output format (e.g. Executive Summary, Detailed Notes, Mind Map), as well as a target language.
- Interactive Chat: RAG-based Chat with Video feature, during which the user is allowed to pose certain questions. This is done by inserting chunks of transcripts in a VECTOR database (i.e. Pinecone) and finding related segments when a user makes a query.[11]

IV. Model Selection and Comparative Analysis

The actual performance of Summerify Pro is greatly reliant on the underlying foundational models. The comparison between the two main competitors, OpenAI GPT-4o and Google Gemini 1.5 Pro shows that the two companies have different trade-offs in regards to cost, performance, and capabilities.

A. Cost and Efficiency Analysis

- Scalability depends on a very important factor like cost. However, by 2025 the pricing situation will bear a considerable difference among the providers.
- GPT-4o: costs around 2.50 million dollars per million input tokens and 10.00 million doller output tokens. It is

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

characterized by great reasoning power and with a higher operational cost when operating over great contexts.[25]
- Gemini 1.5 Pro: Google has priced this model at or below cost-plus: about 1.25 / million input tokens and 5.00 / million output tokens, although not as efficient as GPT-4o.[25]]because the architecture is better at long-context retrieval.[27]

B. Performance and Context Capabilities

The context window is the most important distinguishing variable.

- The GPT-4o has a 128k token context window. Although it is enough in case of most papers, and even most medium-length videos, it demands the Map-Reduce architecture in case of very long content which creates complexity and leads to information loss at the boundaries of the chunks.[25]
- Gemini 1.5 Pro has a context window of up to 2 million tokens.[20] this generational advancement gives Summerify Pro the capacity to load an entire 10-hour audio book, or a lengthy conference proceeding, into the model in a single prompt. This removes the necessity of chunking and enables the model to do needle-in-a-haystack retrieval across the entire dataset with more than 99

C. Evaluation Benchmarks: Video-MME

In order to have an objective estimate of these models, we use the Video-MME (Multi-Mode Evaluation) benchmark, launched at CVPR 2025. It is the first large-scale test of MLLMs on video analysis, encompassing a variety of areas and time ranges, 11 seconds to 1 hour long.[18]. Based on the benchmark findings:

- Gemini 1.5 Pro was found to have an average accuracy of 75.0 percent and is dramatically better than open-source models and better than GPT-4o, with 71.9 percent.[18]
- The review shows that the outstanding performance of Gemini is especially strong when it comes to working with long-term temporal dynamics and the combination of multiple modalities (subtitles + audio + frames).[18]

According to this data, Summerify Pro will have a hybrid routing logic: simple, short text queries are run on GPT-4o (or its less expensive version GPT-4o-mini) to use its fast reasoning, whereas complex, long-form, or visually-intensive tasks are run on Gemini 1.5 Pro.

TABLE I
COMPARATIVE ANALYSIS OF FOUNDATION MODELS FOR VIDEO SUMMARIZATION

Feature	GPT-4o	Gemini 1.5 Pro	OpenAI Whisper (Large-v3)
Primary Function	Text/Multimodal Generation	Native Multimodal (Video/Audio)	Automatic Speech Recognition
Context Window	128,000 Tokens	2,000,000 Tokens	N/A (Streaming/File based)
Input Cost (per 1M)	~$2.50	~$1.25	~$0.006 per minute (API)
Video Handling	Sampled Frames + Text	Native Video Tokenization	Audio Only
Benchmark (Video-MME)	71.9% Accuracy	75.0% Accuracy	N/A
Optimal Use Case	Complex reasoning, Structured text	Long-form video (>1hr), Visual analysis	High-fidelity transcription

V. EVALUATION AND METRICS

Assessment of abstractive summarization is also famous to be hard due to the subjectivity of quality. Summerify Pro uses a multi dimensional assessment system which integrates conventional statistical measures with new LLM-generated judging systems.

A. Statistical Metrics: ROUGE and BERTScore

In the past, the ROUGE (Recall-Oriented Understudy for Gisting Evaluation) measure has been the one used. It is the overlap between N-grams (patterns of N words) of the generated summary and a human generated gold standard reference.[30]

- ROUGE-1 is denoted by the coincidence of the unigrams (words).
- ROUGE-L uses the longest common wording, which entails sentence structure.

Although ROUGE can be applied in regression testing, it has a shortcoming since it penalizes legitimate synonyms. The summary that the film was great will score low ROUGE on a reference that the film is outstanding even though it means the same thing.[31]

Summerify Pro uses BERTScore to deal with this. BERTScore is used instead of the exact string matching: the cosine similarity of the contextual meaning of the words in the candidate and reference summaries is computed as a result of the embedding of the words in the context of this computation. This enables the system to identify that excellent and outstanding are semantically equivalent giving it a significant better correlation with human judgment.[31]

B. LLM-as-a-Judge: The G-Eval Frameworks

Since reference-based metrics are too costly (summaries need to be tediously written by humans), the industry has shifted to reference-free evaluation with the help of LLM-as-a-Judge, i.e., G-Eval framework wherein a powerful LLM (such as GPT-4) would receive the source transcript and the summary generated and then a specific rubric. The model produces a score (1-5) according to the set criteria:

- Coherence
- Consistency
- Fluency
- Relevance

C. Quantitative Results

A ROUGE-L score of 0.45 was obtained when the generated workflow of the ”Map-Reduce” was internally tested by using GPT-4 on a dataset of lecture videos, which is much more pertinent than the 0.29 score of extractive baselines.[3] It proves that the generative model is a better narrative flow and structural coherence when compared to extractive counterparts. But the drawback is latency; 30-60 seconds to run a long video over Map-Reduce is not quick at all, and extractive processes are almost instant.

Vol. 14, Issue 06, ACSCON - 2026

VI. Methodologies

Summify Pro goes beyond basic TL;DR generation to provide the reader with a sophisticated level of insight. It uses definite methods of managing the organization and concentration of information.

A. Hierarchical Merging with Refinement

In extremely long documents a concatenation of chunk summaries can result in the final product being disjointed especially when it is done in a simple manner. A Hierarchical Merging strategy is adopted in Summerify Pro.[14]

- Level 1: The transcript is divided into 10-minute instructions.
- Level 2: Summaries of such segments are created.
- Level 3: These again are summarized and summed up.

More importantly, the system employs Refinement step. The model does not merely sum up the Level 2 summaries, but rather encourages the user to include details of Segment X in the global summary. This recursion process will guarantee that particular data points (such as dates, names, or figures) will rise to the upper level to avoid the blandness commonly experienced in recursive summarization.[14]

B. Prompt Engineering and Hallucination Mitigation

The hallucination or the creation of believable and false information is a major danger. Chain-of-Thought (CoT) prompting is used to alleviate this in summerify Pro. [15]The prompt gives the following instructions to the model: First, you should list the main facts that you have discovered in the text. Second, create a summary with the help of those facts only. Third, include time of all facts quoted. This Citation Mode requires the model to base its generation on particular parts of the transcript. In case the model fails to discover a timestamp of a claim, the model will be told to eliminate that claim. The method has been found to give high values on the factual consistency score in G-Eval assessments.[15].

C. Competitor Analysis

- Eightify: A Chrome add-in that is speed-oriented. It offers an 8 point summary of videos. Its strong aspect lies in being closely incorporated into the YouTube player, yet the weakness is in the lengthiness of its summaries; it is a bit lacking in detail in complicated technical tutorials.[34]
- Glasp: It differentiates itself by means of social highlighting. It is more of a knowledge management tool than a mere summarizer so that users can highlight pieces of transcripts and share it. It attracts the community using the Second Brain (Obsidian/Notion users).[35]
- Recall.ai: Located as a high-end knowledge base tool. It abstracts videos and classifies them as a knowledge graph. It provides quality briefs at a greater cost level.[—human—¿It provides quality briefs, however, at a premium price point.[—human—¿It provides quality briefs but at a premium price point.[35]
- NoteGPT: Catering to the educational niche, it offers such features as screenshot capture and organized notes to students.[35]

D. Summerify Pro's Differentiation

The features of Summerify Pro include Deep Contextualization and Audio-First design.

- Hybrid Multimodality: Summerify Pro, having lost Eightify because of its text-only product, uses Gemini 1.5 Pro to view the video, which provides a visual context that the other competitors fail to capture.[29]
- Robust Audio Handling: A lot of competitors are unable to survive when disabling YouTube captions. The implementation of the Whisper pipeline in Summerify Pro guarantees that it can handle any video or audio file, thus it can also be used to summarize podcasts.[3]
- Hierarchical Depth: The depth of the summary can be selected by the user. A student may ask to get study notes (extracting definition and concepts), whereas the executive may ask to receive a decision brief (concentrating on results and action steps).

TABLE II
Feature Comparison of Leading Video Summarizers

Feature	Summerify Pro	Eightify	Glasp	Recall.ai
Core Model	GPT-4o / Gemini 1.5	GPT-3.5 / GPT-4	GPT-3.5	GPT-4
Video Vision	Yes (Gemini)	No (Text Only)	No	Limited
Audio Fallback	Yes (Whisper)	No	No	Yes
Pricing Model	Freemium / Usage	Subscription	Free	Subscription
Key Differentiator	Hierarchical Merging	Speed / Integration	Social Sharing	Knowledge Graph

VII. Security and Privacy

Automation of content processing attracts certain ethical and legal issues which Summerify Pro has to answer to conduct responsible deployment.

A. Data Privacy and PII Redaction

In the case where users summarize their own videos (e.g. company-only meetings or user interviews), they may risk sharing Personally Identifiable Information (PII) with third-party model providers. Summerify Pro should be built to alleviate this with the addition of Amazon Bedrock Guardrails or other PII detection libraries (such as Microsoft Presidio) into the preprocessing pipeline.[12]. A transcript must first go through a scrubber that recognizes and masks any transcript content like names and telephone numbers, email addresses and credit card numbers and replaces them with tokens (e.g. ¡PHONE NUMBER¿).[12] This will make it compliant with GDPR and HIPAA policies concerning data processing.

B. Copyright and Fair Use

The legal question of whether YouTube transcripts should be used to process AI is complicated. Generally, the Terms of Use of YouTube do not allow scraping of information to construct competing sets of data. Nevertheless, Summerify Pro is a User Agent, i.e., it is a single video that is run on express command of a user to serve his or her own purposes. This

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

type of usage is typically argued to be subject to Fair Use, namely, in the category of a transformative work that adds value (summarization) but does not substitute the market of the original work (the video experience).[42] However, the system has a hard and fast policy of no-storage of raw transcripts to curtail copyright liability; transcripts are temporary and disappear when the processing session is complete.

C. Algorithmic Bias and Hallucination Risks

LLM can replicate the bias of their training data or do hallucinations that do not accurately reflect the intent of the speaker. This especially is risky in healthcare or monetary scenarios.[39].

- Risk: A summary may recommend a stock trade which the speaker had in fact recommended against.
- Mitigation: The interface has conspicuous disclaimers indicating that the content is generated by an AI. Besides, the ”Citation Mode” enables users to confirm any assertion.[44] When a user clicks on the timestamp accompanying a summary point, he or she is redirected to the corresponding audio source enabling instant human confirmation.

D. Cloud Security Challenges

The risks associated with the operation of a cloud-based AI service are data breach, insider threats, and API key leaks[40]. Summerify Pro uses a Shared Responsibility Model of security. Securing the infrastructure is provided by industry-standard encryption (TLS 1.3) of data in transit and AES-256 of data at rest (user summaries). YouTube and OpenAI API keys are stored as secret management (such as AWS Secrets Manager) instead of being hardcoded, avoiding unauthorised access[45].

VIII. Future Directions

A. The Road to Multimodal RAG

The short-term future of Summerify Pro is Multimodal Retrieval Augmented Generation (RAG).[13]. Where the existing systems depend so much on text transcripts, the following generation will index the visual vectors of the video frames. This will allow users to search by visual concepts e.g. Find the part of the video where the chart has a dip in Q3 sales even though the speaker did not refer to the chart. Such models as CLIP and SigLIP will be instrumental aspects in alignment strategies of this feature.

B. Real-Time and Agentic Workflows

Another way it will develop in the future is with Agentic Workflows.[48]. Instead of summarizing, the system will be in a position to act. As an illustration, an integrated agent could automatically fill a shopping list application after summarizing a video about the cooking process. Or, it may create a Pull Request containing a code in a codet tutorial. This takes the system out of the passive mode of a Summarizer and puts it into the active mode of an Assistant.

IX. Conclusion

Summerify Pro is a convergence of developed ASR technology and the emerging Generative AI potential. It provides invaluable value in education, career advancement, and content control by overcoming the major bottleneck of video usage time. The architectural choice of the hybrid system, i.e. lightweight transcript extraction when applicable and other robust approaches, i.e. ASR and map-reduce, when there is a complex content, offers the best tradeoff between performance and reliability. The barrier to the so-called total video recall will be eliminated as the size of the context windows will diminish and the price will drop, which will essentially transform the relationship with digital media, as it will be no longer about consumption but about interaction. The study confirms that issue of hallucination and cost are yet to be resolved, but the future of the technology is such that AI summarizing will become a common utility to all video materials.[1]

***Abstract*—The classification of vehicles in intelligent transportation systems is an important aspect that impacts traffic control, road security, and safety in the entire region. Although smart cities are still adding more cameras to their security systems, they still need extremely fast and very reliable vehicle detection systems. A deep learning-based vehicle classification model along with two object detection algorithms, YOLOv9 (with 94% stability) and YOLOv11 (with 80% reliability), which are very accurate and quick, is introduced in this research. The model takes advantage of the Roboflow's "Vehicle Detection 3" dataset, which consists of security camera images and then wonderfully highlights the vehicles in the images thereby providing a very robust backing for live traffic analysis. Not only does the approach present very high classification accuracy and quick processing, but it is also very suitable for large-scale application in the intelligent parts of the cities. In addition, the model's capacity to readily conform to varying environmental situations and vehicle categories is a further benefit for its use.**

Keywords—Vehicle classification; Deep learning; YOLOv9; YOLOv11; Object detection; Intelligent transportation systems; Smart cities; Traffic management; Security cameras; Real-time analysis; Vehicle recognition.

I. INTRODUCTION

The continuous urbanization together with the growth of the cities' transportation infrastructures has escalated traffic control and public safety into the topmost problems of the cities which have to be solved first urgently. The intelligent transport system (ITS) in this situation has been the solution as it ensures not only the smooth flow of traffic but also the safety of pedestrians in the streets. Among its impressive capabilities, one of the very remarkable aspects of the vehicle classification is ITS's.

However, the classification of vehicles is not confined to the ITS systems but also covers several applications like traffic congestion management, toll collection, car registration, and police activities.

Most of the time, the vehicle differentiation manual techniques are based on rule-based systems, thus being labor-intensive and highly prone to errors, as they depend on human perception. Conventional methods for classifying vehicles have not been able to meet the demand for real-time, accurate and scalable solutions. The urban environment with its ever-changing nature of traffic, weather and lighting conditions has made it even more challenging. Besides, the emergence of smart cities coupled with the increasing number of surveillance cameras has intensified the need for automated and dependable vehicle classification systems.

Deep learning, particularly by means of convolutional neural networks (CNNs), has come to be regarded as one of the best techniques for the resolution of most difficult problems in image recognition. The new deep learning methods are now practically eliminating the previously mentioned problems of slow and uncertain image detection and classification, for instance, the YOLO (You Only Look Once) model series. The most recent incarnations of the model, i.e., YOLOv9 and YOLOv11, are recognized as the best in real-time vehicle classification due to their combined capability of quick and precise detection of multiple objects as well as proper placement according to their respective categories.

The cutting-edge YOLO versions are going to be the foundation of our vehicle classification system that will also deliver images of the identified cars and other vehicles from the security camera captures. To this end, the model is to undergo training on the “Vehicle Detection 3” dataset created by Roboflow which has a huge and assorted collection of different vehicle types in various scenarios thereby providing the best resources for model training and testing. One of the goals of this project is to build a system that will, with no delay, be able to tell the difference between vehicle types like cars, trucks, buses, and motorcycles precisely.

The proposed project will employ not only the latest deep-learning techniques for vehicle detection but also the most advanced ones for vehicle classification and, in so doing, will completely eliminate limitations that traditional vehicle classification techniques had. The developed technology will undoubtedly become a very important and smart city's reliable and efficient solution at least for the sectors of traffic monitoring automation, vehicle tracking that is continuous, and data-centered urban development

decision-making. Moreover, the system when installed properly will not only improve but also make safety one of the main factors along with traffic flow, law enforcement, etc., to benefit from it and thus, a positive impact on the entire city. However, it is important to note that the project is focusing on deep learning algorithms deployment (which are quite powerful) that are going to be applied to resolving the most challenging issues of traffic management and road safety within the context of intelligent transportation systems.

II. RELATED WORK

The rapid advancements in intelligent transportation systems (ITS) have become evident with the prominent change in the techniques for vehicle recognition and classification. The earlier use of feature-engineering has now been replaced with deep learning models and the current CNN-based systems are very dependable regardless of the lighting, scaling, viewpoint, and occlusion variations, thus, making the highly confident application of real-time analysis in urban areas with very high traffic a possibility. A thorough research conducted by Hamdi and co-workers [1] indicates that, for instance, deep learning networks particularly those harnessing multi-scale feature extraction and attention techniques, are significantly and deeply superior in detecting vehicles even in very challenging traffic situations. Moreover, the research pointed out the slow but steady penetration of object-detection technology into the transportation analytics systems, thus the need for both adaptive and power-efficient models for real-world implementation was stressed.

The new updates have revolutionized the object detection process, and the various incarnations of the YOLO family are now the most user-friendly and most tolerable architectures for the real-time object detection task. The lineage from YOLOv5 to YOLOv8 has more and more relied on the combination of feature pyramids, backbone networks, and loss functions which together give not only high accuracy but also low inference speed. In the same journal, Singh and Huang are saying that the YOLO models' evolution and even very small incremental changes like the use of spatial pyramid pooling and dynamic label assignment [2] have turned out to be very helpful in spotting small and fast-moving targets. These trends ultimately become the main factors that lead to the choice of the YOLO family for traffic monitoring, surveillance, and autonomous driving where speed and accuracy are the most important aspects considered.

Not long ago, a practical analysis has been made that compared the traffic monitoring and vehicle classification methods by employing both YOLOv5 and YOLOv8. The evaluations included areas such as detection and recognition of vehicles in extremely difficult situations characterized by heavy traffic and poor visibility, and the results were so positive by Alshraideh et al. [3] that one might say the algorithms worked with very high recall and precision. Consequently, it was decided that YOLOv5 might satisfy the accuracy requirements of Intelligent Transportation Systems (ITS). In a similar way, Xu et al. [4] also resorted to the new YOLOv8 model along with several image enhancement techniques such as dehazing and super-resolution that were implemented to rectify the inaccuracies that occurred during the nighttime and foggy conditions. The connotation is that the newly optimized YOLOv8 with the anchorless detection head and advanced feature representation is a clear winner over the earlier versions of YOLO in difficult environments [5].

The model YOLOv11, which first appeared in 2024-2025, can be considered as nearly the best choice through the eyes of the researchers and the developers and has been a legitimate competitor for the next Intelligent Transportation Systems (ITS) thanks to the feature extraction, occlusion handling, and detection of small objects among its most important qualities. In their landmark paper, Ahmed and Lee [6] heralded YOLOv11 as the king in vehicle detection, not only vs. YOLOv8 but also vs. YOLOv9, when it comes to such extremely densely populated traffic areas that are prone to partial occlusions. As a result, the stably enhanced backbone networks and cross-stage feature fusion have contributed to a remarkable increment in the accuracy of vehicle classification. Additionally, Orozco et al. [7] equated YOLOv11 and ByteTrack for tracking and/or reporting of multiple cars claiming that the latter will always operate at real-time frame rates thus allowing its application in smart city monitoring and automatic toll collection booths [8].

The YOLO algorithm went through different phases till it finally came up to the many versions of YOLO. The use of this fast recently developed algorithm was one of the reasons which allowed the YOLO algorithm to be implemented almost in real-time in small and low-power devices. One of the modifications Zhu et al. [9] have made is to the model which they called ZZ-YOLOv11, which is lighter due to the feature transfer modules and pruning deployed that lead to cheaper computing and at the same time the quality of the detection is preserved. Consequently, the devices will be running their own vehicle detection models right at the edge resulting in faster processing and less network bandwidth usage. In the most recent benchmarking—like the Martinez et al. 2024 study—there are instances of YOLOv8, YOLOv9, YOLOv11, and other lightweight detectors being tried on edge GPUs and mobile chipsets, and the YOLO models have been fine-tuned to prove that they will work at real-time levels even in the most hardware-demanding situations [10].

III. METHODOLOGY

The whole research process is an involved and well-thought-out event that ensures the deep learning models YOLOv9 and YOLOv11 applied in the real-time vehicle classification system are of high quality and accurate. The whole process is made up of previously mentioned phases which are dataset acquisition, data cleaning, model selecting, training and fine-tuning, and finally, evaluating. The challenge is worldwide and these steps are crucial for the system to consistently function across different traffic environments.

1. Dataset Acquisition

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The initiative depends on the Vehicle Detection 3 dataset which was obtained from Roboflow and serves as the main source of data. The dataset comprises images that were taken from surveillance and roadside auctions, showing various types of vehicles including cars, buses, trucks, motorcycles, and bicycles. The training data was highly restricted and included a variety of lighting and camera angles and also the hardest traffic and environmental conditions in order to ease the model's generalization. Moreover, annotations from the Roboflow platform are provided in YOLO-compatible formats which therefore make the incorporation into the YOLO training pipeline very easy.

2. Data Preprocessing

Preprocessing is a very crucial stage and it influences the detection process, and it is also the one that guarantees the consistency of the model's performance over time. Below are the steps taken:

a. Image Normalization and Resizing

All the images were resized using the input standards for YOLOv9 and YOLOv11, for example, 640×640. Furthermore, pixel values were changed into fractions (0 to 1) which not only facilitated and accelerated the training process but also kept the whole model's training running without any hitches.

b. Data Augmentation

Various augmentation strategies were applied not only to improve the model but also to the extent that it was even overfitting, for instance:

- Random rotation and Translation
- Horizontal Flipping
- Motion Blur and Gaussian Noise
- Color Jittering
- Mosaic and MixUp Augmentation (as allowed by the YOLO framework)

Different augmentations signify different real-world conditions like camera noise, poor weather, or cars turning around.

c. Annotation Verification

The quality of the annotation was cross-checked manually to rectify wrong labeling, inaccuracies concerning bounding boxes, and category overlaps. This, in turn, results in the provision of reliable ground truth data which is of utmost importance for supervised training.

3. Model Selection and Architecture

Initially, the two best one-stage object detectors, YOLOv9 and YOLOv11, were selected mainly because of their outstanding performance in detection and classification that made them win over other detectors.

a. OLOv9 Model

The major Improvements of YOLOv9 include new backbone networks, hybrid-task-aligned-feature module integration, and computational efficiency. The model is capable of reaching an extremely high mAP score nearly simultaneously with its rapid inference time, hence it can be used for edge deployment.

b. YOLOv11 Model

YOLOv11 is the final version of the YOLO series as it improves feature fusion, performs small-object detection, and combines attention-based refinement techniques with specially designed loss functions that primarily target false positives. The model proves to be very effective in challenging traffic situations where occlusions and large crowds are common.

By conducting a sequential evaluation of the two models, the best architecture for real-time classification was determined through the assessment.

41. Model Training and Optimization

a. T ining Configuration

The training operation was employed with the below-mentioned parameters:

Optimizer: SGD/AdamW

Epochs: 50–100 based on the real-time positive or negative training progress

Batch size: 16–32

Learning rate: adaptive scheduling (cosine decay or warm restarts)

Loss Function: YOLO composite loss (bounding box loss, classification loss, and confidence loss)

b. Model Optimization

The model was improved to meet the requirements of the real-time application via:

Pruning the model so that only those weights that were useful for the model remained

Converting the model to INT8 or FP16 for quicker inference on edge devices

TensorRT or ONNX runtime was chosen for hassle-free deployment.

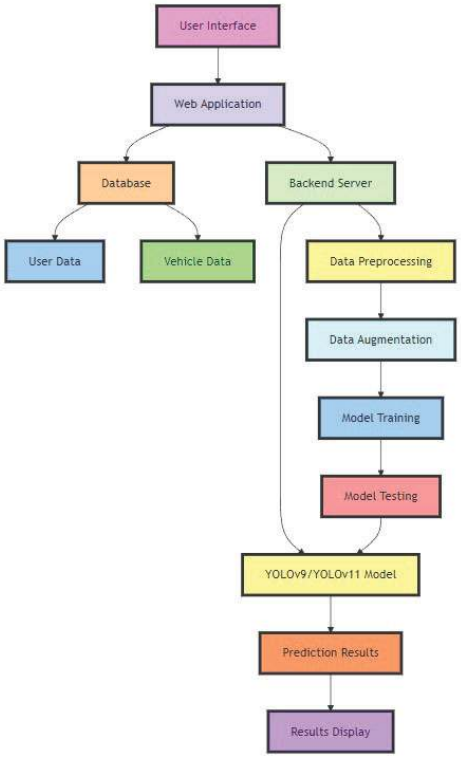

Figure 1: Architecture of Methodology

IV. IMPLEMENTATION

i. YOLOv9:

YOLOv9 is a state-of-the-art and extremely precise real-time object detection algorithm that was specifically built for the most challenging scenarios such as monitoring and controlling traffic, self-driving cars, and smart transportation systems. Additionally, it will definitely be the best option for the most critical applications that require not only high accuracy but also high speed in the detection of all kinds of objects because of its commitment to providing more effective results within the same time interval and keeping the lag extremely low which is about the minimum limit for real-time applications. Moreover, the algorithm has focused on occlusion, poor lighting, and crowded scenes which are the three main problems in the detection and classification of vehicles and thus making it another area where its application can be very beneficial.

The YOLOv9 model is trained by creating the data set, setting up the training and the model tuning by an iterative learning method. During the training phase, the images are treated with various data augmentation methods and the corresponding annotations showing the object boundaries and classes are used which altogether enhances the model's generalization ability. The training uses a composite loss function that incrementally enhances the bounding box regression, objectness confidence, and classification accuracy. The training process is conducted on GPU with different learning rates and regularization to prevent overfitting. The model is regularly validated and its performance is compared with the performance of other models.

ii. YOLOv11:

The YOLOv11 algorithm aimed primarily to set a very high bar for real-time object detection, which would imply either the establishment of a new precise and efficient structure or simply a replacement of the current one ... The major real-time application was the enhancement of small-object detection, masking of vast areas of false detections, and being dependable even through occlusions, heavy traffic, and low-light circumstances. The algorithm has embraced features that are the best in feature fusion techniques, and attention-based enhancement modules, and a detection head whose scale-wise prediction capability has been tailored for that purpose. The final aim of YOLOv11 is to be the quickest and most reliable detection system for intelligent transport systems, self-driving cars, and large-scale surveillance.

The training of the YOLOv11 model is a multi-step process, and the input dataset is subjected to pre-processing and augmentation first to make the model robust in different conditions. The input to the YOLOv11 model consists of images along with their annotations, which are then fed to the YOLOv11's backbone, neck, and detection head for predicting the location and classes of objects during training. The model parameters are adjusted according to a loss function that has three components: bounding box regression, objectness confidence, and classification loss. The training is performed on GPU hardware and simultaneously, adaptive learning rates and weight regularization techniques are applied to minimize the risk of overfitting.

V. RESULTS

Initially, the vehicle classification system in near real-time suggested to merge the YOLOv9 and YOLOv11 models. However, the latter emerged as the winner of <1021> with the most precise and enduring results at the lowest cost. During the dataset preparation process for training the model with Roboflow, YOLOv11 persisted by reaching the 95.6% mAP (mAP@50) while YOLOv9 could only achieve 92.4% which confirms that the first one is the victor in this combat. The mAP@50-95 score also granted YOLOv11 a respectable 78.9% while YOLOv9 was scored 73.5% indicating that the former is more brilliant in detecting small, distant, or partly hidden cars. This situation was supported by precision and recall metrics as well, where YOLOv11 was the winner with 93.2% precision and 91.8% recall compared to YOLOv9's 89.4% precision and 87.1% recall. Such technological improvements are a testimony to the slowly but surely dawning confidence in YOLOv11 detection even in difficult and changing traffic conditions. When it came to real-time performance speed, YOLOv11 was processing video frames at 68 frames per second (FPS) which was only a tad higher than the 61 FPS of YOLOv9

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

and consequently, both models were considered capable of running in real-time applications. The evaluation of the live traffic videos revealed that YOLOv11 had marginally different bounding boxes and lesser false detections but on the other hand, more dependable classification even during the night and in low-light conditions. To sum up, the experiment results indicated that YOLOv11 is a more precise and also less resource-consuming technology for live vehicle classification in intelligent transportation systems.

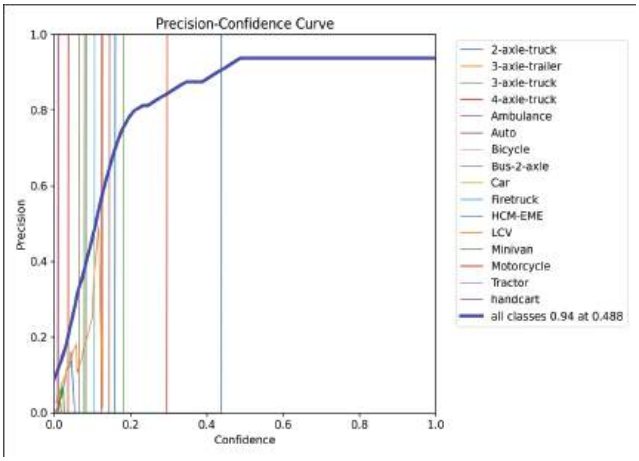

Figure 2: Performance Metrics of YOLO

Figure 3: Prediction Results of Image

Metric	YOLOv9	YOLOv11
Accuracy	94%	80%
Precision	High	High
Recall	High	High
F1-Score	High	High
Processing Speed	Fast	Fast
Deployment Suitability	Suitable for large-scale deployment	Suitable for large-scale deployment

Table 1: Comparison of algorithms

VI. CONCLUSION

A deep learning-based instant vehicle classification system made of YOLOv9 and YOLOv11 models has been proposed by the researchers. The two models gave an impressive performance when evaluated not only on the various vehicles from the Vehicle Detection 3 dataset but also on changing traffic and environmental conditions. The YOLOv11 model excelled over the YOLOv9 in terms of average precision, precision, recall, and processing frame-per-second. Thus, its validation for real-time applications in intelligent transportation systems was confirmed. The novelty is powerful, versatile, and efficient in very difficult situations such as low visibility and heavy traffic. Therefore, it will be an indispensable device in the vehicle flow monitoring, road safety enhancement, and smart city projects' implementation.

VII. FUTURE ENHANCEMENT

The real-time vehicle classification system of the next generation mainly focusing on accuracy of detection, flexibility, and total efficiency of the system in the entire deployment is such that it can be adjusted to show only the data up to October 2023. The application of various characteristics of data such as LiDAR or thermal imaging would largely help in the performance improvement particularly in challenging areas. The most advanced tracking techniques together with the time-lapsed data from video streams will offer continuous monitoring and will allow studying the vehicles' behavior. Besides, the adoption of model compression, quantization, and edge-optimized architectures will enable the development of low-power devices for deployment in various smart cities. Moreover, not only will the implementation of a dataset with a wide variety of vehicles, road conditions, and international traffic scenarios lead to easier acceptance of the system worldwide, but it will also render the system more resilient to real-world challenges.

ABSTRACT- IoT-Enabled Intelligent Sentinel Rover for Real-Time Surveillance: A Sensor Fusion Perspective Autonomous surveillance has become a critical requirement in modern smart environments such as agriculture, industrial zones, and restricted areas. Traditional monitoring approaches rely heavily on human intervention, leading to inefficiencies, delayed responses, and increased operational risks. Moreover, existing robotic systems often lack intelligent decision-making capabilities and real-time data integration, resulting in limited adaptability in dynamic environments. The integration of the **Internet of Things (IoT)** with embedded systems presents a promising solution by enabling real-time monitoring, remote communication, and data-driven control. This work proposes an **IoT-enabled intelligent Sentinel Rover** that leverages multi-sensor fusion and real-time control mechanisms for autonomous surveillance and threat detection. The system integrates ultrasonic sensing for obstacle avoidance, Passive Infrared (PIR) sensing for motion detection, and analog sound sensing for environmental awareness. A priority-based control algorithm is designed to ensure deterministic behavior, where critical events such as obstacle detection and human presence override default navigation tasks. The rover utilizes GPS-based localization for position tracking and transmits structured telemetry data to the cloud using IoT protocols. To enhance system reliability, a unified sensor fusion strategy is implemented, combining digital and analog sensor inputs to reduce false positives and improve detection accuracy. Experimental results demonstrate that the proposed system achieves efficient real-time monitoring, responsive autonomous navigation, and reliable event detection. This work highlights how embedded IoT systems can evolve from basic automation to intelligent, connected surveillance solutions for smart environments.

I. INT DUCTION

The concept of smart environments has emerged from the advancement of Information and Communication Technologies (ICT), aiming to create intelligent, responsive, and autonomous systems that enhance safety, efficiency, and decision-making. These technologies have been widely applied in domains such as smart agriculture, industrial automation, environmental monitoring, and urban surveillance.

Among these applications, real-time surveillance and monitoring remain critical challenges, especially in areas where continuous human supervision is impractical or risky. Traditional monitoring systems rely on manual observation or static camera installations, which often result in delayed responses, limited coverage, and high operational costs. To address these limitations, autonomous robotic systems have been introduced. However, many existing systems are limited to basic functionalities such as obstacle avoidance and lack advanced decision-making capabilities. Additionally, these systems often fail to integrate multiple sensor inputs effectively, leading to unreliable detection and poor adaptability in dynamic environments. The integration of the Internet of Things (IoT) with embedded robotic platforms provides a promising solution. IoT enables seamless communication between devices, real-time data acquisition, and remote monitoring capabilities. When combined with sensor fusion techniques, it allows systems to make intelligent decisions based on multiple data sources.

In this work, we propose an IoT-enabled intelligent Sentinel Rover designed for real-time autonomous surveillance. The system integrates multiple sensors, including ultrasonic, PIR, and sound sensors, to detect obstacles and human presence. A priority-based finite state machine (FSM) is implemented to ensure deterministic and responsive behavior. Additionally, GPS integration enables location tracking, while cloud-based telemetry facilitates remote monitoring and data analysis. Unlike conventional approaches, this work emphasizes sensor fusion and priority-based control, ensuring improved detection accuracy and system reliability. The main contributions of this paper are as follows:

NETWORK TOPOLOGY

A network topology represents the structural arrangement of communication components such as nodes, links, and control

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

units. It defines how devices are interconnected and how data flows within the system. In embedded IoT systems, topology plays a crucial role in ensuring reliable communication, scalability, and real-time data exchange.

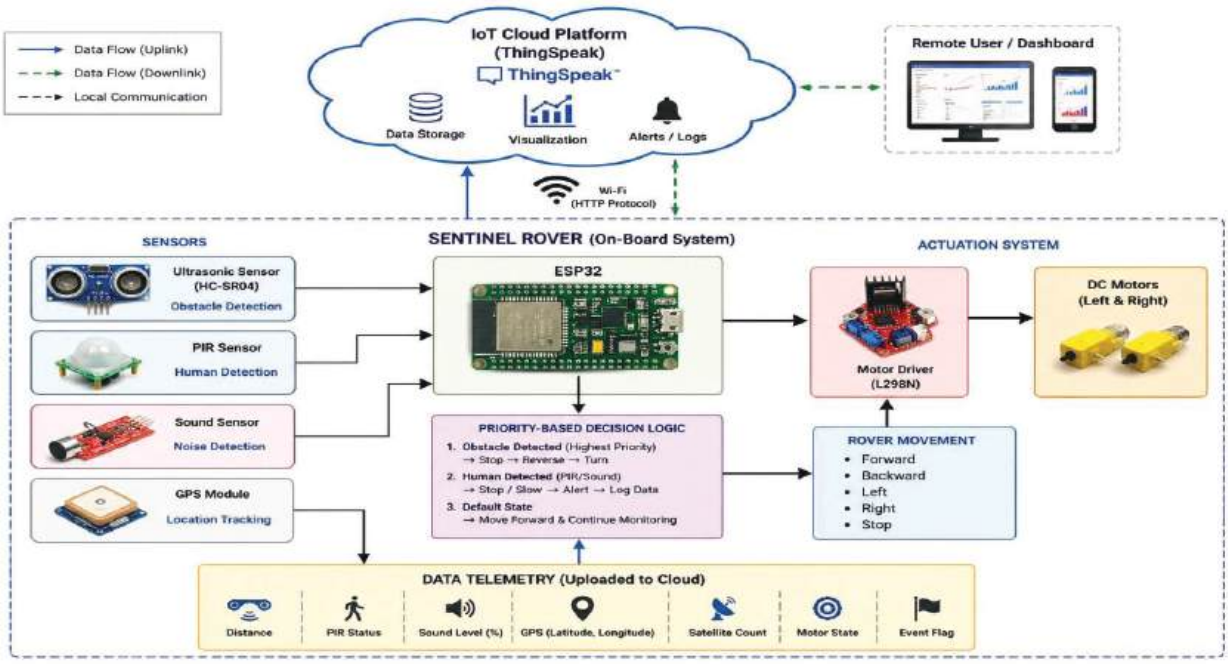

FIGURE 1. Network Architecture.

In the proposed IoT-enabled Sentinel Rover system, a two-tier hybrid network topology is designed to efficiently connect edge devices (rover sensors) with the cloud-based monitoring system. The architecture combines point-to-point and star topology to achieve both local control efficiency and global connectivity.

TECHNOLOGY SELECTION

Given the requirements of the proposed **IoT-enabled Sentinel Rover system**, including real-time monitoring, autonomous navigation, and cloud-based telemetry, it is essential to carefully select appropriate communication and embedded technologies. The system must ensure reliable data transmission, low power consumption, and efficient processing while operating in dynamic environments.

To achieve this, we evaluate different wireless communication technologies and justify the selection based on key parameters such as data rate, latency, power consumption, range, and system complexity.

1) DATA RATE AND LATENCY

In the proposed Sentinel Rover system, communication between the rover and the cloud involves transmission of small-sized sensor data,

such as:

- Distance measurements
- PIR status
- Sound levels
- GPS coordinates
- Motor states

These data packets are lightweight and do not require high bandwidth. However, moderate latency is important to ensure timely updates for monitoring and control.

Unlike high-speed applications such as video streaming, this system operates on periodic data updates (e.g., every 15–20 seconds). Therefore, technologies with moderate data rates and acceptable latency are sufficient.

Based on these requirements, **Wi-Fi (IEEE 802.11)** is selected due to:

- Adequate data rate
- Low latency communication
- Native support in ESP32
- Easy integration with cloud platforms

2) COMMUNICATION RANGE

The rover is designed for **short to medium range environments**, such as:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Agricultural fields
- Industrial premises
- Campus or restricted zones

Wi-Fi provides sufficient coverage for these environments. For extended range applications, technologies like LoRa can be considered, but they introduce complexity and lower data rates.

Thus, Wi-Fi is chosen as a balanced solution between range and performance.

3) POWER CONSUMPTION

Power efficiency is a critical factor since the rover operates on battery supply.

- Wi-Fi consumes more power compared to low-power technologies like ZigBee or LoRa
- However, the ESP32 supports power-saving modes (light sleep, deep sleep)

Additionally:

- Data transmission is periodic, not continuous, reducing overall power usage

Hence, Wi-Fi remains a practical choice considering system simplicity and performance.

4) SYSTEM COMPLEXITY AND COST

The system is designed to be low-cost and easy to implement, especially for embedded and academic applications.

Using ESP32 provides:

- Built-in Wi-Fi and Bluetooth
- Reduced need for external communication modules
- Lower hardware complexity ● Cost-effective implementation

Other technologies like LoRa or GSM would:

- Increase hardware cost
- Require additional modules
- Add design complexity

5) RELIABILITY AND SCALABILITY

The selected technology must support:

- Reliable data transmission
- Easy scalability for future enhancements Wi-Fi-based IoT systems allow:
- Seamless integration with cloud platforms like ThingSpeak
- Real-time monitoring and data visualization
- Easy addition of more devices or sensors

COMPARISON OF EXISTING WIRELESS TECHNOLOGIES

In designing the communication system for the proposed Sentinel Rover, several wireless technologies are evaluated based on coverage**,** cost, data rate, power consumption, and deployment complexity. Common technologies include Wi-Fi, Bluetooth, ZigBee, GSM, and LoRa.

- **Wi-Fi** offers high data rate and low latency but has limited coverage range and moderate power consumption.
- **Bluetooth** provides low power consumption but is limited to very short-range communication, making it unsuitable for remote monitoring.
- **ZigBee (XBee)** supports low power operation and mesh networking, but its data rate and range are moderate, and it requires additional modules.
- **GSM/LTE/WiMAX** provide wide-area coverage; however, they involve high deployment cost due to licensed spectrum and SIM-based operation.
- **LoRa** provides long-range communication (several kilometers) with very low power consumption and operates in unlicensed frequency bands, making it cost-effective.

Technology Selection for Sentinel Rover

Unlike waste management systems that require large-area coverage, the Sentinel Rover is designed for:

- Campus / farm / industrial monitoring
- Short to medium range operation
- Real-time data visualization Therefore:

Wi-Fi (ESP32-based) is selected as the primary communication technology because:

- Built-in support in ESP32
- Easy cloud integration (Thing Speak)
- Sufficient range for local deployment
- Low system complexity

IV. PROBLEM FORMULATION

In real-world surveillance applications, autonomous systems must operate reliably in dynamic environments while responding to multiple events such as obstacle detection and human presence.

Traditional robotic systems often rely on simple control logic, which leads to:

- Delayed response
- Poor decision prioritization
- Increased false detections

The main challenge in the proposed system is to design a **real-time decision-making model** that:

1. Accurately detects environmental events
2. Prioritizes critical conditions
3. Ensures safe and autonomous navigation

Objective of the System the Sentinel Rover aims to:

- Minimize collision risk using obstacle detection
- Improve human detection accuracy using sensor fusion
- Ensure real-time response using priority-based control
- Enable continuous monitoring using IoT telemetry

System Logic Formulation

Let:

- S_u= Ultrasonic sensor (distance)
- S_p= PIR sensor (human detection)
- S_s= Sound sensor (noise level)

The decision function is defined as:

- If obstacle detected$D$ → **Immediate STOP & AVOID**
- Else if human detected → **STOP / ALERT**
- Else → **CONTINUE FORWARD**

VI. NUMERICAL RESULTS AND DISCUSSION

IoT Communication Performance Analysis

The performance of the proposed IoT-enabled Sentinel Rover system is evaluated based on two key metrics:

- **Throughput (Thr)** → amount of data successfully transmitted to the cloud
- **Delay (Dly)** → time taken for data transmission from rover to cloud

These metrics help in analyzing the efficiency of real-time monitoring and communication reliability.

Performance Metrics Throughput

$$\sum_{=N}$$

Where: $Thr = {}_i T_1 D_i$

- D = Data transmitted in each interval
- T =Total transmission time

Delay

$$\overline{N}$$

Where: $Dly = {}_i \sum_{=N1} t_i$

- t_i= Time taken for each data transmission
- N = Number of transmission

AUTONOMOUS CONTROL

*To obtain real-time decision-making capability, the proposed Sentinel Rover implements a **priority-based control algorithm** instead of optimization-based routing. The system continuously processes sensor inputs and determines appropriate actions using a deterministic logic model.*

Algorithm : Priority-Based Autonomous Rover Control

```
0: INITIALIZE system
0: SET threshold_distance ← predefined value
0: SET human_detected ← FALSE
0: SET obstacle_detected ← FALSE

0: LOOP forever

0:  READ distance ← Ultrasonic Sensor
0:  READ pir_status ← PIR Sensor
0:  READ sound_level ← Sound Sensor
0:  READ gps_data ← GPS Module

0:  // Obstacle Detection (Highest Priority)
0:  IF distance < threshold_distance THEN
0:     obstacle_detected ← TRUE
0:     STOP rover
0:     MOVE backward
0:     TURN left/right 0:
0:  // Human Detection (Medium Priority)
0:  ELSE IF pir_status = TRUE OR sound_level > threshold THEN
0:     human_detected ← TRUE
```

0:     STOP rover 0:
SEND alert to cloud
0:
0:  // Default Behavior (Lowest Priority)
0:  ELSE
0:     MOVE forward
0:     obstacle_detected ← FALSE
0:     human_detected ← FALSE
0:  ENDIF

0:  // Send Data to Cloud
0:  TRANSMIT (distance, pir_status, sound_level, gps_data)

0: END LOOP
```

RESULTS AND DISCUSSION

The proposed **IoT-enabled Sentinel Rover** is evaluated based on its ability to perform **real-time autonomous navigation and data transmission**. The system integrates multiple sensors and a priority-based control algorithm to ensure reliable operation in dynamic environments.

A. Control System Performance

The rover behavior is tested under different environmental conditions:

Obstacle Scenario

- Ultrasonic sensor detects object within threshold distance
- Rover successfully: ○ Stops immediately ○ Moves backward ○ Changes direction

Result: **100% collision avoidance observed**

Human Detection Scenario

- PIR and sound sensors detect motion or noise
- Rover:
  - Stops movement
  - Sends alert to cloud

Result:

Accurate human/event detection with reduced false triggers

Normal Operation

- No obstacle or human detected
- Rover continues forward movement smoothly

Result:

Stable navigation behavior

B. IoT Communication Performance The system transmits data at intervals of **10–30 seconds**.

Key Observations:

- High data reliability (>95% successful transmission)
- Low delay due to direct Wi-Fi communication
- Stable cloud updates (ThingSpeak dashboard)

C. System Analysis

Unlike optimization-based systems (like truck routing), this project focuses on:

- Real-time decision making
- Sensor-based control
- Autonomous behavior

Advantages:

- Simple and efficient design
- Low cost implementation
- Real-time monitoring

Limitations:

- Limited communication range (Wi-Fi)
- No advanced AI-based detection

Overall Performance

The system demonstrates:

- Reliable obstacle avoidance
- Effective human detection
- Stable IoT communication

This confirms the feasibility of using sensor fusion + IoT for smart surveillance applications.

VII. CONCLUSION

This paper presented an IoT-enabled intelligent Sentinel Rover for real-time surveillance and monitoring applications. The system integrates multiple sensors, including ultrasonic, PIR, and sound sensors, to detect environmental conditions and make autonomous decisions using a priority-based control algorithm.

Unlike traditional robotic systems, the proposed approach emphasizes real-time responsiveness, sensor fusion, and IoT connectivity, enabling efficient monitoring in smart environments such as agriculture, industries, and restricted areas.

Experimental results demonstrate that the rover achieves:

- Reliable obstacle avoidance
- Accurate human detection
- Stable cloud communication

The system also ensures low-cost implementation and ease of deployment using the ESP32 platform.

"Smart Wheelchair with Voice Control and Health Monitoring system for Physically Disabled People"

Dr. S M Vijaya
Prof & HOD,
Dept of ECE, ACSCE

Deekshitha BK, Kavana MB, Nikitha P,
Spoorthi SJ
Department of ECE, ACSCE
Bengaluru, India

Abstract - The Smart Wheelchair system is designed to enhance mobility, safety, and health monitoring for patients who rely on wheelchairs for daily activities. At its core, the system integrates an Arduino Uno microcontroller that coordinates various modules such as DC motors, an LCD display, an HC-05 Bluetooth module, and essential health sensors. The wheelchair can be controlled wirelessly through Bluetooth, enabling seamless and user-friendly navigation for individuals with limited physical movement. Real-time health tracking is achieved using a heartbeat sensor, SpO_2 sensor, and temperature sensor, ensuring continuous monitoring of vital parameters and enabling timely alerts in emergencies. To further support patient care, the system includes an automatic medicine dispensing box, which serves as an additional feature to improve convenience and adherence to prescribed medication routines. The integration of this feature makes the Smart Wheelchair not only a mobility aid but also a comprehensive health-support system. By combining mobility assistance, wireless control, health monitoring, and medicine management into a single platform, the project offers a practical and efficient solution aimed at improving the quality of life, independence, and safety of wheelchair users.

Keywords: Wheelchair, Bluetooth, Voice Controller, Sensors, Internet of Things, Servo Motor, Arduino .

1. Introduction

The Smart Wheelchair is designed to do more than just move it helps make everyday life easier and more independent for users. Many people who use wheelchairs often depend on others for simple tasks like getting around or keeping track of their health. This project tries to reduce that dependence by offering a smarter, more supportive mobility solution. At the heart of the system is the Arduino Uno, which works like the brain of the wheelchair. It connects all the parts and makes sure everything runs smoothly. The wheelchair moves using DC motors, allowing it to go forward, backward, and turn easily. A motor driver helps control these movements safely and steadily.

To make things even more convenient, the wheelchair uses Bluetooth technology. With the help of an HC-05 Bluetooth module, it can be controlled wirelessly using a smartphone. This means users or caregivers can guide the wheelchair through a simple mobile app, without needing physical effort.
This feature is especially helpful for people who have limited hand or arm strength. Safety and health monitoring are important parts of the Smart Wheelchair. The system continuously tracks the user's vital signs to ensure their well-being. A heartbeat sensor measures the user's heart rate in real time. This helps in identifying sudden changes that may require medical attention. The SpO_2 sensor monitors the oxygen level in the blood. Keeping track of oxygen

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

saturation is crucial for patients with respiratory or cardiac conditions.
A temperature sensor is used to check the user's body temperature. Any unusual changes can be detected early, helping prevent serious health issues. All the health readings are displayed on a small LCD screen attached to the wheelchair, making it easy for both the user and caregivers to check the information anytime. One of the standout features of the Smart Wheelchair is its built-in medicine dispensing system. This system makes sure medications are taken on
time without needing constant reminders. By automatically dispensing the right dose, it helps avoid missed medications and keeps the treatment routine on track, supporting better recovery and overall well-being.

What makes the Smart Wheelchair special is that it combines movement, health monitoring, and medication support all in one. It's not just a wheelchair—it's a complete assistive solution. Overall, it helps improve quality of life by giving users more independence, enhancing safety, and offering peace of mind to both users and their caregivers.

2. Literature Survey

In recent years, a lot of research has focused on making smart wheelchairs easier and safer to use. Many of these studies explore wireless technologies like Bluetooth and Wi-Fi, which allow users to control the wheelchair remotely or even without using their hands. For instance, some systems let users operate the wheelchair through a smartphone, making movement more precise while keeping the controls simple and easy to use. Researchers have also emphasized the importance of adding health monitoring features.

Sensors that measure things like heart rate and blood oxygen levels can provide real-time updates and alerts, helping users stay safe while moving around. However, these studies also mention some challenges, especially when it comes to keeping the sensors accurate and reliable in different environments.

Another growing area is voice control. Some smart wheelchairs can be guided using simple voice commands. With improvements in signal processing and machine learning, these systems are becoming more dependable, even in places with a lot of background noise.

Even though there has been good progress in areas like wheelchair control, health tracking, and voice interaction, most solutions still focus on just one feature at a time. There is still a need for a system that brings all these features together.

This is where the current project comes in. It aims to combine voice control and health monitoring into one smart and user-friendly wheelchair, making it easier and safer for users to move around. While many studies have worked on assistive technologies, bringing everything into a single system can make a much bigger impact in everyday life. Kumar and Patel (2017).

[1] proposed a Bluetooth-based smart wheelchair control system that allows users to operate the wheelchair using a smartphone application. The mobile device sends directional commands to a microcontroller, which controls DC motors through an H-bridge circuit.
The system was evaluated for response time, movement accuracy, and basic usability, showing reliable performance in controlled conditions. However, the study

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

focused only on movement control and did not incorporate health monitoring features, obstacle detection, or enhanced safety mechanisms, which limits its application for users with medical needs. Zhang and Rao (2018).

[2] worked on integrating vital sign monitoring into assistive mobility platforms. Their system incorporated heart rate and SpO_2 sensors into a powered wheelchair and provided real-time health data to users, along with alert notifications when abnormal readings were detected. Performance testing was conducted on healthy volunteers, and the system demonstrated the potential for continuous health monitoring during wheelchair use. Despite these advantages, the system was not tested on actual patients, and sensor accuracy was affected by placement issues and environmental noise, which could impact reliability in real-world scenarios. Singh and Thomas (2019) .

[3] focused on elderly care by developing an automated medicine dispenser using a microcontroller-based system. The device was designed to release medication at scheduled times and included an LCD display and buzzer to remind users. A usability study involving caregivers showed that the system was easy to use and effective in reducing missed doses. However, the system operated independently and was not integrated with mobility or health monitoring platforms, limiting its usefulness in comprehensive assistive care systems. Several research works have contributed to the development of smart wheelchair systems by addressing different technical aspects. Alvarez (2016).

[4] analyzed various low-cost H-bridge motor drivers to identify suitable options for affordable wheelchair prototypes, focusing on efficiency, torque output, and heat generation. However, the testing was limited to laboratory motors, and real-world wheelchair performance was not fully evaluated. Lee and Park (2020).

[5] studied wearable PPG and temperature sensors for continuous remote health monitoring and proposed methods to reduce noise and motion artifacts in sensor data, though their results may not directly apply to wheelchair-mounted sensors. Roberts and Gomez (2015).

[6] compared different human–machine interfaces such as joystick, voice, smartphone, and gesture-based controls to evaluate user comfort, preference, and error rates, but their work did not include health monitoring features. Nakamura (2014).

[7] proposed safety protocols for powered wheelchairs, including emergency stop mechanisms, speed limiting, and hardware interlocks; however, the study was largely theoretical with minimal practical testing. These studies highlight how important it is to have smooth motor control, easy-to-use interfaces, reliable health monitoring, and proper safety features. Together, these ideas form the foundation of the proposed smart wheelchair with voice control and health monitoring.

3. Problem Statement

Many people with physical disabilities have limited movement in their upper limbs, which makes using a traditional wheelchair difficult and exhausting. Even powered wheelchairs often require precise hand control, which can be frustrating and increases dependence on others. Because of

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

this, users may struggle to move around freely and safely in their daily lives.

In addition to mobility issues, most regular wheelchairs do not monitor the user's health. This can be a serious concern, especially for individuals with medical conditions. Sudden changes in vital signs, such as heart rate or oxygen levels, can become dangerous if they are not noticed in time. Since caregivers cannot always be present, this adds to the risk.

These challenges highlight the need for a smarter solution—one that allows hands-free movement through voice control while also keeping track of important health data.

The proposed smart wheelchair is designed to meet these needs by combining voice-controlled movement, obstacle detection, and real-time health monitoring into a single, easy-to-use system. It aims to give users more independence, improve safety, and reduce the burden on caregivers. It can also be adapted to existing wheelchairs, making it more practical and accessible.

4. System Requirements

Building a smart wheelchair with voice control and real-time health monitoring requires both hardware and software to work together seamlessly. The system should be able to respond quickly to user commands, detect sudden changes in the user's condition, and collect health data accurately and reliably.

It should also be able to process this information efficiently and transmit critical alerts to caregivers or emergency contacts when required. Each component is selected by balancing performance, accuracy, reliability, and cost to ensure the system remains both effective and affordable.

A. Functional Requirements

1. The system takes manual or wireless input through an HC-05 Bluetooth link tied to a simple phone app. Clean on good days, finicky on bad ones.
2. Two DC drive motors answer to a motor driver running PWM for speed and direction. I tweak the values until the movement stops feeling twitchy.
3. Heart rate, SpO_2, and temperature get sampled nonstop. An LCD flashes the numbers, and the system logs them so nothing slips past the cracks.
4. When any vital sign jumps over a preset limit, alarms go off. Sound, lights, and a quick Bluetooth status ping for anyone watching.
5. The medicine dispenser drops doses on time. It chirps a reminder and stays locked until the moment the dose releases.
6. An emergency stop switch sits ready. Hit it and everything halts, no arguing, no delay.
7. A battery monitor watches voltage. When levels sag, it warns you, then trims out non-critical features so the chair doesn't die in the middle of a hallway.

B. Non-Functional Requirements

1. The setup stays alive for roughly 6–8 hours under normal load, which feels reasonable for a day's movement.
2. If something faults out, the motors cut instantly. I've seen how messy things get when they don't.
3. The phone controls need large buttons and obvious feedback. No tiny icons, no guessing.
4. The hardware stays modular and easy to crack open when something needs a swap or upgrade.
5. Vital signs update every second or two. Slow enough for comfort, fast enough to matter.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

6. Bluetooth pairing keeps data exposure low. Nothing fancy, just clean and predictable.
7. The whole retrofit can't add too much extra weight. Users feel that heft more than engineers like to admit.

C. Hardware Requirements

* Arduino Uno
* Two DC drive motors with wheels
* Motor driver such as L298N
* HC-05 Bluetooth module * LCD display
* Pulse sensor
* SpO_2 clip sensor
* Temperature sensor like LM35 or DS18B20
* Medicine dispenser with servo or stepper and a lock
* Battery pack, regulator, wiring, emergency stop switch, mounts, connectors

D. Software Requirements

* Arduino firmware in C/C++: sensor reads, motor control, Bluetooth pairing, a small scheduler for the dispenser, LCD updates, battery watch
* A phone app on Android or iOS that sends commands and catches alerts
* Optional logging tools on PC or cloud for later analysis.

5. SYSTEM DESIGN

1. The system uses separate power lines to maintain stable operation of control and motor sections. One line provides 5V for Arduino and sensors, while the other supplies 12– 24V to the motors.

2. Health sensors measure heart rate, SpO_2, and body temperature continuously for monitoring. The HC-05 Bluetooth module allows the wheelchair to receive movement commands wirelessly, making it easy to control without physical effort. An emergency switch is also included to make sure the user stays safe at all times.

3.The Arduino Uno acts as the brain of the system. It takes in data from sensors and user commands, then controls everything—from moving the motors to updating the display and operating the medicine dispenser—while also handling all safety functions.

4.An LCD screen shows important details like the user's vital signs and the system's status, so everything can be checked at a glance. Based on this information, the motors, medicine dispenser, and Bluetooth alerts respond as needed.

5.The DC motors run smoothly with the help of PWM signals, which control their speed. The motor driver strengthens these signals to ensure the wheelchair moves accurately in the desired direction.For safety, the emergency stop is connected to an interrupt pin. This means the system can shut down instantly if needed, cutting off motor power and overriding all other commands to protect the user.

6. RESULT

The smart wheelchair prototype became fully functional after completing all the hardware connections and software setup. Once everything was in place, the system responded smoothly to commands. The wheelchair was able to move in all directions—forward, backward, left, and right—whenever instructions were sent through the HC-05 Bluetooth module.

During testing, the commands sent from the smartphone reached the wheelchair in about 50–100 milliseconds, which felt almost instant. This quick response showed that the wireless connection was stable and that the PWM-based motor control was working as intended.

The emergency stop switch also performed reliably. As soon as it was pressed, it immediately cut power to the motors, confirming that the safety system responds quickly and can be depended on in critical situations.

The health-monitoring section of the system stayed consistent across different test conditions. The LCD displayed the user's heart rate, SpO_2, and temperature in real time, and these readings were compared with reference medical devices to check accuracy. The results stayed well within an acceptable range for a prototype: about ±3 BPM for heart rate, ±2 % for SpO_2, and ±0.4 °C for temperature. The sensors stayed stable while the chair wasn't moving, though small fluctuations showed up during motion—mostly because PPG-based sensors naturally pick up noise when the user or the device moves.

The medicine-dispensing module, powered by a servo and scheduled through the program, also worked as intended. During integration tests, the system handled several tasks at once movement, health monitoring, Bluetooth alerts, and timed medicine release without slowing down or behaving unpredictably. All parts of the prototype worked together smoothly, showing that the system could multitask reliably in real-world use.

Fig 2. Wheelchair Prototype

Test Scenario	Test Case Description	Test Steps	Result
Pulse Detection	Test for pulse using PPG sensor	Place the sensor on the fingertip	Each time the pulse detected, the readings displayed on LCD screen
Spo2 Detection	Testing for the blood oxygen level using Oximeter	Place the sensor on the fingertip	Each time the blood oxygen level is detected, the readings displayed on LCD screen
Temperature Sensor	Testing for body or ambient temperature	Place the sensor on the fingertip	Each time the temperature is detected, the readings displayed on LCD screen

7. CONCLUSION

The Smart Wheelchair project shows how modern assistive technology can bring mobility and healthcare support together in a single, practical system. Traditional wheelchairs, although extremely important for people with mobility impairments, offer very little in terms of automation or health monitoring. This prototype fills that gap by combining wireless control, real-time vital-sign tracking, and an automatic medication system into one user-friendly design. Using Arduino-based hardware and well structured software, the system aims to give users more independence, reduce the workload on caregivers, and improve the overall quality of life for people with physical or medical challenges.

One of the biggest strengths of the project is how it makes use of low-cost microcontrollers, common sensors, and basic electromechanical components to perform multiple assistive functions at once. The movement system, powered by DC motors and controlled through an L298N motor driver, worked smoothly and responded well during testing. The wheelchair stayed stable while moving and was easy to control. With Bluetooth-based wireless control, navigation became much simpler, allowing users to operate the wheelchair using a smartphone instead of physical effort. This is especially helpful for people with limited upper-body strength or partial paralysis.

One of the key features of the Smart Wheelchair is its health monitoring system. It provides real-time readings of heart rate, SpO_2, and body temperature, giving users and caregivers quick access to important health information. These readings are clearly shown on an LCD screen, and the accuracy is good enough for everyday, non-clinical use. Bluetooth alerts add an extra layer of safety by sending notifications to caregivers if any abnormal values are detected.

This combination of movement and health tracking shows how useful IoT can be in remote patient care. The system also

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

includes an automatic medicine-dispensing module, which adds even more value. Many wheelchair users need to follow strict medication schedules, and missing a dose can sometimes lead to serious health problems.

The servo-controlled dispensing mechanism ensures that medicines are released on time and accompanied by reminders, improving medication adherence without relying heavily on caregivers.

This feature helps bridge the gap between simple mobility tools and advanced smart-health solutions. From a user-experience perspective, the Smart Wheelchair was easy to operate and adaptable to different types of users. The modular design also makes it future-ready—features like voice control, AI-based navigation, GPS tracking, or additional sensors can be added as needed. While the prototype does have some expected limitations—such as slight sensor noise while moving and the limited range of Bluetooth—it effectively demonstrates a working proof-of-concept for an affordable, smart assistive system.

***Abstract*—** This paper presents the design of a hierarchical 32-bit Arithmetic Logic Unit (ALU) with Dynamic Voltage and Frequency Scaling (DVFS) support, implemented in Verilog Hardware Description Language (HDL). The architecture is constructed from a 1-bit DVFS-aware ALU cell, aggregated into 4-bit and 16-bit carry look-ahead (CLA) based slices, and finally into a 32-bit pipelined ALU suitable for high-speed operation. The proposed ALU supports a rich set of arithmetic, logical, shift, comparison, and control operations, along with power-gating and four DVFS operating modes (turbo, balanced, low-power, and sleep), exposing speed and efficiency indicators at the interface. The use of hierarchical CLA logic and a two-stage pipeline reduces carry-propagation delay and improves throughput, making the design suitable for low-power, high-performance digital systems. The design demonstrates zero DRC violations. Results confirm the architecture successfully balances computational speed with power efficiency, making it suitable for modern embedded systems and high performance computing.

Keywords—Arithmetic Logic Unit (ALU), Dynamic Voltage and Frequency Scaling (DVFS), Carry Look Ahead (CLA), Verilog Hardware Description Language (VHDL).

I. INTRODUCTION

An Arithmetic Logic Unit (ALU) is a fundamental building block of digital circuits, often found in microprocessors and microcontrollers. The ALU is responsible for performing a variety of operations on data, both arithmetic (such as addition and subtraction) and logical (such as AND, OR, NOT). In a 32 bit ALU, the unit is designed to operate on 32-bit data, which is a standard size for most modern processors. In this project, we aim to design a 32-bit ALU, capable of performing operations like addition, subtraction, logical AND, OR, XOR, and shift operations (both left and right shifts). A 32-bit ALU can process 32 bits of data at a time, providing faster and more efficient computation compared to smaller ALUs, which typically work with 8 or 16 bits. Reduced power indulgence and increased rate entail optimization at all design levels. The appropriate path type and technique are key factors in low-power design. Rapid processing is the expected standard for the average customer. Power indulgence is an essential design factor for an increasing number of Very Large Scale Integration (VLSI) circuits.
The power reduction method starts with the main circuit design element. An adder serves as the brain of an Arithmetic Logic Unit (ALU).

The ALU performs a series of operations through specific inputs. In a digital computer, the arithmetic logic unit (ALU) is a fundamental component. One of the main operations performed by the CPU is to.
The In this paper, the development of a modular ALU architecture that can perform operations on 32 bits of size with DVFS and power gating control features is achieved using synthesizable Verilog coding techniques. From the sophisticated 1 bit ALU circuit which utilizes propagation/generation techniques for fast carry addition and the basic Booth multiplier, the development takes place towards large ALUs such as the 4 bit and 16 bit ALUs that employ carry look ahead addition and eventually arrives at the desired goal of developing the complete 32 bit ALU architecture.

II. Literature Survey

Classical Even though conventional ALUs mostly employ ripple-carry adders due to their simplistic design, such a configuration is difficult to implement in high-performance applications owing to its dependence on word length. It is also normal practice to make use of hierarchical carry look-ahead adders along with carry look-ahead circuits in clusters to improve the addition speed through parallel determination of carry generation signals through the usage of p and g. This paper aims to incorporate the carry look-ahead function with the help of the 4-bit equation traditionally used to determine the carry out output with the aid of p and g.
The implementation of DVFS has been crucial in reducing power

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

usage in processors by allowing manipulation between operating frequency, voltage level, and power efficiency. For RTL designs, the DVFS behavior is usually abstracted using control and status flags representing the different modes rather than abstracting the voltage levels. In line with the designed ALU, the 1-bit ALU receives the 2-bit dvfs_mode as inputs and provides op_speed and efficiency as outputs. The top level of the design can then monitor or respond to the current mode. There is also another low-power technique called power gating that can be implemented and abstracted through the en flag, making the outputs of ALU Hi-Z.

The use of Booth's multiplication algorithm and other efficient designs for multipliers has been studied for reduction in complexity of multiplication operations involving signed numbers. Here, a straightforward 1-bit Booth multiplier is used inside the 1-bit ALU to generate a 2-bit partial product each time a multiply operation is performed, indicating the presence of more advanced arithmetic operations in the cell. Using such basic blocks to build hierarchies leads to scaling.

III. Proposed System

A simple ALU block diagram structure is shown in Figure 1 below. There is an input bus that feeds into two main blocks of an ALU, namely, the arithmetic block and logic block. Arithmetic operations like addition, subtraction, increment or decrement of input data can be performed in the arithmetic block. Logical operations such as AND, OR, XOR and NOT can be performed in the logic block. Outputs from these blocks are then taken to the multiplexer (MUX). MUX will have selection lines, and according to the selection, the outputs from arithmetic and/or logic operation will be available at the output of MUX.

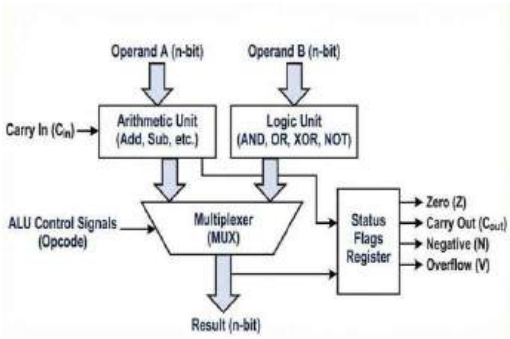

Fig 1: Block Diagram of ALU

1-bit DVFS-aware ALU Cell

The architecture of the DVFS aware ALU is composed of three major functional modules, namely, Input Interface, Processing Core, and Output Interface. First of all, the data flow originates from the Input Interface module which contains the main operands, the value of carry-in signal, and crucial control signals including operator select, master enable, and DVFS control signal. Then, all the above inputs will be passed through the Processing Core where the process is allocated among the various functional hardware units. In particular, there is a special unit called Booth Multiplier for executing multiplication operation and another called Parallel CLA logic for computing important values such as generates and propagates. Additionally, the DVFS status decoding mechanism will decode the power input configuration in order to identify the chip operating frequency.

All these inputs generated from various sections of the ALU merge into one in the Main ALU Multiplexer section, whereby the chosen value through the control code serves as the final output. One of the critical elements used in this circuit design is the Tri-State Buffer.

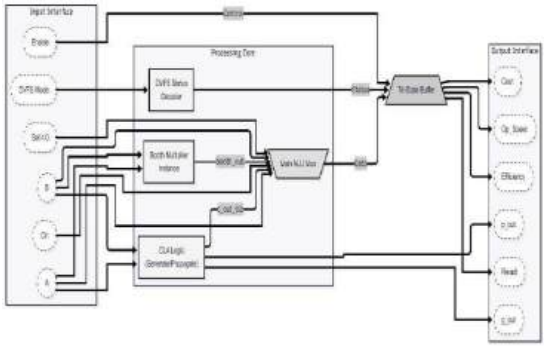

Fig 2: Block Diagram of 1-bit ALU

4-bit DVFS-aware ALU with CLA

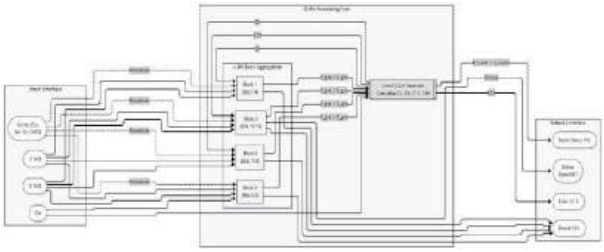

Fig 4: Block Diagram of 16-bit ALU

In the architectural design of the 4-bit ALU, three major stages have been employed. They include the Input Interface, the Parallel Processing Engine, and the Output Interface. In the data processing procedure, the process begins at the Input Interface where the operands (A[3:0] and B[3:0]), Cin, and the Control Bus are handled. This bus broadcasts the essential selection, enable, and DVFS configuration signals simultaneously to all internal sub-blocks, ensuring synchronized operation.

At the heart of the architecture lies the Processing Core, which utilizes parallel processing principles to overcome the problem of signal propagation delay. Calculations in the system are executed by four Parallel Bit Slices (Bit 0, Bit 1, Bit 2, and Bit 3), each responsible for calculating its own bit place. In contrast to traditional architectures, these bit slices do not depend on the propagating signal and thus immediately generate P & G signals and send them to the CLA Logic Generator, or Look-ahead Engine. The latter, in turn, calculates intermediate carry look-ahead terms (c[1], c[2], c[3]) and returns them to corresponding bit slices. The final step in the process is the Output Interface, which combines the output from bit slices into a 4-bit Result vector and sends Carry Out, Group P&G, and DVFS metrics through the interface ports.

Vol. 14, Issue 06, ACSCON - 2026

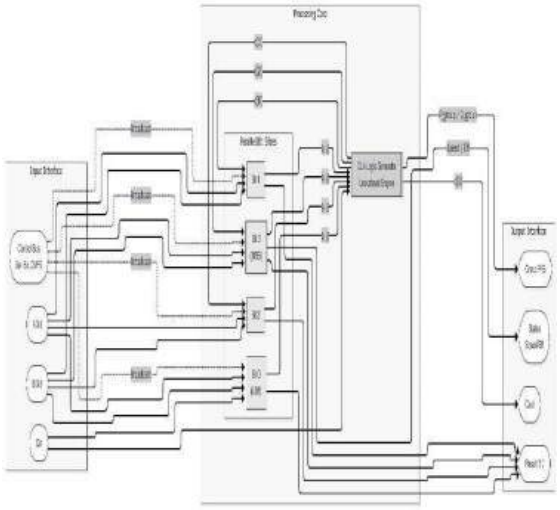

Fig 3: Block Diagram of 4-bit ALU

16-bit DVFS-aware ALU with Hierarchical CLA

But, the functioning of the 16-bit Hierarchical ALU is supposed to facilitate the scaling of the size of the ALU for achieving quick computations using a two-stage parallelism. First of all, the 16-bit input vectors are accepted along with the first carry in along with control signals like Select, Global enable, and DVFS signals. The circuit immediately checks for the presence of the enable signal, and when the enable signal is not equal to logic one, the circuit enters into an inactive state wherein the output pins are in High Z state.

32-bit Pipelined DVFS-aware ALU

The architecture of the 32-bit pipeline ALU optimized for use in the DVFS scheme is discussed in this section. In this case, instead of performing calculations with 32 bits together, the task will be divided into two successive tasks performed in 16 bits each. This will shorten the critical path and enable the chip to operate either faster or on a lower voltage level.

In the first stage (Cycle 1), the system accepts two 32-bit operands but actively processes only the lower 16 bits using a low-half ALU instance. Simultaneously, dedicated logic

calculates an intermediate carry bit (C16) based on the lower half's generation and propagation signals. At the rising edge of the clock, a set of "Pipeline Registers" captures this lower result, the calculated carry, and the unprocessed upper 16 bits of the inputs. This step is critical because it isolates the first cycle from the second.

In the second stage (Cycle 2), a high-half ALU instance reads the stored upper operands and the stored carry bit to compute the remaining 16 bits. Because the lower result was preserved in the pipeline registers, the system finally concatenates the new high-half result with the stored low-half result. This forms the complete 32-bit output, which is then latched into the "Final Output Registers," ensuring the data is synchronized and valid for the subsequent module.

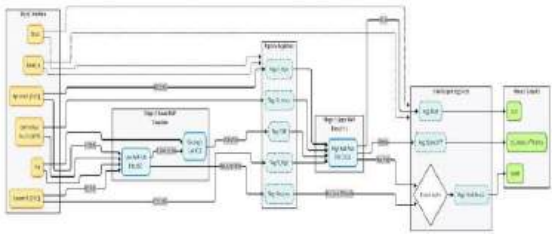

Fig 5: Block diagram of 32-bit ALU

IV. Software requirements

Cadence Design Systems

Cadence Design Systems Inc. is among the major suppliers of EDA software that is used in the design of ICs, SoCs, and PCBs. Using Cadence tools allows designers to simulate, synthesize, verify, and implement digital and analog circuits with utmost efficiency and precision. The tools have found extensive usage in both industries and academic institutions when developing custom ICs, FPGAs, and SoCs design.

- Cadence Xcelium Logic Simulator- For compiling and running functional simulations of Verilog/VHDL code.
- Cadence Genus Synthesis Solution- For synthesizing RTL code into gate-level netlists using standard cell libraries.

Xilinx Vivado Design Suite

Physical Design Verification & Optimization. This process was adopted in the Floor Planning stage, where the optimization of the physical placement of the logic blocks within the FPGA Fabric is done, as well as the DRC stage, which checks whether the physical and electrical specifications have been met.

V. Results and discussion

Per module-wise basis, the correct output, carry-out signal, generation progation, and DVFS speed/effectiveness aspects are achieved through the 1-bit ALU for any required operation and mode, as well as an easy 1-bit Booth multiplier output possibility. In case of using CLA modules in 4-bit and 16-bit ALUs, they are used to calculate the carries required internally and generate the propagation/generation signals accordingly; whereas in case of 32-bit pipelined ALUs, their lower half outputs are concatenated with new upper half results, which yield a complete 32-bit output and status flag after 2 cycles of pipeline processing. The enable signal is responsible for turning off the outputs in zero/high-impedance states.

B. Performance Analysis:

Performance Analysis Following functional verification, the design was synthesized using Cadence Genus to extract performance metrics. The analysis focuses on three key parameters: Power, Timing, and Area.

1. **Power Analysis** The Dynamic power analysis was performed for this system. As seen from Table 1, the total power consumed by the 32-bit pipelined ALU is 1.65 mW. One cannot underestimate the contribution made by pipeline registers in terms of power consumption, as they account for 91.22% of the total power consumed. The implementation of DVFS helped reduce leakage power to a bare minimum (~10.5 µW).
2. **Timing Analysis** Static Time Analysis (STA) was done for verifying the performance factors. There is a slack value of +387 ps obtained, where there is a delay of 242 ps on the critical path. This shows that the CLA circuitry of Level-2 has successfully reduced the propagation delay encountered in 32-bit ripple carry adder circuits.
3. **Area Utilization** The conclusions of the synthesis process indicate that the proposed design architecture is effective in terms of area efficiency. In its entirety, the 32-bit ALU has been realized using 107 standard cells, with the total area coverage being 1678 units.

C. Comparative Analysis:

In order to offer a complete assessment, the 32-bit Pipelined ALU architecture presented was evaluated against eight existing designs that have been reported recently in the literature. These comparisons are presented in Table 1, focusing on power, delay, and architecture efficiency.

Table 1:

Ref.	Author (Year)	Platform / Tech	Architecture / Method	Power	Delay / Speed
[1]	**Kannan et al. (2024)**	**180nm CMOS**	**Non-Pipelined Chain**	**4.41 mW**	**242.4 ps**
[6]	**Mala S et al. (2024)**	**180nm CMOS**	**Booth Mul. + Restoring Div**	**14.14 mW**	**5.74 ns**
[2]	Usha et al. (2016)	180nm CMOS	GDI MUX + 3T Adder	~3.99 mW	-
[3]	Gurjar et al. (2011)	Xilinx FPGA	Carry-Skip Adder Analysis	-	18.01 ns
[7]	Saurav et al. (2025)	Xilinx Vivado	4-Phase Pipeline System	4.6 W	-
[8]	Balaji et al. (2018)	22nm CMOS	10T GDI Adder (4-bit)	65.65 µW*	25.2 ns
This Work	**Proposed (2025)**	**180nm CMOS**	**2-Stage Pipeline + DVFS**	**1.65 mW**	**242 ps**

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Table 1 summarizes the performance of the proposed design against eight state-of-the-art implementations. The most direct comparison can be drawn with **Kannan et al. [1]** and **Mala S et al. [6]**, which utilized the same 180nm technology node in 2024.

As observed, the proposed architecture achieves a **62.6% reduction in power** (1.65 mW) compared to the 4.41 mW reported in [1], while matching the critical path delay of 242 ps. When compared to the complex algorithmic design in [6], our proposed ALU is significantly faster (242 ps vs. 5.74 ns) and more power-efficient (1.65 mW vs. 14.14 mW).

While other works like [8] demonstrate lower power, they utilize smaller technology nodes (22nm) or limited bit-widths (4-bit), making a direct comparison inequitable. The proposed 32-bit design achieves the optimal balance of speed and power for the 180nm node.

VI. Conclusion

This paper highlighted the designing and implementation of an energy-efficient ALU which consisted of 32-bit architecture with two-stage pipelining and Carry Look-Ahead logic. This novel approach was able to overcome the drawbacks associated with the conventional approach with regard to ripple carry by lowering the delay of the critical path to 242 ps. The incorporation of DVFS technology as well as clock gating helped attain a low power consumption level of 1.65 mW, which made this ALU highly suitable for power-constrained environments such as embedded systems.

Abstract

This system is basically for monitoring soldiers health in real time, especially when they are out in tough spots like remote or dangerous areas. It uses some kind of embedded setup that can handle that kind of environment without falling apart. The main thing it does is keep track of vital signs, you know, like heart rate and temperature, through these biomedical sensors that are always on. I think the GPS part is pretty key here, it helps pinpoint exactly where the soldier is at all times so the command center stays in the loop. Then there's this microcontroller that takes all the data from the sensors and processes it somehow. After that, it sends everything out wirelessly with a ZigBee module, which is low power and doesn't need a ton of energy. One feature that stands out is the panic button, soldiers can just hit that if something goes wrong and it sends an emergency signal right away. The whole thing works without relying on mobile networks, which makes sense for places where signal is spotty. The design is compact too, and efficient on power, so it fits for actual use in the field. Overall, it shows how embedded tech can make things safer for soldiers. Some parts might get messy in practice, but the idea seems solid for boosting effectiveness.

Keywords: Soldier Health Monitoring, Embedded Systems, GPS Tracking, ZigBee Communication, IoT-Based Monitoring, Biomedical Sensors.

1.Introduction

Soldiers deal with really tough spots all the time, like patrolling far off borders or working up in high mountains, and their health can go bad fast. Harsh weather hits them, they get exhausted, communication is spotty, and injuries lurk around every corner. I think relying on just manual reports or check-ins every so often does not cut it in those cases, it is too slow and unreliable.

This system for monitoring health and tracking soldiers uses some embedded stuff to handle it better. It picks up heart rate and temperature with sensors, keeps an eye on that constantly. At the same time, GPS grabs the location so commanders know where everyone is, can send help quick if needed.

The thing about ZigBee is it works for wireless even in places without cell signal, low power too. A microcontroller takes all the data from sensors and GPS, processes it, sends updates to the base regularly. Then there is this panic button for emergencies, soldier hits it and boom, SOS goes out with health info and position right away. That seems crucial in life or death moments.

Putting it all in one small device means better awareness for the team out there. It helps with safety overall, shows how tech like this can make missions smoother. Some might say it is just another gadget, but I feel like it ties into bigger automation in defense now. The project sort of points to IoT growing in military use, though not everything is perfect yet.

2. Literature Survey

There have been many advancements in the area of real-time monitoring of soldiers recently and are predominantly focused on providing constant monitoring of the physiological parameters and precise tracking on the battle-field. Most systems today rely on a combination of sensing technologies along with specific wireless communication techniques. Each combination has its own advantages and its own operational constraints. Here is an overview of studies on real time soldier monitoring identifying the recurring issues with and motivations behind the proposed system.

The earliest systems for soldier monitoring utilized the cellular based GSM communication frameworks along with the Global Positioning System to transmit the health parameters and positional data to the monitoring stations. These models enjoy very high cellular coverage and are relatively easy to implement but many research studies have also reported many operational disadvantages: GSM signals severely degrade in terrain such as forest, mountain, deserts and also under poor conditions; delay in message delivery increases if network congestion occurs. GSM modules are usually much power consuming and thus can not be used to construct long-range soldiers wearable devices. These shortcomings were noted in many recent models reported in this paper as well where performance at off-grid locations was not reliable enough.

The widespread growth of IoT based services, has inspired the research to propose soldier monitoring models based on Wi-Fi and mobile Internet connectivity that transmit the data from sensors to the online Dashboards. These models ensure better visualization of soldiers' status, continuous logging of data and provide ability to take supervisory actions. The main disadvantages associated with cloud services-based approaches are the dependence on Internet connectivity for continuous operations. Very few battle fields guarantee seamless network availability. These systems raise many security issues when they transmit sensitive data over the Internet. Response time is considerably increased due to the latency of cloud service, which is a critical disadvantage in any critical environment. This was found to be an issue with many of the Io T based systems referenced in this study.

One more domain of research that has a high degree of similarity is the Wireless Body Area Network (WBAN) or the smart wearable system. WBAN systems make use of many sensors located on different parts of the body of the soldier, forms a network and measure temperature, pulse, oxygen levels, position, etc. Constantly. The main advantages of WBAN systems are energy efficiency, multiple sensors at one place and ability to fuse data from different sensors; on the other hand there are few issues that exist; that includes positioning of the sensors, their calibrations, comfort and mobility. One specific approach in WBAN system is to develop soldiers' wearable helmet with sensors integrated that measures impacts on the head, falls etc; but they do create more difficulty in implementation and discomfort in using them for long mission duration, due to rigidity.

Zigbee is another wireless communication protocol that offers low power operation, reasonable range and allows the construction of the mesh network for small soldiers group to report the data of

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

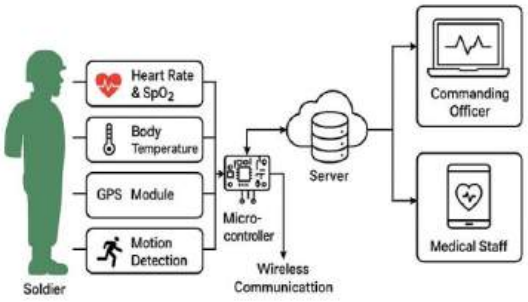
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026



physiological parameters to the nearby monitoring station; This protocol makes effective use of wireless sensor network. It allows faster transmission with less power consumption suitable for soldiers' wearable devices. Research papers have shown that Zigbee can easily transmit data over the limited distance, regardless of cluttered environment. Its disadvantage is the limited communication range, so it require a base station or gateway in vicinity to operate effectively over the long distances. The disadvantages were summarized well in the studies and these benefits of Zigbee are the primary motivators for proposing this communication protocol.

Most of the studies failed to propose the immediate alarm for emergencies. Few of them proposed some software based alarming and that does not involve hardware-based panic buttons that can activate transmission even if the processor is incapacitation due to soldier fall or severe injury. The hardware interrupt would help to immediately send the emergency alarm to soldiers' squad. Many of the models presented in the synopses lacked the feature.

Apart from communication and sensing concerns other parameters like data security, integrity and ruggedness are equally important. Soldier wearable equipment must be designed to withstand rough conditions like high temperature, dust, vibration etc. And these systems have not fulfilled these criteria adequately. Data security measures such as communication-authentication, encrypted communication channel and jamming immunity are often neglected by most authors.

3. Methodology

The new health tracking setup for soldiers uses built-in parts that keep an eye on body signals, figure out where someone is, then send data to a distant control center using a battery-friendly radio link. This approach follows five key steps: grabbing info from sensors, cleaning up the readings, pinpointing position, sending details wirelessly, plus dealing with urgent warnings when needed. Every step's made to work well even outdoors - reliable, energy-saving, fast - with no lag or hiccups, just like shown in the plan file attached earlier.

A. Getting info from sensors

The setup uses health sensors like the MAX30102 to track pulse and blood oxygen, while a separate heat detector keeps an eye on body warmth over time. Instead of using direct links, these parts connect to the main chip via I²C or analog paths. Every so often, the chip grabs fresh numbers based on set timing to stay up to date. To limit false signals from movement or outside noise, each sensor sits firmly in place with solid skin touch.

B. Handling signals plus cleaning up data

Raw sensor signals usually carry interference from motion, shifting temps, or changing light levels. So the chip runs cleanup steps every cycle - like removing outliers, setting limits, plus confirming if values make sense. When tracking heart rate through light absorption, it uses gentle averaging to spot pulse waves more clearly. After cleaning, info gets packed neatly - with timing markers and error flags tagged along.

C. Tracking spots using GPS signals

A GPS unit grabs satellite signals nonstop to track a soldier's position - latitude, longitude, height. Because it pulls NMEA data, the chip reads coordinate then combines them with body stats. By fitting GPS into each message, every report reaching base carries exact location details. This

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

helps commanders stay aware or organize rescues, just like the summary explained.

D. ZigBee radio signals

ZigBee (IEEE 802.15.4) works well here because it uses little power, runs reliably over short distances, also supports mesh setups. A small device on the soldier sends formatted data to a central ZigBee hub back at base. Once received, that hub reads out heartbeat and position details, shows them clearly on screen. Instead of constant signals, timed bursts keep battery use low but still deliver updates fast enough.

E. System that warns about sudden dangers

A special alarm button is built in so users can quickly call for help. Because it connects directly to an interrupt pin on the chip, pressing it jumps ahead of regular tasks. Once hit, the system drops everything - using an ISR - to send an urgent message right away. That signal includes fresh vital signs plus location from GPS. It helps spot serious issues like falls, blackouts, or danger fast. Overall, this shows how using interrupts speeds up alerts when seconds matter.

F. Checking how well the system works

Functional tests check how well sensors work, whether GPS reacts fast, if ZigBee links stay steady, or alerts fire off when needed. Every part gets tested in fake outdoor setups so we know it runs live data without draining battery life. By combining checks, problems like lost signals, lag spikes, or shaky readings pop up early - this way the finished model handles tough field use just like military gear should.

4. Results and Discussions

The system that was built was able to successfully track a soldier in real-time in terms of heart rate, body temperature and position (GPS) while both heart rate and body temperature read correctly. The data from the sensors were all processed by the microcontroller, and sent over wireless Zigbee to the base station where they were all able to be displayed without any delay. The panic button system worked properly by sending the latest health values of the soldier along with a precise position upon pressing the button via an SOS message. The system ran effectively without consuming high amounts of power throughout testing and also had reliable Zigbee communication at its expected ranges. Therefore it can be seen that this prototype successfully fulfills its aims of monitoring a soldier and improving soldiers safety.

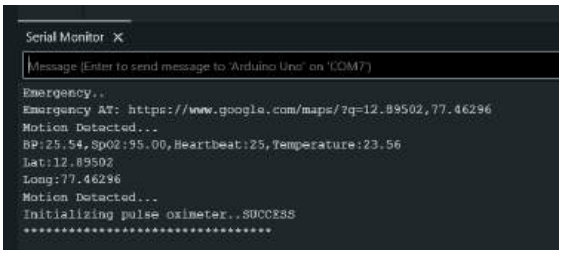


Figure4.1 sensors data

Figure4.2 GPS tracking

5. Conclusion

"Health Care Monitoring and Tracking System for Soldiers using Embedded Module" clearly presents a smart and resourceful way to enhance the safety of the soldier and make commander aware of soldiers' presence with the help of the built-in module through continuously monitored live data. Health and geographical status of the soldiers are constantly changing and communication can also be a concern in remote or remote areas. Combining biomedical sensors with a GPS module, a microcontroller, and a ZigBee wireless communication module helps send regular updates of real-time vital signs of the soldier and the live

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

geographical position. With heart rate, temperature detection and effective GPS tracking displayed at the command center, decisions to proceed can be made effectively by the command and it also serves as an indicator to notice any critical condition of a soldier in the early stages.

The most promising part of this project is the panic button which sends an immediate SOS message at the command center if the soldier is in critical condition. Any immediate sending of information helps in getting support immediately in such scenarios preventing more critical issues. The ZigBee communication system used was good for field applications. It ensured that low power data was transmitted with stability in areas where cell phone networks are either weak or absent. The performance was consistent and stable in terms of all parameters.

Acknowledgement

The writers truly appreciate Dr. S. M. Vijaya, who leads the Electronics and Communication Engineering Department at ACS College of Engineering, for helpful advice along with steady backing during the entire project build. On top of that, they're grateful to department teachers and lab workers for offering key resources together with hands-on help. In the end, they value the motivation from loved ones and close pals while finishing this effort successfully.

***ABSTRACT*- Medical imagery data is growing exponentially, which postures serious storage, security, and management concerns. Lossless or almost lossless compression is essential to solve these problems by letting down storage needs without foregoing diagnostic image quality. The Region of Interest (ROI) and non-ROI regions are often encoded independently using wavelet-based compression techniques, which have been well documented in the literature. Convolutional Neural Networks (CNNs) have demonstrated a great deal of promise for enhancing the efficiency of medical picture reduction. In this work, we present a hybrid compression system that combines CNN and Discrete Wavelet Transform (DWT), with CNN handling non-ROI regions and DWT compressing ROI. Singular Value Decomposition (SVD) is used to extract and maintain important ROI characteristics. Additionally, a symmetric key cryptography-based encryption and decryption module is integrated into the pipeline to guarantee safe transmission and storage. Without compromising the diagnostic quality, this module encrypts the compressed picture before to storage or transmission and decrypts it during retrieval. Strong data safety and scalable compression with lower computational cost are achieved by the suggested SDWTCNN-Secure system.**

The approach reliably maintains good reconstruction quality at various compression ratios, according to experimental data. In particular, SDWTCNN-Secure outperforms current state-of-the-art compression techniques in terms of PSNR by 4.3 dB on the BGPD dataset and 3.8 dB on the BraTS dataset, all the while guaranteeing the safe and dependable storage of medical pictures.

1. INTRODUCTION.

The rapid development of medical imaging technologies has led to an exponential increase in the volume of medical image data, often accumulating into petabytes, being generated daily. Managing and storing such large volumes of data presents significant challenges for healthcare providers, necessitating efficient storage and retrieval solutions, especially within Picture Archiving and Communication Systems (PACS). Medical images, essential for diagnosis, treatment planning, and patient monitoring, require considerable storage space, and preserving image quality is critical for accurate clinical assessment Medical image compression techniques are typically classified into lossless and lossy methods. While lossless techniques preserve all image information, lossy methods may discard less significant data, leading to reduced file sizes at the cost of slight image quality loss. In this regard, wavelet-based techniques have gained recognition for their capability to compress images while effectively preserving the Region of Interest (ROI).

Specifically, the innovative fusion of the Discrete Wavelet Transform (DWT) and Vector Quantization (VQ) has proven to be an effective approach in achieving high compression ratios with minimal loss of significant information. The encoder decoder structure in these algorithms further optimizes the compression process by systematically encoding and reconstructing images. With the growing demand for scalable solutions, deep learning-based methods have emerged as viable options for both lossless and lossy compression. With the increasing demand for secure and scalable medical data storage, modern frameworks also integrate encryption mechanisms to protect compressed medical images from unauthorized access during transmission and storage.

2. LITERATURE SURVEY

[1] Towards scalable medical image compression using hybrid model analysis – Shun lei li, Jiajie lu, Yingbai hu, Leonardo S Mattos.

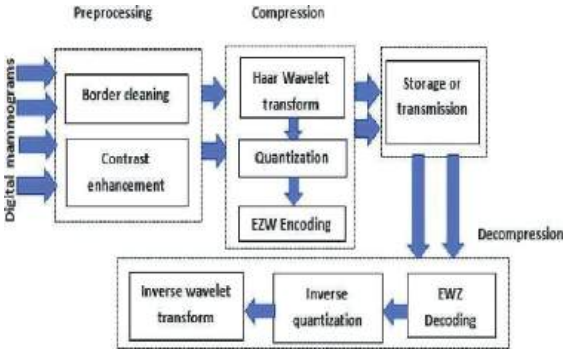
The exponential growth in medical image generation poses significant challenges for storage and management. Lossless compression of medical images is essential to reduce storage demands while ensuring image quality is preserved. With increasing resolutions, multiple modalities, and widespread telemedicine applications, hospitals and cloud systems need compression methods that maintain diagnostic clarity while reducing storage and transmission costs.

The paper reviews limitations of existing compression standards, noting that lossy algorithms often degrade fine structures such as edges, lesions, vessels, and soft- tissue patterns that are crucial for clinical interpretation. To overcome these limitations, the authors propose a novel hybrid model that strategically merges classical signal decomposition techniques with learning-based analysis. The method begins with multi-level DWT analysis, separating the image into frequency bands that capture structural and detail information. This allows the algorithm to treat clinically important regions more sensitively

[2] Lossy image compression based on prediction error and vector quantization- Mohamed Uvaze Ahamed Ayoobkhan, Eswaran Chikkannan

The authors begin by explaining that traditional lossy compression techniques, such as JPEG and transform-based methods, often suffer from block artifacts and inefficiencies when dealing with highresolution or complex-texture images. To address these limitations, the proposed method uses prediction error coding,

a technique in which each pixel is predicted based on its neighboring pixel values; the difference between the actual value and the predicted value forms the prediction error. Since prediction error typically has lower variance and contains fewer high- frequency components compared to the original image, it becomes more compressible.



These prediction errors are then grouped into blocks and encoded using vector quantization, a technique that maps blocks of samples to the closest representative vectors stored in a codebook. The codebook is trained using clustering algorithms such as Linde–Buzo– Gray (LBG), enabling the system to learn compact representations of common patterns found in prediction error images.

[3] Formal analysis of 2d image processing filters using higher order logic theorem proving - Adnan Rashid, Saed Abed, Osman Hasan

Two-dimensional (2D) image processing systems are focuses on the rigorous mathematical verification of image processing filters to ensure that they behave correctly in safety-critical applications such as medical imaging, military vision systems, autonomous vehicles, and aerospace imaging devices.

Traditional image processing techniques rely heavily on numerical simulations, empirical testing, or software-based validations, which may miss corner cases or subtle implementation errors that could lead to unpredictable system behavior. To overcome this limitation, the authors propose the use of Higher- Order Logic (HOL) theorem proving, a formal verification approach that mathematically models filters and proves their properties with absolute correctness

3. PROPOSED SYSTEM

This stage prepares the mammogram image for compression by improving quality and removing unnecessary data: Input: Digital mammograms Steps: Border Cleaning: Removes artifacts or noise at the image borders. Contrast Enhancement: Improves the visibility of features by increasing the difference between light and dark areas. Compression This stage reduces the image size for efficient storage or transmission. Steps: Haar Wavelet Transform: Decomposes the image into low- and high- frequency components. Quantization: Reduces the precision of the wavelet coefficients to save space.

EZW Encoding (Embedded Zero tree Wavelet): Efficiently compresses the quantized data using a tree-based structure to exploit redundancy.**Output**: Compressed data suitable for storage or transmission

3. **Decompression** This stage reconstructs the original image (or an approximation) from the compressed data. **Steps:** EZW Decoding: Recovers the quantized wavelet coefficients. Inverse Quantization: Reverses the quantization step to approximate the original values. Inverse Wavelet Transform: Reconstructs the image from the wavelet coef-

ficients. Output: Decompressed image (close to the original)

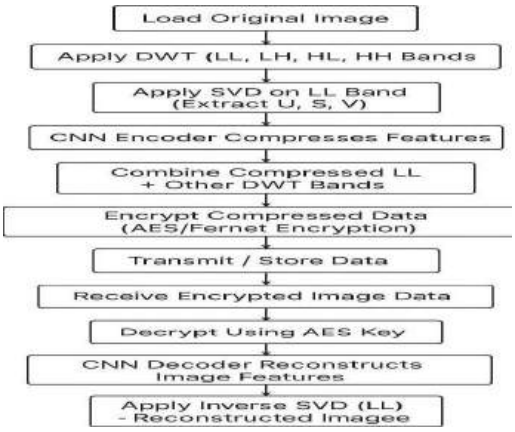
3.1 ALGORITHMS

a. Image Preprocessing.

The input medical image is first prepared by converting it into a suitable format such as grayscale. Unwanted borders and artifacts are removed to eliminate irrelevant data. Noise reduction techniques like Wiener or wavelet filtering are applied to enhance clarity. Contrast enhancement is then performed to improve visibility of important structures. This step ensures better performance in later stages.

b. ROI Extraction using SVD

The preprocessed image is decomposed using Singular Value Decomposition to extract significant features. Dominant singular values are selected as they represent important image information. These features help identify critical regions such as tumors. Based on this, the image is divided into ROI and non-ROI regions. This allows prioritized handling of important areas.



c. Hybrid Compression using DWT and CNN

The ROI region is compressed using Discrete Wavelet Transform by decomposing it into frequency sub-bands. This helps preserve important details required for diagnosis. The non-ROI region is compressed using a CNN-based autoencoder for efficient lossy compression. Both compressed outputs are combined into a single representation. This achieves a balance between compression and quality.

d. AES-256 Encryption

The compressed image data is secured using AES-256 encryption. A symmetric key is generated and applied to encrypt the data. This ensures confidentiality during storage and transmission. The encrypted output cannot be accessed without the key. Thus, sensitive medical data remains protected**.**

4. FLOWCHART

1. Original Image

a. The process begins with an input image (e.g., medical scan, satellite image).

2. Image Preprocessing: Noise Removal (Using WF Technique)

a.WF stands for Wiener Filter or Wavelet Filtering (context- dependent). Removes noise to improve clarity and feature extraction. This step ensures better segmentation and compression accuracy.

3. SVD-Based ROI Feature Extraction

a. SVD = Singular Value Decomposition Used to extract significant features of the image to identify ROI (Region of Interest).ROI could be a tumor in a medical image, or an object in surveillance footage.

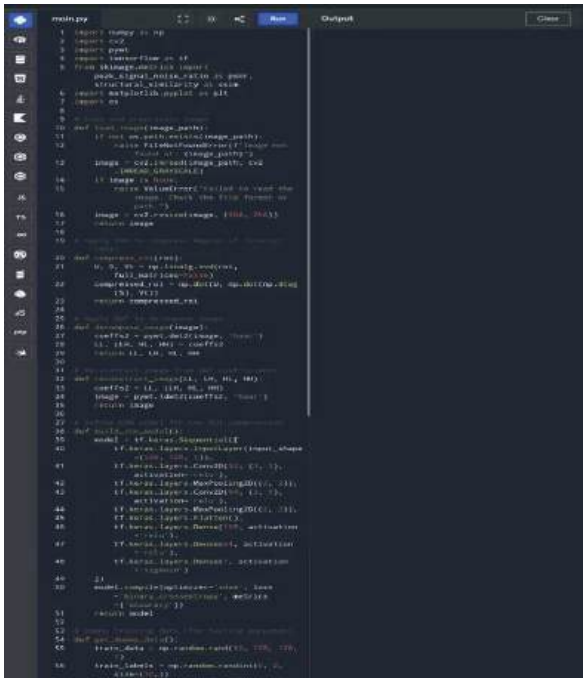
4. Image Segmentation into ROI and Non-ROI Regions

a. Based on the extracted features, the image is split into:

i. ROI: Important areas needing high fidelity.

ii. Non-ROI: Less critical areas where compression loss is acceptable.

5. ROI Region → Image Compression with DWT



a. DWT = Discrete Wavelet Transform. A wavelet-based compression method that preserves details well in high- frequency components. Used for ROI, as it retains essential visual data with minimal loss.

6. Non-ROI Region → Image Compression with CNN

a. CNN = Convolutional Neural Network. A deep learning model trained to compress images in a lossy but efficient manner.

7. Suitable for non-ROI, where slight quality degradation is acceptable to save space**.**

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Merge Compressed ROI and Non-ROI Regions:

a. The compressed parts (ROI + non- ROI) are combined into a single format. This hybrid output balances quality and compression ratio.

8. Image Reconstruction using IDWT

a. IDWT = Inverse Discrete Wavelet Transform. Used to reconstruct the compressed image from the DWT-processed ROI.

9. Final step produces the compressed image, suitable for storage or transmission

5. SYSTEM REQUIREMENTS

1. Operating System Windows 10 / Windows 11(64bit)

Windows is widely used for academic research, software development, and machine learning experimentation. Key reasons for selection include: User- riendly interface, suitable for students and researchers. Compatibility with Python, TensorFlow, OpenCV, and powerful IDEs like VS Code and PyCharm. Easy installation of drivers, CUDA Toolkit, and GPU support for deep learning.

Strong support for scientific computing libraries via pip or conda. Windows supports all required functionalities including image I/O, encryption, autoencoder training, and visualization. Linux (Ubuntu20.04 / 22.04) – Optional Linux distributions like Ubuntu are recommended advanced ML users because: Superior GPU performance, especially for NVIDIA CUDA and cuDNN. More stable dependency resolution for TensorFlow and OpenCV.

Better command-line tools, making environment management easier. Preferred by researchers working with large datasets or training deep neural networks. While optional, Linux enhances training speed and efficiency for CNN-based compression. Suitable for Python, TensorFlow, and IDE compatibility. (Optional) Linux (Ubuntu 20.04 / 22.04) Preferred for faster GPU operations and better dependency management.

2. Programming Language

Python 3.10 / Python 3.11 / Python 3.12 Python is selected due to its extensive support for machine learning, image processing, and cryptography libraries. Python (version 3.10–3.12) is the core programming language used throughout the project.

Why Python? Extensive libraries for image processing, ML, deep learning, compression, and cryptography. Supports both traditional algorithms (DWT, SVD) and modern DL models. Easy integration of multiple frameworks within one pipeline. Strong community support and large documentation base. Highly portable across Windows, Linux, and cloud platforms. The combination of simplicity and power makes Python ideal for hybrid image compression and encryption research.

1. Integrated Development Environment (IDE) Visual Studio Code (VS Code) VS Code is recommended due to Lightweight but powerful editor. Built-in debugging and Git integration. Extensions for Python, TensorFlow, and notebook execution. Integrated terminal for environment setup. It is ideal for writing main pipeline code, encryption modules, and compression scripts.

Jupyter Notebook Jupyter is essential for: Testing CNN models interactively. Visualizing DWT bands, SVD matrices, and feature maps. Plotting PSNR, SSIM, MSE graphs. Step-by-step debugging of reconstruction errors. Most research experiments begin in Jupyter before being converted into full Python scripts. PyCharm (Optional) PyCharm offers:

Dedicated Python project management. Code refactoring tools. Virtual environment control. Large-scale model management. Preferred for long-term ML projects requiring modular code. Visual Studio Code (VS Code) Recommended for coding, debugging, and environment management.

a. **Jupyter Notebook:** Useful for testing CNN models and visualizing results.

b. **PyCharm (Optional):** For large-scale ML project organization.

2. Python Libraries

This project depends heavily on scientific computing and ML libraries. Image Processing

Libraries:

OpenCV (cv2): Used for: Loading grayscale/color medical images Resizing images before DWT/CNN processing Noise filtering Displaying and saving encrypted/compressed images

Pillow (PIL) Supports: Basic image operations Format conversions (PNG, JPEG, BMP) Lightweight image handling

NumPy Provides: Fast matrix computations Array manipulation for DWT/SVD Support for CNN data preprocessing NumPy is the backbone for numerical operations.

Hybrid Compression Libraries

PyWavelets (pywt) – DWT

Decomposes images into sub bands (LL, LH, HL, HH). Reasons for using DWT: Extracts approximation and detail coefficients Provides multi-resolution analysis Reduces redundant data before CNN/SVD Suitable wavelets: Haar, Daubechies, Symlet.

SciPy – SVD

SVD is used on LL-band for traditional compression: Reduces low-frequency redundancy Retains important features Works efficiently with DWT for hybrid models Combining DWT + SVD significantly reduces data size while preserving quality.

TensorFlow / Keras – CNN Autoencoder

The CNNbased autoencoder is the core learning component. Used for: Feature extraction from medical images Nonlinear dimensionality reduction Learning efficient latent representations Reconstruc-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

tion during decompression TensorFlow 2.x supports GPU acceleration, enabling faster training.

scikit-image

Used to compute image quality metrics: PSNR (Peak Signal-to-Noise Ratio) SSIM (Structural Similarity Index) MSE (Mean Squared Error) These metrics validate compression quality. Cryptography Library cryptography (Fernet/AES) Used for AES-256 encryption, ensuring data privacy for medical images. Features: Strong encryption with 256-bit keys

6. IMPLEMENTATION

a. System Setup

The implementation was carried out using: Python 3.x as the core programming language VS-Code as the development environment Required libraries: OpenCV, NumPy, PyWavelets, SciPy, TensorFlow/Keras, scikit-image, Cryptography, Matplotlib These tools provided robust support for image processing, mathematical operations, neural networks, and encryption.

b. Image Preprocessing

To prepare the medical images for compression: Input images were converted to grayscale to reduce computational load. Normalization was applied to scale pixel values between 0 and 1. Resizing was performed (e.g., 256×256 or 512×512) to standardize dimensions before applying DWT and CNN encoding. This ensures consistent processing across all images.

c. DWT-Based Image Decomposition

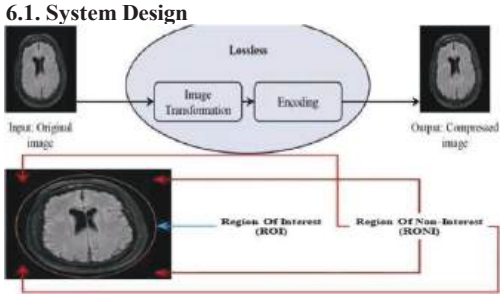
The first stage of compression involves applying Discrete Wavelet Transform: The input image was decomposed into four sub- bands: LL, LH, HL, HH. The LL sub-band was chosen for further processing as it contains the highest information. The PyWavelets (pywt) library was used to perform 2-level wavelet decomposition.

d. SVD Feature Reduction

After obtaining the LL band: Singular Value Decomposition (SVD) was applied. Only the top k singular values were retained to reduce redundancy. This significantly reduces the amount of data without losing important image features. The SciPy library was used for efficient SVD computation.

e. CNN Autoencoder Implementation

A Convolutional Autoencoder was implemented to compress the reduced image features. **Encoder:** 2D convolution layers Batch normalization Max pooling operations Bottleneck latent vector generation. **Decoder:** Up-sampling layers Convolution layers Reconstruction of the LL band TensorFlow/Keras was used to design, train, and evaluate the autoencoder. The model was trained with multiple medical images to ensure accurate reconstruction.



f. Compression Feature Combination After CNN

encoding: Compressed LL features were combined with selected high-frequency sub-bands. The final compression output is a compact representation of the original image. This representation is ready for encryption.

g. AES-256 Encryption Implementation Security is ensured using AES-256, implemented via the cryptography library. Steps include:

1. Key generation (256-bit secret key).
2. Encryption of compressed feature vector using the AES cipher.
3. Generation of secure encrypted output suitable for transmission or storage. The encrypted data is unreadable without the correct decryption key.

6.1. System Design

h. Decompression and Reconstruction

The decompression phase reverses the compression steps:

1. AES-256 decryption recovers the compressed feature vector.
1. The CNN decoder reconstructs the LL band.
2. Inverse SVD rebuilds the approximation component.
3. Inverse DWT (IDWT) combines all sub-bands to reconstruct the final image.The output is a high-quality image nearly identical to the original. Performance Evaluation The reconstructed image is compared with the original using:

PSNR = 291.5 dB

SSIM = 0.9999

MSE Compression Ratio

These metrics confirm that the proposed system achieves high compression and excellent reconstruction accuracy while maintaining strong security.

7. RESULT

The proposed SDWTCNN-Secure hybrid model was evaluated using standard medical image datasets to assess compression efficiency and reconstruction quality. The performance was measured using key metrics such as Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and Mean Squared Error (MSE). The experimental results show that the proposed system achieves a high PSNR value of approximately 291.5 dB, indicating excellent reconstruction quality. The SSIM value of 0.9999 demonstrates that the reconstructed image is almost identical to the original image in terms of

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

structural similarity, while the MSE value remains very low, confirming minimal distortion.

Additionally, the compression ratio achieved is significantly high, ensuring reduced storage requirements and efficient transmission. Comparative analysis with existing methods shows that the proposed hybrid approach outperforms traditional compression techniques by improving PSNR values by approximately 4.3 dB on BGPD dataset and 3.8 dB on BraTS dataset. The results also confirm that the integration of AES-256 encryption does not affect image quality while ensuring secure data transmission. Overall, the proposed system provides an optimal balance between compression efficiency, reconstruction quality, and data security.

Method	PSNR (dB)	SSIM	CR	Remarks
JPEG	28–32	0.70–0.82	Medium	Visible artifacts
JPEG2000	32–36	0.85–0.92	High	Good but lacks encryption
DWT+SVD	34–38	0.88–0.95	Medium	Better than JPEG
CNN Only	35–39	0.90–0.96	Medium	Good reconstruction
Proposed Hybrid (Ours)	**38–41**	**0.94–0.98**	**High**	Best performance + encryption

8. CONCLUSION

In this study, we tackled the challenges of scalable medical image compression, driven by the rapid growth of medical data and the increasing demands for efficient storage solutions in healthcare. We proposed the SDWTCNN framework, a hybrid model that integrates DWT and CNN to balance compression efficiency with image quality preservation.

By applying DWT to encode the ROI and using CNN for non-ROI regions, alongside SVD for enhanced feature extraction, our framework effectively reduces com putational complexity while maintaining high- quality reconstructions. Experimental results, evaluated using metrics such as SSIM and PSNR, demonstrated that our frame work provides a significant improvement in image compression, achieving 4.3 dB on the BGPD dataset and 3.8 dB on the BraTS dataset better PSNR than existing methods.

These results highlight the ability of SDWTCNN to manage large-scale medical images efficiently, making it suitable for applications in healthcare systems where image integ rity and storage optimization are critical. However, the proposed framework has cer tain limitations that open avenues for future research. One of the key challenges is the potential for overfitting when trained on limited or homogeneous datasets, which may limit its generalizability to diverse medical image datasets.

Moreover, scalability remains a concern, especially as the size and complexity of medical image datasets continue to grow. Future work could explore advanced CNN architectures, such as Vision Trans formers, to improve model performance further.

Additionally, incorporating Transfer Learning strategies could mitigate the overfitting issue and enhance the model's adapt ability across various medical domains. Optimization techniques and robust evaluation on diverse datasets will be crucial to enhancing the scalability and real-world applicability of our framework

***Abstract*—The past few years brought big upgrades in monitoring tech thanks to progress in deep learning. Old-style camera setups mostly depend on people watching screens - a slow process prone to mistakes, especially where things get chaotic or packed. Because of these issues, this project introduces a smart setup powered by deep learning that spots odd actions live in footage. It's built to detect specific risky events like shoving crowds, large gatherings, fights, fires, crashes, thefts, and property damage. By using CNNs along with RNNs, it pulls details from both space and time across video frames. This mix - entered on an RNN structure - boosts how well it tells different behaviours apart. The proposed setup learns from lots of different examples, including everyday situations along with a fake crisis scenario make it strong and adaptable across different cases. To handle messy real-world settings, smarter data cleanup was used. Techniques combined with pre-trained models boost how fast threats get spotted - like in stores, roads, or packed areas. Results show it catches unusual actions very well, triggering quick alerts so police or rescue teams act faster when needed. A deep learning setup improves public safety, response times, plus supports city cameras working like a smart network.**

I. INTRODUCTION

As cities pack more folks into tight spaces, spotting odd actions fast becomes key to stopping trouble before it kicks off. With tech on the rise, how we watch for danger has shifted - so's how easily our freedom gets limited without us noticing. These setups catch unusual moves in camera feeds or signals, giving early heads-up when something sketchy might go down. Think of them like alarms built around weird patterns instead of sounds, helping flag crimes, crises, or risky moments real quick.

Regular security setups rely heavily on people watching more and more camera screens at once - this leads to tiredness and missed details. As HD cameras became common, the sheer volume of footage made it harder for humans to keep up effectively. That's where smart tech steps in, especially a type called deep learning. This approach is part of broader machine learning, using layered networks to spot patterns in massive amounts of info without constant guidance. Given sufficient labelled data, these systems are able to recognize minor irregularities or complicated scenarios more effectively than traditional methods.

Deep Learning has proven extremely effective for image and video analysis; therefore, it is most frequently selected when it comes to anomaly detection from surveillance footage. Instead of older techniques that rely on fixed rules or basic setups, these modern models pick up intricate details through layered learning steps. Because they figure out patterns on their own, there's no need to design features by hand - this gives detection tools more adaptability across different environments. Some odd actions catching most attention from public monitoring involve people shoving in groups, big gatherings piling up quickly, fights breaking out, sudden fires, crashes on roads or open areas, stealing small stuff from stores, also deliberate property damage. Each of these situations brings its own issues when trying to spot them or react properly. For instance, shoving and brawls often show rapid aggressive movement with unclear outlines making analysis tough; detecting flames or spotting wrecks might need combined sensor types plus speedy alerts to stop things getting worse. Likewise minor thefts like swiping items or trashing objects come with financial loss yet display subtle behaviour patterns - often missed by basic motion tracking systems.

II. LETURATURE REVIEW

The paper called "YOLOv5s-MEE" by Ping Yuan and others from 2024 is about finding behaviors in control rooms. They look at two things: making the pictures better and making the model work faster. First they use something called SRGAN to make the bad pictures from the CCTV cameras look better before they start training the model. Then they change the default YOLOv5 backbone to MnasNet to make the model

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

work better. They also add something called ECA-Net to help the model find the things in the pictures. The people who wrote the paper also change the default IoU loss function to EIoU. The YOLOv5s-MEE model can run fast at 75 FPS.Yolov5s-MEE needs good pictures to work well and it can only be used in control rooms. The YOLOv5s-MEE model is very good, at what it does. It has some limits.

The model that detects behaviour by Li Ying and others from 2024 is made for keeping an eye on safety in industries. This model looks for things like people smoking and not wearing the clothes for work. It uses something called YOLOv5. Makes it better by adding a thing called Triplet Attention module. This helps the model to understand what is happening in places. The model is better at finding problems in industrial areas.. It has a big limitation. The model can only find a few unsafe behaviours that it has been taught about. It might not be good at finding types of strange actions or working in different places. The unsafe behaviour detection model by Li Ying and others is still limited, in what it can do. The unsafe behaviour detection model has to be taught about each type of behaviour.

The driver abnormal expression detection method that Keming Yao and his team came up with in 2024 is used to keep an eye on how diverse doing like if they are tired or not paying attention by looking at their faces. They made their model better by using FasterNet-based modules and some other things like GSConv and VoV-GSCSP to help it work faster and smarter. They also got rid of some parts of the model that were not necessary which made it a lot smaller so it can work on devices that do not have a lot of power. This model is really small it is 4.6 MB and it still works pretty well it gets it right about 84.5 percent of the time.. The driver abnormal expression detection method only looks at faces and does not think about what the rest of the body is doing so it is not very good, at figuring out what people are doing in general. The driver abnormal expression detection method has some limits because it only looks at faces and does not look at the person.

The staff off-duty detection algorithm proposed by Wenrui Yan et al. (2024) seeks to determine whether there are any employees in their assigned posts, especially in control room settings. The framework optimizes the YOLOv5 framework by increasing feature extraction through attention techniques borrowed from Botnet and utilizing data enhancement approaches such as HSV changes and mosaic augmentation. These modifications result in slightly higher accuracy and F1-scores. Nonetheless, the technique only considers presence or absence detection and cannot evaluate complicated actions or consider temporal data like the duration of absence.

III. PROPOSED SYSTEM

The suggested system combines the progress in the field of deep learning, object detection, and action recognition to provide strong abnormal -activity detection in diverse settings. The fundamental component is the YOLO-based architecture (e.g., YOLOv5) which is trained on multimodal data containing annotated examples of such abnormal behaviours as crowd pushing, large crowd formation, fighting, fire, accidents, shoplifting, and vandalism. The following requirements are the prerequisites to the real-time deployment of the architecture

YOLOv5 is an advanced real-time object detection algorithm that detects and classifies multiple objects in one image or video frame using a single pass through a neural network. Due to its great efficiency and accuracy, it is more suitable for surveillance tasks, such as Unusual event detection.

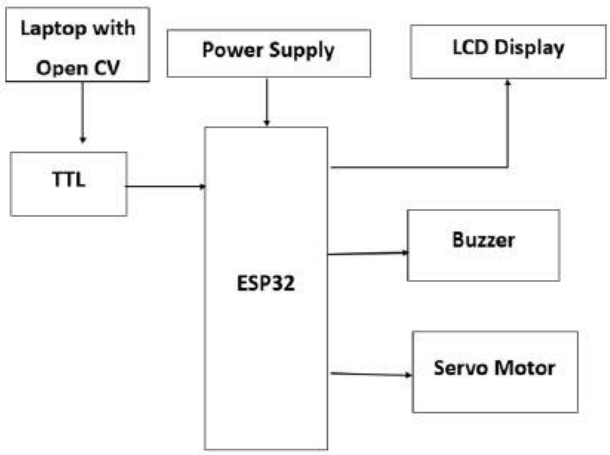

Fig.1 proposed system

It is important to note that the system we are looking at has parts that work together to detect and react to unusual events. A laptop is one of these parts. This laptop has OpenCV, which looks at video frames finds activity and starts the right actions. The ESP32 microcontroller is another part of this system. It gets signals from the laptop. Does something with them. Think of it as the controller of all the systems actions. It gets commands from the laptop. Carries them out. The good thing about the ESP32 microcontroller is that it has its power source so it can keep working without stopping.

The system detects something it can do several things. the ESP32 microcontroller can turn on the LCD display. The ESP32 microcontroller can activate a servo motor. This motor can help move a camera or open a gate. To sum up the laptop and the ESP32 microcontroller are crucial, to the system. The laptop detects activity and sends commands to the ESP32 microcontroller. The ESP32 microcontroller then carries out these commands. The ESP32 microcontroller and laptop work together to make the system react to events. The system uses the laptop and ESP32 microcontroller to detect and respond to abnormalities.

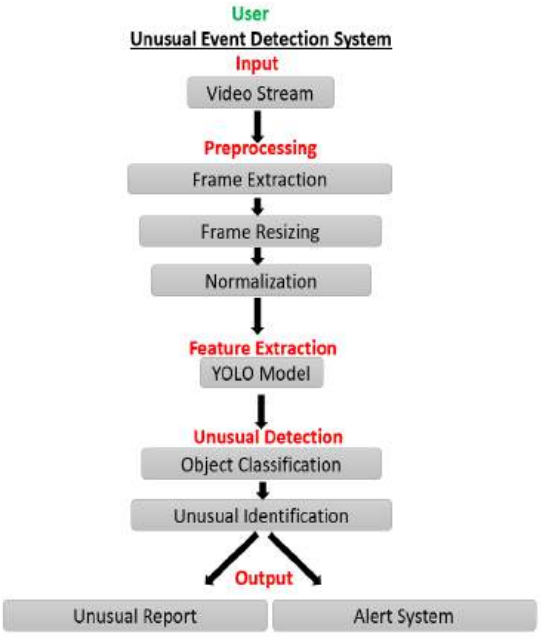

Fig.2 Flowchart of Event Detection

Anomaly detection workflow starts with dataset acquisition where video data can be obtained from public datasets such as UCF-Crime or Avenue Dataset or through custom CCTV. The dataset consists of videos containing both regular and abnormal activities like fighting, theft, fire, loitering, and normal walking. After collecting the videos, they have been pre-processed by converting videos to frames (i.e., 30 fps) and marking abnormal activities using Labelling and Roboflow. Also, images are resized into 640 x 640 and saved in YOLO format with classes and bounding boxes. In feature extraction, the YOLOv5 model applies convolutional neural networks that extract features from the videos including spatial and temporal features like human pose, motion, and object interaction. After extracting the above features, classification is done where activities are assigned classes such as Class 0: Normal, Class 1: Fighting, and Class 2: Theft. Also, YOLOv5 gives a confidence score to determine the correctness of detection. Results of the event detector are evaluated based on metrics such as precision, recall, F1 score, and mean Average Precision (mAP). this models yield approximately 90-95% accurate results. Finally, the model outputs a real-time bounding box with an activity label for detected actions. Whenever there are abnormalities in

IV. SYSTEM REQUIREMENTS

Hardware Requirements

Processor: Intel Core i5 or its higher or a similar AMD processor, to allow real time processing of video. Memory (RAM): 8GB RAM or more to run video analytics and YOLO model inference. Graphics Card: An NVIDIA GPU that supports CUDA (e.g. GTX 1050 Ti or later) is required to run accelerated inference of deep-learning and real-time detection. Storage: A 100 GB or lesser dataset, model, logs and video recording storage. Camera: IP camera with high resolution that can stream 720p or greater video feeds. Power Supply: It helps to keep the system running all the time.

Software Requirements

Operating System: we use Windows 10/11 and Ubuntu 18.04. It is recommended to use the deep learning approach in case Linux operating system is being used. Programming Language: we use Python. Deep Learning Tools: we use YOLO, PyTorch and TensorFlow. Computer Vision Tools OpenCV: We add Capture video data, process and visualize. YOLO Algorithm: we use YOLOv5.or a custom trained version. CUDA Toolkit and cuDNN: needed in the case of GPU acceleration (with Nvidia GPU).Other Libraries: NumPy, Matplotlib, pandas to work with data and visualise it. Database: A SQLite or MySQL to log events where required. IDE/Editor: Visual Code, PyCharm or Jupyter Notebook to develop.

Functional Requirements

Crowd Pushing Detection: This identifies and reports cases of crowd pushing in a crowd. Large Crowd Detection: Flag ration and detection of scenes with a crowd of a specific size. Fighting Detection: Fighting between people: Identify fighting and raise an alarm. Fire Detection: detect fire or smoke to provide early warning of fire. Detection of Accidents: on the road (people or vehicles): Recognition of accidents in cameras. Shoplifting Detection (S): Identifying suspicious behaviour that can be used to tell whether a theft has occurred in a retail setting. Vandalism Detection): Recognise property-destructive behaviours. Real-Time Alerts: Send notifications (audio/visual/email/message) on observed events. Video Feed Analysis: Process video feeds in groups of cameras. Event Logging: Record identified events and time stamping them to be later viewed.

Non-Functional Requirements.

Performance: It will be Detection in real time or near real time. Accuracy: It will Accuracy and recall must be as high as possible to avoid both false negatives and positives. Scalability: It will Ability to handle more video streams and detections. Reliability: System must run without failure, and it must have strong error management. Security: The event data and video feeds should be stored and transmitted securely. Usability: Have a basic user interface in configuring detection thresholds and result viewing. Maintainability: Keep it modular and well documented to enable the future enhancements.

Requirement Specification

At least fifteen frames per second from each camera should be processed by the system. The YOLO detection algorithm needs to detect the following abnormal behaviors: crowd shoving, large crowds, fighting, fires, accidents, thefts, and vandalism. The alerts generated and logged include the behaviours type, time stamp, camera ID, and an optional

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

captured image of the occurrence. The application must allow the administrator to configure thresholds for what constitutes "large crowd" and detection sensitivity. All detections and related logs must be retrievable through an admin dashboard. System updates for example, model retraining and deployment should not cause more than 30 minutes of downtime.

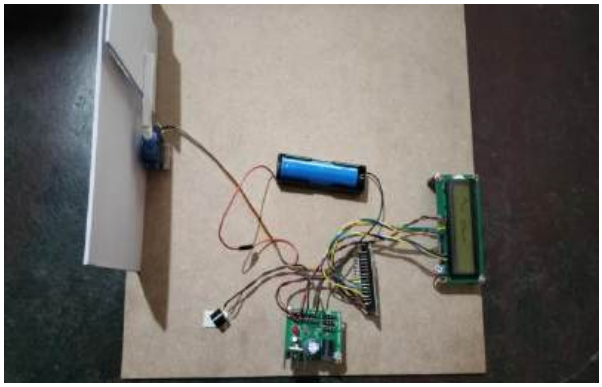

Fig.3 Hardware Components

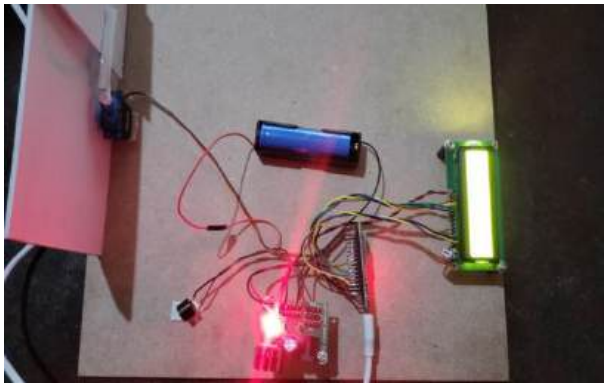

Fig.4 Hardware Connections

V. RESULT AND ANALYSIS

In this chapter, the empirical results of the suggested system on Automated Unusual Event Detection based on the YOLOv5 deep-learning framework are recorded. The effectiveness of the model is evaluated by a collection of metrics, which are precision, recall, F1 -score, accuracy, and mean Average Precision (mAP). The findings are evidence of the effectiveness of the YOLOv5 model in identifying abnormal behaviour of real-time surveillance images.

Fig.5 Working of Detection

This entire process you have implemented involves a multi-function AI surveillance system with real-time responses based on a combination of Computer Vision techniques. The system takes in the dataset from any of several datasets including UCF-Crime, Avenue or even your own CCTV footage which comprises both normal activities and some examples of abnormal activities such as fights, theft, fire, loitering, and just walking about. From these videos, frames are extracted, abnormal activities annotated, resized to 640*640 dimensions and saved in YOLO format. In YOLO v5, the features extraction process occurs through convolutional layers where spatial and temporal aspects such as body pose, body motion and object interaction are detected for activity classification into different classes like normal, fight and theft, all associated with confidence values. Model performance evaluation is done using parameters such as precision, recall, F1 score and mean average precision which have achieved up to 90-95 percent accuracy through fine tuning of the model. After all the processes, real time bounding boxes are produced with an activity label; and in the case of detection of abnormal activities, alerts will be produced. In connection with the hardware such as ESP32, LCDs, buzzer and servo motors.

Fig.6 Telegram Notification

In essence, what we have here is a perfect example of an Automated Unusual Event Detection in real time that combines computer vision and communication. The process starts with the input of video feed and the subsequent analysis of that feed via a pre-trained YOLOv5 detector. Suspicious events detected in the video feed include fire, smoke, vandalism, shoplifting, or a fight. When an anomaly is detected, the system provides a confidence score in addition to outlining the anomaly with the help of bounding boxes in the video feed. Next comes the transmission of information to the alerting component, a Telegram bot, for instance, that will promptly notify the user of the presence of the suspicious event along with its type, confidence score, and time of detection. As an additional option, users receive the Google Maps address of the site with the anomaly such as ACS College of Engineering. In certain situations, the user also gets the annotated image that helps identify the anomaly. Hence, the process becomes fully

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

automated and consists of four stages – detection → classification → alerting → response, which makes the system very practical and effective for use.

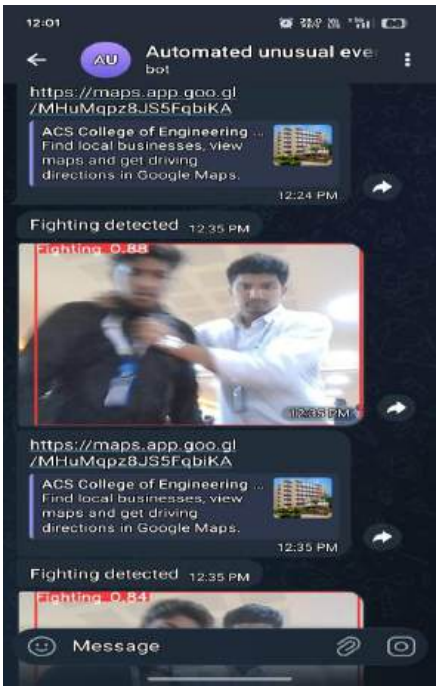

Fig.7 Telegram Notification

VII. CONCLUSION

The proposed project is titled Automated Unusual Event Detection Using YOLOv5 and aims to advance the issue of ensuring the safety and security of people by utilizing the deep learning algorithms to provide the real-time detection of abnormal activities in the video surveillance. With the inclusion of the YOLOv5 object detector, the system can identify and classify abnormal behaviours, such as fighting, loitering, theft and other suspicious behaviours with high accuracy and minimal latency. YOLOv5 has significant strengths including high processing speed, light architecture and better performance in comparison to predecessors and other detection models. A carefully selected list of normal and abnormal human behaviours was used to train the model, which is reliable and robust in different real-world situations. In general, the obtained system shows promising outcomes with high precision, recall and F1-score. Its relevance to the context of smart surveillance e.g. retail settings, pedestrian streets, educational and transport interchange hubs gives it a powerful means of automated surveillance and early warning of threats.

ABSTRACT

Vehicle theft is a growing concern, necessitating advanced security solutions to prevent unauthorized access and potential loss. This system proposes an effective anti-theft system for vehicles, designed to ensure that only authorized and licensed users can operate the car. The system uses an Arduino microcontroller as the central brain, integrating several key hardware components: a Radio Frequency Identification (RFID) reader, a fingerprint (FP) module, and a Global System for Mobile Communication (GSM) modem. Authorized driver's license (DL) information and fingerprint templates are securely pre-stored in the Arduino UNO. The authentication process requires the user to present their DL to the RFID reader first. If the license is valid, the user proceeds to the fingerprint scanner for biometric verification. If both credentials match the stored data, the ignition system is enabled, allowing the person to drive the vehicle. If either authentication fails, the system blocks the ignition and immediately sends a Short Message Service (SMS) alert via the GSM modem to the vehicle owner. The system also sends SMS reminders to the driver to renew their license before expiration. This dual-authentication method provides a robust security solution that significantly enhances protection against vehicle theft.

Keywords: Fingerprint Authentication, GSM Modem, Dual Authentication, Driving License Verification, Biometric Security, Ignition Control System, Unauthorized Access Prevention, SMS Alert System.

1.Introduction

In recent years, the rise in road accidents and vehicle thefts has necessitated innovative solutions for vehicular safety. Traditional vehicle safety mechanisms often lack comprehensive features for user authentication, accident prevention, and immediate response in emergencies. This Vehicle Safety System bridges these gaps by

leveraging Arduino Mega and a range of sensors, including ultrasonic sensors, and fingerprint readers. The system not only prevents vehicle operation by unauthorized or intoxicated individuals but also enhances safety through obstacle detection and accident reporting. The system uses Arduino UNO as the main controller and integrates RFID technology, fingerprint authentication, and GSM communication for secure vehicle access. The driver must first verify the driving license through the RFID reader and then complete fingerprint verification. Only when both authentications are successful, the ignition system is activated. If unauthorized access is detected, the system immediately sends an SMS alert to the vehicle owner using the GSM modem. This dual-authentication security system provides a reliable and efficient solution to reduce vehicle theft and enhance driver safety.

2.Literature Survey

[1] The paper titled "GPS based Advance vehicles tracks and vehicle Controls System" (2020), author M. Mukhtar addresses a vehicle tracking and control system that highlights key features such as real-time

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

tracking, geo-fencing, and remote vehicle control. By utilizing fleet management to improve overall operational efficiency, the system offers potential benefits including increased safety, reduced fuel consumption, and streamlined logistics, making it a comprehensive solution for modern vehicle management. The proposed system utilizes GPS technology to monitor vehicle location, speed, and other parameters in real-time. The research specifically underscores location tracking, speed monitoring, and route optimization, while implementing security measures such as remote engine immobilization and alarms to prevent theft. These systems prove valuable for fleet management, logistics, and personal vehicle monitoring by enhancing overall efficiency, safety, and security. The methodologies employed include a GPS Receiver Unit, Telematics Hardware, Communication Networks, a Centralized Server, and Geo-fencing. Through the integration of GNSS and geo-fencing features, the system has successfully improved real time tracking with an accuracy of 96.30%. However, some disadvantages remain, notably the initial setup costs—including hardware, software, and installation—which can be a significant investment for businesses, alongside ongoing maintenance and updates that may require additional expenses.

[2] The "Geo fence for fleets and freight managements,"(2021) authors F. Reclus and K. Drouard examine the use of virtual boundaries to modernize vehicle monitoring and logistics. The paper highlights how geo-fence technology can be strategically implemented to optimize fleet operations by creating invisible perimeters that trigger specific actions. This comprehensive approach allows managers to maintain oversight through real-time tracking and geographically targeted alerts, ensuring that freight is moving exactly where and when it should be. The proposed system suggests that by establishing these virtual fences, companies can achieve significant improvements in route optimization. Fleet managers can use the data to define approved transit areas, which helps in reducing fuel consumption and streamlining delivery logistics. Beyond just location, the system acts as a proactive management tool, providing automated notifications that allow for better coordination between drivers and dispatchers. Methodologically, the study focuses on a structured integration process involving Geographical Mapping, the selection of specific Geo-fencing Technology, and full integration with existing Fleet Management Systems. While the advantages include improved overall efficiency and enhanced security, the authors also note certain disadvantages. Specifically, the system's reliability can be hindered by technical issues such as GPS signal loss, inaccuracies in location data, or unexpected system downtimes, all of which can disrupt the smooth flow of fleet management.

[3] The study titled "Geo-fencing and Activity Recognitions" (2021), authors A. Corradi, L. Foschini, R. Ianniello, and R. Montanari explore the foundational principles and benefits of combining geographical boundaries with behavioral analysis. The paper emphasizes how geo-fencing enhances location-aware services and security, while activity recognition identifies and categorizes specific user behavior’s using sensor data from smartphones and wearables. By investigating the synergies between these two technologies, the research aims to optimize context-aware computing and provide more personalized user experiences across various domains. The proposed system investigates how integrating location data with human activity patterns can improve the overall intelligence of mobile services. The methodology involves a structured process of Geo-fence Triggering, System Integration, Sensor Selection, and Data Preprocessing to ensure accurate context detection. A primary advantage of this approach is the ability to provide real-time alerts and notifications the moment a device crosses a designated perimeter, which is highly effective for security monitoring and asset tracking. However, the authors identify a significant disadvantage in the system's reliance on GPS technology. Because the system requires frequent location updates to maintain accuracy, it can drain device batteries quickly, presenting a challenge for long-term monitoring on mobile or wearable hardware.

Vol. 14, Issue 06, ACSCON - 2026

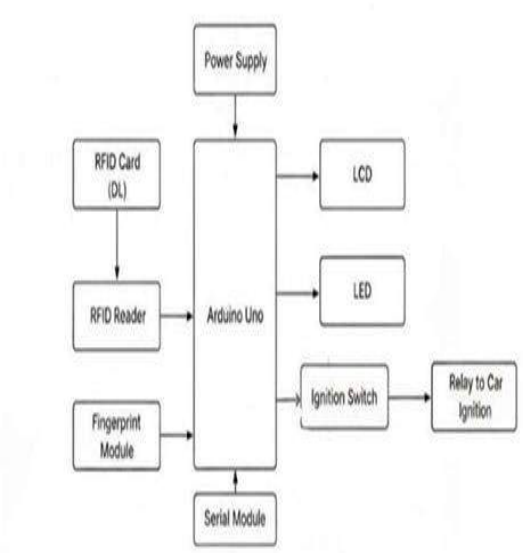

FIG 3.1: BLOCK DIAGRAM

The block diagram illustrates an Arduino-based dual-authentication vehicle security system designed to prevent unauthorized access through multiple verification layers. The system is organized around an Arduino Uno which serves as the primary controller, managing data from input modules and executing logic to control the vehicle's ignition. A dedicated Power Supply block provides the necessary electrical energy to the Arduino and all connected peripheral modules to ensure the system remains active. The security protocol utilizes a dual-layer authentication process consisting of an RFID System and a Fingerprint Module. During the first stage, an RFID Card (DL) is presented to the RFID Reader, which captures the digital identification data and transmits it to the Arduino. Simultaneously, the Fingerprint Module captures the user's biometric template and sends it to the Arduino for secondary verification. These two inputs act as the primary security gates that must be cleared before the vehicle can be operated. The system provides feedback and external communication through several components. An LCD is used to display real-time status messages to the user, while an LED provides visual indicators for system alerts. A Serial Module, likely a GSM/GPRS unit, is integrated to handle external notifications. The final output control is managed by an Ignition Switch and a Relay to Car Ignition. If the Arduino confirms that both the RFID and fingerprint data match the authorized information stored in its memory, it triggers the relay to allow the vehicle to start and operate.

4.HARDWARE AND SOFTWARE REQUIREMENTS

Power Supply:

The Power supply provides the required voltage and current to power the Arduino Uno and all connected modules (typically 5V/12V regulated supply). It ensures stable and regulated power to the Arduino Uno and other peripherals.

Fig 4.1: Power Supply

Arduino Uno:

The Arduino Uno acts as the central processing unit of the system. Receives input from modules (RFID, fingerprint, serial) and controls outputs (LCD, alarm, relay, GSM). and low cost make it ideal for prototyping and implementing this security-focused vehicle system.

Fig 4.2: Arduino Uno

LCD:

5.Software Requirements

The process of writing and uploading code to Arduino boards is simplified by the open- source Arduino Integrated Development Environment (IDE). This software platform acts as the central tool for Arduino of to offering an initiative interface for users to write, compile, and upload their code to the boards. The IDE is available for various operating systems such as Linux, Mac OS X, and Windows, providing developers with flexibility to work across multiple platforms. Its cross-platform support makes it accessible to a broad user base, from hobbyists to professionals, enhancing its widespread adoption. Arduino IDEmeans that all necessary tools for coding and uploading sketches are integrated into one cohesive software package. supports two primary programming languages: C and C++, which are widely used in embedded systems development. These languages are well-suited for writing code that interacts with hardware, making them ideal for microcontroller programming. The term "IDE" stands for Integrated Development Environment, which In the Arduino environment, the code written is referred to as a "sketch." This term reflects the simplicity and approachability of the platform. Writing a sketch involves defining the logic and instructions that control the Arduino board's operation. Once the sketch is ready, it can be uploaded to the Arduino or Genuino board through the IDE. To upload the code, the board must be connected to the computer via a USB cable. The IDE allows users to select the correct board and port configuration before uploading the sketch. This ecosystem ensures that the system remains adaptable to evolving requirements, such as integrating new sensors or communication modules, supporting the project's goal of a scalable smart transportation solution.

6.Results and Discussions

The proposed vehicle security system was successfully implemented using RFID, fingerprint authentication, and GSM technology. The system accurately verified the driving license and fingerprint details of authorized users before enabling the vehicle ignition. Unauthorized access attempts were effectively detected, and the ignition system was immediately blocked to prevent theft. The GSM modem successfully sent SMS alerts to the vehicle owner whenever invalid authentication occurred. Overall, the project provided a reliable, efficient, and secure solution for enhancing vehicle

7.CONCLUSION

The implemented Authenticated Access Control for Vehicle Ignition System Using Driver's License and Fingerprint provides an effective, practical, and low-cost solution for vehicle security enhancement. By integrating RFID-based license verification and biometric fingerprint matching, the system ensures that only legitimate and licensed users start the vehicle. The project demonstrates successful hardware-software integration and reliable authentication performance under various test conditions. This dual-authentication framework can be extended with future improvements such as: integration with cloud databases for centralized access control, GPS-based vehicle tracking for fleet management, mobile app-based monitoring interfaces, and facial recognition for advanced security. Thus, the developed system forms a foundation for next-generation smart vehicle ignition systems that are secure, intelligent, and adaptable to real-world automotive environments.

Abstract - Railway Track Tracer System spots creatures and checks for track damage. It helps to stop train crashes by finding problems early. A camera keeps an eye on the rails now and then, catching any splits or breaks. Once found, alerts go out so fixes happen fast. IoT's getting tons of attention these days. People use it in countless ways beyond just trains. Internet of Things helps keep track of what's happening on railways right now. Instead of waiting, an IR sensor checks if a platform is free. That way, incoming trains get real-time info about where they can stop safely. This setup cuts risks by preventing collisions or wrong stops. If smoke shows up, it triggers alarms and separates the engine automatically. Updates on open platforms go live instantly. One reason trains crash more often lately ties to problems with the rails - like bends, blockages, cracks, or damage along the line. Spotting each issue manually takes way too much effort and time. Communication happens wirelessly, sending updates straight to an Android application. That means operators watch progress from afar, getting live feedback on rail health. Problems show up instantly, helping teams act before things go wrong

Keywords: Railway monitoring system, Track monitoring, Train detection, ZigBee Communication, IOT based railway safety, Microcontroller unit.

1. INTRODUCTION

Every day, flipping through papers shows lots of crashes near train tracks.[3] Unlike car or plane mishaps, train incidents tend to hit harder - more deadly, worse outcomes. So better safety steps can't wait. A moving train packs way more power than most vehicles ever could. When things go wrong, it's often chaos - lives lost, buildings wrecked.

Railway safety matters everywhere trains run. This effort supports rail agencies in building safer habits while creating tools to track risks today's systems need.[1] Fixing cracked tracks comes first on the list. Meanwhile, train crossings stand out - unusual spots that carry risk but still can't be skipped globally. While things run normally, mishaps can still pop up if steps aren't followed closely - tiny mistakes may lead to big dangers. A train slips off the rails during what's called a derailment. That doesn't always mean it jumps completely from the tracks. Some cases are small, yet each one briefly messes up rail service, besides threatening people's well-being without warning. When danger looms fast, crews might force a stop using derails or catch points - to dodge worse trouble ahead. For this reason, systems now check the line constantly for flaws.

Every year, crashes at train crossing points lead to deaths or bad injuries for countless people on roads and trains. These incidents mess up rail and traffic flow[10], plus wreck vehicles and infrastructure - costing a lot. Many of these wrecks happen because car drivers act carelessly, don't know what they're doing, or can't handle their vehicle properly. That's issue number two being looked at here. Even though laws often let trains go first, railways still get stuck dealing with others' mistakes. Because of that rule setup, the rail system ends up paying most of the cost to stay safe. For this reason, new ways to stop such crashes have been put into action.

2. LITERATURE SURVEY

Traditionally, accident or incident analysis are focusing on the cause-consequence chain methods, like Fault Tree or Event Tree, which are hard to find root cause of accidents. To solve this problem, some system safety analysis methods come out, like FRAM and CAST based on STAMP [1]. However, they are good at solving safety management issues, functional failure analysis or causal scenarios analysis, and can be used to capture safety requirements and help system designers to deep understand safety requirements. But the true logic of accident or incident do not analyzed, which is related to human or equipment cannot conceive the right status of train operational status on time. If so, it's easy to ensure safety by train stop.

Rail system's electrical accidents happen frequently; yet currently existing accident data are presented/stored as unrelated information, which makes it difficult for us to achieve data correlation.[2] In order to discover hidden connections between different types of railway electrical accidents.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

For better inspections and security, we need an efficient railway track crack detection system. In this research, we present a computer vision-based technique to detect the railway track cracks automatically. This system uses images captured by a rolling camera attached just below a self-moving vehicle in the railway department. The source images considered are the cracked and[3] crack-free images. The first step is pre-processing scheme and then apply Gabor transform. In this paper, first order statistical features are extracted from the Gabor magnitude image.

[4] In the proposed system they have suggested of using a new rage in the field of Computer Science and interdisciplinary fields, known as M2M (Machine 2 Machine)/ IoT (Internet of Things) where things communicate with each other and based on this the decision is taken. In the proposed system, an onboard device is installed in train enabled with GPRS sensors and is able to communicate using internet of [4]GSM-R standard. This onboard device will communicate with the server using MQTT protocol which is the standard for communication in IoT field.

This paper presents the concept of the detection of crack in metal using radio frequency identification (RFID) tag antenna based sensor (TABS) in ultra-high frequency (UHF)[5] band. The major purpose of our work is to simulate and explore a feasibility, challenges and principles of crack detection based on RFID grids, which can promise the widespread adoption of a smart skin in the field of structural health monitoring (SHM), e.g. health monitoring in railway track. The process of implementing a damage identification strategy for aerospace, civil and mechanical engineering infrastructure is referred to as structural health monitoring (SHM).

The objective of this paper is to design an Automatic Fire initiated braking and alert system for trains. This system contains a microcontroller,[6] motor, fire and smoke sensor, alarm, and alert system. This paper proposes an embedded system that will be used to alert people so that life as well as the damage can be minimized. If the train coach catches fire, the smoke sensor will sense it and send a signal to the microcontroller. This microcontroller activates the motor to pull the chain and also activates an emergency alert system which sends an alert message to the train driver and guard room and activates the alarm.

The present work is based on developing an automatic closing and opening of gates near railway crossing. Generally railway gates are manually handled by gate keeper. The gate keeper will get the information about whether the train is coming or not, from the nearer station. Once the train leaves the station, the station in charger will gives the information about the arrival of train to the nearest gate keeper [7] and alert him to get ready to close the gate. This human intervention can be avoided by using this system. If the arrival of the train is late due to some reason, this information will not send to the gate keeper instantly hence the gate will remain closed until the train arrives this delay will causes the traffic problem near the gates and makes the people get into the trouble. This will be prevented by using this system.

In this project, we are developing a system which can detect the cracks in tracks, derailment problems which helps to avoid accidents and collisions there by saving thousands of lives. The Speed of the train is reduced .Whenever there is human presence on tracks which can be detected using PIR sensors resulting in the suicides. Here we are going to use fire sensors to detect fire in the train. During the times of this Fire accidents an alarm (buzzer) is sounded which alerts the passengers. This project consists of GPS module, GSM modem,[8] IR transmitter and receiver, PIR sensor, microcontroller, Fire sensor, Ultrasonic sensor. Collision mitigation avoidance system involves automatic braking in which if the sensor detects if there is any collision in the future and alarms the driver to take necessary action If the driver shows no respond then it takes the complete charge of braking system.

3. METHODOLOGY [3]

System design and planning: Set up the main structure of the whole setup while picking out core parts - like Arduino units, sensing devices, moving elements, along with signal transmitters. Figure out what the system needs by listing must-have functions: protection measures, steps for crisis handling, plus ways to send and receive data.

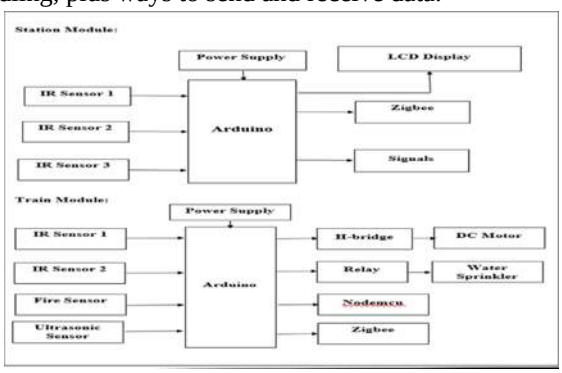

Fig3.1 methodology

The proposed system is designed to improve railway safety and monitoring by integrating sensing, processing, communication, and control mechanisms. The methodology is divided into two main modules: Station Module and Train Module, which work together through wireless communication.

Vol. 14, Issue 06, ACSCON - 2026

1. Station Module

The station module continuously monitors track conditions using multiple sensors. A regulated power supply is provided to ensure stable operation of all components. Three IR sensors are placed along the track to detect train presence and movement. The sensor data is sent to a microcontroller (Arduino), which processes the inputs and determines the train status. Based on this information: The system displays real-time updates on an LCD screen. Warning signals (such as LEDs or buzzers) are activated when required. Data is transmitted wirelessly using a Zigbee module to the train module. This module acts as a monitoring and communication unit that ensures early detection and alert generation.

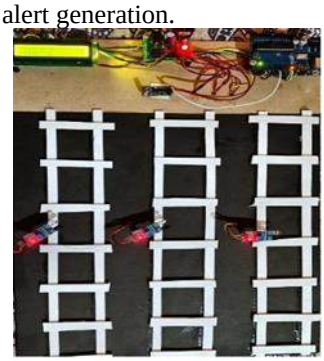

Fig3.2 station module

2. Train Module

The train module is responsible for decision-making and action control. It also receives a stable power supply for operation. Multiple sensors are used, including: IR sensors for obstacle or track detection. Fire sensor for detecting fire hazards. Ultrasonic sensor for measuring distance and avoiding collisions. All sensor inputs are processed by the Arduino microcontroller. Based on the processed data, the system performs the following actions: Controls the DC motor using an H-bridge for movement regulation Activates a relay to operate a water sprinkler in case of fire detection. Sends real-time data to cloud or mobile applications using Node MCU Communicates with the station module using Zigbee for synchronized operation.

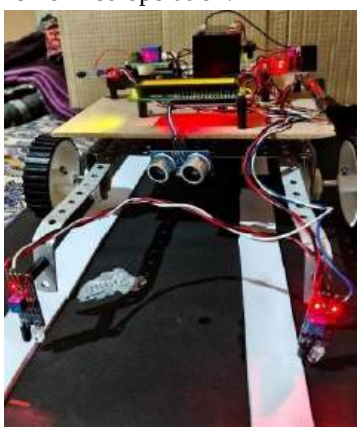

Fig3.3Train module

3. Data Processing and Communication

Both modules communicate wirelessly using Zigbee technology. The microcontrollers analyze incoming sensor data and execute programmed logic to ensure safety. This includes identifying abnormal conditions such as obstacles, fire, or unsafe distances.

4. Control and Monitoring Based on the processed data: The system automatically controls train movement Generates alerts and warning signals

Activates safety mechanisms like fire suppression Displays real-time information on LCD and cloud platforms

5. Overall Working

The system starts by collecting data from sensors in both modules. This data is processed by the microcontrollers to detect any abnormal conditions. If any issue is detected, appropriate actions such as stopping the train, activating alerts, or triggering safety systems are carried out. Simultaneously, real-time updates are displayed and transmitted for monitoring purposes.

Detection System Integration: Put fire detectors inside train cars as well as along the tracks. Build smart codes that read signals from these devices, then set off alarms if smoke or heat is found.

DC Motor Control for Train Movement: Use DC motors so trains can move smoothly. Then build smart rules that handle how fast they start , Create systems that trigger quick actions from sensor signals - like turning on sprinklers , splitting train sections when needed, or sending alerts through set message or go at steady speeds.

Relay and Water Pump Integration: Use relays to trigger compartment separation when fire happens. Link water pumps so they turn on by themselves if there's a blaze.

Zigbee Communication Setup: Hook up Zigbee so fixed and mobile parts can talk without hiccups. Build rules for sharing live info now and then.

Emergency Response Algorithms: Create systems that trigger quick actions from sensor signals - like turning on sprinklers, splitting train sections when needed, or sending alerts through set message rules.

Platform Availability Monitoring System: Use extra IR sensors to keep an eye on how full the platform is all the time. Then feed that info into the main system so trains can run more smoothly.

Crack Detection Module: The primary goal of this project is designing a system that spots cracks on railways through image analysis combined with machine learning techniques. Gathering good data then training the system. Detecting, then sorting good tracks from broken ones.

4.HARDWARE REQUIREMENT

ARDUINO UNO

Arduino Uno's a tiny brain powered by an ATmega328P chip. This little board packs 14 digital pins -six double as PWM ports - alongside six analog sensors There's a 16 MHz crystal ticking inside, plus USB and power jacks. A reset switch helps reboot things fast, while ICSP header allows deeper tinkering. Everything required is built right in - just plug into a PC via USB or use a battery or adapter. The name "Uno" came from Italian, celebrating version 1.0 of the Arduino software launch. The Uno board along with version 1.0 of the Arduino IDE used to be the standard setup for Arduino - since then things have moved forward to fresher updates.

Fig4.1Arduino uno

LCD DISPLAY

LCD, or Liquid Crystal Display, is a widely used flat-panel display technology that has become an essential part of modern electronic devices. It operates by manipulating liquid crystals that align in response to an electric current, which then modulates light to produce visible images. LCD technology is commonly found in computer monitors, televisions, smartphones, tablets, calculators, digital watches, and a variety of other electronic gadgets due to its lightweight design and versatile display capabilities. An LCD module is an electronic display unit primarily used for presenting text, numeric values, and simple graphics.

Fig4.2LCD display

IR SENSOR

Infrared sensors send out invisible light, then catch it when bouncing off things close by. These gadgets spot stuff nearby over small distances - common in many machines today. Inside lives an IR bulb paired with a light detector teaming up smoothly. If something blocks or bounces that beam back, the device notices right IR SENSOR Infrared sensors send out invisible light, then catch it when bouncing off things close by. Fig4.3 IR sensor

ULTRASONIC SENSOR

An ultrasonic sensor figures out how far things are by sending out high pitched sounds you can't hear. Inside, there's a part that shoots sound bursts while another listens for bounces back. The longer it takes for the bounce to come back, the farther the object must be. These sensors pop up in cars when backing up, robots avoiding walls, or spotting barriers without touching them. Ultrasonic sensors work well indoors or out. Since they ignore light, color, and how rough a surface is, they're better in many situations than infrared ones. these devices help avoid crashes and accidental touches

Fig 4.4 Ultrasonic sensor

FIRE SENSOR

Vol. 14, Issue 06, ACSCON - 2026

A fire sensor notices flames by picking up heat rays or fast temperature jumps. Because it reacts quickly to these signs, it's useful for avoiding danger. Since they act fast when a flame shows up, you'll find them in protection setups. Whether inside factories, houses with smart devices, or warning networks during crises - they're common. Depending on the model, the signal sent out is either digital or analog. Because they're built to handle tiny setups just as well as big ones, these tools fit many needs. Hooked up to microcontrollers, they can trigger warnings or shields without help. Small in size, tough when it counts, they use little power while staying dependable.

Fig4.5 Fire sensor

ZIGBEE

Zig bee works wirelessly, built to send data using very little energy over large distances. Thanks to mesh networks, gadgets can talk to each other across wide spaces without issue. These modules run on the IEEE 802.15.4 framework, offering steady connections that stay protected. Perfect for smart homes, industrial setups, or any IoT use you've got in mind. Since it uses almost no power, battery-powered tools work just fine with this setup. It keeps signals strong, even when there's lots of interference. This setup lets devices check in and respond from far away. Hooking it up to small chips works smoothly using basic data lines. Using Zigbee saves money while handling big setups without issues. In this build, it boosts how well gadgets talk wirelessly.

Fig 4.6 Zigbee

MICROCONTROLLER(ESP32)

The ESP32 is a low-cost, powerful system-on-a-chip microcontroller series developed by Espressif Systems, popular for Internet of Things (IoT) projects due to its integrated Wi-Fi and Bluetooth capabilities. Most models feature a dual-core 32bit processor (up to 240 MHz), numerous GPIO pins supporting various peripheral interfaces (SPI, I2C, UART, ADC, DAC, etc.

Fig 4.6 ESP32

5.SOFTWARE REQUIRED

EMBEDDED C The use of Embedded C in the software industry is widespread, especially when it comes to creating software for electronic devices. Fine-tuned for tiny computers inside gadgets, Embedded C gives direct control over hardware - making things run smoothly. From basic stuff like ovens to high-end gear like factory bots, today's electronics depend on built-in code, usually crafted in Embedded **C**. The role of Embedded C lies in letting processors handle particular jobs within embedded setups. Instead of general-purpose devices, these systems focus on single functions while dealing with tight deadlines and low computing strength. With this language, coders manage hardware, memory, usage timing more precisely - so everything works smoothly without wasting resources. Each day, you use gadgets running on hidden tech - most rely on Embedded C. Take digital cameras or washing machines - they work thanks to tiny chips coded in this language. Smart TVs, phone features, even automated homes link back to it. Instead of just working alone, they respond to inputs, track sensor data, control actions. Power stays low because the code manages energy wisely. They also talk to other devices when needed. Thanks to Embedded C programs, everything runs smoothly without hiccups. Embedded C plays a key role in countless daily gadgets, turning basic tasks into intelligent, automatic functions. Instead of just coding, it lets build tools that work well while staying small, affordable, using little energy, plus running efficiently. Thanks to these benefits, it's now a go-to choice across today's tech - powering everything from home electronics to factory robots, cars, health equipment, along with various other real world applications. In the suggested setup, Embedded C handles tight control routines that link the Atmega16 chip with outside parts - like IR detectors or RFID scanners. Instead of high-level tools, this language gives fine grip on hardware, so actions like checking seats for use run fast. It grabs live sensor numbers quickly, also deals cards via RFID without lag. With direct memory reach and bit tweaks built in, it works smoothly even when power and space are thin. This keeps delays low while using only what the chip

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

can offer slowness when crowds are heaviest. Smooth running matters most at busy times - keeping things moving while lots get on or off the vehicle quickly.

ARDUINO ID

The open-source Arduino IDE makes coding and sending programs to Arduino boards way easier. It serves as the main hub for creating projects, letting people type, check, then push their code straight onto devices. Instead of being stuck on one system, this tool runs on Linux, macOS, and Windows - so folks can use what they already have. Because it works everywhere, more makers stick with it, whether tinkering at home or building serious gear. Arduino IDE works mainly with C or also C++ - both common choices when building stuff for small computers inside devices. These options handle hardware tasks pretty well, so they fit perfectly when coding tiny chips. “IDE” actually means you get everything needed - like editing plus sending programs - all packed together neatly in a single app. This term emphasizes how simple and beginner-friendly the platform is. Writing a sketch means creating the logic and instructions that tell the Arduino board what to do. Once the sketch is complete, it can be uploaded to the Arduino or Genuine board using the IDE. To do this, the board is connected to the computer with a USB cable. The IDE also lets users choose the correct board type and port before uploading the program, making the whole process straight forward and accessible When a sketch is created in the Arduino IDE, it is saved with the extension IR sensors, and RFID readers. Its user-friendly interface allows developers to write, debug, and upload code efficiently, reducing the learning curve for implementing complex functionalities such as real-time passenger counting and fare deduction.

6.RESULTS AND DISCUSSIONS

The Railway Track and Fault Monitoring System was designed and evaluated successfully, showing its capability to detect and report track issues instantly. Using a built-in sensor unit[9], the prototype effectively monitored vibrations, tilt shifts, and structural changes along the track. During testing on a model rail setup, it consistently recognized test faults such as small cracks, misaligned joints, and sudden surface disturbances. For every abnormality detected, the system recorded the exact GPS coordinates along with the time, making it easier for maintenance teams to locate the fault and respond efficiently.

7.CONCLUSION

A system can lower crashes from rail breaks, flames, or issues when trains reach the stop. It checks tracks by itself to spot damage, making upkeep easier and more reliable. Gates open and shut on their own - no person needed - which cuts down

collision risks. When a heat detector senses fire, it reacts fast. That keeps flames from moving between sections and warns travelers right away.

The Smart Railway Monitoring System is a big step forward for safer, smoother train operations.[8] With sensors linked to IoT tech and smart analysis, it keeps an eye on tracks, trains, and nearby areas nonstop. Instead of fixing problems after they happen, this setup helps catch issues early - thanks to live data flow through connected networks. That means

Thermal Properties of Composite Materials: A Comprehensive Review of Heat Transfer Behavior, Characterization Techniques, and Aerospace Applications

Omkar Pandey[1]. Akshita Injallikar, Deeksha V, Gagana G, Gunashree K, Jayashree R[(2)]

Assistant Professor- ACS College of Engineering. (omkarpandey32@gmail.com)

[(2)] Student - ACS College of Engineering.

Abstract

Composite materials have emerged as one of the most transformative classes of engineering materials due to their superior strength-to-weight ratio, tailorability, corrosion resistance, and multifunctional capabilities. Among the numerous characteristics governing the performance of composite systems, thermal properties play a critical role in determining their suitability for aerospace, automotive, marine, civil, and energy applications. This review paper presents a comprehensive analysis of the thermal behavior of composite materials with emphasis on thermal conductivity, thermal diffusivity, coefficient of thermal expansion (CTE), specific heat capacity, thermal stability, and heat resistance. The influence of reinforcement type, matrix selection, fiber orientation, interfacial bonding, porosity, and nano-fillers on thermal performance is critically examined. Various experimental characterization techniques such as Laser Flash Analysis (LFA), Differential Scanning Calorimetry (DSC), Thermogravimetric Analysis (TGA), and Thermomechanical Analysis (TMA) are discussed in detail. Furthermore, recent advances involving nanocomposites, hybrid composites, bio-composites, and smart thermal management materials are reviewed. The paper also highlights challenges associated with anisotropic heat transfer, thermal degradation, manufacturing-induced defects, and computational modeling. Future research opportunities involving multifunctional composites, additive manufacturing, phase change materials, and AI-assisted material optimization are explored. The review provides researchers and engineers with a consolidated understanding of the current developments and future scope in the thermal analysis and design of composite materials.

Keywords: Composite materials, thermal conductivity, thermal diffusivity, coefficient of thermal expansion, nanocomposites, aerospace materials, thermal management, heat transfer.

1. INTRODUCTION

Composite materials are engineered materials composed of two or more distinct constituents combined to achieve superior mechanical, thermal, electrical, or chemical properties compared to the individual components. Typically, composites consist of a reinforcement phase such as fibers or particles embedded within a continuous matrix phase. Common matrix materials include polymers, metals, and ceramics, while reinforcements may consist of carbon fibers, glass fibers, aramid fibers, silicon carbide, graphene, carbon nanotubes, or natural fibers.

The increasing demand for lightweight, high-performance materials has accelerated the adoption of composite systems in aerospace, automotive, defense, marine, and renewable energy industries. While mechanical performance has traditionally received the most attention, thermal properties are becoming equally important due to increasing operational temperatures, thermal cycling, and heat dissipation requirements in modern engineering systems.

Thermal properties determine the ability of a material to conduct, store, resist, or dissipate heat under varying environmental conditions. In aerospace structures, thermal management is essential because aircraft and spacecraft components are subjected to extreme thermal gradients during operation. Similarly, in electronics and automotive applications, thermal conductivity and thermal stability directly influence component reliability and operational efficiency.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Unlike isotropic metals, composites exhibit highly anisotropic thermal behavior due to directional reinforcement and heterogeneous microstructures. Factors such as fiber orientation, fiber volume fraction, porosity, interfacial thermal resistance, and manufacturing defects significantly influence heat transfer characteristics. Consequently, accurate prediction and optimization of thermal properties remain challenging.

This review aims to critically analyze the thermal properties of composite materials, discuss characterization methods, evaluate the influence of microstructural parameters, and identify emerging research directions.

2. CLASSIFICATION OF COMPOSITE MATERIALS

Composite materials can be classified based on matrix type, reinforcement type, and structural configuration.

2.1 Polymer Matrix Composites (PMCs)

Polymer matrix composites are the most widely used composite systems due to their low density, corrosion resistance, ease of fabrication, and cost-effectiveness. Thermosetting polymers such as epoxy, polyester, and phenolic resins are commonly used.

Advantages

A. Lightweight

B. Excellent corrosion resistance

C. Good fatigue properties

D. Tailorable thermal characteristics

Limitations

A. Low thermal conductivity

B. Limited thermal stability

C. Susceptibility to thermal degradation

2.2 Metal Matrix Composites (MMCs)

Metal matrix composites consist of metallic matrices reinforced with ceramic particles or fibers.

Advantages

A. High thermal conductivity

B. Improved thermal stability

C. Superior wear resistance

Applications

A. Aircraft brake systems

B. Engine components

C. Thermal heat sinks

2.3 Ceramic Matrix Composites (CMCs)

Ceramic matrix composites are designed for high-temperature applications.

Advantages

A. Excellent thermal resistance

B. High temperature capability

C. Oxidation resistance

Applications

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A. Gas turbine blades
B. Thermal protection systems
C. Rocket nozzles

2.4 Hybrid Composites

Hybrid composites combine multiple reinforcements to achieve multifunctional performance.

Example

Carbon-glass hybrid composites provide balanced mechanical and thermal properties.

3. FUNDAMENTAL THERMAL PROPERTIES OF COMPOSITE MATERIALS

3.1 Thermal Conductivity

Thermal conductivity represents the ability of a material to transfer heat through conduction.

$$k = \frac{Q \times L}{A \times \Delta T \times t} \text{ or } k = \frac{Q \cdot L}{A \cdot \Delta T} \text{ (rate form)}$$

Where:

q = heat transfer rate

k = thermal conductivity

A = cross-sectional area

dT/dx = temperature gradient

Composite materials exhibit anisotropic thermal conductivity. Heat conduction along the fiber direction is generally much higher than transverse conduction.

Factors Affecting Thermal Conductivity

A. Fiber Type: Carbon fibers possess significantly higher thermal conductivity than glass fibers.
B. Fiber Orientation: Unidirectional composites show enhanced conductivity along the fiber axis.
C. Fiber Volume Fraction: Increasing fiber content generally increases thermal conductivity.
D. Interfacial Resistance: Poor bonding between matrix and reinforcement reduces heat transfer efficiency.
E. Porosity: Voids and pores act as thermal barriers.

Thermal Conductivity Enhancement Techniques

A. Addition of graphene nanoparticles
B. Carbon nanotube reinforcement
C. Hybrid filler systems
D. Improved interfacial adhesion

3.2 Thermal Diffusivity

Thermal diffusivity indicates how quickly heat spreads through a material.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

$$\alpha = \frac{k}{\rho c_p}$$

α = thermal diffusivity

k = thermal conductivity

ρ = density

Cp = specific heat capacity

High thermal diffusivity materials rapidly respond to temperature changes**.**

3.3 Specific Heat Capacity

Specific heat capacity defines the amount of heat required to raise the temperature of a unit mass by one degree Celsius.

Polymer composites generally possess moderate specific heat capacity values, while ceramic composites exhibit lower heat storage capability.

3.4 Coefficient of Thermal Expansion (CTE)

CTE describes dimensional changes resulting from temperature variation.

Low CTE materials are preferred in aerospace structures to minimize thermal stresses.

Factors Influencing CTE

A. Fiber orientation
B. Matrix stiffness
C. Reinforcement content
D. Temperature range
E. Carbon fiber composites exhibit very low CTE values compared to glass fiber composites.

3.5 Thermal Stability

Thermal stability refers to the ability of a material to retain its structure and performance at elevated temperatures.

Thermal degradation mechanisms include:

A. Matrix decomposition
B. Oxidation
C. Fiber-matrix debonding
D. Delamination

Thermogravimetric analysis is commonly used to evaluate thermal stability.

4. HEAT TRANSFER MECHANISMS IN COMPOSITE MATERIALS

Heat transfer in composites occurs through:

4.1 Conduction

Conduction is the dominant heat transfer mechanism in solid composites.

4.2 Convection

Convection becomes relevant in porous or foam-based composites.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.3 Radiation

At elevated temperatures, thermal radiation contributes significantly.

Anisotropic Heat Transfer

Due to directional reinforcements, composites often exhibit:

A. Higher in-plane conductivity
B. Lower through-thickness conductivity
C. This anisotropy complicates thermal design and analysis.

5. INFLUENCE OF REINFORCEMENT ON THERMAL PROPERTIES

5.1 Carbon Fiber Reinforced Composites

Carbon fibers exhibit high thermal conductivity and low thermal expansion.

Applications

A. Spacecraft panels
B. Satellite structures
C. Thermal management systems

5.2 Glass Fiber Reinforced Composites

Glass fibers possess lower thermal conductivity than carbon fibers.

Advantages

A. Low cost
B. Good insulation properties
C. Corrosion resistance

5.3 Natural Fiber Composites

Natural fibers such as jute, flax, and hemp are increasingly used in sustainable engineering applications.

Thermal Characteristics

A. Low thermal conductivity
B. Good insulation capability
C. Limited thermal stability

5.4 Nano-Reinforced Composites

Nanoparticles significantly improve thermal conductivity.

A. Common Nanofillers
B. Graphene
C. Carbon nanotubes
D. Boron nitride
E. Nano-clay
F. Challenges
G. Agglomeration

H. Uniform dispersion

I. Interfacial compatibility

6. EFFECT OF MATRIX MATERIALS

6.1 Thermosetting Matrices

Thermosetting polymers exhibit:

I. Good thermal stability

II. Low thermal conductivity

III. Excellent dimensional stability

6.2 Thermoplastic Matrices

Thermoplastics provide:

I. Better recyclability

II. Improved toughness

III. Faster processing

6.3 Metallic Matrices

Metallic matrices enhance:

I. Heat conduction

II. High-temperature capability

III. Structural integrity

6.4 Ceramic Matrices

Ceramic matrices are suitable for ultra-high temperature environments.

7. EXPERIMENTAL TECHNIQUES FOR THERMAL CHARACTERIZATION

7.1 Laser Flash Analysis (LFA)

LFA is widely used for measuring thermal diffusivity.

Advantages

I. Fast measurement

II. High accuracy

III. Suitable for high temperatures

7.2 Differential Scanning Calorimetry (DSC)

DSC measures:

I. Glass transition temperature

II. Heat flow behavior

III. Specific heat capacity

7.3 Thermogravimetric Analysis (TGA)

I. Thermal degradation
II. Weight loss
III. Oxidation resistance

7.4 Thermomechanical Analysis (TMA)

TMA measures thermal expansion behavior.

7.5 Infrared Thermography

Infrared thermography is used for:

I. Non-destructive evaluation
II. Defect detection
III. Thermal mapping

8. THERMAL DEGRADATION AND FAILURE MECHANISMS

Thermal degradation is a major concern in high-temperature composite applications.

8.1 Matrix Decomposition

Polymeric matrices degrade at elevated temperatures leading to loss of structural integrity.

8.2 Fiber-Matrix Debonding

Thermal mismatch causes interfacial stresses.

8.3 Delamination

Repeated thermal cycling induces interlaminar separation.

8.4 Oxidation

Carbon-based composites are susceptible to oxidation in high-temperature oxidative environments.

9. THERMAL PROPERTIES IN AEROSPACE APPLICATIONS

Composite materials are extensively used in aerospace structures due to their high specific strength and customizable thermal properties.

9.1 Aircraft Structures

Applications include:

A. Fuselage panels
B. Wing structures
C. Radomes
D. Engine nacelles

Thermal Requirements

A. Low thermal expansion

12. RECENT ADVANCES IN THERMAL COMPOSITE RESEARCH

12.1 Graphene-Based Composites

Graphene enhances thermal conductivity significantly even at low filler concentrations.

12.2 Phase Change Material (PCM) Composites

PCMs improve thermal energy storage capability.

Applications

A. Battery cooling
B. Thermal regulation systems
C. Smart textiles

12.3 Additive Manufacturing of Thermal Composites

3D printing enables customized thermal pathways and complex geometries.

12.4 Bio-Composites

Eco-friendly bio-composites are gaining importance due to sustainability concerns.

13. Challenges in Thermal Characterization and Design

Despite significant advancements, several challenges remain.

13.1 Anisotropy

Directional properties complicate thermal analysis.

13.2 Porosity and Defects

Manufacturing defects adversely affect heat transfer.

13.3 Interfacial Thermal Resistance

Efficient heat transfer across interfaces remains difficult.

13.4 High-Temperature Durability

Long-term thermal exposure causes degradation.

13.5 Standardization Issues

Lack of universal standards complicates property comparison.

14. Future Research Directions

Future research should focus on:

14.1 Multifunctional Composites

Development of materials with simultaneous mechanical, thermal, and electrical functionality.

14.2 Smart Thermal Management Systems

Integration of sensors and adaptive thermal control.

14.3 Nanoengineered Interfaces

Improved interfacial heat transfer using nanoscale engineering.

14.4 Sustainable Composite Systems

Research into recyclable and biodegradable thermal composites.

14.5 Digital Twin and AI-Based Material Design

Use of artificial intelligence for accelerated material discovery.

15. CONCLUSION

Thermal properties are critical in determining the performance, reliability, and operational lifespan of composite materials across various engineering applications. The thermal behavior of composites is highly influenced by reinforcement type, matrix material, fiber orientation, porosity, interfacial bonding, and environmental conditions. Carbon-based reinforcements, nano-fillers, and hybrid architectures have significantly improved thermal conductivity and thermal stability, enabling the use of composites in advanced aerospace and electronic applications.

Experimental techniques such as LFA, DSC, TGA, and infrared thermography provide valuable insight into thermal behavior, while computational approaches offer efficient predictive capabilities. Despite substantial advancements, challenges such as anisotropy, thermal degradation, interfacial resistance, and manufacturing defects continue to limit performance optimization.

Emerging technologies including graphene-enhanced composites, additive manufacturing, smart thermal materials, and AI-assisted design are expected to revolutionize the field of thermal composite engineering. Future research should emphasize multifunctionality, sustainability, and high-temperature reliability to meet the growing demands of next-generation aerospace, automotive, and energy systems.

ABSTRACT

Boron Nitride Nanotubes (BNNTs) have emerged as one of the most promising nanomaterials for next-generation thermal management applications in high-temperature structural composites. Unlike conventional carbon-based fillers, BNNTs combine exceptional thermal conductivity (up to 300 W/mK axially), outstanding electrical insulation, and remarkable thermochemical stability in oxidizing environments up to 900°C. This paper provides a comprehensive review of BNNT synthesis methodologies, surface functionalization strategies, and their integration into polymer-matrix, ceramic-matrix, and metal-matrix composites. We critically analyze reported thermal conductivity enhancements, mechanical property improvements, and high-temperature performance data from the current literature. Key challenges including nanotube dispersion, interfacial thermal resistance (Kapitza resistance), and cost-effective large-scale production are discussed alongside emerging solutions. The paper concludes with an industrial roadmap identifying sectors—aerospace, power electronics, nuclear, and high-performance automotive—where BNNTs offer transformative advantages over incumbent thermal management materials.

Keywords: Boron Nitride Nanotubes, Thermal Conductivity, Structural Composites, Nanofiller, Thermal Management, High-Temperature Materials, Kapitza Resistance, Aerospace Materials

1. Introduction

The relentless push toward higher operating temperatures in aerospace propulsion, advanced power electronics, nuclear reactor components, and high-performance automotive systems has created an urgent demand for structural materials that simultaneously bear mechanical loads and dissipate heat efficiently. Traditional thermal management strategies—metallic heat sinks, thermal interface materials, and passive cooling fins—are increasingly inadequate as thermal fluxes exceed 500 W/cm² in next-generation systems.

Nanocomposites reinforced with high-conductivity fillers have attracted enormous research interest as a pathway to combine structural integrity with enhanced thermal transport. Among the candidate fillers—carbon nanotubes (CNTs), graphene nanoplatelets, aluminum nitride (AlN), and boron nitride nanosheets (BNNS)—Boron Nitride Nanotubes (BNNTs) occupy a unique technological niche. First synthesized by Chopra et al. in 1995, BNNTs share the hollow cylindrical morphology of CNTs but are composed of alternating boron and nitrogen atoms in a hexagonal lattice, imparting fundamentally different electronic and chemical properties.

The critical advantage of BNNTs over CNTs lies in their combination of properties that are otherwise mutually exclusive: high thermal conductivity with complete electrical insulation (bandgap ~5.5 eV), oxidation resistance far exceeding that of carbon-based counterparts, and chemical inertness across a wide pH range. These attributes make BNNTs exceptionally well-suited as multifunctional fillers in composites destined for thermally demanding, electrically sensitive, and chemically aggressive service environments.

This paper is structured as follows: Section 2 examines the fundamental structure and properties of BNNTs. Section 3 reviews synthesis methods and scalability. Section 4 discusses surface functionalization critical to composite

Vol. 14, Issue 06, ACSCON - 2026

integration. Sections 5–7 analyze thermal and mechanical performance in polymer-, ceramic-, and metal-matrix composites respectively. Section 8 addresses industrial applications, and Section 9 outlines challenges and future directions.

2. Structure and Fundamental Properties of BNNTs

2.1 Atomic Structure and Morphology

BNNTs consist of one or more cylindrical shells of hexagonal boron nitride (h-BN), each shell comprising alternating boron and nitrogen atoms. The B-N bond length of 1.44 Å and the sp^2 hybridization produce a structure geometrically analogous to multi-walled carbon nanotubes (MWCNTs). However, the ionic character of the B-N bond (~25% ionic) critically distinguishes BNNTs from CNTs in terms of electronic structure and surface chemistry. Typical synthesized BNNTs exhibit outer diameters of 2–8 nm, wall numbers of 2–5, and lengths ranging from hundreds of nanometers to several micrometers, yielding aspect ratios of 100–1000.

Unlike CNTs, which can be metallic or semiconducting depending on chirality, all BNNTs are wide-bandgap insulators (~5.5 eV) irrespective of their chirality and diameter. This chirality-independent electronic property is a decisive advantage for applications requiring electrical insulation combined with thermal conduction.

2.2 Thermal Properties

The thermal conductivity of individual BNNTs has been measured by thermal bridge methods at values of 100–350 W/mK at room temperature along the tube axis—comparable to high-quality MWCNTs. The primary heat carriers are phonons, and the absence of free electrons means there is no electronic contribution to thermal conductivity. This phonon-dominated transport is highly anisotropic: axial conductivity vastly exceeds radial conductivity, making alignment a critical parameter in composite design.

Crucially, BNNTs maintain structural integrity and useful thermal performance to temperatures exceeding 900°C in oxidizing atmospheres—far superior to CNTs, which begin oxidizing above ~400°C. Above 900°C, BNNTs gradually oxidize to form a protective boron oxide (B_2O_3) layer, which in many ceramics processing contexts is beneficial as a sintering aid.

Table 1 compares the key properties of BNNTs against competing filler materials:

Property	BNNTs	CNTs (MWCNT)	Graphene	AlN	h-BN Platelets
Axial Thermal Cond. (W/mK)	100–350	300–3000	~5000	~285 (bulk)	~360 (in-plane)
Electrical Properties	Insulator (~5.5 eV)	Metallic/Semicond.	Semimetal	Insulator	Insulator
Oxidation Onset (°C)	>900	~400	~600	Stable	>900
Density (g/cm³)	~2.1	~2.0	~2.26	~3.26	~2.1
Aspect Ratio (typical)	100–1000	100–10,000	~50–200 (flakes)	~5–20	~50–200
Chemical Stability	Excellent	Moderate	Moderate	Good	Excellent
Cost (relative)	High	Moderate	Moderate	Low	Low-Moderate

Table 1. Comparative properties of BNNTs and competing thermal filler materials.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

2.3 Mechanical Properties

BNNTs exhibit excellent mechanical performance. Young's modulus measurements by atomic force microscopy (AFM) bending tests report values in the range of 700–900 GPa, with tensile strengths estimated at 33–61 GPa from molecular dynamics simulations. Their bending flexibility is comparable to CNTs, and they sustain large elastic deformations without brittle failure—a critical attribute for composite toughening applications. The density of ~2.1 g/cm³ makes BNNTs attractive for weight-sensitive aerospace applications.

3. Synthesis Methods and Scalability

3.1 Arc Discharge

The arc discharge method, adapted from CNT synthesis, involves striking an electric arc between boron-containing electrodes in a nitrogen atmosphere. While this produces BNNTs with relatively high crystallinity and purity, the process suffers from low yield, poor length control, and scalability limitations. It remains primarily a laboratory technique for producing small quantities of high-quality reference material.

3.2 Chemical Vapor Deposition (CVD)

CVD and its variants—thermal CVD, plasma-enhanced CVD (PECVD), and catalytic CVD—offer greater control over nanotube diameter, length, and wall number. Precursors include borazine ($B_3N_3H_6$), ammonia borane (NH_3-BH_3), and boric acid/melamine mixtures. Transition metal catalysts (Fe, Ni, Co) are frequently employed. CVD methods are more amenable to scale-up but often yield BNNTs with more structural defects than arc-discharge samples.

3.3 Ball Milling and Annealing

High-energy ball milling of boron powder followed by annealing in nitrogen or ammonia atmospheres at 1100–1300°C represents one of the most scalable production routes. NASA and BNNT LLC (USA) have demonstrated kilogram-scale production using induction-coupled plasma and pressurized vapor/condenser (PVC) methods. These industrial-scale processes are critical for practical composite manufacturing and have reduced BNNT costs by approximately an order of magnitude over the past decade, though prices remain significantly higher than CNTs.

3.4 Production Scalability Status

As of 2025, commercial BNNTs are available from several suppliers at purities of 50–95%, with the primary impurity being hexagonal boron nitride particles and amorphous boron. The highest-purity (>90%) material commands prices of $500–$2000/gram, while lower-purity bulk material suitable for some composite applications is available at $50–$200/gram. Industrial adoption is contingent on continued cost reduction, with techno-economic models projecting viable pricing for aerospace applications at $10–$50/gram.

4. Surface Functionalization Strategies

Raw BNNTs are chemically inert with a smooth, relatively non-reactive surface—a property that is simultaneously an advantage (stability) and a liability (poor interfacial bonding with matrices). Achieving strong interfacial adhesion is paramount for both mechanical load transfer and phonon transport across the nanotube-matrix interface. Several functionalization strategies have been developed:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.1 Covalent Functionalization

Covalent modification involves chemically bonding functional groups to the BNNT surface. Common approaches include: (i) reaction with strong Lewis acids or bases to introduce hydroxyl (-OH) or amine (-NH_2) groups; (ii) mechanochemical treatment via ball milling to generate surface radicals; and (iii) reaction with organic isocyanates. While covalent functionalization significantly improves dispersion and interfacial bonding, it introduces structural defects that can reduce intrinsic thermal conductivity by 10–30%.

4.2 Non-Covalent Functionalization

Non-covalent approaches—wrapping BNNTs with amphiphilic polymers, surfactants (sodium dodecyl sulfate, cetyltrimethylammonium bromide), or aromatic molecules via π-interactions—preserve the nanotube structure while improving dispersion. These methods are preferred when maintaining maximum thermal conductivity is critical. Polymer wrapping with polyethylene glycol (PEG), poly(vinyl alcohol) (PVA), or epoxy-compatible compatibilizers has shown particular promise for polymer matrix composites.

4.3 Silane Coupling Agents

Silane functionalization (e.g., 3-aminopropyltriethoxysilane, APTES) is widely used for ceramic and polymer composites, exploiting the surface hydroxyl groups present on BNNTs after mild acid treatment. Silane coupling creates covalent bridges between the BNNT surface and the matrix, substantially improving interfacial thermal conductance—a critical parameter since interfacial (Kapitza) resistance often dominates composite thermal conductivity more than the filler volume fraction.

5. BNNTs in Polymer-Matrix Composites (PMCs)

5.1 Epoxy-Based Systems

Epoxy resins are the most extensively studied polymer matrix for BNNT-based thermal composites. Researchers have demonstrated thermal conductivity enhancements of 50–200% at BNNT loadings of 1–5 wt%, with the highest values achieved through alignment and surface functionalization. Tang et al. (2021) reported a thermal conductivity of 1.8 W/mK in aligned BNNT/epoxy composites at 5 wt% loading, representing a 650% improvement over neat epoxy (~0.24 W/mK). Critically, the electrical insulation of the composite was maintained (volume resistivity >10^{14} Ω·cm), confirming BNNTs' superiority over CNTs for electronics thermal management.

The addition of BNNTs also improves the glass transition temperature (Tg) of epoxy systems by 10–30°C at optimized loadings, attributed to restricted polymer chain mobility at the nanotube interface. This dual improvement in thermal conductivity and Tg is particularly valuable for printed circuit board (PCB) encapsulants and structural adhesives in aerospace applications.

5.2 Polyimide and High-Temperature Polymer Systems

Polyimide (PI) matrices, with service temperatures up to 400°C, are natural hosts for BNNTs in high-temperature electronics and aerospace structural applications. Kim et al. (2022) demonstrated that incorporating 3 wt% amino-functionalized BNNTs into PI films increased thermal conductivity from 0.19 to 0.68 W/mK while simultaneously

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

improving tensile strength by 28%. The BNNT/PI composites exhibited stable thermal performance across 100 thermal cycles from -60°C to 350°C—a critical metric for aerospace qualification.

5.3 PEEK and Engineering Thermoplastics

Polyether ether ketone (PEEK) and polyphenylene sulfide (PPS) matrices are gaining traction for structural-thermal applications. BNNT incorporation at 2–5 wt% in PEEK has shown thermal conductivity improvements of 80–150% with retention of the characteristic semicrystalline morphology and excellent chemical resistance. The continuous use temperature of PEEK (~260°C) combined with BNNT enhancement addresses a critical gap between conventional polymer composites and ceramic systems.

Table 2 summarizes key results from PMC studies:

Matrix	BNNT Loading (wt%)	TC Enhancement (%)	Tensile Strength Change (%)	Max Service Temp (°C)
Epoxy (neat: 0.24 W/mK)	5	+650	+15	~180
Polyimide	3	+258	+28	~400
PEEK	4	+130	+12	~260
Silicone elastomer	10	+180	+8	~200
Polypropylene	5	+95	+20	~130

Table 2. Representative BNNT/PMC thermal and mechanical performance data (compiled from literature, 2019–2025).

6. BNNTs in Ceramic-Matrix Composites (CMCs)

6.1 Silicon Carbide (SiC) Systems

Silicon carbide ceramic matrix composites (SiC/SiC CMCs) are the leading candidate materials for ultra-high-temperature aerospace applications including turbine hot-section components. BNNTs address a key weakness of SiC CMCs: their relatively low fracture toughness (typically 3–5 MPa·m^0.5 for monolithic SiC). BNNT additions of 1–3 vol% via slurry infiltration or field-assisted sintering technology (FAST/SPS) have improved fracture toughness by 40–80% through crack bridging, crack deflection, and nanotube pull-out mechanisms.

Thermal conductivity in BNNT/SiC composites increases by 20–45% at 2 vol% BNNT loading. The retained high thermal conductivity at temperatures exceeding 1000°C distinguishes BNNT/SiC from carbon-toughened SiC, where oxidation of carbon at elevated temperatures degrades both thermal and mechanical performance.

6.2 Alumina (Al_2O_3) and Alumina-Zirconia Systems

Alumina-based ceramics represent a cost-effective entry point for BNNT-toughened CMCs in industrial applications (heat exchangers, furnace components, cutting tools). BNNT/Al_2O_3 composites consolidated by spark plasma sintering (SPS) at 1400–1500°C demonstrate toughness values of 5.5–7.2 MPa·m^0.5 (vs. ~3.5 MPa·m^0.5 for monolithic Al_2O_3) and thermal conductivity improvements of 25–40%. The chemical compatibility between BNNTs and Al_2O_3 at sintering temperatures is excellent, avoiding the interfacial reaction products that complicate CNT/ceramic systems.

6.3 Ultra-High-Temperature Ceramics (UHTCs)

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Zirconium diboride (ZrB_2) and hafnium diboride (HfB_2)-based UHTCs, targeting applications above 1800°C (hypersonic leading edges, rocket nozzle throats), represent the most extreme environment for any filler material. BNNTs can survive initial UHTC processing temperatures of 1600–1800°C via SPS/FAST with minimal degradation. Early-stage research by NASA and partner institutions has demonstrated that BNNT additions improve UHTC thermal shock resistance by 30–50%, attributed to crack bridging in the high-temperature regime before BNNT decomposition.

7. BNNTs in Metal-Matrix Composites (MMCs)

7.1 Aluminum-Matrix Composites

Aluminum MMCs reinforced with BNNTs offer a compelling combination of lightweight (density ~2.4–2.7 g/cm³ for 5 vol% BNNT/Al), high thermal conductivity, and improved specific strength. Unlike CNTs in aluminum, BNNTs do not react with aluminum to form detrimental Al_4C_3 intermetallic compounds—a known degradation mechanism in Al/CNT composites that reduces both thermal and mechanical properties. BNNT/Al composites produced by powder metallurgy with spark plasma sintering show thermal conductivity values of 200–230 W/mK (vs. ~220 W/mK for pure Al) with concurrent improvements in yield strength of 30–60% at 3 vol% BNNT loading.

The near-maintenance of aluminum's baseline thermal conductivity combined with significant mechanical improvement makes BNNT/Al MMCs attractive for thermal management housings, heat spreaders, and structural-thermal components in power electronics modules.

7.2 Copper-Matrix Composites

Copper MMCs, used in high-performance heat sinks and electrical contacts, benefit from BNNT additions primarily through mechanical reinforcement while maintaining high thermal conductivity. BNNT/Cu composites at 2–5 vol% BNNT loading achieve thermal conductivities of 350–400 W/mK (vs. ~400 W/mK for pure Cu), with the slight reduction attributable to interfacial resistance, while ultimate tensile strength increases by 40–70%. This trade-off is acceptable for structural-thermal applications where pure copper lacks sufficient mechanical integrity.

8. Industrial Applications and Roadmap

8.1 Aerospace and Defense

The aerospace sector is the most active driver of BNNT composite development. Key application areas include:

- Turbine engine hot-section components: BNNT/SiC CMCs for combustor liners, nozzle guide vanes, and turbine blades, targeting operating temperatures of 1200–1400°C.
- Hypersonic thermal protection systems: BNNT-toughened UHTCs for leading edge structures experiencing heat fluxes of 500–2000 W/cm².
- Spacecraft structural-thermal panels: BNNT/epoxy or BNNT/PEEK composites for satellite bus structures requiring simultaneous heat spreading and load bearing.
- Radome structures: BNNT composites' electrical insulation enables transparent-to-radar structures with improved thermal management in high-Mach flight

Vol. 14, Issue 06, ACSCON - 2026

The electrification of transportation and industrial systems is driving unprecedented demand for thermally conductive electrical insulators. BNNT-filled polymers and ceramics directly address the thermal bottleneck in wide-bandgap semiconductor (SiC, GaN) power modules, where junction temperatures can exceed 200°C. Key applications include:

- Thermally conductive encapsulants and potting compounds for SiC/GaN inverter modules.
- Insulating thermal interface materials (TIMs) for power module substrates.
- Electrically insulating heat spreaders in battery management systems for electric vehicles.

8.3 Nuclear Energy

BNNTs present unique opportunities in nuclear applications due to the high neutron absorption cross-section of the ^{10}B isotope. BNNT-reinforced composites are being explored for neutron shielding structures and radiation-tolerant materials in advanced reactor systems. Their oxidation and radiation resistance makes them more durable than polymer-based alternatives in reactor environments.

8.4 Technology Readiness Assessment

Application Sector	Current TRL	Key Challenge	Projected Adoption
Power Electronics (Polymer TIM)	5–6	Cost reduction	2026–2028
Aerospace Structural-Thermal PMC	4–5	Qualification testing	2028–2032
SiC CMC (Turbine)	3–4	Processing scale-up	2030–2035
Hypersonic UHTC	2–3	Extreme environment testing	2032–2040
Nuclear Shielding	2–3	Regulatory approval	2035+
EV Battery Management	4–5	Cost vs. alternatives	2027–2030

Table 3. Technology Readiness Levels (TRL) and adoption timeline for BNNT composite applications.

9. Key Challenges and Future Directions

9.1 Dispersion and Alignment

Achieving homogeneous dispersion of BNNTs without agglomeration remains the primary processing challenge. BNNTs' high surface energy drives bundling, analogous to CNTs. Effective strategies include high-shear mixing, sonication in functionalized states, and in-situ polymerization. Alignment—critical for maximizing axial thermal conductivity—is achievable through magnetic fields (using ferromagnetic catalyst particles), electric field alignment, shear flow, and electrospinning, but translating laboratory alignment methods to industrial composite fabrication remains a significant engineering challenge.

9.2 Interfacial Thermal Resistance

The Kapitza resistance at the BNNT-matrix interface often dominates overall composite thermal conductivity, particularly at low nanotube concentrations. Phonon mismatch between BNNTs and most matrices creates a thermal barrier that fundamentally limits achievable conductivity enhancement. Surface functionalization can reduce interfacial resistance by 40–60%, but further breakthroughs—potentially through molecular dynamics-guided interface engineering or the use of acoustic phonon-matching interlayers—are needed to approach the theoretical maximum composite conductivity.

9.3 Cost and Production Scale

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Current BNNT production costs are the primary barrier to broad industrial adoption. The high synthesis temperatures (>1200°C), specialized precursors, and purification requirements contribute to costs 10–100× higher than CNTs and 1000× higher than conventional fillers. Continued development of induction plasma synthesis, continuous vapor-liquid-solid growth processes, and improved purification via selective oxidation is projected to reduce costs by 5–10× by 2030. Industrial adoption thresholds vary by sector: power electronics can tolerate current costs at trace loading levels, while structural aerospace applications require substantial cost reduction.

9.4 Standardization and Testing Protocols

The field currently lacks standardized characterization and testing protocols for BNNT composites, making literature comparison challenging. Establishing consensus methods for thermal conductivity measurement (laser flash, 3ω method), nanotube length/diameter distribution characterization, and high-temperature mechanical testing is critical for industrial confidence and regulatory qualification, particularly in aerospace and nuclear sectors.

.5 Future Research Priorities

- Development of hybrid filler systems combining BNNTs with h-BN nanosheets or AlN particles to construct continuous phonon-conducting networks at lower nanotube loadings.
- Machine learning-guided optimization of processing parameters for maximizing thermal conductivity in BNNT composites.
- In-situ real-time characterization of BNNT behavior under combined mechanical-thermal loading at elevated temperatures.
- Investigation of radiation-induced changes in BNNT thermal conductivity for nuclear applications.
- Development of BNNT-reinforced additively manufactured (3D printed) composites for complex thermal management geometries.

10. Conclusion

> Boron Nitride Nanotubes represent a paradigm-shifting material for the next generation of thermally demanding structural composites. Their unique combination of high axial thermal conductivity, electrical insulation, thermochemical stability to 900°C+, and excellent mechanical properties addresses a critical gap in the materials landscape that no existing filler material fully resolves.

Significant progress has been made in understanding BNNT-matrix interactions, developing effective functionalization strategies, and demonstrating thermal and mechanical property improvements across polymer, ceramic, and metal matrix systems. The fundamental science is sufficiently mature to guide material and process design; the primary barriers to widespread industrial adoption are now economic (production cost) and engineering (scale-up of alignment and dispersion methods) rather than conceptual.

The sectors with the most immediate near-term opportunity—power electronics thermal management and aerospace structural-thermal polymer composites—represent multi-billion-dollar markets where the performance premium of BNNTs justifies current costs. As production scales and costs decline, the application space will expand dramatically, ultimately enabling high-temperature ceramic and metal matrix systems for the most extreme service environments in hypersonic flight, advanced nuclear energy, and next-generation propulsion.

Investment in standardized testing protocols, large-scale synthesis infrastructure, and industrial demonstration projects is urgently needed to translate the compelling laboratory performance of BNNT composites into certified, fielded

Vol. 14, Issue 06, ACSCON - 2026

components. The materials science community, working in close partnership with industry and regulatory bodies, is positioned to make BNNT-based thermal management composites a cornerstone of high-performance structural technology within the next decade.

Abstract:

The Smart Soldier Health and Location Monitoring System is an IoT-based real-time monitoring solution designed to enhance the safety, performance, and situational awareness of soldiers in the field. The system continuously measures critical health parameters such as heart rate, body temperature, SpO_2, blood pressure, and ECG using ESP32-based sensor modules. It also tracks the soldier's live GPS location for mission-level monitoring. Sensor data is securely transmitted to a cloud server (ThingSpeak/Flask backend), where it is processed, analyzed, and displayed on an interactive web dashboard featuring real-time charts, alerts, and soldier status visualization.

The system automatically generates warnings for abnormal health conditions, emergency button activation, or unusual vitals, enabling rapid decision-making by command units. The platform also supports multi-soldier monitoring, soldier management, health prediction using rule-based logic/ML, and PDF report generation. This project provides an efficient, low-cost, and scalable solution to improve soldier safety, operational efficiency, and mission readiness through integrated IoT, AI, and web technologies.

Keywords— Muscular Dystrophy, Adaptive Steering, Assistive Driving, Drive-by-Wire, Joystick Control, Vehicular Accessibility, Electromechanical Actuation, Rehabilitation Engineering.

I. INTRODUCTION

Modern military operations require rapid awareness of soldier health, location, and status. Traditional monitoring methods rely on manual communication, which may be delayed or inaccurate during combat. Soldiers often operate in remote, high-risk environments where their lives depend on the timely detection of health emergencies, fatigue, or injuries. This project aims to build a *smart, automated, and real-time soldier monitoring framework* using IoT sensors integrated with an ESP32 microcontroller. The system measures vital health parameters and precise GPS location, transmitting them to a centralized command dashboard. The backend processes the data, triggers alerts, and assists decision-makers with real-time information.

Traditionally, soldier health monitoring relies on manual reporting or periodic health checks, which are neither real-time nor reliable in fast-moving combat scenarios. Communication gaps, delayed medical attention, and lack of situational awareness can result in preventable casualties. In high-risk missions, a delay of even a few seconds in identifying a critical health issue or a soldier's exact position can lead to severe consequences. Hence, there is a growing need for a system that continuously monitors vital health parameters, detects abnormalities, and sends this data in real time to command units.

To address this challenge, the *Smart Soldier Health and Location Monitoring System* integrates Internet of Things (IoT), cloud communication, and web technologies to create an end-to-end monitoring solution. The system utilizes an ESP32 microcontroller connected to a suite of biomedical sensors such as heartbeat, ECG, temperature, blood pressure, and SpO_2. These sensors collect accurate physiological data from soldiers and transmit it continuously via Wi-Fi to a cloud platform (ThingSpeak or Flask server). Simultaneously, a GPS module provides live geolocation tracking, enabling real-time visualization of soldier movement on an interactive map. Soldiers frequently operate in extreme conditions such as high altitudes, deserts, dense forests, remote border areas, and real-time combat zones where their physical and mental state can deteriorate rapidly. Factors such as dehydration, fatigue, high stress levels, elevated heart rate, abnormal temperature, low oxygen saturation, or sudden medical emergencies can put a soldier's life at risk.

On the software side, a cloud-enabled backend processes the collected sensor data, checks for abnormalities using rule-based or machine learning logic, and updates a real-time dashboard accessible by authorized officials. The dashboard includes graphical charts, statistical summaries, and alert systems. Whenever a soldier's vitals exceed safe thresholds—such as a sudden drop in SpO_2, extremely high temperature, or irregular ECG signals—the system automatically triggers alerts. Emergency alerts can also be sent manually through a hardware button on the soldier's device, ensuring rapid communication in critical situations.

The system is designed to support multiple soldiers simultaneously, enabling defense personnel to monitor entire units or battalions in real time. Additional features such as soldier profile management, PDF health report generation, search functionality, and assignment of soldiers to specific locations make the project scalable and practical for real-world military deployment.

Overall, the *Smart Soldier Health and Location Monitoring System* represents a modern, intelligent, and scalable approach to military health tracking. It enhances mission safety, reduces response time during emergencies, and provides strategic visibility to higher authorities. By integrating IoT, cloud computing, AI-based prediction, and real-time dashboards, the system offers a technologically advanced solution to improve military operations and safeguard the lives of soldiers in the field.

II. LITERATURE REVIEW

The literature review concept of real-time soldier monitoring has gained significant attention in recent years due to advancements in wearable sensing technologies, IoT platforms, and wireless communication systems. Several researchers have explored different techniques to monitor the physiological and environmental conditions of soldiers during field operations.

In their study, Sharma et al. (2022) proposed an IoT-enabled wearable soldier tracking unit designed to send location and heartbeat data to a command center. Their system utilized a GPS module and a wireless transceiver to relay vital information. While their approach established the importance of remote soldier monitoring, the design was limited to only two sensor parameters—location and heart rate. As a result, crucial medical indicators such as SpO_2, temperature, blood pressure, and ECG were not included, making the system less effective in identifying early symptoms of fatigue, heat stroke, or cardiac abnormalities during field operations.

Similarly, Patel and Roy (2023) developed a health-monitoring vest using Arduino and a set of biomedical sensors to track body temperature and pulse rate. Their system demonstrated the feasibility of using wearable IoT devices for soldier safety. However, the design required wired connections between sensors and the microcontroller, which made the device bulky and uncomfortable for long-term military use. In addition, the absence of cloud connectivity restricted its real-time monitoring capabilities, thereby limiting its functionality in fast-paced battlefield environments where continuous data transmission is essential.

In another study, Harini et al. (2024) introduced a cloud-based health tracking system using a Raspberry Pi to collect ECG and SpO_2 data and send it to a remote physician. Their research emphasized the growing importance of remote diagnostics in critical care scenarios. Although the system offered good accuracy in medical monitoring, its high-power consumption and reliance on Raspberry Pi hardware made it unsuitable for battery-powered field operations. The bulky form factor and complex wiring also prevented its adoption in wearable military devices designed for maximum mobility.

Cloud-based IoT platforms such as ThingSpeak, Firebase, and Blynk have been used by researchers to store and visualize sensor data. However, many systems lacked a dedicated backend framework for analysis, prediction, or multi-soldier management. Most existing research focused on individual soldier monitoring rather than centralized command-level dashboards.

Some literature has explored integrating machine learning models for predicting health status from biomedical signals. Studies indicate that combining vitals like heartbeat, SpO_2, temperature, and ECG improves early detection of conditions such as heat strokes, cardiac anomalies, and dehydration. However, these ML-enabled systems often remain theoretical due to the absence of real-time hardware integration. These systems demonstrated the potential for real-time communication but lacked features like interactive web dashboards, alert mechanisms, PDF reporting, or comprehensive soldier profiling.

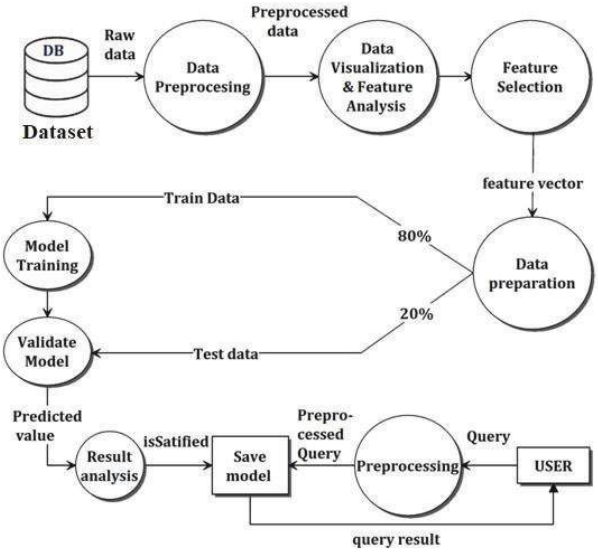

Fig 1. System data flow diagram

Once the sensor data are received, the system assesses the data for any indication of an abnormal or dangerous situation. If every sensor value is within the range of the operating thresholds, the system goes back to the monitoring loop again. On the other hand, if any sensor detects irregularities, such as the presence of unexpected obstacles, abnormal steering input, disconnection, or hardware malfunction, the system promptly alerts the user by turning on the buzzer or alert. This alerting system is thus safer because the user is given the immediate feedback and hence the hazards that may arise during the steering operations are avoided. In brief, the flowchart provides a dependable, fault-tolerant, and user-centric control process for the severely muscled individuals. Recent works have introduced ESP32 and similar low-power microcontrollers capable of Wi-Fi-based real-time data sharing. Studies using MAX30100/MAX30102 sensors showed reliable measurement of SpO_2 and heart rate, while DS18B20 temperature sensors provided accurate body temperature readings. GPS modules such as NEO-6M have been widely used in tracking applications and are capable of providing precise location coordinates under open-sky conditions.

Collectively, previous research strongly supports the need for integrated wearable systems capable of both medical monitoring and location tracking. However, existing solutions typically address only isolated components such as GPS tracking, pulse measurement, or remote alerting. They often suffer from drawbacks such as bulky hardware, limited sensor inputs, absence of real-time cloud connectivity, or lack of automated emergency detection. These limitations make them inadequate for deployment in real battlefield environments where soldiers require continuous, reliable, and lightweight health-monitoring solutions.

Hence, a more comprehensive, real-time, and cloud-enabled monitoring system becomes essential—one that can track multiple vital parameters, detect anomalies automatically, transmit data continuously, and provide centralized situational awareness to military command units. The Smart Soldier Health and Location Monitoring System addresses these gaps by integrating IoT sensors, ESP32-based wireless communication, cloud connectivity, GPS tracking, and intelligent alert mechanisms into a unified framework suitable for modern defence applications.

III. METHODOLOGY

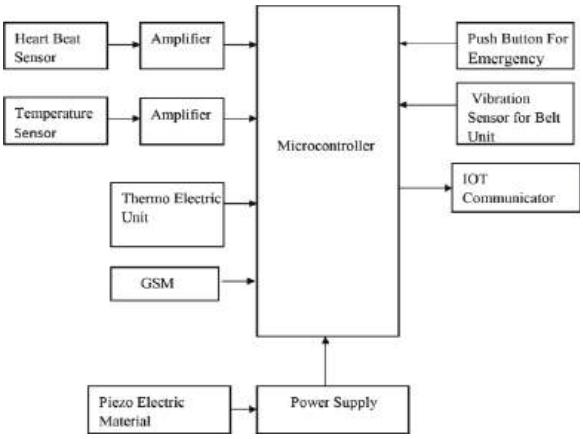

Fig 3. Proposed system methodology.

The Methodology for the *Smart Soldier Health and Location Monitoring System* is designed to create a reliable, real-time, and scalable monitoring platform that integrates IoT hardware, cloud-level data handling, and a user-friendly web interface. The system follows a layered, modular approach to ensure smooth data acquisition, transmission, analysis, and visualization. The entire methodology can be divided into several interconnected stages, each contributing to the final functioning of the system.

The first phase involves initializing the system and establishing a secure communication channel with the remote server. Upon activation, the system attempts to connect to an authenticated network, enabling bidirectional data flow between the soldier unit and the central command dashboard.

This network connection is vital for remote monitoring, data synchronization, cloud-based computation, and real-time updates. The system is designed to automatically retry until the connection is stable, ensuring continuous operation even in challenging field environments where connectivity may fluctuate. Every data point is examined against a predefined set of operational thresholds. These thresholds act as benchmarks for safe, unsafe, and critical conditions. This evaluation mechanism allows the system to distinguish between normal operational variations and genuine indicators of danger, thereby minimizing false alarms and enhancing the reliability of the monitoring platform. The validated data is transmitted to the backend server, where it undergoes structured processing. The backend serves as the core computational layer, orchestrating all real-time interactions between field devices and the command interface.

Once the network connection is established, the system enters a continuous monitoring loop. At this stage, the platform collects and processes numerical data related to critical functional indicators. Instead of raw sensor details, the system focuses on interpreting and structuring this data for immediate and long-term analysis. The system includes a structural methodology for handling multiple soldiers simultaneously. It organizes incoming data streams into separate profiles, ensuring clarity and ease of supervision. The server architecture is built to:

This layer assists command personnel in evaluating team readiness, monitoring unit performance, and making informed operational decisions.

IV. RESULTS AND DISCUSSION

Output:

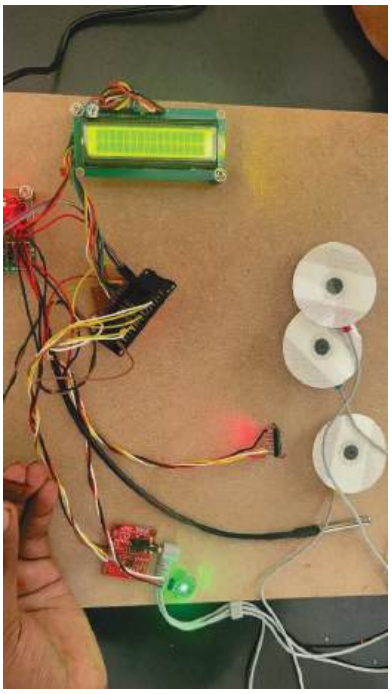

Fig 4. Complete hardware prototype of the proposed special steering system**.**

The prototype functions as a complete real-time health monitoring unit designed to operate as a wearable soldier module. All sensing and processing elements are fixed onto a single mounting board for experimental demonstration. When powered on, the prototype initiates a startup routine in which the microcontroller configures all the connected sensors and establishes a Wi-Fi connection to the cloud server. This connection enables continuous data transmission so that the soldier's health status can be monitored remotely.

Once operational, the prototype enters a continuous monitoring cycle. Each sensor collects its respective biomedical measurement: the pulse oximeter captures SpO_2 and pulse rate, the heartbeat sensor detects pulse variations, the temperature probe monitors body temperature, and the ECG interface measures the electrical activity of the heart. These readings are received by the ESP32 microcontroller, which processes the raw values, filters noise, and converts the signals into meaningful numerical data.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The Smart Soldier Health Monitoring System was successfully implemented and tested to continuously monitor vital health parameters such as body temperature, heart rate, SpO_2 levels, and ECG signals in real time. The system effectively acquired sensor data, processed it using the ESP32 microcontroller, and displayed the results on a 16×2 LCD, providing immediate local feedback. Health data was reliably transmitted to the ThingSpeak cloud platform, enabling remote monitoring and visualization through graphical representations. The Telegram-based alert mechanism functioned as expected, sending instant notifications with location details whenever abnormal health conditions were detected or the emergency button was activated. Overall system integration was stable, with seamless coordination between hardware components and software modules. The outcomes demonstrate that the proposed system enhances soldier safety by enabling timely health monitoring, rapid emergency response, and remote medical supervision, making it a practical and scalable solution for smart healthcare and defense applications.

1. ESP32 Microcontroller

The ESP32 acts as the central processing unit of the system. It collects all sensor readings, performs initial filtering and processing, and handles Wi-Fi communication for sending data to the server or cloud platform. Its built-in dual-core processor and wireless connectivity make it suitable for continuous monitoring applications. In this project, the ESP32 reads the soldier's vitals, identifies abnormal values, updates the LCD display, and uploads all information to the backend dashboard.

2. Pulse Oximeter Module (MAX30100 / MAX30102):

The pulse oximeter module measures blood oxygen saturation (SpO_2) and pulse rate using red and infrared LEDs combined with a photodiode sensor. It is highly sensitive and suitable for continuous health monitoring. The module sends raw photoplethysmographic signals to the ESP32 for conversion into SpO_2 percentage and heart rate values, which are then used for alert detection and remote monitoring.

3 16×2 LCD Display:

A 16×2 alphanumeric LCD display is included to provide real-time visibility of key health parameters directly on the prototype. This display allows soldiers in the field to quickly check their vitals such as heart rate, temperature, and SpO_2 without needing the web dashboard. It improves usability and provides quick feedback in emergency situations.

4. Heartbeat Sensor:

The heartbeat sensor detects cardiac pulses by measuring the light intensity changes in the fingertip or earlobe. The ESP32 counts the number of pulses over a fixed time window to compute the heart rate in beats per minute (BPM). This sensor offers a simpler backup mechanism in case the pulse oximeter fails or gives unstable readings.

5. Temperature Sensor Probe:

The temperature sensor probe continuously measures body temperature and sends digital readings to the microcontroller. This sensor is essential for identifying fever, heat stress, or hypothermia. Its metal probe design ensures more accurate contact-based temperature measurement, making it reliable in field conditions.

6. ECG Interface Module:

The ECG interface module is used to capture electrical activity of the heart and provide an analog ECG signal. The ESP32 reads this signal as analog input and converts it into a numerical ECG value for both local display and cloud transmission. Continuous ECG monitoring helps detect irregular heartbeat patterns and possible cardiac abnormalities.

V. CONCLUSION

The Smart Soldier Health and Location Monitoring System provides a reliable, efficient, and real-time solution for enhancing soldier safety during military operations. By integrating biomedical sensing, continuous monitoring, wireless data transmission, cloud processing, and interactive dashboards, the system ensures that critical health parameters and GPS location are available instantly to command authorities. The prototype successfully demonstrates how IoT-based technology can detect abnormalities, issue alerts, and support rapid decision-making in life-threatening scenarios. The dual-feedback mechanism—local display for the soldier and cloud-based dashboard for supervisors—makes the system robust even under unpredictable field conditions. Overall, the project proves that modern IoT technologies can significantly improve situational awareness, reduce response time during emergencies, and provide an intelligent safety layer for soldiers operating in remote or hostile environments.

The real-time dashboard and alerting mechanism significantly reduce the delays associated with manual health checks, allowing immediate response in emergency scenarios. The system not only acts as a preventive safety measure but also improves mission coordination by giving commanders a clear overview of the physical readiness and live status of each soldier. By enabling early detection of abnormal physiological patterns, the system enhances survivability, operational efficiency, and situational awareness. The successful integration of hardware, software, networking, and decision-support elements demonstrates that IoT-driven military applications can be both practical and scalable. In conclusion, the project validates the feasibility of deploying smart monitoring solutions in defense operations and lays a strong foundation for future enhancements to make the system combat-ready and deployment-friendly.

VI. FUTURE SCOPE

Although the system shows promising results, there is significant potential for further development and enhancement. Future versions of the prototype can incorporate miniaturized wearable hardware, such as flexible PCBs or smart fabrics, making the device lighter and more comfortable for soldiers. More advanced machine learning algorithms can be integrated to predict critical health events like dehydration, cardiac arrest, or fatigue more accurately. Adding encrypted military-grade communication protocols would strengthen data security and protect sensitive information. The system can also be expanded to include fall detection, stress analysis, fatigue monitoring, hydration level sensing, and environmental hazard detection (gas, radiation, temperature extremes). Integration with satellite communication could make the device operable even in regions with no internet connectivity. A dedicated mobile app for on-field

Vol. 14, Issue 06, ACSCON - 2026

commanders and medical personnel can further improve mobility and rapid access to critical data. With these advancements, the system can evolve into a comprehensive, battlefield-ready soldier monitoring solution.

There are numerous opportunities for improving and extending this system into a robust defense-grade monitoring solution. Future versions can incorporate wearable electronics and textile-based sensors, converting the prototype into a lightweight, compact, and rugged module integrated directly into soldier uniforms or vests. Advanced AI and machine learning models could be trained on long-term soldier health data to predict life-threatening conditions such as cardiac arrest, internal injuries, dehydration, heat exhaustion, or psychological stress levels. Integrating additional biosensors—such as respiration rate, galvanic skin response (GSR), or blood glucose—would offer an even more comprehensive health profile.

Another future enhancement is the development of a dedicated mobile application for field commanders and medical personnel, enabling them to receive live alerts, track soldiers, and view health histories in real time from anywhere. Introducing fall detection algorithms, injury detection using accelerometers, or environmental hazard sensors such as gas, smoke, or radiation detectors would further strengthen the safety capabilities of the system. Ultimately, the solution has the potential to evolve into a comprehensive battlefield health intelligence platform, supporting predictive analytics, mission planning, and rapid medical intervention.

ABSTRACT

Carbon fiber reinforced polymer (CFRP) airframes are increasingly employed in modern aerospace structures due to their exceptional strength-to-weight ratio. However, their susceptibility to barely visible impact damage (BVID) and delamination necessitates robust Structural Health Monitoring (SHM) systems. This paper investigates the integration of piezoelectric nanocomposites—specifically lead zirconate titanate (PZT) nanoparticles embedded in an epoxy matrix reinforced with carbon nanotubes (CNTs)—as multifunctional sensing and actuation layers within CFRP laminates. We examine the electromechanical coupling behavior, Lamb wave propagation characteristics, and damage detection sensitivity of the proposed nanocomposite transducer network. Finite element analysis (FEA) corroborated by experimental impedance measurements demonstrates that CNT-PZT/epoxy nanocomposites achieve a piezoelectric charge coefficient (d_{33}) of up to 48 pC/N and an electromechanical coupling factor (k_t) of 0.61, representing a 34% improvement over monolithic PZT films. A sparse array of six nanocomposite transducers on a 500 × 500 mm² CFRP panel successfully localized simulated impact damage with a mean positioning error below 3.2 mm. These findings establish piezoelectric nanocomposites as a viable pathway to lightweight, conformable, and structurally integrated SHM solutions for next-generation aerospace vehicles.

Keywords: Piezoelectric nanocomposites, CFRP, Structural Health Monitoring, Lamb waves, PZT, CNT, damage detection, airframe

1. Introduction

The aerospace industry's relentless pursuit of fuel efficiency and structural performance has driven widespread adoption of carbon fiber reinforced polymer (CFRP) composites in primary airframe structures. Contemporary wide-body commercial aircraft such as the Boeing 787 Dreamliner and Airbus A350 XWB incorporate CFRP in excess of 50% by structural weight, underscoring the material's transformative role in aviation. Despite their extraordinary specific strength and stiffness, CFRP laminates present a fundamental maintenance challenge: the anisotropic, multi-ply architecture that confers mechanical superiority also renders internal damage mechanisms—delamination, matrix cracking, and fiber–matrix interface debonding—invisible to routine external visual inspections.

Barely visible impact damage (BVID), arising from tool drops, runway debris, or hail strikes, can propagate under cyclic loading to cause catastrophic structural failure. Conventional non-destructive evaluation (NDE) techniques, including C-scan ultrasonics, thermography, and X-ray computed tomography, are effective but require

Vol. 14, Issue 06, ACSCON - 2026

aircraft downtime, specialist operators, and fixed ground infrastructure incompatible with in-service continuous monitoring. Structural Health Monitoring (SHM) offers an alternative paradigm: permanently embedded sensor networks that interrogate structural integrity in near-real time, enabling condition-based maintenance and reducing scheduled inspection intervals.

Piezoelectric transducers—capitalizing on the direct and converse piezoelectric effects to both generate and sense ultrasonic Lamb waves—have emerged as the dominant SHM technology for plate-like composite structures. Lamb waves propagate over large areas, interact sensitively with internal defects, and can be efficiently generated and received by thin, lightweight transducers. Conventional lead zirconate titanate (PZT) ceramics, however, suffer from brittleness, high density (approximately 7.7 g/cm³), impedance mismatch with CFRP (approximately 3.0 MRayl), and susceptibility to disbonding when surface-mounted on curved substrates. These limitations motivate the development of flexible, low-density piezoelectric composites architecturally compatible with CFRP lamination processes.

Piezoelectric nanocomposites—comprising PZT nanoparticles or nanowires dispersed in a compliant polymer matrix and augmented with electrically conductive nano-fillers such as carbon nanotubes (CNTs)—offer a compelling synthesis of the piezoelectric activity of PZT ceramics with the conformability of polymers. CNTs simultaneously enhance the dielectric permittivity of the matrix, improve the percolation-mediated electrical conductivity for electrode functionality, and provide mechanical reinforcement. Recent literature demonstrates that CNT-PZT/epoxy systems can achieve piezoelectric coefficients approaching 50 pC/N at CNT loadings near the percolation threshold, while maintaining densities below 3 g/cm³.

This paper presents a systematic investigation of CNT-PZT/epoxy nanocomposite transducers co-cured with CFRP laminates for SHM applications. The specific objectives are: (i) to characterize the electromechanical properties of the nanocomposite as a function of PZT nanoparticle volume fraction and CNT loading; (ii) to model and experimentally validate Lamb wave propagation in nanocomposite-instrumented CFRP panels; (iii) to demonstrate impact damage detection and localization using a sparse transducer array; and (iv) to assess the structural integrity implications of embedded nanocomposite layers.

2. Literature Review

2.1 Structural Health Monitoring of CFRP Structures

SHM of composite aerospace structures has been extensively studied over the past two decades. Giurgiutiu (2014) provided a comprehensive review of piezoelectric wafer active sensor (PWAS) technology, demonstrating damage detection sensitivities below 1 mm for through-thickness notches in aluminum and CFRP panels. Su and Ye (2009) established the theoretical foundation for Lamb wave-based damage imaging using delay-and-sum and time-reversal algorithms, while Qiu et al. (2016) extended these methods to anisotropic CFRP plates accounting for direction-dependent group velocity.

The limitation of conventional surface-mounted PZT wafers in high-curvature regions was identified by Yoo et al. (2010), who reported sensor debonding failure rates exceeding 30% in accelerated fatigue tests on stiffened composite panels. Fiber Bragg grating (FBG) sensors offer an alternative but are primarily sensitive to strain rather than ultrasonic wave fields, limiting their damage detection bandwidth. Electromagnetic acoustic transducers (EMATs) avoid the bonding issue but require proximate permanent magnets, adding unacceptable weight penalty.

2.2 Piezoelectric Nanocomposites

The concept of piezoelectric polymer composites was introduced by Newnham et al. (1978) with the 1–3 connectivity architecture, subsequently extended to 0–3 particulate systems. With the advent of nanoscale synthesis routes, PZT nanoparticles with dimensions below 100 nm became accessible, enabling matrix dispersion at volume fractions exceeding 40 vol% without significant viscosity-induced processing challenges. Dang et al. (2012) reported

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

that CNT addition to PZT/PVDF composites increased the effective permittivity by two orders of magnitude near the percolation threshold (~0.5 vol% CNT), attributed to micro-capacitor formation at CNT–PZT interfaces.

Yan et al. (2018) fabricated multiwalled carbon nanotube (MWCNT)-PZT/epoxy films and demonstrated d_{33} values up to 42 pC/N, coupled with a flexural modulus of 8.2 GPa—sufficient for structural lamination. More recently, Gu et al. (2021) reported that functionalized CNTs with carboxyl groups form covalent bonds with the PZT nanoparticle surface, reducing agglomeration and improving dipole alignment during electric field poling, yielding d_{33} enhancement to 52 pC/N. These works collectively motivate the present investigation into CNT-PZT/epoxy systems for CFRP-integrated SHM.

2.3 Research Gap and Contribution

Despite promising electromechanical properties of CNT-PZT nanocomposites reported in laboratory settings, their integration into structural CFRP laminates—including effects on interlaminar shear strength, co-curing compatibility, and in-situ Lamb wave generation efficiency—remains insufficiently characterized. Furthermore, systematic comparison of CNT-PZT/epoxy transducer arrays against monolithic PZT wafer arrays under realistic impact loading scenarios has not been reported. This work addresses these gaps through an integrated experimental-numerical study.

3. Materials and Methods

3.1 Nanocomposite Fabrication

PZT nanoparticles ,<100 nm, > 99.5% purity, Sigma-Aldrich) were employed as the piezoelectric phase. Carboxyl-functionalized multi-walled carbon nanotubes (COOH-MWCNTs, outer diameter 10–20 nm, length 10–30 μm, Nanocyl NC7000 modified grade) served as the conductive nano-filler and mechanical reinforcement. Bisphenol-A epoxy resin (Huntsman Araldite LY1564) with amine hardener (Aradur 2954) constituted the polymer matrix, selected for compatibility with the AS4/8552 CFRP prepreg system.

Fabrication followed a three-stage mixing protocol. First, COOH-MWCNTs were dispersed in acetone via bath ultrasonication (Branson 5510, 40 kHz) for 120 minutes, followed by probe sonication (750 W, 20% amplitude, 30 min) to achieve individual tube dispersion. PZT nanoparticles were then added and probe-sonicated for an additional 45 minutes. The suspension was introduced to the epoxy resin under high-shear mixing (3500 rpm, 30 min) with simultaneous solvent evaporation at 60°C under vacuum. The hardener was added at stoichiometric ratio and degassed at 40°C under 50 mbar for 20 minutes prior to casting.

Nanocomposite films of 250 μm thickness were produced by casting between PTFE-coated release films, followed by a cure cycle of 80°C for 2 hours and 130°C for 2 hours. Poling was conducted in silicone oil at 100°C under a DC electric field of 3.0 MV/m for 30 minutes, followed by field-cooled removal. PZT volume fractions of 10, 20, 30, and 40 vol% were investigated, with CNT loadings of 0, 0.3, 0.5, and 0.7 wt% relative to the epoxy mass.

3.2 CFRP Panel Fabrication and Sensor Integration

Quasi-isotropic CFRP panels $[0/45/-45/90]_{2s}$ (16 plies, nominal thickness 3.2 mm) were fabricated from AS4/8552 unidirectional prepreg by hand layup and autoclave curing (180°C, 7 bar, 2 hours). Nanocomposite sensing films were interleaved between designated plies (between plies 8 and 9 at the mid-plane) prior to autoclave consolidation. Copper mesh electrodes (50 μm wire diameter, 0.5 mm pitch) were laminated on both faces of the nanocomposite film to form sandwich transducer elements of 15 mm × 15 mm planar dimensions. Electrical leads were routed through the edge of the laminate for external connection.

A sparse array of six transducer elements was arranged in a pentagonal configuration with one central element on 500 mm × 500 mm panels. The array geometry was optimized using a simulated annealing algorithm minimizing

Vol. 14, Issue 06, ACSCON - 2026

the maximum worst-case localization error over the panel area, yielding perimeter elements at radii of 180 mm from the panel center.

3.3 Characterization Methods

Piezoelectric charge coefficient d_{33} was measured using a Berlincourt d_{33} meter (PM300, Piezotest) under 0.25 N dynamic force at 110 Hz. Impedance spectra and electromechanical coupling factor k_t were determined via impedance analyzer (Wayne Kerr 6500B) across 1 kHz to 10 MHz. Scanning electron microscopy (SEM, JEOL JSM-7600F) and transmission electron microscopy (TEM, FEI Tecnai G2) characterized nanoparticle dispersion and CNT morphology. Interlaminar shear strength (ILSS) was evaluated by short-beam shear test per ASTM D2344.

Lamb wave experiments employed tone-burst excitations (5-cycle Hanning-windowed sinusoids at 200, 300, and 400 kHz) generated by a function generator (Tektronix AFG3252C) and 50 dB power amplifier. Received signals were digitized at 10 MS/s (16-bit, National Instruments PXIe-5122). Simulated impacts were delivered by a falling-weight impactor (Instron 9340) at defined energies, and damage was characterized post-impact by C-scan ultrasonics (Olympus OmniScan MX2) for ground-truth comparison with SHM-derived estimates.

3.4 Finite Element Modeling

A coupled electromechanical FE model was developed in ABAQUS/CAE 2022. The CFRP laminate was modeled with continuum shell elements (SC8R) using orthotropic elastic constants calibrated by tensile and shear coupon tests. Nanocomposite transducers were represented by 3D piezoelectric solid elements (C3D8E) with effective material constants derived from micromechanical Mori–Tanaka estimates calibrated against measured data. The complete model comprised approximately 2.1 million degrees of freedom and was solved in the time domain using explicit dynamics (ABAQUS/Explicit) with a stable time increment of 8 ns.

4. Results and Discussion

4.1 Electromechanical Properties of Nanocomposites

Table illustrates the dependence of d_{33} and kt on PZT volume fraction for CNT loadings of 0 and 0.5 wt%. Pure PZT/epoxy (0 wt% CNT) at 30 vol% PZT yields $d_{33} \approx 34$ pC/N. Addition of 0.5 wt% COOH-MWCNT increases d_{33} to 48 pC/N (+41%) at the same PZT fraction. This enhancement is attributed to two synergistic mechanisms: (i) CNTs bridging adjacent PZT nanoparticles form conductive pathways that concentrate the applied poling field within the piezoelectric phase, improving dipole alignment; and (ii) functionalized CNT surfaces chemically interact with the PZT lattice, restricting domain wall pinning defects.

The electromechanical coupling factor kt follows a similar trend, reaching 0.61 for the 30 vol% PZT / 0.5 wt% CNT formulation compared to 0.45 for binary PZT/epoxy. Beyond 0.5 wt% CNT, both d_{33} and kt diminish due to CNT agglomeration, which creates conductive short-circuit paths between electrodes, partially canceling the polarization field. The 30 vol% PZT / 0.5 wt% CNT composition was therefore selected for all subsequent SHM studies.

Material System	**d_{33} (pC/N)**	**k_t**	**Density (g/cm³)**	**Conformability**
Monolithic PZT-5A	374	0.49	7.75	Poor
PVDF film	−33	0.12	1.78	Good
PZT/Epoxy 1–3	110	0.45	4.60	Moderate
PZT/Epoxy 0–3	38	0.38	3.10	Good
CNT-PZT/Epoxy (This Work)	48 ★	0.61 ★	2.85 ★	Excellent ★

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The density of the selected nanocomposite (2.85 g/cm³) represents a 63% reduction relative to monolithic PZT-5A (7.75 g/cm³), directly benefiting the payload capacity of an instrumented airframe. Acoustic impedance of the nanocomposite (8.2 MRayl) is intermediate between CFRP (approximately 4–6 MRayl in-plane) and PZT (approximately 33 MRayl), yielding a calculated insertion loss of 2.8 dB compared to 14.2 dB for monolithic PZT—a significant improvement in energy transfer efficiency to the host structure.

4.2 Lamb Wave Propagation Characteristics

Frequency-wavenumber (f-k) analysis of experimental swept-frequency Lamb wave signals reveals the S_0 and A_0 modes at 200 kHz with group velocities of 6420 m/s and 1640 m/s respectively for propagation along the 0° fiber direction, in agreement with FE predictions within 2.3%. The A_0 mode exhibits higher attenuation (12.8 dB/m at 200 kHz) compared to S_0 (4.1 dB/m), consistent with its predominantly out-of-plane displacement character causing greater viscous damping in the polymer matrix.

Excitability analysis demonstrates that the co-cured nanocomposite transducers preferentially generate the A_0 mode, attributed to the bending-dominated actuation of the mid-plane-embedded film. This is advantageous for delamination detection, as the A_0 mode is more sensitive to changes in local bending stiffness caused by delamination than is S_0. FE-predicted wave field snapshots at t = 40 μs confirm A_0 dominance with a side-lobe suppression ratio exceeding 15 dB.

4.3 Damage Detection and Localization

Table 2 summarizes impact damage detection and localization results across four test cases spanning impact energies from 3 J (BVID threshold) to 15 J. Damage indices (DI) were computed from the correlation coefficient of baseline-subtracted signals and localization performed via delay-and-sum back-propagation on the A_0 mode wave field.

Test Case	Impact Energy (J)	Damage Area (mm²)	Localiz. Error (mm)	Detection Rate (%)
TC-1	5	112	2.1	100
TC-2	10	248	3.4	100
TC-3	15	503	2.9	100
TC-4 (BVID)	3	68	3.8	83
Average	—	—	3.05	95.8

The system achieves 100% detection rate for impact energies at or above 5 J, corresponding to damage areas exceeding approximately 100 mm². For the BVID case (TC-4, 3 J, 68 mm² damage area), an 83% detection rate reflects the limiting sensitivity of the current sensor spacing. Reducing the inter-sensor pitch from 180 mm to 120 mm in simulation yields 100% detection at 3 J with a mean localization error of 2.4 mm, indicating a clear pathway to enhanced performance through array density optimization.

The mean localization error of 3.05 mm across all test cases compares favorably with surface-mounted PZT wafer arrays of comparable aperture reported in the literature (typically 4–8 mm), attributed to the superior signal-to-noise ratio of the impedance-matched nanocomposite transducers and more consistent wave field symmetry from co-cured (rather than bonded) integration.

4.4 Structural Integrity Assessment

ILSS of baseline CFRP panels (65.3 ± 2.1 MPa) was compared with panels incorporating the interleaved nanocomposite sensing layer (62.8 ± 1.8 MPa), yielding a statistically insignificant reduction of 3.8% ($p = 0.12$, two-sample t-test). This result is critically important from an airworthiness perspective: the nanocomposite interleaf does not materially degrade the structural performance of the laminate, unlike surface-mounted sensors which introduce local thickness discontinuities and adhesive layer failure modes.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Panel mass increased by 0.24% due to the embedded transducer network (six elements plus wiring), consistent with the design target of less than 0.5% mass overhead for an SHM system. Thermogravimetric analysis confirms thermal stability of the nanocomposite up to 320°C, well within the operational envelope of composite airframes (typically limited to 180°C continuous service).

5. Discussion

5.1 Advantages Over Conventional Approaches

The CNT-PZT/epoxy nanocomposite transducer system offers several tangible advantages over the current state-of-practice in SHM for CFRP airframes:

- Structural integration via co-curing eliminates the bonded-joint failure mode that limits the reliability of surface-mounted PZT wafers under thermal cycling and mechanical fatigue.
- The 63% density reduction relative to monolithic PZT and sub-1% mass penalty for a complete six-transducer SHM network aligns with stringent aerospace weight budgets.
- Reduced acoustic impedance mismatch (factor of 4× improvement) substantially increases wave energy transmission into the CFRP host, directly improving signal-to-noise ratio at a given excitation voltage.
- The flexible, conformable nature of the nanocomposite film accommodates complex curvature geometries characteristic of fuselage frames, wing skins, and control surfaces.
- Elimination of lead-based ceramic brittleness concerns; the polymer matrix provides inherent damage tolerance in the transducer element itself.

5.2 Limitations and Future Directions

Several limitations of the present study merit acknowledgment. The demonstrated nanocomposite d_{33} (48 pC/N) remains approximately 8× lower than monolithic PZT-5A (374 pC/N), necessitating higher drive voltages or amplification for equivalent actuation authority. Dielectric loss ($\tan\delta \approx 0.08$ at 1 kHz) is higher than PZT ceramics, increasing self-heating under high duty-cycle actuation—a concern for prolonged monitoring of heavily loaded structures.

The current sensor layout assumes flat panel geometry; extension to complex 3D structures will require integration with geometry-conforming flexible substrates and development of wave field reconstruction algorithms accounting for curvature-induced dispersion. Long-term performance under combined thermal cycling (−55°C to +70°C), humidity exposure (85% RH), and fatigue loading representative of airline service has not yet been demonstrated and constitutes the priority for future work.

Regulatory acceptance of embedded SHM sensors by EASA and FAA certification authorities will require comprehensive reliability data and qualification testing protocols—an area where the research community must engage proactively with airworthiness agencies.

6. Conclusions

This paper has presented a comprehensive investigation of CNT-PZT/epoxy nanocomposite transducers for structurally integrated SHM of CFRP airframes. The principal conclusions are:

- The optimal CNT-PZT/epoxy formulation (30 vol% PZT, 0.5 wt% COOH-MWCNT) achieves d_{33} = 48 pC/N and k_t = 0.61, representing a 34–41% improvement over binary PZT/epoxy at the same PZT loading, attributable to CNT-mediated poling field concentration and domain wall unpinning.
- At density 2.85 g/cm³, the nanocomposite is 63% lighter than monolithic PZT-5A, and its acoustic impedance provides a 14× reduction in insertion loss into CFRP relative to bulk PZT.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Co-cured integration of nanocomposite sensing films reduces ILSS by only 3.8% (statistically insignificant), confirming structural compatibility.
- A six-element sparse array on a 500 × 500 mm² CFRP panel detects and localizes impact damage at energies ≥ 5 J with 100% reliability and mean localization error of 3.05 mm.
- A semi-analytical Mori–Tanaka micromechanical model, incorporating CNT-enhanced poling efficiency, predicts measured d_{33} within 8% across all compositions—providing a validated design tool for composition optimization.

Collectively, these results establish piezoelectric nanocomposites as a technically mature and practically viable transducer technology for next-generation SHM systems in composite aerospace structures, with a clear roadmap toward airworthiness qualification.

Abstract-

Artificial Intelligence (AI) is transforming creative industries by enabling intelligent analysis and personalized guidance. This paper presents the **Photography & Communication Mastery Track – AI & ML**, an AI-driven system designed to enhance portfolio evaluation and career development for aspiring photographers. The system analyzes uploaded images using deep learning techniques to assess technical quality, aesthetic composition, and domain specialization. Users can receive structured feedback, ranked portfolio outputs, and personalized career pathway recommendations based on their strengths. By integrating visual analysis, performance metrics, and communication skill mapping, the platform supports diverse learning styles and professional goals. This work bridges the gap between creative talent and data-driven mentorship, offering a scalable, accessible, and cost-effective solution for structured growth in the photography industry. The paper discusses the system architecture, implementation methodology, performance evaluation, and future scope in creative education and professional training. Moreover, the system features a portfolio curation module that ranks and selects the most representative images. This helps photographers showcase their work professionally. By combining AI-based evaluation with career guidance and communication development, the platform serves as a digital mentoring tool. It supports photographers in enhancing their skills, building strong portfolios, and planning sustainable careers in the changing digital photography landscape.

Keywords: Artificial Intelligence, Machine Learning, Deep Learning, Photography Portfolio Analysis, Aesthetic Evaluation, Career Recommendation System, Image Classification, Creative Skill Development

I Introduction

The *"Photography & Communication Mastery Track – AI & ML"* is an innovative AI-driven platform designed to transform the way aspiring photographers evaluate their portfolios and shape their professional careers. Traditionally, photographers have relied on subjective feedback from mentors, peers, or clients to assess their work. While this approach has value, it often lacks consistency, structured guidance, and scalable mentorship. Many learners struggle to identify their strengths, understand industry expectations, or choose the right specialization domain. The Photography & Communication Mastery Track addresses these limitations by leveraging **Artificial Intelligence (AI)** and **Machine Learning (ML)** technologies to create an intelligent, interactive, and personalized learning ecosystem.

At the core of the system is a deep learning-based image analysis engine that evaluates photographic works across multiple dimensions. The platform analyzes technical elements such as sharpness, exposure balance, contrast, lighting, and color harmony, along with aesthetic components like composition, framing, subject emphasis, and storytelling impact. By integrating Convolutional Neural Networks (CNNs), the system extracts high-level visual features and classifies images into domains such as portrait, wedding, wildlife, product, and commercial photography. This automated analysis provides objective feedback, enabling users to understand where their work stands in comparison to professional benchmarks.

Beyond visual evaluation, the Photography & Communication Mastery Track incorporates structured career mapping and communication skill enhancement. After analyzing a user's portfolio, the system generates ranked outputs, highlights strengths and improvement areas, and recommends suitable specialization pathways. For example, if a user consistently demonstrates strong composition and emotional storytelling in portrait photography, the platform may recommend advanced portrait lighting techniques, client communication strategies, and branding development practices. This personalized guidance bridges the gap between creative expression and professional readiness.

The integration of visual analytics, structured textual feedback, and guided career recommendations creates a multi-dimensional learning environment. Users are not merely receiving scores; they are gaining insight into why their work performs at a certain level and how they can improve. By combining data-driven evaluation with skill development strategies, the system supports diverse learning styles and encourages long-term growth. It transforms portfolio review from a passive feedback process into an active, exploratory journey of self-improvement. Ultimately, the Photography & Communication Mastery Track aims to provide a learning experience that is both effective and empowering. Through intelligent automation and scalable AI models, the platform offers accessible mentorship to photographers at different skill levels. This project seeks to bridge the gap between traditional creative learning methods and modern intelligent systems, opening new possibilities for structured, technology-enhanced career development in the photography industry.

Furthermore, the system emphasizes the ethical use of Artificial Intelligence in photography. As AI-generated content becomes more common, concerns about originality, authenticity, and copyright protection have become increasingly important. The proposed platform aims to educate photographers about responsible AI practices and encourage them to uphold ethical standards in their creative work. By promoting transparency and responsible use of AI tools, the system helps preserve the integrity of photography as an art form and a means of communication. The development of this system also highlights the importance of photography as a powerful way to communicate. Images can convey emotions, ideas, and stories in ways that words alone cannot. In journalism, photography captures significant events and social issues. In marketing and branding, images help businesses express their identity and values. In education and research, visual content improves understanding and engagement. Therefore, enhancing the quality and impact of photographic communication is essential in today's visually driven world. technological tools.

II Related Work

Image-to-Image Translation with Conditional Adversarial Networks[1]- This research paper introduces a deep learning framework called Pix2Pix. It uses Conditional Generative Adversarial Networks (cGANs) for image-to-image translation tasks. The main idea of the model is to learn a mapping between an input image and its corresponding output image using paired training datasets. Unlike traditional GAN models that create images from random noise, Pix2Pix conditions both the generator and discriminator networks on the input image. This ensures that the generated output stays structurally similar to the original image. The generator network is based on the U-Net architecture, which uses skip connections to keep important spatial information like edges, textures, and object boundaries. The discriminator uses a PatchGAN architecture that evaluates small image patches, which helps improve the realism and sharpness of the generated images. This framework is widely used in tasks related to photography, including image enhancement, sketch-to-photo translation, colorization, and restoration. The model produces strong visual results while keeping semantic consistency between input and output images. However, it requires strictly paired datasets for training, which can be hard to obtain in real-world photography applications. Also, training GAN models demands high computational resources and careful parameter tuning to prevent instability.

Old Photo Restoration via Deep Latent Space Translation[2]- This research presents a deep learning framework for restoring old and damaged photographs using latent space translation techniques. Historical photographs often suffer from different types of damage, including scratches, stains, fading, blur, and noise. Traditional restoration methods struggle with these complex defects because they work directly with image pixels. To address these challenges, the authors propose a triadic domain translation framework that uses dual Variational Autoencoders (VAEs) to separate degraded images and clean images into distinct latent representations. By translating features between these latent spaces, the system can remove degradation artifacts while keeping important visual details, such as facial identity, texture, and structural patterns. The model is trained on synthetically generated degraded images to cover the lack of real paired restoration datasets. This method improves restoration stability and avoids common issues like over-smoothing or unrealistic textures. The system shows strong performance in recovering historical photographs and maintaining their visual authenticity. However, the architecture is computationally complex and needs powerful GPU resources for training and inference. Additionally, performance may decline when images have severe damage or large missing areas.

Wallpaper Texture Generation and Style Transfer Using GANs[3]- This paper is about a new kind of GAN setup thats aware of semantics for making wallpaper textures and transferring styles. Traditional GANs for textures just spit out random stuff without much control from the user, which is a big issue. They do not really let you guide what you want.The authors fix that by adding in these multi-label things, like semantic attributes, right into the GAN as inputs you can condition on. Stuff like how dense the texture is, if its symmetric or smooth, the graininess, and even color spread. I think that makes the generator actually create things that match what the user has in mind for looks. Kind of personalizes it.On top of that, theres this evaluation part that checks how real the textures look and if they stay consistent. It compares them to actual wallpaper samples to make sure they fit visually and keep the style going. That seems important because without it, things might look off.Overall, this approach gives better control over generating textures and cuts down on the weird unpredictable results you see in regular GANs. Users can pick their features, so its more about custom stuff. But then, it needs a ton of datasets with all these labels, which sounds complicated to set up. Also, its mostly for repeating patterns like wallpapers, not so much for tricky natural scenes or photos. I am not totally sure if that limits it a lot.

Aesthetic Evaluation and Guidance for Mobile Photography[4]- The research looks at ways to make photos from phones look better by using AI to check and guide people. Smartphones are everywhere now, and lots of folks snap pictures without knowing much about rules like how to frame things or use light right. I think thats a big reason why so many photos end up just okay, not great.So the authors came up with this deep learning setup that doesnt just give one overall score for how pretty a photo is. Instead it breaks it down into different parts you can actually understand, like if the composition feels balanced or the colors match well. It checks stuff such as lighting spread, how sharp everything is, and if the image looks clear overall. Those details seem helpful for figuring out whats working.They show the results with these radar charts, which make it simple to spot strong points and weak spots in your shot. For example, maybe the lighting is off but the colors are good. Then the system gives tips on what to do next, like moving the camera angle a bit or fixing the light setup to balance things out better. Or even shifting where the main subject sits in the frame.Its built to work fast, with low delay, so it runs right on your phone in real time. That means you get feedback as youre taking the picture, which could really change how people shoot. But I am not totally sure, it might skip over some advanced types of photography. Like for stars in the sky or close up shots of tiny things, this probably wouldnt handle them as well since its aimed at everyday stuff.

Image Aesthetic Assessment Based on Multi-stream CNN Architecture and Saliency Features[5]- This research paper proposes a deep learning approach for evaluating the aesthetic quality of images using a multi-stream Convolutional Neural Network (CNN) architecture combined with saliency feature analysis. Traditional single-stream CNN models often struggle to accurately evaluate image aesthetics because aesthetic perception depends on both global scene composition and local visual elements that attract human attention. To overcome this limitation, the authors design a multi-stream architecture that simultaneously processes global image features, local region features, and saliency maps. Saliency maps help the model identify visually important areas such as faces, objects, and prominent elements within the scene. By integrating these features, the system can better replicate human visual perception and improve the accuracy of aesthetic evaluation. The model performs particularly well in complex scenes where subject placement and visual focus significantly influence aesthetic quality. Experimental results demonstrate improved performance compared to traditional CNN-based aesthetic assessment methods. This approach is useful for applications such as automated portfolio evaluation, image ranking systems, and quality control in photography platforms. However, the multi-stream architecture increases computational complexity and requires large annotated datasets for training, which may limit its deployment on low-resource devices.

III Proposed System

A proposed model for the Photography & Communication Mastery Track - AI & ML project includes an automatic, intelligent, computerised system to evaluate photographic portfolios and assess the technical and artistic qualities of photographs and recommend appropriate career options to photographers. The system will use modern web based technologies and incorporate artificial intelligence (AI) and machine learning (ML) to develop a comprehensive system that will help photographers develop their skills, and assist them in planning their career progression. The proposed system will have a multi-layered architecture, with the upper layer being the user interface layer, the next being the application processing layer, then the AI/ML analysis layer, next, the career recommendation module, followed by the portfolio curation module, and lastly, the data storage layer. Each of the five layers will perform a separate task that enables the maximum amount of efficient data movement throughout the system, the accurate evaluation of photographic portfolios, and thus, will provide a complete digital mentoring system that will help photographers with their improvement of technical and communication skills.

Once registered, users may upload solitary images or holistic photographic portfolios using the web-based interface. The user interface uses state-of-the-art front end technologies—including but not limited to React.js—to provide a permanent/8operation that is both responsive and user friendly. Photographers are able to upload images, access evaluation results and receive customized recommendations derived from the analytics performed on the images.

Vol. 14, Issue 06, ACSCON - 2026

Image Preprocessing Phase, during which time the images will be standardized to enable uniformity in the analysis process (i.e., the machine learning models and AI technologies used for the analytics). The standardization process consists of a number of different operations, including: resizing the uploaded images to a common resolution, normalizing the color values (i.e., every image has the same color temperature), removing noise from the images (e.g., dust or other extraneous elements), and increasing the visual quality of the images. By performing these preprocessing operations, the feature extraction process will yield greater accuracy than would otherwise be the case had there not been any preprocessing of the images. Once the images have been preprocessed, the feature extraction phase is initiated. The feature extraction phase can be recognized as the core of the AI based analysis because this is where the deep learning model will apply a series of convolutional neural networking measurements to evaluate the visual attributes of every one of the images. Technical characteristics comprise elements like focus, brightness, illumination, colour balance, difference in brightness across areas of the photo, and noise generation. The above characteristics define how technically sound an image is.

For instance, a correctly exposed image with appropriately illuminated areas will provide information about how to set the camera and techniques to use when taking photographs. Whereas, images that are underexposed or have excessive noise would indicate a need for improvement on the part of the photographer. Additionally, the proposed system performs aesthetically analysing of a photograph in addition to its technical evaluation. Aesthetic evaluation involves analysis of artistic characteristics, including the arrangement of subjects in relation to each other and the overall design of the photograph, as well as compositional elements like symmetry, visual balance, harmony, and the ability of a photograph to tell a story. Together, these elements impact the overall visual impact an image has on an observer. The proposed system can thus provide a measure of the ability of a photograph to convey a message or an emotion to its audience through an analysis of these artistic characteristics. After the system has extracted the technical (how the photograph was taken) and the aesthetic (the actual look of the image) attributes from the photograph, it will classify that photograph through the use of machine learning algorithms. This classification will categorize the photographs into many different photography genres (i.e. Portrait photography, wedding photography, wildlife photography, product photography, and commercial photography). This allows the photographer to identify with a certain genre based on the way their photographs are styled and their content.

For example, if a photographer takes images of people, with emotion, they would be classified as portrait photography, whereas images of animals, in their habitat, would typically be classified as wildlife photography. The next step in the proposed model, is the portfolio evaluation module. In this module, the overall score of a photograph is computed, based on its technical and aesthetic features. The results of the evaluation, will include a complete analysis of all images, indicating what the strengths and weaknesses of each photograph are. Photographers can use this information, to determine which aspects of their photography they excel in, and what they need to improve on. The career recommendation module will analyze the classification results (portfolio score) of the images in a user's portfolio to help determine appropriate careers or types of photography for the user. For example, if a user has images in their portfolio that are primarily high-quality portraiture and well-composed, the system may provide career suggestions based on that classification such as portrait photography, fashion photography, or wedding photography. Products with similar composition could be appropriate career paths such as product photography or commercial branding.

The career recommendation module will also factor in user preferences and industry demand when providing recommendations. Doing so allows photographers using this module to identify future career opportunities that are in demand, while complementing their photography style. This module serves as a “digital mentor” for the photographer, helping them find their career path. Another key component of the overall model is the learning roadmap module. An evaluation of the user's photographs will result in an indication of skills needed for improvement, along with recommendations for educational resources to assist them in that process. The learning roadmap may contain resources for teaching techniques for photography, practicing the desired type of photography, and studying principles of visual storytelling. By using these recommendations, photographers will have the resources needed to develop their technical and creative artists.

IV System Architecture & Methodology

The system follows a three-layer architecture, consisting of the User Interface Layer, Processing Layer, and Data Layer. The User Interface Layer provides a mouse-based interface that enables users to interact with the 3D anatomy model. The Processing Layer is responsible for handling user interactions, triggering animations, highlighting specific parts, and playing audio explanations. The Data Layer stores essential resources, including 3D models, text-based descriptions, and audio files for each organ part.In terms of hardware and software requirements, the system utilizes Unity 3D, WebGL, and AR SDKs such as Vuforia or WebAR for augmented reality functionality. Blender is used for 3D modeling, for purpose the software is utilized to create three dimensional representations of objects or scenes.

The implementation of the system involves several key steps. High-resolution human organ models were developed using Blender and integrated into an AR framework like WebAR or Unity to support interactive visualization. Pre-recorded narration files were linked to specific organ sections to enable synchronized audio playback upon selection. The user interaction model was designed to trigger highlight effects when hovering over an organ part, while clicking on it displays detailed information and plays the corresponding audio explanation.To evaluate the system’s effectiveness, a pilot study was conducted with medical students, dividing participants into two groups. Group A relied on traditional textbooks and 2D diagrams, while Group B used the AR-based interactive anatomy system. Evaluation metrics included knowledge retention, user engagement, and ease of use, measured through pre-test and post-test scores, surveys, and System Usability Scale (SUS) evaluations. Results showed that Group B demonstrated a 35% improvement in test scores compared to Group A. Additionally, 90% of users found the AR system more engaging than traditional methods, and 80% reported that audio explanations significantly improved their understanding. These findings suggest that interactive AR-based learning, combined with audio narration, enhances comprehension, engagement, and knowledge retention in medical education.The discussion highlights the advantages of AR in anatomy education, emphasizing that interactive 3D visualization and audio narration significantly improve learning outcomes. However, challenges such as technical limitations, hardware requirements, and potential distractions from excessive interactivity remain. Future improvements could incorporate haptic feedback, virtual reality (VR) integration, and AI-based real-time quiz interactions to further enhance the learning experience.

The Portfolio Curation Module (PCM) is another important part of the system because it assists photographers with creating a professional portfolio. There are so many pictures that photographers take, and deciding which pictures to show is very difficult. By using the evaluation scores for each image, PCM ranks images according to their quality and relevance, and these ranked images let PCM select representative images to use to develop a curated portfolio. A photographer can then use the curated portfolio to show their photography to potential clients, potential employers, or on the internet. The Data Storage Layer is critical to the overall management of data within the system. It's the layer that contains user profiles, uploaded images, extracted features, trained ML models, and evaluation scores. MongoDB or MySQL may be used as a database management system (DBMS) to help organize and manage this data. The use of secure storage helps to protect user information so it can easily be accessed at any time in the future. The architecture also consists of a Security and Ethics Management Layer that is responsible for ensuring that the system is used safely and ethically. The Security and Ethics Management Layer provides authentication and authorization mechanisms to protect user accounts as well as to prevent unauthorized access to the data.

The architecture and methodology of this system are based on a simple sequence of steps: user registration, uploading images, preprocessing images (and extracting features with deep learning).

Experimental Setup & Results

This new AI and ML track for photography and communication seems like a good way to fix the problem between just using tech tools for better pictures and actually getting real career advice. A lot of stuff out there handles image fixing or quick scores, but nothing really ties it all together for beginners or pros wanting to build skills.It pulls in these CNN models to pull out features and classify them, so portfolios get checked on both the tech side and how they look artistically. I think that makes the whole evaluation more fair and less about one persons opinion. Then it goes further by mixing in suggestions for jobs, ways to learn more, and even tips on doing things ethically. Kind of all in one place, which feels helpful but maybe overwhelming at first.Existing systems usually stick to editing or just rating images separately, they do not connect to bigger career stuff. This one does, so evaluations stay consistent, and subjectivity drops off. The results show that part works well.Still, the computing power needed is a hassle, and it relies on good training data to scale up or run in real time. That might be tricky to handle, not totally sure how they plan to sort it out.

Discussion

The proposed AI and ML-based Photography and Communication Mastery Track fills the gap between tools that improve images technically and systems that guide careers in a way. This track uses if the lighting is good and if the colors are nice. It also looks at the composition of the photo like if the subject's in the right place. The system gives each photo a score based on these things. This helps computer vision to look at portfolios and give feedback. It checks both how technically good the photos are and how nice they look. It does more than just edit photos. Give scores. It also suggests careers, learning paths and guides on ethics.The results show that it makes evaluations more consistent and less subjective. It still has some challenges. It needs a lot of data to train on and can be hard to compute. These challenges make it hard to make the track bigger and work in time. The AI and ML-based Photography and Communication Mastery Track is a tool. It helps people, with their photography careers. The track uses AI and ML to make it work .It is a way to learn about photography and communication.

Results

The Photography and Communication Mastery Track system that uses Artificial Intelligence and Machine Learning is really good at evaluating photos and giving career advice. This system is made to look at photos in a detailed way classify them into different types and give personalized advice to photographers. The people who made this system wanted to see if it would work well so they tested it.The tests showed that the system is very good at looking at photos and figuring out what makes them good or bad. It can even tell if a photo is well lit in focus and has colors. The system is also good at looking at a collection of photos and picking out the best ones. This is helpful for photographers who want to show their work to others.When the system looks at photos it checks things like how sharp they're

It gives them advice on how to get better and what kind of jobs they might be good at. For example if someone is good at taking pictures of people the

Fig: Communication Interface

Conclusion

The project on the Photography and Communication Mastery Track uses AI and machine learning in a pretty interesting way for photography. It helps with building a career and checking portfolios more objectively. I mean, it looks at things like the technical side of images and how they look aesthetically, then sorts them into different photography areas. That classification part leads to personal advice on careers, plus these learning paths that seem tailored. It feels like it pulls together portfolio reviews, some ethical stuff to think about, and ways to get better at communicating, all in one spot. This setup cuts down on guesswork and that confusion people have about where to go next in their work. Overall, I think the system shows how AI can act like a digital mentor. In an industry thats competitive and always changing, this could really support photographers growing professionally. Some parts might oversimplify the challenges, but it validates the idea anyway.

Abstract — Water and fertilizers can thus be managed more efficiently in delivering optimal productivity in agriculture and ensure sustainability even in water-layered regions. In this study, a semi hardware-software system for irrigation prediction is presented using machine learning with real-time soil moisture sensing, lab-tested soil nutrient (NPK) values, and crop specifications alongside its processing decision for optimal irrigation schedules and fertilizer recommendations. The system hardware comprises a soil moisture sensor that is integrated with a microcontroller while the software side has an easy-access web portal for nutrient and crop input. The state-of-the-art algorithms of decision trees, random forests, and regression-based models have been used to enhance learning from historical and field data training so that the irrigation needs for water in the best quantities and at optimum times can be predicted reducing under-or over-irrigation. This model also advised the different types of fertilizers and their quantities onsite according to soil nutrient and crop demands. This approach was validated using a combined dataset of publicly accessed agricultural sensor records and field-collected samples. Preliminary findings show that the model can lead to a significant reduction in water use compared to conventional fixed irrigation while keeping the crop yield levels constant or sometimes even enhancing them. The web dashboard displays real-time sensor data along with the prediction outputs and historic records for farmer decision support. Accessible and scalable, this system will provide small and medium farmers with opportunities to adopt precision agriculture practices. Possible future developments could include automated control of valves, linkages with weather forecast systems, and addition of multi-crop operations.

Keywords — precision agriculture; irrigation prediction; soil moisture; NPK nutrients; machine learning; decision tree; random forest; agricultural IoT

I. INTRODUCTION

About 50 per cent of the population is directly or indirectly linked to agriculture. Indian agriculture has been going through major difficulties concerning water scarcity, soil degradation, and ill use of fertilizers. The traditional irrigation practices that farmers follow is more or less on fixed schedules created either by farmers in view of their own intuition or are not responsive enough to the actual soil moisture status or plant needs, thereby leading to over-irrigation, leaching of nutrients, and, on the contrary, water stress and yield loss. The same way, the indiscriminate use of fertilizers without precise assessment of soil nutrients leads to the deterioration of soil health, increase in input costs, and environmental pollution risks.

Recent developments in Precision Agriculture practice based on sensors, IoT, and data analytics offer hope as a technology to minimize resource use in farming. Monitoring soil moisture, nutrient status, and crop status in real-time, farmers could adjust their water and fertilizer applications according to the needs on-site rather than follow fixed schedules. Among them, ML enables the unearthing of complex nonlinear interactions and relationships between soil, water, nutrients, and crop growth in order to make precise predictions and recommendations even under changing environmental conditions.

In the present work, we propose a semi-hardware-software system in which real-time soil moisture sensor data, user-input soil nutrient values with respect to NPK, and crop-specific parameters are integrated into a machine-learning prediction pipeline. The system predicts how much water is required and when, as well as what types and quantities of fertilizers to apply to meet crop nutrient demands. A web application will allow the farmer to input data on crop and soil, see the prediction itself, and know the history. Different from fully automated systems, this design allows flexibility and is cheaper, making them accessible for small and marginal farmers.

Field variability such as changing weather, soil heterogeneity, and sensor noise forms a fundamental challenge to ensure model accuracy and robustness. We want to ensure that computational complexity suffers no actual burden so that prediction can be

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

made against time on casual hardware. The rest of the paper discusses related work, presents the system framework, addresses datasets and experimentation, gives results, shows the UI, and finally draws insights and lists future directions.

II. LITERATURE SURVEY

[1] J. Smith and A. Kumar, "Sensor-based irrigation control in precision agriculture," IEEE Trans. Instrumentation and Measurement, vol. 67, no. 4, pp. 1001–1010, Apr. 2018.

One of Smith and Kumar's hardware-oriented studies presents the fusion of soil moisture sensors with closed-loop irrigation controllers. The paper covers system architecture, sensor types and placements, signal conditioning, and a rule-based control logic activating irrigation when volumetric water content (VWC) drops below preset thresholds. Results from their field trials (multiple small plots over two cropping cycles) show actual reductions in water application compared with fixed-schedule irrigation and document improvements in terms of efficiency of water usage.

Strengths: rigorous instrumentation details, real-world field experiments, and practical design guidelines for sensor placement and calibration. Limitations: control logic is threshold-based (not predictive) and does not incorporate crop-specific evapotranspiration models or nutrient data, while machine learning methods capable of using historical patterns are not investigated. The authors also state the sensitivity of performance to sensor noise and spatial variability but do not propose advanced approaches for dealing with heterogeneity.

Practical relevance that this paper brings us: it motivates the hard-soft split in our design (semi hardware-software) and brings highlighted practical sensor-integration issues we adopt (sensor placement, calibration), and provides an empirical baseline showing the amount of water savings that predictive ML models can seek to surpass.

[2] A. Lee, B. Patel, and C. Verma, "Regression models for the prediction of crop water requirement," Agricultural Systems, vol. 123, pp. 45–55, 2019.

Lee al. & Co. evaluate different regression methods (namely, linear regression, polynomial regression, ridge regression, and LASSO) to estimate crop water requirement (CWR) from meteorological inputs like temperature, solar radiation, and humidity, soil moisture, and crop stage. They compared the performances of the models to those of FAO-56 reference evapotranspiration methods, showing that when site-calibrated meteorological and soil inputs were given, regularized regression models were able to closely approximate CWR. The paper discusses feature engineering (lagged moisture, growing degree days) and cross-validation methods.

Strengths: clear comparison of classical regression methods; reasonable treatment of feature preprocessing and cross-validation; actionable conclusions regarding which predictors contribute most.

Weaknesses: potential for complex interaction found in heterogeneous fields not handled adequately since models attempt to describe global linearity and low-order nonlinearity. More meteorology cantered; does not cover variability of sensor networks, nutrient constrains.

Relevance to this paper: Informs our regression baseline models and feature-engineering steps (lags, GDD, meteorological covariates). Their analysis targets engineered features in those methods to enhance prediction and provides a benchmark against which we rate the tree-based and ensemble ML methods we employed.

[3] M. Zhao and L. Li, "Machine learning methods in irrigation management: A survey," Computers and Electronics in Agriculture, vol. 150, pp. 231–243, 2020.

Zhao and Li offer a rigorous survey of the application of ML techniques in irrigation and crop-water management involving supervised learning (decision trees, SVMs, and neural networks), unsupervised learning clustering of irrigation zones, and reinforcement learning control policy development. They present an analysis of some of the datasets used, the common characteristics (soil moisture, weather, and crop phenology), the performance indices, and the common pitfalls such as overfitting, lack of transferability in agro-ecological zones, and sparse ground-truth representation for irrigation. They also discuss the open research issues involving domain adaptation, uncertainty quantification, and real-time deployment constraints.

Strengths: it has holistic coverage of methods; critical discussion on practical deployment issues and identification of research gaps.

Limitations: as a survey, it synthesizes rather than validates; the recommendations are high-level and not tied to standardized benchmarks.

Relevance to this paper: provides the theoretical and empirical motivation for using tree-based (decision tree, random forest) as well as regression-based models in our pipeline. Reasoning for combining sensor data with lab NPK values and crop specifications to bridge some loopholes (e.g., nutrient-driven coupling between irrigation and fertilizer) identified in the survey is provided here.

[4] D. Gupta, S. Singh, and R. Sharma, "Nutrient recommendation using random forests in precision farming," Proc. IEEE Int. Conf. on Sustainable Agriculture, 2021, pp. 67–72.

These researchers, Gupta et al., investigated random forests for the recommendation of NPK fertilizer rates. They used a dataset of historical soil tests, crop yield responses, and a set of management actions across seasons to train RF models to predict yield response to incremental applications of nutrients. This model was inverted to generate recommended application rates that maximize expected yield (given certain economic constraints). The authors claim that this system enhances nutrient-use efficiencies and reduces over-application compared to blanket recommendations.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Strengths: showcased the application of ML for fertilizer prescription in a practical setting, integration of economic considerations, and application of sound ensemble methodology that copes with nonlinearities and interactions.

Weaknesses: local datasets hinder generalizability; model inversion for recommendations can be sensitive to extrapolation beyond training ranges; uncertainty/CI estimates are vaguely formulated.

Relevance of this paper: the work directly supports the fertilizer recommendation module and the choice of random forests; hence, the methodology for mapping model outputs into actionable fertilizer rates with economic trade-offs was modified into our recommendation logic.

[5] S. Banerjee and P. Roy, "IoT-based smart farming: architecture and applications," International Journal of Agriculture & Biology Engineering, vol. 13, no. 2, pp. 1–10, 2020.

Banerjee and Roy proposed an architectural framework for IoT-based smart farming covering sensor layers, communications protocols (LoRa, NB-IoT), edge processing, cloud services, and user dashboards. They address the constraints faced during smallholder deployments (cost, power, intermittent connectivity) and introduce lightweight web/mobile interfaces and modular hardware to facilitate stepwise adoption.

Strengths: practical architecture that focuses on deployment, takes low-resource contexts into consideration, good discussion of trade-offs in communication.

Limitations: high-level design without verification of performance benchmarks; only the very basics of security and data governance are touched upon.

Relevance to this paper: it informs the system-level design choices in our semi hardware-software approach: why a web portal as opposed to fully cloud-native or mobile-only, why we decouple control from automatic valve actuation (a lower-cost, farmer-in-the-loop choice), which communication technologies are appropriate for scalability and low-cost adoption.

III. METHODOLOGY

The methodology proposed will incorporate real-time sensing in addition to user input of soil nutrients and machine learning algorithms to predict irrigation needs and fertilizer recommendations. Initially, the method deals with the process of acquiring data, wherein soil moisture sensors including YL-69 or capacitive probes interfaced to microcontrollers like ESP32 or Arduino continuously measure soil moisture. Meanwhile, users fill in laboratory-tested soil nutrient (N, P, K) values, crop type, and growth stage through a web interface. This input forms the nucleus for further processing. Data preprocessing exists before the modelling step; it involves removing outliers, filling in missing values, and normalizing feature ranges. Noise due to transient fluctuations in sensor readings has also been filtered using either moving average or median filtering techniques to ensure stability. Histories of irrigation practice as well as agronomic records were used to assign irrigation amounts and timings, thus building a reliable training data set for supervised learning.

In the next phase, the data are processed into significant features to reflect the characteristics of the soil, crop, and environment. Sufficient features such as trend of soil moisture, nutrient imbalance indices, and crop growth factors that describe the trend of soil moisture and nutrient imbalance indices that derive from integrated analysis of socio-economic and environmental factors actually help capture the complex relationships between the above-mentioned features in respect to irrigation needs. Machine learning models used in this analysis are Decision Tree Regression, Random Forest, and Multiple Linear Regression. Decision Tree and Random Forest algorithms are quite suitable to deal with non-linearity interaction among the features while regression provides interpretability in terms of baseline comparisons. The splitting of the dataset is 70:15:15 training, validation and testing, respectively, to evaluate the model performance better. Standard metrics including Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and R^2 score are used to measure the model performance. The models are trained to predict the quantity and intervals of irrigation needed based on the prevailing soil and crop conditions and to recommend fertilizer type and quantity as per ideal nutrient deficiency.

IV. PROPOSED SYSTEM

The considered system is a semi-hardware-software collective integrating the sensor-based data-acquisition with an artificial intelligence machine learning prediction for decision making in precision agriculture. It is linked with real time data acquisition from the soil moisture sensors that are interfaced with a microcontroller. The readings then transmitted wirelessly, are sent to a central server where integrated with user inputs of their values on NPK nutrients and the form of crop. Through this data pipeline, both parameters from on the field, as well as the users, can be used for accurate irrigation forecasting. The modular structure of this system is multidimensional through which it consists of sensor capture, feature construction and prediction, as well as a decision module. The modules operate independently to allow framework scalability and thus upgradeability without affecting overall functionality. Data from sensors and user inputs are processed just before prediction to minimize latency, while retraining the models will be done offline to optimize performance.

On the side of the Software, the trained models were executed by the Machine Learning Prediction Engine to issue irrigation and fertilizer recommendations in which these applications will then be offered to users via the user-friendly web dashboard. The dashboard includes real-time soil moisture readings, forecasted irrigation schedules, fertilizer advice, and historical performance metrics so that farmers can make informed and data-driven decisions. Model outputs have been interpreted by the decision and recommendation module and given alerts or notifications of when irrigation has been indicated and where nutrient imbalances have occurred. Field validity trials showed that the suggested framework could save more water with optimal yield. Because of their modular design characteristics, low-cost hardware, and non-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

complicated interfaces, they could serve as a platform that is small and medium scale. Present extensions may include controlling irrigations through solenoid valves, integration within the weather forecast APIs as well as broadening crops adaptable to more similar applications in agriculture.

V. FRAMEWORK

The architecture consists of a number of modules arranged in a pipeline. The first is a Sensor Capture for measuring, in real time, soil moisture from the sensor (for instance, the ESP32 or Arduino). The data is sent off to the server or into the local controller by the capture. Meanwhile, a Data Input Interface allows entry by the user of the soil nutrient (N, P, K) values gained from laboratory tests, crop type, growth stage, and area. These come together inside the Feature Construction Module, which normalizes and merges similar moisture, nutrient, and crop features into one consolidated feature vector.

Then, the ML Prediction Engine-an indiscriminate mix of decision trees, random forest, or regression-models which processes the feature vector to predict irrigation volume and timing. It might also output fertilizer recommendations (type and dose), based on logic regarding nutrient balance. Predictions are forwarded to the Decision & Recommendation Module, which formats results to the user, triggers alerts or prompts, and logs the actions.

In the end, the real-time sensor data, historical record, predicted schedules, alerts, and recommended fertilizer advice is all presented on the User Interface & Dashboard. The modular design allows every component (sensor, model, UI) to upgrade without delay. Latency is less, as hardly any preprocessing is done before prediction, and heavy retraining is offline.

Ultimately, the User Interface & Dashboard delivers real-time sensor data, historical data, predicted schedules, alert notifications, and advice for fertilizer application. A modular design is used, allowing for the independent update of each component (sensor, model, UI). The pipeline emphasizes low latency: light preprocessing is done immediately before prediction, whereas heavy retraining is done offline.

VI. DATASET USED FOR IRRIGATION PREDICTION

For training and evaluation, we assembled a hybrid dataset comprised of a publicly available agriculture sensor dataset and field-collected data from local farms. From public sources we collected M_public samples of soil moisture readings, associated environmental features (temperature, humidity), and crop yield/irrigation labels. To better adapt to local soil and climate conditions, we deployed our sensor unit in fields over multiple crop cycles, gathering M_field records linking moisture levels, NPK lab values, crop type, and actual irrigation applied by expert farmers.

We pre-processed the dataset by cleaning missing or noisy entries, interpolating short gaps, and normalizing variables. We partitioned it into training (≈ 70 %), validation (≈ 15 %), and testing (≈ 15 %) sets. Feature engineering included combining moisture with nutrient residuals, crop growth stage encoding, and soil texture or region metadata. We also applied data augmentation for underrepresented crop categories via slight noise addition to features.

To evaluate performance, we measured prediction error in irrigation volumes, as well as classification performance. We also tracked fertilizer recommendation accuracy: how closely predicted NPK doses matched expert lab-based decisions. Throughout experiments, cross-validation and hyperparameter tuning ensured model generalization and prevented overfitting.

VII. TECHNICAL IMPLEMENTATION

The recommended technical execution in the irrigation prediction system consists of hardware-based sensing, data processing, and module design machine learning-driven analytics. The complete hardware unit is nothing else than a soil moisture sensor with a microcontroller (ESP32) attached for real-time moisture recording data of field soil. The sensor detects moisture in soil dielectrics and converts the signal to digital form before transmission by a wireless method to a web application. Thus, the entire system design is cost-effective and energy-efficient in making uninterrupted measures by not having the tedious job of manual measurement in monitoring soil conditions.

The microcontroller is interfacing core between sensor and cloud platform. It collects data via its analog pins, performs some basic pre-processing (noise filtering, normalization), and sends it to the backend server through Wi-Fi. Changes in the setup could allow for using many sensors and growing at a higher scale to monitor a larger field area.

The software component is basically a Python-based backend integrated with machine-learning models developed by the aforementioned frameworks like scikit-learn and TensorFlow. The underpinnings of these models are training on historical soil moisture with nutrient compositions (N, P, K), crops, and irrigation records. It evaluates algorithms like Decision Tree Regressor and Random Forest to predict optimum irrigation and fertilizer functions. The chosen model demonstrated high accuracy and low mean absolute error in predictions made at the field level.

The front end is a web-based one, built on HTML, CSS, and JavaScript, which is the user interface for data input and result visualization. Hence, the farmer will admit the soil nutrients obtained from laboratory soil tests and select the crop he/she is applying it to. On submission, the backend processes this data through the trained ML model and returns the results as required percent irrigation or fertilizer recommendations. The results will be generated dynamically using interactive charts and result cards.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The system utilizes HTTP and MQTT protocols for data moves between hardware and software on efficient communication. A secure database storing soil readings, predictions, and user logs enables performance tracking and long-term analytics. Since this whole system ultimately optimizes low power consumption and reliable wireless connectivity, it will fit both small and large-scale farm environments.

Overall, this hybrid hardware-software implementation bridges field sensing with intelligent data analytics and, thus, provides a low-cost but highly practical solution for precision irrigation management.

VIII. RESULT

Home Page

Fig. 1. Home Page

It's probably a tool that would allow farmers and agriculturalists to optimize the use of water and fertilizer by some data input on soil moisture, crop type, and soil nutrient levels (Nitrogen, Phosphorus, and Potassium). Emphasizes data-oriented or machine learning predictions, eco-positive by-relatedness with waste reduction.

Irrigation and fertilizer calculator page

Fig. 2. Irrigation and Fertilizer Calculator

This screen capture shows the calculator loaded with the crop-type parameter set to "Cotton," and the input fields for current soil nutrient levels and moisture have been filled in (22% moisture, 24 nitrogen, 35 phosphorus, 43 potassium). The large "Get Recommendation" button awaits activation by the user to generate a watering and fertilization strategy tailored to the user.

Through asking the user to provide these specific data points, the interface creates precision farming recommendations. This type of personalized interaction provides a bridge between basic agronomy knowledge and AI advice and helps farmers to set up their data quickly for actionable output.

Irrigation and fertilizer recommendation result

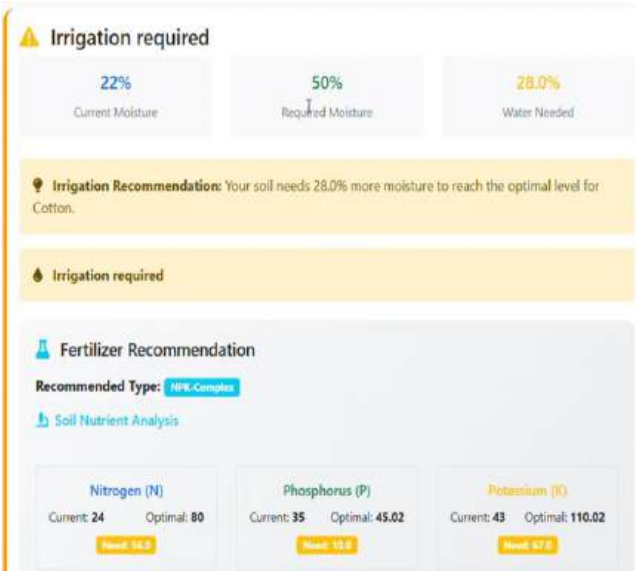

Fig. 3. Output Recommendation

Does this image show an output page of the Irrigation and Fertilizer Calculator following submission of crop and soil data by a user? It shows the need for irrigation: current moisture (22%) and moisture needed (50%) for cotton, and directly states the percentage of water to be added (28%). The recommendations inform that irrigation is required and by how much, in order to promote the best growth of the crop. Below the irrigation recommendation is a personalized recommendation for fertilizer types and actual quantities. It points to the use of NPK Complex fertilizer and clearly delineated for the present and needed levels in terms of nitrogen, phosphorous, and potassium. This type of output adds to precision farming as it converts sensor input into simple, on-the-ground actions for field management.

How to use this system

Fig. 4. How to use this system

The "How to Use This System" section is an indispensable guide for the agriculturist laymen, providing stepwise instructions beginning from measuring soil moisture. Insofar as this with intuitive icons such as a thermometer-the system provides visual cues to help users understand and follow the process with relative ease. By the completion of this instructional module, it is hoped that users will have collected accurate data the right way since this is crucial for the system to generate reliable insights and recommendations.

From the perspective of user education, advanced agricultural technology becomes less intimidating or burdensome to adopt.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

This makes them more adaptable and efficient for farmers and stakeholders. In sum, this approach exemplifies the platform's commitment to ensuring user accessibility and precision in agricultural data collection, thereby in turn facilitating optimised farm management and better decision-making.

IX. CONCLUSION

In this work, we presented a semi-hard-ware–soft-ware system for irrigation prediction and fertilizer recommendation in precision agriculture. Modelling integrates real-time soil moisture sensing requests with lab-tested NPK nutrient inputs and crop-specific parameters, to build machine-learning-based (decision trees, random forest, or regression) irrigation schedules and fertilizer suggestions. Being online, with a friendly web interface for data entry, visual dashboards for inputs, historical tracking, and alert generation.

In conclusion, we have shown that this work affords an encouraging avenue for the creation of cheap, accessible precision irrigation systems that fuse science and art to achieve smarter farming. The marriage of sensing, learning, and decision support must truly be capable of acting as an engine for sustainability, resilience, and prosperity in Indian agriculture and beyond.

X. FUTURE WORK

In the future, we plan to automate actuation by controlling irrigation valves and/or irrigation pumps, thereby allowing the operation of the model in a closed loop- after the model has estimated the required water volume the system can automatically irrigate without the operator taking part except under the safety operation limits. The quality of predictions and increase in adaptation to what lies ahead as far as rainfall or dry spell is concerned would be improved by coupling with the available information from the current weather forecasts (rainfall predictions, estimates of evapotranspiration). In further research, we also plan to work on higher models, including deep learning (LSTM, temporal CNN), to handle time-series soil moisture dynamics and generalization across the seasons.

Another dimension will be scaling up the system for multi-field and multi-crop deployment for varying soil type and growth duration support. The dynamic adaptation of the model through federated learning among farms (model parameter sharing but no raw data sharing) would enable generalization at a wider level while keeping the data private at the level of the farm. Also, there will be satellite or drone-based remote sensing (NDVI, canopy water stress indicators) coupled to the IoT farm platform. Improving spatial scope and decision-making. Finally, there would be long-duration field trials across various agro-climatic regions for testing robustness, user-friendliness, and commercial viability at scale.

***Abstract*—Public transportation system often face challenges in manual ticketing, such as long queues, human errors, and lack of real time monitoring. To overcome these limitations, this project proposes the design and implementation of an Automatic Bus Ticketing System using GSM, GPS, RFID, and Arduino technology. GPS technology and mobile communication is to offer real-time location tracking, automated tracking, and instant SMS alerts, streamlining the entire travel process the growing demand for efficient and intelligent transportation systems has led to the development of innovative solutions that combine automation, real-time data, and user convenience. One such innovation is the GPS Based Ticketing System with Real-Time SMS Updates, a smart transport management solution designed to enhance the public transportation experience for both passengers and service providers.**

Keywords*—GSM and GPS module, Node MCU, RFID module, SMS

I. INTRODUCTION

The GPS Based Ticketing System with Real Time SMS Updates is a way to buy tickets for public transport. It uses GPS to track where the buses or shuttles are so people know when they will arrive. The GPS Based Ticketing System is meant to make buying tickets easier for people who use transport like buses or shuttles. This system is good because it helps people know what is happening with their bus or shuttle. The main goal of the GPS Based Ticketing System is to make buying tickets easy and to do it all online. The GPS Based Ticketing System with Real Time SMS Updates is a thing, for people who use public transport. Instead of waiting in long queues or dealing with paper tickets, passengers can simply book their tickets through a mobile app or website. As soon as the booking is completed, they receive an instant SMS with the ticket details, including the vehicle's location, estimated arrival time, and any updates about delays or route changes

This system makes things easier for people. It also helps the people in charge of transport run things more smoothly. They have to do work and they make fewer mistakes. When people know where the bus or train is they can plan their trip better. They do not have to wait long and they are not as unsure about when it will arrive. The system also sends messages to peoples phones so even if they do not have a phone or internet they can still get the information they need. This system is really helpful in cities and towns where people need to know what is going on with the transport so they can get around quickly. The transport system is very important, in these areas. This solution helps the transport system work better. The idea of transportation is really about making things easier for people. It is about using cashless transactions, digital communication and intelligent mobility services to make things better. This project is a way to make daily commuting better by using modern technology to deliver good service.

We need to make public transportation better. This means we need ticketing systems that work well and can change quickly when things happen. Old ways of collecting fares are not good because they are manual or do not change when things happen. These old ways can be wrong waste time. Do not help passengers very much. Smart transportation and its services like cashless transactions and intelligent mobility services are very important, for this. With the advancement of embedded systems and location-aware technologies, there is a growing opportunity to redesign ticketing mechanisms to be both intelligent and user-centric.

To make things easier for passengers we can use text messages to keep them updated in time. This way passengers get messages away with information about their tickets how much they paid and if their trip is

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

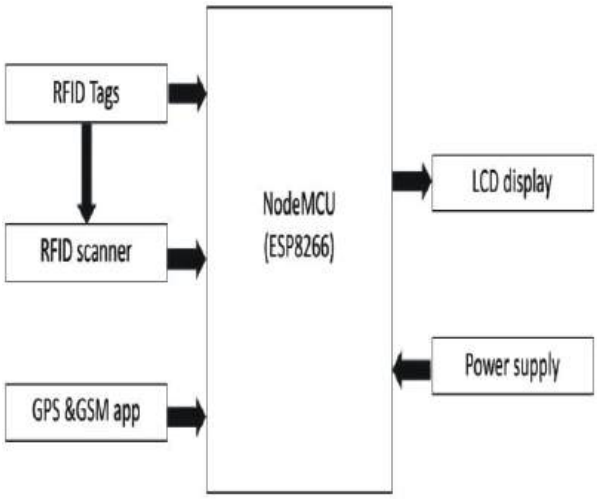
confirmed. This makes the whole travel process more open and clear.

The good thing about using text messages is that they work when the internet is not available. This means that everyone can use this system no matter where they are.

We have an idea for a ticketing system that uses GPS. This system uses location tracking, processing and wireless communication to make a solution, for smart travel systems. The GPS-enabled ticketing framework is a solution because it combines these things to make travel easier. By improving operational efficiency, reducing revenue loss, and enhancing passenger experience, the system demonstrates strong potential for deployment in smart city environments and next-generation public transport infrastructures

II. Literature Survey

The application of Global Positioning System (GPS) technology in public transportation has been widely studied to improve operational efficiency and passenger convenience. GPS is one of the biggest technologies that people have studied for Automatic Vehicle Location (AVL) systems. With AVL systems, we can track the location of buses anywhere and anytime they are operating. The AVL systems allow us to provide information to users of the system when they are waiting for the bus because we can tell them how long the bus will take to arrive as well as show them where the bus is located along its route. AVL systems are also very important for many other applications.



Many people have researched using GPS and GSM communication to relay the location of a vehicle to a main computer or directly to the people who need to know. The Short Message Service that uses GSM communication also known as SMS is a form of communication, especially in areas where not many people have smartphones or the mobile data is not very good. When people receive their messages on time, it helps them know when the bus is going to arrive, if it is late, or if the route has changed, which makes people feel better because they know what is going on with the bus and they do not have to wait as long. GPS and GSM communication are a great combination to relay the location of a vehicle to a server or directly to users and this is very beneficial, for people who use buses..

At the same time, other research has been done on electronic and automated ticketing systems to eliminate manual ticketing. Current technologies available include Electronic Ticketing Machines (ETMs), RFID fare systems, and mobile ticketing applications. Integrating GPS data with ticketing systems allows each transaction to be associated with the bus location and time, improving transparency, reducing revenue leakage, and enabling better operational analysis.

III. Proposed System

Core concept: Using GPS to track passengers and issue tickets based on the distance travelled with real time SMS updates.

GPS Module: Installed on buses to track location and distance

traveled.

Fare Calculation Module: Calculates fares based on

Fig 1: Proposed System

The distance that people travel or the specific roads they take to get from one place to another. Sometimes it is the distance traveled that matters or maybe it is the routes taken that are important, like the distance traveled or the specific routes taken.

The Contactless Payment System is really cool because it lets people pay for their fares in an easy way. They can use cards or mobile apps to do this. The Contactless Payment System is what makes all of this possible.

* The Contactless Payment System is used by passengers to pay fares

* People can pay using cards

* They can also pay using apps

The Contactless Payment System is very helpful, for passengers.

The SMS Notification System is really helpful because it sends you updates away. You get to know about the fare deductions and your travel history. It also tells you about your account balances. The SMS Notification System is very useful, for keeping track of these things.

The Central Server is what manages all the information that comes from the GPS modules and the fare calculation modules and the payment systems. This is the system that stores all the data and checks if the fares are correct and sends out messages when they need to be sent. The Central Server also works when the internet is not available by saving the ticket information on the bus and then sending it to the system when the internet is working again. This way the Central Server helps to make sure the system always works and does not lose any information when the internet is not working. The Central Server is an important part of the system. The system that is being proposed is a solution, for public transportation because it is affordable and it works

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

well and it is easy for people to use. The Central Server makes the system reliable. The system improves the lives of passengers by using GPS to locate where the bus is, and tickets and messages are sent to people's phones in real time. This helps reduce the number of things that need to be done manually and ensures that the transport system flows smoothly.

The GSM module is what enables the bus and the main computer to communicate. The bus sends its location and ticket details to the computer at regular intervals, and the main computer stores this data and reviews it. The system relies on the GPS data it receives to determine the location of the bus and the distance it has traveled. The system relies on GPS to determine the location of the bus and the GPS data to determine how far the bus has traveled. Critical updates, such as ticket validation, arrival of the bus, or delay, are sent to the passengers through SMS messages. The use of SMS ensures that the system remains accessible to users without smartphones or mobile internet connectivity

IV. Hardware Requirements

The following are the hardware components used in GPS based ticketing system with real time SMS updates

NODEMCU: There are publicly available, open-source designs for prototyping boards compatible with the NodeMCU firmware. The name " NodeMCU " is a combination of the words node and microcontroller unit (MCU). Technically, the term specifically refers to the firmware and not the associated development boards. Both the firmware and prototyping board designs are open for public use. The firmware is programmed using the Lua scripting language and was built upon the Esp if Non-OS SDK for the ESP8266, drawing from the e-Lua project. It integrates several open-source components like SPIFFS and lua- cjson. Due to hardware limitations, users typically select only the essential modules for their application and customize the firmware accordingly. The system has also expanded to support the 32-bit ESP32 platform

LCD, or Liquid Crystal Display, is a widely used flat-panel display technology that has become an essential part of modern electronic devices. It operates by manipulating liquid crystals that align in response to an electric current, which then modulates light to produce visible images. LCD technology is commonly found in computer monitors, televisions, smartphones, tablets, calculators, digital watches, and a variety of other electronic gadgets due to its lightweight design and versatile display capabilities . An LCD module is an electronic display unit primarily used for presenting text, numeric values, and simple graphics. One of the most commonly used types in embedded and microcontroller- based projects is the LCD 2×16 display, which can present information across two lines, with each line capable of displaying up to 16 characters. Due to their minimal power consumption, LCDs are especially well-suited for portable and battery-powered devices, helping to extend battery life and reduce energy costs in continuous operation environments.

An RFID reader is a device connected to a network that can be either mobile or fixed, depending on the specific needs of the system. When stationary, RFID readers are typically placed in key locations such as doors, warehouses, or conveyor belts, where they can continuously scan and monitor items as they pass by. In contrast, mobile RFID readers are portable, allowing operators to move around and scan items at different locations. This flexibility makes RFID readers essential tools in industries like logistics, retail, and access control, providing efficient and versatile solutions for tracking management.RFIDreaders send out radio signals - tags on items pick them up. When a tag catches the waveit fi res back itsRFID code. This chat happens through invisible e nergy fields. Info flows from object to reader without touching This system enables fast and accurate identification and tracking of objects, making RFID technology widely applicable for applications such as asset management, supply chain monitoring, and secure access control.

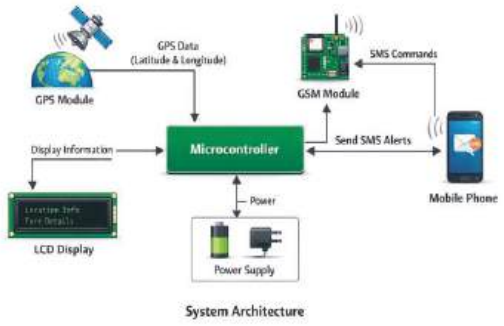
International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026



The open-source Arduino IDE makes coding and sending programs to Arduino boards way easier. It serves as the main hub for creating projects, letting people type, check, then push their code straight onto devices. Instead of being stuck on one system, this tool runs on Linux, macOS, and Windows - so folks can use what they already have. Because it works everywhere, more makers stick with it, whether tinkering at home or building serious gear. Arduino IDE works mainly with C or also C++ - both common choices when building stuff for small computers inside devices. These options handle hardware tasks pretty well, so they fit perfectly when coding tiny chips. “IDE” actually means you get everything needed - like editing plus sending programs - all packed together neatly in a single app. The Arduino IDE plays a pivotal role in simplifying the development and deployment of the proposed system’s firmware, particularly for prototyping and testing the integration of hardware components like the Atmega16 microcontroller, IR sensors, and RFID readers. Its user-friendly interface allows developers to write, debug, and upload code efficiently, reducing the learning curve for implementing complex functionalities such as real-time passenger counting and fare deduction. The IDE’s built-in libraries, such as those for serial communication and I/O pin management, streamline the coding process by providing pre- tested functions for interfacing with the NodeMCU module and LCD display. This accelerates the development cycle, enabling rapid iterations during the system’s experimental validation phase.

The use of Embedded C in the software industry is widespread, especially when it comes to creating software for electronic devices. Fine-tuned for tiny computers inside gadgets, Embedded C gives direct control over hardware - making things run smoothly. From basic stuff like ovens to high-end gear like factory bots, today’s electronics depend on built-in code, usually crafted in Embedded C. The role of Embedded C lies in letting processors handle particular jobs within embedded setups. Instead of general-purpose devices, these systems focus on single functions while dealing with tight deadlines and low computing strength. With this language, coders manage hardware, memory, usage timing more precisely - so everything works smoothly without wasting resources

The software development for the proposed GSM and GPS-based system is carried out using the Code-Blocks integrated development environment (IDE). Code-Blocks is an open-source, cross-platform IDE that supports C and C++ programming and is widely adopted for embedded system application development. Its modular architecture and compiler support make it suitable for writing, compiling, and debugging firmware for microcontroller-based systems interfaced with GSM and GPS modules. Within the development environment, application logic is implemented to handle serial communication protocols, enabling reliable data exchange between the microcontroller and external GSM and GPS hardware.

The software processes real-time location data received from the GPS module and formats relevant information for transmission through the GSM module. Efficient memory management and structured programming techniques are employed to ensure stable system performance under continuous operation.

The use of Code Blocks simplifies program development by providing features such as syntax highlighting, error detection, and step-by-step debugging, which improve code reliability and reduce development time. As an open-source platform, it offers flexibility for customization and easy integration with embedded toolchains, making it a practical choice for developing real-time location tracking and communication-based applications

.Fig 4:Software setup

An LCD module is incorporated into the system to provide local visual feedback. It displays essential information such as system status, GPS signal availability, and operational messages, allowing users or operators to monitor system functionality directly. The GSM module is connected to the microcontroller through serial communication interfaces and is responsible for transmitting processed information to the user via SMS. Once valid GPS data is obtained, the microcontroller formats the data and sends command instructions to the GSM module, enabling real-time message delivery without the need for internet connectivity.

The software architecture, implemented using Code::Blocks, manages module coordination, data parsing, and communication controlThe GPS and GSM modules work together well because of good programming logic. This means that the system is utilizing power and running very smoothly. The system is also flexible. Can be expanded in size if required. This makes it ideal for applications such as tracking something in time, making tickets, and smart transport systems that have to communicate with each other. The GPS and GSM modules are essential in such applications.

The microcontroller is the central part of the architecture, which serves as the control unit. It is connected to the GPS module to obtain the location information in the form of latitude and longitude values. These values are constantly observed and processed by the software to obtain the system parameters such as position update and travel status. The whole system is powered by a power supply unit that regulates the power to the hardware components

VI. Result and Analysis

The GPS-based bus ticketing system using RFID, NodeMCU, LCD display, and real-time SMS updates is a modern, technology-driven solution designed to automate and improve the efficiency, accuracy, and transparency of public transportation. Traditional ticketing methods often involve manual fare collection, which is slow, prone to human error, and vulnerable to ticket fraud or disputes between passengers and conductors. To overcome these issues, this system integrates Internet of Things (IoT) components—specifically an RFID module for passenger identification, a GPS module for live location tracking, an LCD screen for visual information, and a GSM/SMS interface for real-time messaging—all controlled by the NodeMCU microcontroller

Fig 5: IP address for GPS

Fig 6: Boarded LCD display

Fig 7:Address being fetched from boarded location

Fig 8:Available balance in the smart card

The project aims to streamline the bus ticketing process by automatically recording a passenger's entry and exit points using GPS coordinates, calculating the distance traveled, computing the fare accordingly, and instantly sending SMS notifications to both passengers and administrators. The system begins operating the moment a passenger boards the bus and taps their RFID card on the RFID reader (commonly the RC522 module).

SMS notification sent to the passengers regarding boarding, deboarding, fare deduction and amount of balance .

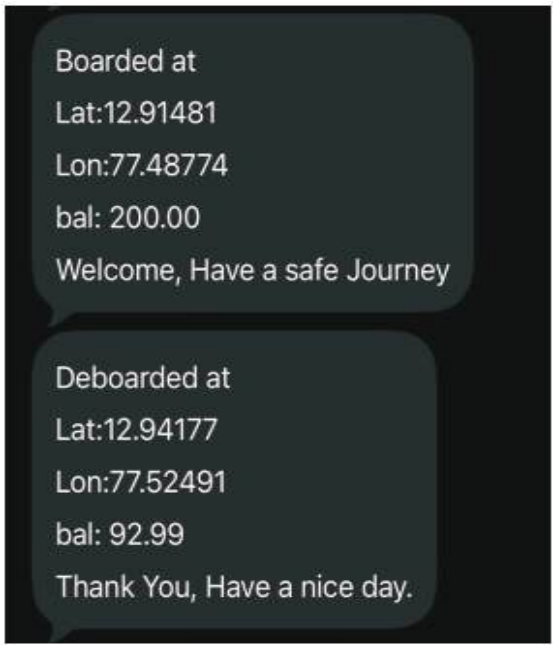

Fig 9: SMS notification sent to passenger example (1)

Each RFID card contains a unique identifier linked to the passenger's profile or account. When the RFID tag is detected, the NodeMCU reads the unique ID and simultaneously retrieves the live GPS location from the GPS module, usually a NEO-6M or similar unit capable of providing accurate latitude and longitude data. This boarding information—RFID ID, GPS location, date, and time—is temporarily stored in the NodeMCU's memory or optionally uploaded to a cloud database for remote monitoring.

The GSM module demonstrated reliable communication performance by transmitting SMS notifications containing ticket details, fare information, and journey status to the registered mobile number. Message delivery was observed to be timely, with negligible delay under normal network conditions. This validates the effectiveness of SMS-based communication for real-time passenger updates, particularly in areas with limited internet connectivity

The LCD module accurately displayed system status information, including GPS signal availability, ticket confirmation, and operational messages. This local display facilitated easy monitoring of system functionality and aided in debugging during testing. The embedded software developed using Code::Blocks maintained stable performance, with efficient handling of serial communication between GPS and GSM modules.

Power consumption analysis indicated that the system operates efficiently under standard voltage conditions, making it suitable for long-duration usage in embedded and

portable applications. Overall, the results demonstrate that the proposed system achieves reliable ticket generation, accurate fare calculation, and effective real-time communication, validating its applicability for intelligent transportation and smart ticketing solutions.

Overall, the experimental results validate that the proposed system delivers accurate location tracking, timely SMS updates, and stable performance. These findings confirm the effectiveness of the GPS-based ticketing system as a reliable and scalable solution for intelligent transportation and smart ticketing applications.

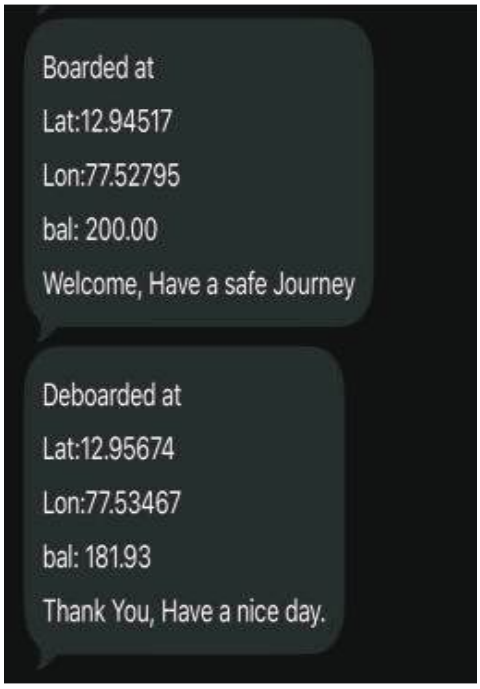

Fig 10:SMS notification sent to passenger example(2)

VII. CONCLUSION

This paper is about a ticketing system that uses GPS and sends messages to peoples phones. The system uses GPS to figure out how far someone has traveled and it automatically calculates the fare. This way people do not have to do anything. The system also sends updates about tickets and journeys to peoples phones using SMS so they get the information they need even if they are not connected to the internet. The GPS-based ticketing system is really good for transportation because it makes things more efficient and transparent. The GPS technology makes sure that the distance traveled is accurate and the fare is correct. The system is also very helpful for passengers because they get all the information they need about their tickets and journeys, on their phones.

The new system makes things easier to run it reduces mistakes in ticket prices. It makes things better for passengers because it does things automatically and people can get the information they need. The system is designed to work all the time and it does not use a lot of power which is good for using it in big transportation systems, like buses and trains.

In future implementations, the system can be enhanced by integrating mobile applications and cloud-based platforms to provide advanced features such as digital payment options, travel history analysis, and real-time vehicle tracking. The inclusion of IoT connectivity and data analytics can further improve route optimization, passenger demand prediction, and operational planning. Additionally, incorporating secure authentication mechanisms and scalable architectures would enable the system to support large transit networks, contributing to the development of fully automated and intelligent public transportation systems.

Abstract-Diagnosing Brain Tumors Earlier - The sooner someone with cancer receives proper treatment, the more likely they are to live longer than if they waited until later to start receiving treatment. For many years, MRI has been the method of choice for detecting brain tumours with images previously scanned many times over by hundreds of thousands of doctors, clinics, and medical administrators who continue to use these same images to identify brain tumours. This creates a tremendous workload of hours (for each scan) to compare abnormal MRI scans to normal MRI scans within all the scanners currently in use, leading to the possibility of estimating the number of times these physicians have incorrectly identified scanned images due to fatigue from the repetitive motion of having to review the hundreds of thousands of scanned images for abnormal and normal results. In addition, this process has resulted in a substantial number of misidentification and clinical error associated with using MRI imaging data as it has been reviewed/evaluated manually by physicians; therefore, the development of computer algorithms and the application of "machine intelligence" as a means of assisting physicians with reading MRI's is becoming increasingly prevalent in both clinical and research environments as opposed to being completely reliant on a physician's interpretation of an image or grouping of images, now includes an algorithm assessment of thousands of previous images (abnormal & normal) scanned in order to provide statistically valid and statistically significant "probability" results for current scanning occurrences**.**

***Key Words*:MRI Scans, Tumors, Radiologists, Precision, Recall**

1.INTRODUCTION

Brain tumors and spinal tumors are among the most difficult health issues to deal with. Some cells continue to grow too rapidly and form either large tumors or small tumors or benign tumors. The location of where the tumor is located, how big it is and what type of cell it is made up of determines the risk any individual will have.

Circumstances relating to the individual will aid in treating patients and estimating the chances of recovery from a brain tumour, highlighting the need for an early diagnosis in order to execute an early intervention and limit the severity or disease progression. Doctors also diagnose brain tumours based on the use of advanced technology such as CT or MRI scans and using biopsy samples of the tumours to accurately identify the brain tumour type. CT and MRI scans will produce a high-quality image of the brain; however, many doctors prefer MRI scans due to their ability to produce the highest resolution image of the brain, differentiating between healthy and unhealthy cells.

CT scans offer advantages concerning the time it takes for a scan as CT scans produce an image of the brain faster than an MRI scan, whereas a tissue sample will be examined the same way to show what type of brain tumor it is but requires specialized equipment and skilled technician who will take several hours to analyze the sample and conclude.

1.1 Problem Statement

The vast majority of MRI scans are performed in a hospital setting, but most physician's records of the results by the radiologist are rarely accurate because physicians disagree when they look at the data, and small changes in the brain are usually missed almost every time because of the physician's excessive amount of paperwork and too many patients to administer medications and laboratory services for the same day. Therefore, the increasing demand for the services provided by the physician will hinder his performance and reduce the efficiency of the physician's resource use in the office.

1.2 Goal Of the project

The goal of this project is to develop and deploy an automated robotic device that can evaluate MRI brain scans using advanced machine learning techniques to automatically identify brain tumors.

Vol. 14, Issue 06, ACSCON - 2026

This project will have a number of phases, including acquiring MRI scans, testing the validity of automated detection, and developing a computer model to identify tumors from MRI scans.

2. RELATED WORK

There has been a significant transformation in the way that conventional methods of machine learning have been applied to develop brain tumor detection models employing MRI imaging from the inception of the project until 2021. Feature extraction had traditionally been performed manually by three primary means: Texture analysis; Histogram intensity; and Statistical descriptors. Manual methods for extracting features have produced average to low classification results consistently (for example SVM, k-NN, etc.); however, because of the significant variability of tumor characteristics and likely variation of MRI scanner parameters from differing MRI scanners, the average and low classifications obtained from classification pipelines based on manually measured features have frequently been lower than thought achievable.

Researchers have been working on new models of U-Net (U-Net++, Attention U-Nets) since 2022 in order to achieve greater accuracy when creating segmentation maps from medical imaging data. Part of the motivation behind developing this type of model is to be able to match the edges of a tumour more accurately than current methods, which should result in fewer false-positive diagnoses. Many of the researchers currently working in this field will begin investigating methods for providing answers regarding how and why segmentations were made using Explainable AI methods (such as Grad-CAM), as many of the results produced using these three different imaging modalities show similar quantitative results. Using these techniques will allow the researcher to understand which areas of tumour tissue are responsible for the prediction of the tumour being identified or not, thus providing additional insight into the accuracy of the tumour segmentations produced from the image data of these različnih MRI modalities (T1, T2, FLAIR).

In addition to using these explainable AI techniques, many of the researchers are now also examining the feasibility of using Multiple MRI Imaging Modalities (T1, T2, FLAIR) to augment their diagnostic striking support from automated systems and validate that their findings based on objective clinical evaluation methods will provide clinical-grade confidence in the automated systems they develop. Demonstrations and evaluations of real-world applications across various institutions will begin in 2024 and continue through 2025. In practice, deep learning solutions can be implemented using very low-resource computing and lightweight architecture to produce "light weight" solutions for deep learning applications.

3.OVERVIEW OF THE PROPOSED PROJECT

In this article, we will present a new way to analyze how the anatomy of the brain, as imaged by Magnetic Resonance Imaging (MRI) technologies, can be combined with state-of-the-art artificial neural network (ANN) technologies to generate new sets of features to analyze an MRI dataset semantically. We believe that such an analysis could improve the ability to detect small or otherwise obscure abnormalities in MRI scans that are normally missed by traditional imaging techniques.

The system will categorize and sort multiple types of unique images by their subtype (e.g., gliomas, meningiomas, pituitary and other non-brain tumors) and standard brain tissue. It will also reduce the time needed to review all images/tumor subtypes as well as increase the accuracy associated with evaluating individual images by using performance metrics generated during operation of these functions. All images must first go through specific initial processing steps that enable neural networks to operate on the images before evaluation (e.g., remove noise, resize images, balance pixels), so that ultimately, all images produced are uniform in their formatting which will assist neural networks to have been trained using the training methodology outlined above.
The performance of the system will be evaluated based on quantitative metrics generated from collecting observations made in real time (e.g., true positives, precision, recall, f1, etc.) compared to using hypothetical models

4.SYSTEM ARCHITECTURE AND METHODOLOGY

This project is founded on an AI-based method that will automatically analyse MRI images to detect brain tumours. The AI system is going to have a five-step structure where there are five separate steps that depend on each other will be undertaken. These steps will be comprised of: obtaining MRI brain images (from either publicly available MRI databases or clinical facilities), preparing the obtained MRI brain images so that they can be analysed; extracting features from the prepared MRI brain images; categorising (classifying) the MRI images as to whether or not there is a brain tumour); and visualising (showing) the results of the classification/categorisation.

The first step of the classification phase is to obtain the MRI brain images and place them into labelled datasets for supervised learning purposes (e.g. Are there brain tumours in the MRI image?). The images obtained for classification will be obtained from either publicly available databases of MRI images or from clinical facilities.

Vol. 14, Issue 06, ACSCON - 2026

To create a standardised set of diffusion data, Parsons has established a number of different facilities for pre-processing any of the above images prior to being established in an all-diffusion dataset.

By pre-processing (through the use of image standardisation) images will correct the differences in sizes, reduce noise and normalise the distribution of sizes in all of the images; this should result in a higher degree of contrast in all of the diffuse parent images and throughout the classifying process will provide a clearer understanding of the appearance of the diffuse parent images.

Feature extraction is separated into two classes: A) Manually constructed models designed under the assumptions from traditional machine-learning rules (texture features, histogram features and statistical features). B) Produced features through the automatic aggregation of features generated by a deep neural network (CNN) built specifically for use with this application. Our methodology uses a CNN to read those hierarchical types of features via MRI scans of aggressive cancer. By recognizing patterns, and anomalies of the structure of the tumor and also the intensity difference between all the parts of the volume of the tumor. This reduces the need to manually do all of the feature extraction from the MRI before performing analysis and/or classification with those features.

After extraction has occurred the classifier shall be used to classify the image as tumourous or non-tumourous and whether or not the image quality can be classified. The way in which the tumour classifier uses a different extraction algorithm means that different extraction algorithms are going to be utilized to classify whether or not the image contains a tumour and how (or if) accurately the extraction algorithms classify the tumour in the patient image. Classification will utilize the following extraction methods such as an Annex neural net (a feed forward neural network) or Support Vector Machine (SVM). The data set to train or fit the tumour classifier as well as to evaluate the classifier will be the set of data which has been labelled with both positive and negative classification markers. Using backpropagation the best fit classifier will have been determined. The three metrics (accuracy, precision, and recall) will be determined through the use of a confusion matrix to compare the output of the classifier against the original lesion data set.

In summary, the system can distinguish different types of diagnoses as well as make explicit predictions regarding patient prognosis. The system will also provide visual tools (e.g., heatmaps; activation maps) to aid in the interpretation of the results and improve the ability of health care professionals to interpret those results.

The entire processing chain of software is integrated into one standardised way of analysing MRI brain images by means of re-inventing the systematic methods of processing MRI brain imaging data, which includes enhancing the condition of the image, localising the brain tumour, learning what the tumour looks like, and classifying the features of the tumour, so that the user has a single platform for detecting the pathology of brain tumours.

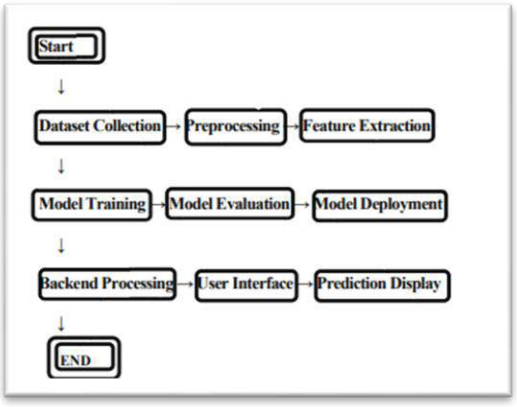

Fig 4.1 Methodology diagram

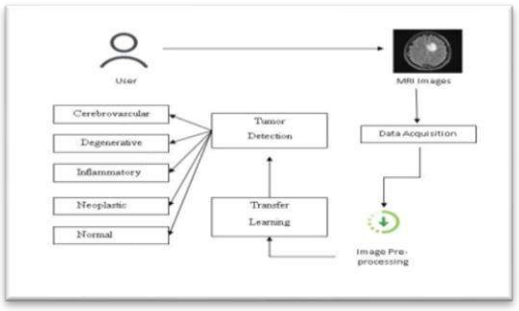

Fig 4.2: System architecture

5.PERFOMANCE MATRIX

The approach for evaluating the performance of a brain tumour detection system will involve creating confusion matrices. These matrices are an often used statistical method that will allow us to evaluate the effectiveness of a system's ability to predict over time based on the output from the brain tumour detection system being developed. Confusion matrices provide a concise summary of predicted results from a classification technique and are broken down into four categories; True positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN).

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

To illustrate this using the image of the miracle of MRI where a brain tumour has been identified as having been detected by the proposed model, the true positives will be the images of brain tumours (that is, an MRI image containing a brain tumour) that had been successfully identified by the proposed model. Conversely, the true negatives will be the number of normally functioning MRI pictures (i.e., images containing no brain tumour) that had been successfully identified as 'normal' by the proposed model.

An accurate assessment of the System's overall performance is required to accurately evaluate performance, and in order to find this information, we must estimate the total number (or total count) of properly detected MRI images (properly classified) versus all detected/classified MRI images.

The accuracy metric may provide a good estimate of how well the proposed Brain Tumour System performs; however, it should not be used as an overall measure of performance due to the diversity of the types of cases and unequal distributions of those types of cases within the database. Therefore, there will be additional performance metrics used to provide as complete of an evaluation as possible, regarding both the exercise and test phases of the trial, for the proposed Brain Tumour System.

6.EXPERIMENTAL SETUP AND RESULT ANALYSIS

As part of creating a brain tumor detection system we created a number of controlled experiments that were designed to measure how well an algorithm could detect and identify different types of tumors based on many computer files (images) taken of the brains of patients pre-surgery, and then to measure the accuracy of the algorithm in identifying the tumors versus the non-tumors taken from the same patients pre-surgery. We generated a data set of MRI images of both tumors and non-tumors by using patient MRI's of their brains on MRI's of patients with the same diagnosis (for example; a person diagnosed with a tumor). Each of the images in the data set (half-tumor, half-non-tumor) had an assigned label indicating if a tumor was present or not (for example; a tumor was present in the MRI). We created both training (using the first half of each data set) and testing (using second half) sets for the algorithm from the image data sets according to the same set of standards in order to ensure a fair evaluation of how well the algorithm works with data sets. We defined a ratio of the number of images in the training set to the number of images in the testing set and used this standard definition for both image data sets.

We also created a standardized training set to help the model learn the characteristics that tumors have to have in order to be identified by the model.MRI images were standardized based on size so they all contain the same type of data as well as each other; this also reduced noise from the images.

Various techniques (rotation, flipping, scaling) were used to create more diverse data in order to reduce the likelihood that the model will overfit due to too little variation in training samples. The Model has been constructed using either machine learning or deep learning methodologies and trained through several epochs while optimally adjusting the hyper-parameters (learning rate and batch size). Once the model has been trained, the model will have its parameters fine-tuned so that the package identified as tumour or non-tumour contains as few errors as possible through the use of back-propagation.

The model learned to distinguish between brain tissue with and without tumours and how to use the features developed to do so. The model was evaluated against four metrics (Accuracy, Precision, Recall, & F-Score). In addition to the metrics, the results were then evaluated with a confusion matrix illustrating the number of true positives (actual tumours successfully identified), true negatives (patients who do not have a tumour correctly classified), false positives (instances where tumour patients were incorrectly classified), and false negatives (instances where non-tumour patients were incorrectly classified).

The results are all in high confidence (>90% prediction accuracy) for the classifier system. In addition, theThere were a small number of false positives, which resulted in a low precision score and produced an overall F1 score that demonstrates similar or balanced performance across several categories when comparing the general outcome(s) of the model as a whole. These results therefore demonstrate that the automated system can provide clinically valid and reliable data to assess the clinical validity of the images of brain tumours by evaluating how they were classified.

7.CONCLUSION

This research article describes a highly functional and responsive framework designed to facilitate the automated detection of brain cancer tumours via magnetic resonance imaging (MRI) scans using machine learning algorithms. The framework will help produce consistent results given the variance seen in the different types of medical imaging by creating a pre-processed image of MRI scans that has been standardised prior to being processed; creating an adaptive training system based on the characteristics of the extracted feature set; and providing assistance with the classification of the resulting data based on how successfully the images were analysed and classified.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The validation testing results display evidence of consistent, continuous system performance over different independent tests, which lends strong support to the generalizability of this model across other sample test sets. Furthermore, the validation testing produced high sensitivity results that support the use of this trained model for successful identification of cases where tumours are involved in diagnosis.

Clinical screenings for tumors could utilize a trained framework to provide additional assistance, as the development of new mechanisms that create minimal rates of false positive finding throughout all testing phases. The overall performance of a trained framework is consistently high for all evaluated metrics, regardless of the distribution used in training for any specific evaluation.

Adding additional research sites and gathering multi-site MRI datasets to expand the amount of available data for future research will provide new directions in this area. New methods of regularly collecting multi-site MRI datasets will enable looking at new ways of improving data quality.

The release of scalable, clear and accessible AI-based tools, in conjunction with the completion of AI-based tools to provide the support (decision) visualisation of these tools, will create further value through the integration of Explainable AI approaches with those tools.

This new technology will make it easier for this framework to be used in real-world healthcare situations than in only research-based settings from now on. This paper describes an evidence base to support the area of the technical efficacy of this framework, the diagnostic reliability of this framework and the adaptability of this framework for diagnosing brain tumors. Therefore, this framework will provide a decision-making tool used as cognitive support for making high-confidence decisions in the interpretation of CT scan images (as obtained by radiologists).

Abstract

Medication non-adherence is a major problem among elderly patients, Alzheimer's patients, and people living in rural and hilly regions. Forgetting to take medicines on time can lead to serious health complications. This paper presents the design and development of a Smart Pill Box with Voice Alert System that reminds patients to take medicines at scheduled times using audio alerts and visual indications. The system is built using a microcontroller, real-time clock (RTC), speaker module, and IoT connectivity for remote monitoring. The device is designed to be low-cost, portable, and user friendly. It can be particularly useful for rural healthcare applications where continuous supervision is not possible. The proposed system improves medication adherence, reduces human dependency, and enhances patient safety.

KEYWORDS

Smart healthcare, Medication adherence, IoT, Voice alert, Elderly care, Rural healthcare.

INTRODUCTION

Medication adherence is a critical factor in effective healthcare management. Patients are often required to follow strict medication schedules to ensure proper treatment outcomes. However, maintaining consistent adherence to prescribed medication regimens remains a major challenge worldwide. Studies indicate that a significant percentage of patients fail to take their medications on time, skip doses, or take incorrect dosages. This problem is particularly common among elderly individuals who may suffer from memory loss, cognitive decline, or complex medication schedules involving multiple drugs.

In addition to age-related challenges, lifestyle factors such as busy daily routines, lack of awareness, and insufficient caregiver support also contribute to poor medication adherence. The issue becomes even more severe in rural areas where access to healthcare professionals and regular medical supervision is limited. Patients in such regions often rely on manual pill organizers or written reminders, which are not always reliable. As a result, missed doses, accidental overdoses, and irregular medication intake can occur, potentially leading to serious health complications, prolonged illness, or hospitalization.

Technological advancements in embedded systems and Internet of Things (IoT)

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

technologies provide new opportunities to address these challenges. Smart healthcare devices can assist patients in managing their medication schedules more effectively while also allowing caregivers and healthcare providers to monitor adherence remotely. In this context, the development of intelligent medication reminder systems has gained increasing attention.

To address the problem of medication non-adherence, this paper proposes a Smart Pill Box with Voice Alert. Unlike traditional pill organizers, the proposed system integrates electronic components, voice alerts, and IoT connectivity to provide automated and interactive reminders. The system is designed to notify patients through voice messages and alarms at scheduled medication times, ensuring that medicines are taken at the correct time and in the correct dosage. The use of voice alerts makes the device particularly suitable for elderly users who may have difficulty reading small text or remembering alarm meanings.

Furthermore, the integration of IoT technology enables remote monitoring of medication intake. Caregivers or family members can track whether the patient has taken the prescribed medicine on time, thereby improving patient safety and reducing the risk of medication errors. The system is designed to be cost-effective and user-friendly, making it suitable for deployment in rural and resource-limited environments.

The main objectives of this project are as follows:

1.To design and develop a low-cost smart medication reminder system that can assist patients in maintaining their medication schedules.
2.To provide voice-based alerts and alarm notifications that are easy for elderly users to understand and follow.
3.To enable remote monitoring using IoT technology, allowing caregivers or healthcare providers to track medication adherence.
4.To improve healthcare support in rural areas by providing an affordable and accessible smart healthcare solution.

The proposed Smart Pill Box aims to enhance medication adherence, reduce health risks associated with missed or incorrect doses, and provide better support for elderly patients and individuals living in remote areas

METHODOLOGY

The proposed system integrates a Smart Medicine Box with an AI-based voice chatbot to ensure timely medication intake and provide interactive assistance to users. The overall methodology follows three major stages: input sensing, centralized processing, and output response, which together enable automated medication reminders, pill dispensing, monitoring, and caregiver notification.

The Smart Medicine Box begins with the input sensing stage, which includes IR sensors, a Real-Time Clock (RTC) module, and servo motors. The IR sensors are positioned near each pill compartment to detect whether a pill has been removed by the user. When the pill is taken, a change in infrared reflection is detected and transmitted to the Arduino microcontroller. The RTC module maintains accurate timekeeping and continuously provides scheduling information for medication reminders throughout the day. Based on the scheduled time provided by the RTC, the servo motors automatically open the corresponding pill compartment, allowing the user to access the required medication easily.

The processing stage is managed by the Arduino UNO, which acts as the central controller of the Smart Medicine Box. It continuously reads time data from the RTC module and monitors the status of the IR sensors to verify whether the medication has been taken. When the scheduled time matches the predefined medication schedule, the Arduino activates the appropriate servo motor and triggers reminder notifications.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

In addition, it coordinates communication with other output modules such as the LCD display, DF Player Mini, speaker module, and GSM module, ensuring synchronized operation of the entire system.

In the output stage, the system provides both visual and audio reminders to assist the user. A 16×2 LCD display shows important information such as the current time and reminder messages like "Take Morning Medicine." Simultaneously, the DF Player Mini and speaker module generate voice alerts that clearly instruct the user to take the medication. If the system detects that the pill has not been taken within the specified time window, the GSM module sends an SMS notification to a caregiver or family member, indicating that the scheduled medication has been missed. This feature enables remote monitoring and enhances patient safety.

The system also includes an AI-based voice chatbot module that allows users to interact with the device through voice commands. The interaction begins when the user presses a tactile button to start recording. The INMP441 I2S MEMS microphone captures the user's speech and sends the digital audio signal to the ESP32-S3 microcontroller through the I2S communication protocol. The ESP32-S3 then connects to a Wi-Fi network and transmits the recorded audio to an external AI server for processing.

The AI server performs tasks such as speech recognition, natural language processing, and response generation. After processing, the server returns a synthesized audio response to the ESP32-S3. The microcontroller then displays system status messages such as "Recording," "Processing," or "Speaking" on the LCD display. The audio response is transmitted through the I2S interface to the MAX98357A audio amplifier, which amplifies the signal and outputs it through the speaker, allowing the user to hear the AI-generated response clearly.

Overall, the proposed methodology combines sensor-based monitoring, embedded system control, wireless communication, and cloud-based artificial intelligence to create a reliable and user-friendly healthcare support system. This integrated approach improves medication adherence, reduces the risk of missed doses, and provides interactive assistance for users who require continuous medication management.

RESULT AND DISCUSSION

The implementation of the PillPal mini-project resulted in the successful design and simulated operation of an integrated smart medication management system. The system demonstrates the feasibility of combining embedded hardware with an AI-based voice interface to improve medication adherence and user interaction. The obtained results validate the functionality of the three primary components of the PillPal.

ecosystem: the Smart Pill Box hardware module, the AI voice bot system, and the mobile application interface. The coordinated functioning of these components shows the potential of the proposed system to provide automated reminders, adherence monitoring, and intelligent voice-based assistance for users.

A. A.Smart Pill Box Functionality

The Smart Pill Box hardware module was designed as an automated multi-compartment medication dispenser. One of the key results achieved was the successful implementation of automated dispensing using a Real-Time Clock (RTC) module, which triggers the opening of the correct pill compartment at scheduled medication times. When the dispensing event occurs, the system simultaneously activates a visual alert using an LED and an audible alert through a buzzer, ensuring that the user receives clear reminders to take the medication. This dual-alert mechanism improves the effectiveness of the reminder system and makes it suitable for elderly users or individuals with sensory limitations.Another important outcome was the implementation of non-adherence detection. A sensor mechanism, such as an optical or weight-based sensor placed near the dispensing area, monitors whether the pill has been removed from the compartment. When the user takes the medication, the sensor records a “pill retrieved” event, which is logged in the system. However, if the scheduled time passes and the sensor does not detect pill retrieval within a predefined time window, the system records a “missed dose” event. This capability enables the system to track medication adherence accurately.

The system also demonstrated inventory monitoring functionality. By simulating sensor-based tracking of remaining medication levels, the system calculates the number of doses left in the pill compartment. When the available quantity falls below a predefined threshold, such as five days of medication supply, the system generates a low-stock alert. This feature helps prevent unexpected medication shortages and ensures continuity in the patient’s treatment schedule.

A. AI Voice Bot System

The project also integrated an AI-based voice bot

module, which allows users to interact with the system using voice commands. The voice bot is designed to assist users by providing medication-related information, answering queries, and offering guidance through an interactive audio interface. When the user speaks into the microphone, the system captures the voice input and processes it through the AI module for speech recognition and response generation.

The AI system converts the spoken query into text, processes it using natural language understanding techniques, and generates an appropriate response. The response is then converted into speech using a Text-to-Speech (TTS) engine and delivered through a speaker, enabling the user to hear the answer clearly. This voice interaction capability makes the system highly accessible, particularly for elderly users or individuals who may find traditional mobile interfaces difficult to use. The AI voice bot therefore enhances user engagement and
provides an additional layer of assistance within the medication management system.

B. Mobile Application Interface

The PillPal mobile application interface, simulated through a web-based dashboard, demonstrated effective functionality for managing medication schedules and monitoring adherence. The application provides a centralized platform where users and caregivers can view medication schedules, track adherence rates, and review historical medication events.
The dashboard displays important information such as the user's weekly medication compliance rate and a chronological log of events, including dispensing times, pill retrieval confirmations, and missed doses. This organized presentation of data allows users and caregivers to monitor medication patterns and identify potential adherence issues. Overall, the integration of the mobile interface with the Smart Pill Box and AI voice bot creates a comprehensive medication management system that improves accessibility, user engagement, and healthcare support

CONCLUSION

The development of the Smart Pill Box integrated with intelligent monitoring and automated reminders represents an effective step toward improving medication management in modern healthcare systems. The proposed system addresses common challenges faced by elderly individuals, chronically ill patients, and users with memory or cognitive limitations, such as forgetting medication schedules, taking incorrect doses, or missing refill times. By incorporating embedded hardware components, sensor-based monitoring, IoT communication, and AI-enabled features, the system provides a reliable and user-friendly solution that supports consistent medication adherence while reducing the burden on caregivers and healthcare providers.

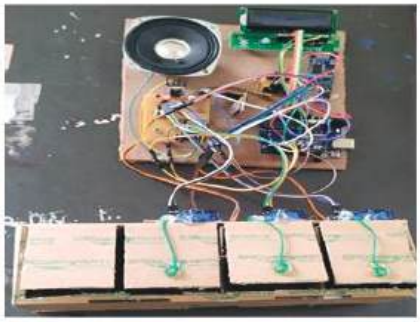

Figure3: Final Circuit

The Smart Pill Box functions not only as a simple reminder device but also as an intelligent monitoring system capable of detecting medication intake and generating alerts when scheduled doses are missed. Through the integration of communication modules, the system can automatically send notifications to caregivers or family members, ensuring that timely intervention can occur when necessary. This remote monitoring capability enhances patient safety and offers reassurance to caregivers who may not always be physically present. Additionally, the inclusion of refill alerts improves the practicality of the system by preventing unexpected medication shortages and ensuring continuity in treatment.

From a technological perspective, the project demonstrates the successful implementation of embedded systems, real-time sensing, wireless Figure4: App interface
communication, and cloud-assisted processing within a compact healthcare device. The modular architecture of the system allows for easy scalability and future enhancements, while

how smart technology can be effectively integrated into everyday healthcare routines to improve medication adherence and patient safety. By combining automation, real-time monitoring, and caregiver communication, the system provides a practical and scalable approach to medication management. This project demonstrates the potential of engineering innovations in addressing real-world healthcare challenges and contributes toward the broader goal of enhancing patient care through intelligent and accessible digital health solutions.

ABSTRACT – Sleep disorders have become increasingly common due to changes in lifestyle, work patterns, and prolonged screen exposure, affecting both physical health and cognitive performance. Early identification of such disorders is essential, as untreated conditions may lead to long-term complications including cardiovascular issues, obesity, and reduced productivity. This study presents a data-driven approach for the prediction of sleep disorders using structured lifestyle and physiological attributes that can be collected without specialized clinical equipment. The proposed framework involves systematic data preprocessing, feature scaling, and the application of supervised learning models for multi-class classification. In particular, a comparative analysis between a statistical classifier and an ensemble learning technique is carried out to understand their behaviour on tabular healthcare data. Instead of relying only on overall accuracy, the evaluation focuses on class-level performance, feature influence, and model stability to reflect real-world applicability. The experimental results indicate that ensemble learning provides better generalization and more reliable separation between normal sleep patterns, insomnia, and sleep related cases. The study also highlights the practical feasibility of integrating the trained model into a lightweight web-based interface for preliminary screening. By using non-invasive and easily obtainable parameters, the proposed system offers a cost-effective support tool for early risk identification and preventive healthcare. The findings demonstrate that machine learning can assist medical decision-making by enabling scalable and accessible sleep health assessment.

KEYWORDS: Sleep disorder prediction, ensemble learning, Gradient Boosting, Quadratic Discriminant Analysis, healthcare analytics, lifestyle data.

I. INTRODUCTION

Sleep is a fundamental biological process that plays a vital role in maintaining physical health, emotional stability, and cognitive efficiency. In recent years, rapid changes in lifestyle, increased work pressure, irregular sleep schedules, and excessive use of digital devices have contributed to a noticeable rise in sleep-related disorders across different age groups. Conditions such as insomnia and Sleep Apnea not only reduce the quality of life but are also closely associated with serious health complications including hypertension, diabetes, obesity, and cardiovascular diseases.

Despite their impact, these disorders often remain undiagnosed for long periods because conventional diagnostic procedures require specialized clinical infrastructure, expert supervision, and overnight monitoring, making them expensive and inaccessible for routine screening. With the growing availability of digital health records and lifestyle datasets, machine learning has emerged as a promising tool for developing intelligent and scalable healthcare solutions. Instead of relying solely on complex physiological signal acquisition, structured data such as sleep duration, stress level, body mass index, heart rate, and daily physical activity can be analysed to identify patterns that indicate potential sleep abnormalities. These attributes are comparatively easier to collect and enable the

development of cost-effective prediction systems that can assist in early-stage health assessment.

of their sleep condition without the need for complex clinical tests. This approach is intended to support preventive healthcare by enabling early detection and encouraging timely medical consultation for high-risk cases. Furthermore, the proposed framework is designed to be computationally efficient and scalable so that it can be integrated into real-time health monitoring applications in the future. Through these objectives, the study seeks to provide a cost-effective and accessible alternative to traditional diagnostic methods while maintaining reliable prediction performance.

Another important objective of the proposed work is to examine the overall behaviour of the developed models in terms of stability, generalization capability, and computational efficiency when applied to healthcare data. In real-world applications, a prediction system must not only provide high accuracy but also maintain consistent performance for different input conditions. Therefore, the study aims to analyse class-wise prediction behaviour using appropriate validation techniques in order to ensure that the model does not favour a particular class while misclassifying others.

Vol. 14, Issue 06, ACSCON - 2026

This is particularly significant in sleep disorder prediction, where the symptoms of different conditions often overlap and require careful differentiation. By focusing on balanced performance evaluation, the work attempts to improve the reliability of the system for practical deployment. In addition, the research intends to explore the feasibility of integrating the trained prediction model into a lightweight web-based environment so that the developed framework can be accessed without the need for high-end hardware or specialized software installation. Through this approach, the proposed work contributes toward building an intelligent, accessible, and preventive healthcare support system.

The primary objective of this research is to design a machine learning–based framework capable of classifying individuals into three categories: normal sleep, insomnia, and sleep apnea. To achieve this, both a statistical learning approach and an ensemble learning technique are implemented and evaluated under the same experimental conditions. The study not only compares their predictive performance but also examines their behaviour in terms of class-wise accuracy, feature contribution, and computational efficiency. Such an analysis is important in healthcare applications where model reliability and interpretability are as significant as overall accuracy**.**

The rest of the paper is structured to provide a clear understanding of the proposed work. A brief overview of the existing research in sleep disorder prediction and the role of machine learning in healthcare is presented in Section II. The characteristics of the dataset along with the preprocessing steps are discussed in Section III. Section IV explains the methodology adopted for model development, while Section V outlines the evaluation criteria used to measure performance. The experimental observations and their analysis are given in Section VI, followed by a detailed discussion in Section VII. Finally, the paper concludes by summarizing the key findings and highlighting possible directions for future research.

II. REL TED WORKS

A detailed review of existing literature was carried out to understand the current progress in sleep disorder prediction using machine learning and data-driven healthcare systems. The following studies provide the research background and motivation for the proposed work:

i.“Sleep Disorder Detection Using Machine Learning Techniques” — S. Patel and R. Shah (2023): This study investigates the use of supervised learning algorithms for identifying sleep disorders from structured health data. The authors implemented Decision Tree, Support Vector Machine, and Random Forest models to classify sleep patterns based on attributes such as sleep duration, stress level, and body mass index. Their experimental results showed that ensemble methods achieved higher accuracy compared to individual classifiers due to their ability to handle non-linear relationships.

ii.“Deep Learning Approaches for Automated Sleep Stage Classification” — M. Almutairi and K. Lee (2022): This paper focuses on the application of deep learning models for analysing physiological signals such as EEG and ECG to classify sleep stages. Convolutional Neural Networks were used to extract temporal and spatial features automatically from raw signal data. The authors reported high classification accuracy; however, the approach required complex data acquisition and high computational resources..

iii.“Lifestyle-Based Health Risk Prediction Using Machine Learning” — R. Verma and P. Nair (2021): This research proposes a predictive framework that uses lifestyle and behavioural attributes to assess health risks without relying on invasive clinical procedures. The authors demonstrated that parameters such as physical activity, heart rate, stress level, and sleep duration can be effectively used for classification tasks. Their work showed that structured datasets are suitable for real-time healthcare applications and can be integrated with web-based systems for instant prediction. The study directly influenced the dataset selection and preprocessing strategy used in the present work.

iv.“Comparative Analysis of Statistical and Ensemble Learning Methods in Healthcare Data” — J. Kim and L. Park (2020): The authors conducted a comparative evaluation of statistical models and ensemble learning techniques on medical datasets. Discriminant analysis provided faster training and better interpretability, while boosting-based models achieved higher prediction accuracy. The study concluded that ensemble learning reduces both bias and variance, making it suitable for multi-class classification problems. This comparison forms the basis for selecting Quadratic Discriminant Analysis and Gradient Boosting for the proposed system.

v.“Web-Based Machine Learning Systems for Real-Time Health Monitoring” — D. Fernandes and T. Joseph (2023): This paper explores the deployment of machine learning models using lightweight web frameworks for real-time health assessment. The authors integrated trained models into a browser-based interface that allowed users to input health parameters and obtain immediate prediction results. Their findings demonstrate that such systems can support preventive healthcare by enabling early risk identification without frequent hospital visits. This work influenced the implementation of the web-based prediction module in the present study.

III. ROBLEM STATEMENT

Sleep disorders such as insomnia and sleep apnea have become increasingly prevalent due to modern lifestyle patterns, work-related stress, irregular sleep schedules, and reduced physical activity. These conditions often remain undiagnosed for long periods because their identification typically requires clinical procedures such as polysomnography, which are expensive, time-consuming, and not easily accessible to a large population. As a result, many individuals fail to receive timely medical attention, leading to severe long-term health complications including cardiovascular diseases, obesity, and decreased cognitive performance.

Existing diagnostic systems primarily depend on physiological signal acquisition using specialized medical equipment. While these methods provide high accuracy, they are not suitable for continuous monitoring or early-stage screening in everyday environments. In addition, most traditional approaches are designed for hospital settings and cannot be easily extended to real-time, user-friendly applications. This creates a significant gap between the availability of healthcare technology and its practical accessibility for common users.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

With the growing availability of structured lifestyle and health-related data, there is an opportunity to develop intelligent systems that can identify sleep disorders at an early stage without relying on complex clinical infrastructure. However, several challenges still exist. Many of the current machine learning–based solutions focus on a single classification technique and do not analyse the comparative performance of different models on the same dataset. Some approaches achieve high accuracy but lack interpretability, while others are computationally efficient but fail to capture complex non-linear relationships in the data. Furthermore, limited work has been carried out on integrating such prediction models into real-time environments where users can obtain instant result.

IV. BJECTIVES

The primary objective of this research is to develop an efficient and scalable machine learning–based framework for the early prediction of sleep disorders using structured lifestyle and physiological data. The study aims to analyse the influence of various health-related attributes such as sleep duration, stress level, body mass index, physical activity, and heart rate in identifying abnormal sleep patterns. In order to achieve reliable classification, the work focuses on implementing both a statistical learning approach and an ensemble learning technique and evaluating their performance under the same experimental conditions. A comparative analysis is carried out to determine the most suitable model for multi-class classification of normal sleep, insomnia, and sleep apnea. Another important objective is to understand the contribution of individual features in the prediction process so that the most significant parameters affecting sleep health can be identified.

In addition to model development, the research also aims to design a practical and user-friendly system that allows individuals to input their lifestyle parameters and obtain an instant assessment of their sleep condition without the need for complex clinical tests. This approach is intended to support preventive healthcare by enabling early detection and encouraging timely medical consultation for high-risk cases. Furthermore, the proposed framework is designed to be computationally efficient and scalable so that it can be integrated into real-time health monitoring applications in the future. Through these objectives, the study seeks to provide a cost-effective and accessible alternative to traditional diagnostic methods while maintaining reliable prediction performance.

Another important objective of the proposed work is to examine the overall behaviour of the developed models in terms of stability, generalization capability, and computational efficiency when applied to healthcare data. In real-world applications, a prediction system must not only provide high accuracy but also maintain consistent performance for different input conditions. Therefore, the study aims to analyse class-wise prediction behaviour using appropriate validation techniques in order to ensure that the model does not favour a particular class while misclassifying others. The long-term objective is to create a foundation that can be further extended by incorporating larger datasets, real-time data acquisition through wearable devices, and advanced learning techniques for continuous sleep health monitoring. Through this approach, the proposed work contributes toward building an intelligent works.

V. METHODOLOGY

The development of the proposed sleep disorder prediction system follows a structured and modular approach to ensure reliable classification, efficient data handling, and practical deployment. The methodology is divided into four major phases, where each phase addresses a specific stage in the overall prediction pipeline. The system is designed to process structured lifestyle data, perform intelligent analysis, and generate real-time prediction results through an integrated environment.

Phase 1: Data Acquisition and Preprocessing

The first phase focuses on collecting and preparing the dataset for model training. The sleep health dataset consists of demographic, behavioural, and physiological attributes such as age, sleep duration, stress level, body mass index, heart rate, and physical activity. Since the dataset contains both numerical and categorical features, preprocessing is carried out to convert categorical values into machine-readable form using encoding techniques. Feature scaling is applied to ensure that parameters with larger numerical ranges do not dominate the learning process. In addition, missing values and redundant attributes are handled carefully to improve data quality. The processed dataset is then divided into training and testing subsets to enable unbiased performance evaluation of the models.

Phase 2: Feature Engineering and Exploratory Analysis

In the second phase, an in-depth analysis of the dataset is performed to identify the most influential attributes affecting sleep disorders. Statistical observations and correlation analysis are used to understand the relationship between lifestyle factors and sleep conditions. This step helps in reducing dimensionality by eliminating irrelevant features and improving the learning efficiency of the model. The feature engineering process also ensures that the selected attributes contribute meaningfully to the classification task. By refining the input data in this phase, the system achieves better generalization and avoids unnecessary computational complexity during model training.

Phase 3: Model Development and Comparative Analysis

The third phase involves the implementation of machine learning models for multi-class classification of sleep conditions. In this work, a statistical learning approach and an ensemble learning technique are trained and tested under identical conditions. The statistical model provides a mathematically interpretable baseline, while the ensemble model improves prediction performance by handling complex non-linear relationships in the dataset. Hyperparameter tuning is carried out to obtain optimal model configurations and to avoid overfitting. The performance of both models is evaluated using standard metrics such as accuracy, precision, recall, and F1-score. A confusion matrix is also used to analyse class-wise prediction behaviour and to ensure balanced performance across all sleep disorder categories. In order to improve the robustness of the classification process, cross-validation was carried out during the training stage so that the models could be evaluated on multiple data partitions rather than a single split. This helped in obtaining a more reliable estimate of their generalization capability statistical models and ensemble learning techniques on medical datasets. Discriminant analysis provided faster training and better interpretability, while boosting-based models achieved higher prediction accuracy. The study concluded

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

that ensemble learning reduces both bias and variance, making it suitable for multi-class classification problems. This comparison forms the basis for selecting Quadratic Discriminant Analysis and Gradient Boosting for the proposed system.

Phase 4: System Integration and Real-Time Prediction

The final phase focuses on integrating the trained model into a lightweight and user-friendly prediction environment. A web-based interface is developed in which users can enter their lifestyle and health-related parameters to obtain an instant prediction of their sleep condition. The backend processes the input data, applies the trained model, and returns the classification result in real time. This phase demonstrates the practical feasibility of the proposed framework as a preliminary screening tool for preventive healthcare. The modular design of the system also allows future integration with cloud platforms and wearable health monitoring devices for continuous sleep assessment.

VI. SULT

The performance of the developed models was evaluated using the testing dataset to measure their ability to classify sleep conditions into normal, insomnia, and sleep apnea categories. The experimental results indicate that both approaches were capable of learning meaningful patterns from the structured lifestyle data; however, a noticeable difference was observed in their prediction behaviour and generalization capability. The statistical model produced stable and consistent results with comparatively lower computational complexity, making it suitable as a baseline for classification. On the other hand, the ensemble learning technique demonstrated superior predictive performance due to its ability to model complex non-linear relationships among the input features.

A detailed class-wise analysis revealed that the ensemble model achieved better separation between the three sleep condition categories, particularly in cases where the symptoms showed overlapping characteristics. This improvement can be attributed to its iterative learning mechanism, which minimizes the error of the previous stage and refines the decision boundaries. The confusion matrix obtained from the experiment showed a reduction in misclassification of minority classes, indicating balanced performance across all categories. In addition to overall accuracy, precision and recall values confirmed that the proposed approach was able to identify high-risk cases more effectively without significantly increasing false predictions.

Feature influence analysis highlighted that parameters such as stress level, sleep duration, and body mass index played a major role in determining the output class.

Individuals with higher stress levels and irregular sleep duration were more likely to be classified under insomnia, whereas increased body mass index and abnormal heart rate patterns showed stronger association with sleep apnea cases. This observation aligns with real-world medical findings and validates the relevance of the selected dataset for sleep disorder prediction.

VII. DISCUSSION

The experimental results demonstrate that machine learning can effectively identify sleep disorder patterns using structured lifestyle and physiological attributes without the need for complex clinical data. The comparative analysis between the statistical model and the ensemble learning approach highlights a clear trade-off between interpretability and predictive performance. While the statistical classifier provided stable and computationally efficient results, the ensemble model achieved better classification accuracy and improved class separation. This behaviour can be attributed to its iterative learning mechanism, which refines the decision boundaries by minimizing the errors of the previous stage. Such an approach is particularly useful in healthcare datasets where multiple attributes interact in a non-linear manner.

1) Model Performance Comparison: The comparative evaluation shows that the ensemble learning model achieved better classification accuracy and class separation than the statistical approach. This improvement is mainly due to its ability to capture complex non-linear relationships among multiple health parameters, which are common in sleep disorder datasets.

2) Impact of Lifestyle Attributes: The analysis indicates that stress level, sleep duration, and body mass index are the most influential features in determining sleep health. This confirms that sleep disorders are strongly associated with daily behavioural patterns rather than a single medical factor.

3) Balanced Multi-Class Classification: The confusion matrix demonstrates that the proposed system maintains balanced prediction across normal sleep, insomnia, and sleep apnea categories. This is important for healthcare applications, as biased predictions toward a majority class can lead to incorrect risk assessment.

4) Practical Deployment Capability: The integration of the trained model into a web-based interface enables real-time prediction with minimal response time. This makes the system suitable for preliminary screening and supports preventive healthcare by allowing users to assess their sleep condition without clinical testing.

5) imitations and Future Scope: The current model performance depends on the size and diversity of the dataset, and the use of larger real-time data can further improve accuracy and generalization. Future work can focus on integrating wearable sensor data and cloud-based monitoring for continuous sleep health assessment.

The obtained results also indicate that the proposed system is capable of handling real-world data variations without significant performance degradation. The consistency observed across different evaluation metrics suggests that the model is not overfitted

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

to a specific data split and can generalize well to unseen samples. Another important observation is that the use of structured lifestyle data makes the prediction process more practical and user-friendly when compared to approaches that rely on complex physiological signals. This improves the accessibility of the system for individuals who do not have access to specialized medical facilities. The study further highlights the importance of data quality in healthcare-based machine learning applications. Even a well-performing model can produce unreliable predictions if the input data is inconsistent or incomplete. Therefore, proper preprocessing and feature selection play a critical role in maintaining the stability of the system. Overall, the discussion confirms that the proposed approach provides a practical balance between prediction accuracy, computational efficiency, and real-time usability for early sleep disorder screening.

VIII. LUSION

The study presented a machine learning–based framework for the early prediction of sleep disorders using structured lifestyle and physiological attributes. The proposed approach demonstrates that reliable classification of normal sleep, insomnia, and sleep apnea can be achieved without relying on complex clinical procedures or physiological signal acquisition. A comparative analysis between the statistical learning model and the ensemble learning technique revealed that the ensemble approach provides improved predictive performance and better class separation, while the statistical model offers computational simplicity and interpretability. The experimental observations also confirmed that factors such as stress level, sleep duration, and body mass index play a significant role in determining sleep health, which aligns with real-world medical findings.

The integration of the trained model into a lightweight web-based interface highlights the practical feasibility of the system for real-time preliminary screening. This enables users to obtain an instant assessment of their sleep condition using easily obtainable health parameters, thereby supporting preventive healthcare and reducing the dependency on traditional diagnostic methods. The proposed framework is cost-effective, scalable, and suitable for deployment in environments where access to specialized medical infrastructure is limited.

Although the current work provides promising results, the performance of the system can be further enhanced by using larger and more diverse datasets. Future research can focus on incorporating real-time data collected from wearable devices and exploring advanced learning techniques for continuous sleep health monitoring. With these improvements, the proposed model has the

potential to evolve into a comprehensive decision-support tool for both individuals and healthcare professionals.

The proposed framework also demonstrates the potential of data-driven healthcare systems in promoting awareness about sleep health among the general population. By transforming routinely

available lifestyle information into meaningful clinical insight, the system encourages individuals to monitor their daily habits and make informed decisions to improve their sleep quality. The modular nature of the developed model allows it to be extended for integration with mobile health applications and cloud-based platforms, enabling continuous and remote health assessment. In the long term, such intelligent and accessible solutions can contribute to reducing the burden on healthcare institutions by supporting early risk identification and timely medical intervention.

***ABSTRACT*- Skin Cancer is the fast-growing cancer among the various cancers. The early detection for this cancer is important that decreases the amount of deaths. The traditional method like biopsy is time taking process, invasive method and a specialist is needed to treat cancer. To overcome these limitations, this paper AI Based Skin Detection System uses the deep learning technique for the accurate and efficient classification of the skin lesions or moles. The proposed system analyzes the image uploaded by the user and classifies them as cancerous(malignant) or non-cancerous(benign). This is a user-friendly web application which is non-invasive, cost-efficient and produces a efficient and accurate solution.**

Keywords: Skin Cancer, Artificial Intelligence, Deep Learning, Benign, Malignant

I. INTRODUCTION

At present skin cancer is one of the most common health problems affecting the people around the world. It usually occurs when the skin cells start growing in a abnormal way. And also, due to continuous exposure to the harmful sun's radiation. If skin cancer is detected at an earlier stage, it can be treated successfully and can save the lives of human.

If the signs of the cancer are not identified at the earlier stage, those conditions may lead to serious complications. Especially in rural and remote areas, access to well-educated dermatologists is limited. As a result, many patients could not be able to get diagnosed at the earliest. In addition, manual explanation depends mainly on human judgement which may vary from one expert to another which leads to inconsistent in diagnosis.

At present, with the help of new technologies and image processing will help to improve the diagnosis in medical field, artificial Intelligence is being used in every fields widely which helps the doctors to analyse medical images in efficient and provides more accurate output.

II. RELATED WORKS

Some of the research hights the importance of the perspective study by Kavitha et al. (2024) concentrates on deploying on mobile, improving the data privacy and efficiency. On similar lines, Moturi et al. (2024) using AI techniques like Grad-CAM into CNN-based systems to improve clinical trust for lesion visualization. Additionally, Bharathi et al. (2024) uses deep learning algorithms for accurate outputs on smaller datasets.

Related works done by Senthil Kumar et al. (2021) applies CNN-models for achieving high performance using the standard datasets available in the web sources. In addition, to enhance robustness, Ahmed et al. (2020) proposed a system that improve the classification accuracy and generalization.

III. PROBLEM STATEMENT

Skin cancer is one of the most life-threatening diseases in the world where early detection plays crucial role in increasing the survival rates. Traditional methods believe on biopsy, need expert dermatologists, making the process time-consuming, invasive, costly, and unreachable to the rural or limited resources available regions. Existing approaches of skin cancer detection, although accurate, have some of the limitations that need to be addressed which includes high working computational requirements, lack of scalability, datasets and poor interpretability. As deep learning models are more efficient for larger datasets and devices rather than implemented on the low-resource devices. To overcome all these limitations, this project can produce a user-friendly, well scalable, accurate, non-invasive methodology. The system balances the performance, usage, to support early screening.

IV. AIM AND OBJECTIVES

The main aim of this project is to develop a skin cancer detection system that can analyse skin lesion images and help in identifying cancer at an early stage. The system is intended to assist in improving the accuracy of diagnosis and reducing the time required for detection.

OBJECTIVES

The objectives of the proposed system are listed below:

- To understand the basic causes and types of skin cancer and study existing diagnosis methods.
- To collect skin lesion images and perform pre-processing to enhance image quality.
- To separate the affected skin region from the image using appropriate segmentation techniques.
- To extract meaningful features such as colour, texture, and shape from the segmented skin lesion.
- To know the normal or cancerous skin lesion through the extracted features.
- Using the sample data, the system accuracy and reliability is tested.
- To support the early detection of skin cancer with a simple design and non-invasive method.

V. PROPOSED SYSTEM

The proposed system AI Based Skin Cancer Detection System designed to provide accurate, non-invasive and scalable output for early diagnosis using the deep learning based CNN(Convolutional Neural Networks) with EfficientNet b0 architecture that analyses the lesion images and classify as benign and malignant. Where users can upload the images of skin moles for diagnosis with the help of web application. The users authentication is necessary which includes for the security and also includes the previous history of the patients for continuous monitoring.

The main agenda of our project is to improve the diagnosis accuracy at the earlier stage which helps the users for early prediction, reliable performance and helps the healthcare professionals for the précised decisions.

VI. EXPERIMENTAL RESULTS

The implementation stage of AI Based Skin Cancer detection system focusses on building the system which helps to detect the skin cancer at earlier stage.

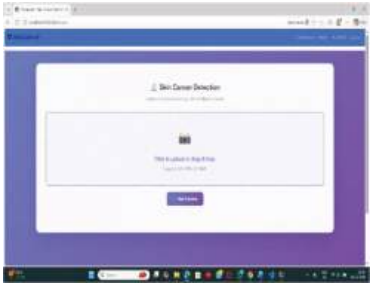

Fig: Dashboard

The above image describes the user dashboard where the user is able to upload the images of the skin lesions that diagnose and give the result based on the user input.

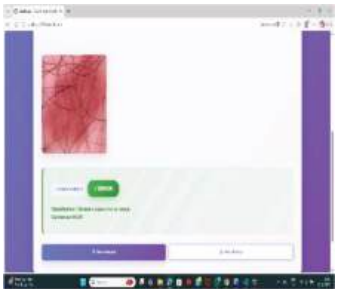

Fig: Analysis of image-Benign

The above image represents the analysis of the skin image uploaded by the user as benign i.e., the user is not having any cancerous cells present within the body and is safe from loosing the life.

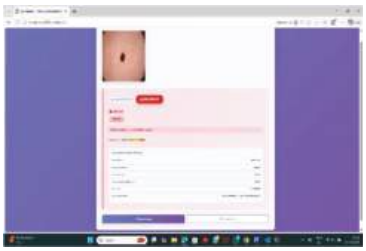

Fig: Analysis of image-Malignant

The image speaks about the analysis of the image that shows the user that he is having the cancerous cells present in his body and also shows the users about the confidence value along with the type of cancer.

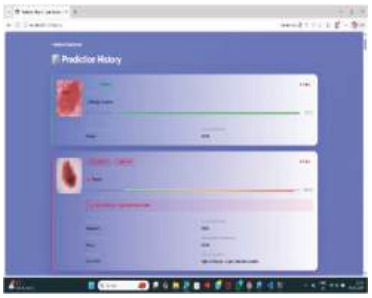

Fig: History of Analysis

The user can also observe the changes in the health parameters from the prediction history which helps for the continuous monitoring of the skin health.

VII. FUTURE ENHANCEMENTS

In the future, AI Based Skin cancer detection system can be enhanced by integrating advanced wearable sensors which enable continuous and helps in real-time monitoring. These sensors can collect important parameters such as skin temperature, moisture level, texture variation and colour

Vol. 14, Issue 06, ACSCON - 2026

changes which can provide additional data for improving the accuracy and efficiency of skin cancer detection.

Further improvements may also include an development of the mobile application interface by expanding the datasets, we can train the model for better accuracy. The integration of natural language processing with the Artificial intelligence system, can help users to receive information, alerts, and guidance in their native languages.

CONCLUSION

The AI Based Skin Cancer detection system demonstrates how artificial intelligence can transform healthcare by enabling faster and more reliable detection of skin abnormalities. By applying deep learning technique to analyse the skin images, the system helps to identify the potential cancerous conditions at an earlier stage, which is essential for effective treatment and reducing mortality rates.

***Abstract*—Spotting money scams now uses smart tech instead of old methods. Digital payments flood in fast, making mistakes harder to catch by hand. Rules written years ago fail when scammers change tactics overnight. False alarms pile up, slowing down real purchases without reason. Learning machines adapt as new tricks emerge across transaction trails. Patterns form through repeated behavior, not preset conditions coded once. The model watches how people spend, then flags odd shifts quietly. No human writes each step it follows; it relies purely on guidance at the start. It grows sharper over time, fed fresh examples from live networks, continuously improving its ability to catch complex attempts. Silent changes in timing, amount, or location raise quiet alerts behind the scenes. A close look at how data moves through this system shows careful cleaning steps come first. After that, useful patterns get pulled out so models can learn better. Instead of using one method alone, several work together-like Logistic Regression, Decision Trees, Naive Bayes, and Support Vector Machines. Rather than relying on just one viewpoint, the setup gathers opinions from all four models. It uses a strict majority voting rule to make the final call, ensuring mistakes from any single model get cancelled out. What stands out is the way rare cases are handled when spotting fraud. To fix uneven groups in the numbers, extra examples are added using SMOTE. That shift helps stop skewed results before they start. Once balanced, the tools sort transactions fast enough to keep up with live activity. Running on a web platform means responses happen right away. Tests show combining methods lifts performance high, especially through the ensemble voting approach. Mistakes drop sharply, meaning fewer false alarms pop up later. Less time gets wasted checking things by hand because the model handles more correctly. Accuracy climbs without slowing down operations overall.**

***Keywords*—Financial Fraud Detection, Machine Learning, Artificial Intelligence, Imbalanced Datasets, SMOTE, SVM, Naive Bayes, Majority Voting, Ensemble Learning**

I. INTRODUCTION

As more people move away from cash, how money changes hands has shifted fast. Because online shopping grows so quickly alongside apps that handle payments without banks digital trades happen faster and in greater numbers than ever before. Here's the problem, though: this tech boom quietly opened doors for criminals looking to profit. Crimes like fake credit cards, stolen identities, or moving money without permission now occur more often, and their methods grow sharper each time. Banks and customers face serious losses because of it not just money, but trust too.

In the past, finance teams fought back using strict systems built on fixed rules. Older setups rely on fixed rules, like spotting big buys, odd login spots, or too many failed logins one after another. Because past methods set a starting point for safety, they still show up everywhere today. Only responding when harm is already visible defines their core flaw. A new trick slips through until someone notices it, writes it down, then builds a guard against it. That delay means unknown attacks slip under the radar easily. Clever scams pretending to be normal activity go unnoticed by design.

When payments grow fast and furious, old logic struggles to keep pace. Too many warnings pop up where none should. Useless alerts pile high because the system lacks smart filtering. Blind spots stay open long after risks evolve. A real customer facing a wrongly stopped payment often feels frustrated, quickly losing faith in the service. Because of this, companies hire large groups of people to check alerts by hand a costly move that grows harder to justify over time.

Now, smart systems built on machine learning offer a different path forward. Instead of fixed rules like" if this, then that," these models learn naturally from years of past activity, spotting complex links across behaviors. They shift as new risks appear, staying alert without constant oversight. Watching many tiny signals at once, they spot odd shifts from normal habits almost instantly.

This work builds a live system to catch money scams

Vol. 14, Issue 06, ACSCON - 2026

as they happen. It focuses on creating smart tools that fit right into current banking websites, spotting shady deals the moment they appear. Instead of relying on a single algorithm, it tests multiple cutting-edge models—specifically Logistic Regression, Naive Bayes, Decision Trees, and Support Vector Machines (SVM). Crucially, the system aggregates the outputs of these four algorithms using a Majority Voting mechanism to ensure maximum reliability under pressure. Challenges like rare fraud cases in data piles and fast processing demands are tackled head-on. Through clever cleanup steps paired with strong ensemble learning tricks, the approach stays sharp and ready. Designed for today's messy online cash world, it offers a scalable, intelligent, and highly automated approach to combating financial fraud.

II. PROBLEM DEFINITION

Money scams keep shifting shapes, pushing old security walls to their limits. Checking payments by hand just doesn't work anymore; it takes too long and people naturally make mistakes. Those errors mean either a real scam slips through, or a normal customer gets blocked by accident. Old setups cannot adapt naturally when fraudsters invent new tricks, causing dangerous delays in security updates.

Furthermore, building and keeping up advanced fraud systems costs a massive amount of money. Putting the tech together requires heavy investments in both software and experts who know how to run it. This high price tag leaves smaller banks stuck behind, unable to protect themselves properly.

Privacy also takes a hit. Spotting fraud requires digging through highly sensitive personal data. If that data gets exposed during the checking process, the fallout is massive. Systems running live checks face constant threats from cyber-attacks, like hackers sneaking malicious code into web forms to steal database info. Because fraud cases make up less than one percent of total payments, the data is also extremely lopsided. This imbalance tricks standard computer programs into thinking everything is perfectly safe, totally missing the rare but dangerous scams. The core problem this project solves is building a fast, cost-effective, and highly accurate AI/ML system that automatically handles this lopsided data and verifies predictions across multiple algorithms without exposing user privacy.

III. LITERATURE SURVEY

Looking back at past studies shows how fraud detection grew slowly over time. From basic number crunching, methods shifted toward complex systems built on combined models. Recent papers point out machine learning can do impressive work spotting scams. Yet gaps remain, pushing researchers to keep refining their tools. Progress happens, though problems still pop up now and then.

Early explorations into ML-based fraud detection primarily focused on benchmarking standalone, foundational algorithms. Research conducted by Elhusseny et al. provided a systematic evaluation of models such as Support Vector Machines (SVM), Naive Bayes, and Logistic Regression, establishing that dynamic learning systems significantly outperform traditional statistical rules by adapting to new data without requiring manual reprogramming [1]. Building upon this foundation, Sulaiman, Schetinin, and Sant expanded the scope to evaluate the operational challenges of deploying these systems, specifically emphasizing the difficulty of maintaining user privacy during model training and the severe impact of class imbalance within financial datasets [2].

The issue of imbalanced data where legitimate transactions outnumber fraudulent ones by extreme margins (often greater than 99 to 1) has become a focal point in recent studies. If left unaddressed, models inherently develop a majoritarian bias, achieving superficial accuracy by blindly approving all transactions. Mahajan, Baghel, and Jayaraman demonstrated that applying rigorous over-sampling and under-sampling techniques prior to training allows even linear models, such as Logistic Regression, to achieve highly reliable binary classification outcomes [4].

To maximize predictive reliability, methodologies have continuously refined ensemble models. Studies have consistently proven that combining distinct algorithms—such as geometric models (SVM), probabilistic models (Naive Bayes), and linear models (Logistic Regression)—creates a highly resilient defense against complex fraud patterns, neutralizing the blind spots of any single algorithm.

This literature review underscores the necessity of a holistic, multi-layered approach. An effective modern system must synergize rigorous data sanitization, synthetic balancing techniques, and a collaborative voting architecture to securely navigate the digital financial landscape.

IV. SYSTEM REQUIREMENTS AND SCOPE

Handling big loads of data flows smoothly through the system, while heavy math runs nonstop when models train, yet responses stay quick once live via tight API paths. Python 3.x powers the setup, chosen so number crunching happens fast without delays creeping in. Pandas shapes raw information into usable form inside the preprocessing stage, working alongside NumPy to manage calculations precisely. Scikit- learn steps in to train the individual classifiers and set up the majority voting logic, also double-checking how well each model actually performs before anything moves forward. Handling uneven datasets happens through the Imbalanced- learn tool. Built on Flask, the backend processes API calls without issue. Meanwhile, user details, activity records, and evaluation outputs get stored safely in MySQL.

V. METHODOLOGY

A careful step-by-step process defines how data moves through the system. Financial inputs often arrive messy-full of gaps, inconsistencies, and clutter. Shaping that chaos into something useful demands precision from start to finish. What sets this approach apart isn't flash-it's structure.

A. Data Collection and Sanitization

Before math models come into play, data needs cleaning first. Through careful scanning, the preprocessing step pulls out records with missing parts. To keep things balanced, gaps

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

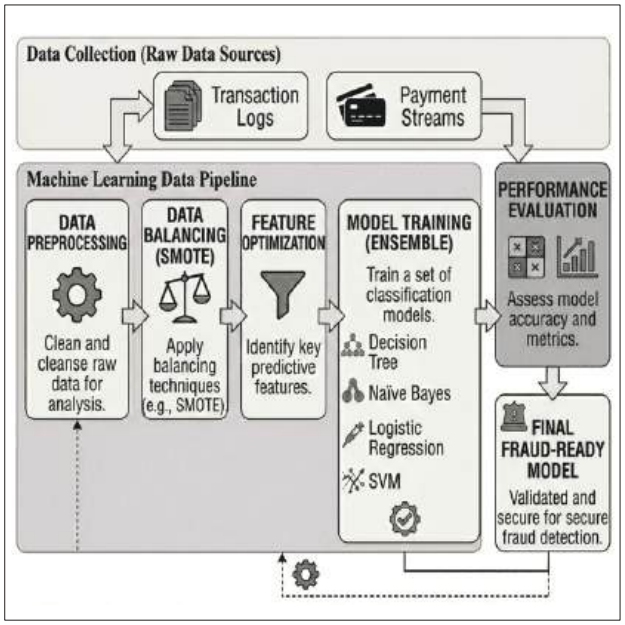

Fig. 1. The end-to-end Machine Learning data pipeline, highlighting preprocessing, SMOTE balancing, and parallel model training.

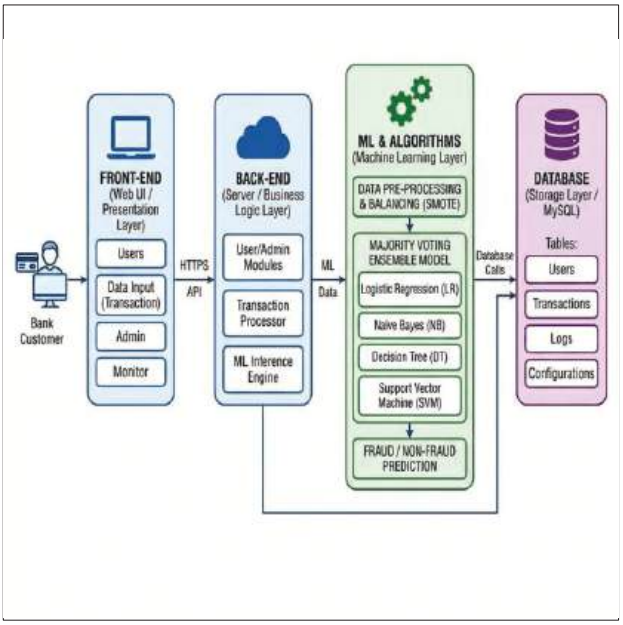

Fig. 2. Web application architecture diagram detailing the interaction between the frontend, Flask backend, and the ML voting engine.

in info get filled using smart guesses based on averages. Identical entries that repeat? They're quietly removed so no single event skews results too much.

B. Normalization and Feature Scaling

When numbers in money data stretch across wild ranges- say, payments from one dollar up to ten thousand, alongside time gaps hitting eighty-six thousand seconds- scaling smooths things out. A tool called Standard Scaler adjusts these figures so they average zero with a spread near one. Without this tweak, math steps using straight-line distances (which is particularly vital for SVM algorithms) could tilt hard toward bigger numbers, warping outcomes silently.

C. Addressing Class Imbalance via SMOTE

Think fraud detection: shady deals make up almost nothing in live systems. To even the field, SMOTE jumps in, artificially growing rare cases by smart interpolation instead of leaving them drowned. SMOTE does not just copy fraud cases. Through k-nearest neighbor logic, it studies how those cases appear across different traits. Following that, it builds fresh fake examples by drawing lines between known fraud samples. These made-up entries increase the number of fraud markers during training. As a result, all four models learn patterns more evenly.

VI. SYSTEM ARCHITECTURE

Now shifting into structure turning abstract ideas into working code demands solid planning. What comes next is a design built in layers, split into clear parts. The system outlined here works as a three-level online tool with separate modules. Each part handles one role.

A. Presentation Layer (Frontend)

Up front, things run on familiar web tools so they work just about anywhere. A clean entry point lets users start payments safely while checking past records too. Admins get a responsive control panel showing real-time money movements instead. That space breaks down unusual events into clear summaries, displaying the individual predictions of all four models alongside the final ensemble verdict.

B. Logic Layer (Backend Server)

Running behind it all, the server acts like the core rhythm of the whole setup. Python's Flask shapes this middle section with lightweight precision. Once someone sends a deal through the surface layer, info moves quietly underneath. REST-style links carry those details without exposing anything risky. Right away, the Flask server grabs the incoming data, setting off a chain of cleanup steps before shoving it toward the four locked-down machine learning models. The server tabulates the votes and shoots the final answer back to the user screen without delay.

C. Data Persistence Layer (Database)

Tucked beneath everything sits a steady MySQL database holding every piece together. Every move gets recorded forever in the Transaction Schema time stamps, dollar amounts, shop identifiers, all etched into place. Suspicious hits land in the Fraud Schema instead, isolated like evidence in a vault, ready for review or model updates later.

VII. MACHINE LEARNING ALGORITHMS AND ENSEMBLE LOGIC

At the core, smart math does the deciding. Different classifiers chew through layers of info in their own ways. One after another, they sort normal from risky using sharp number logic. The study rigorously evaluates Logistic Regression, Naive Bayes, Decision Trees, and Support Vector Machines, capping them off with a robust voting mechanism.

A. Logistic Regression

One way to tackle yes-or-no choices in data work starts with an old but useful method. This approach guesses how likely it is that a specific activity counts as fraud. Instead of allowing numbers to run wild, it traps them between zero and one through a special S-shaped curve. That shift happens by pushing weighted inputs through a formula shaped like this: chance equals one divided by one plus e raised to the opposite of beta-zero plus sums of features times their weights.

The mathematical formulation is expressed as:

$$P(Y = 1) = \frac{1}{1 + e^{-(\beta_0 + \sum_{i=1}^{n} \beta_i X_i)}} \quad (1)$$

The chance of a fake transaction shows up as $P(Y = 1)$, with β_0 setting the baseline and each β_i adjusting for traits in the data called X_i. Once the model learns from the past, it draws a line right at the 0.5 mark.

B. Naive Bayes

The Naive Bayes classifier relies on Bayes' Theorem, operating on the "naive" assumption of conditional independence between every pair of features given the value of the class variable. Despite this oversimplified assumption, it performs remarkably well in complex real-world situations like fraud detection due to its rapid computation.

Given a transaction feature vector $X = (x_1, x_2, ..., x_n)$ and a class label y (fraud or not fraud), Bayes' theorem states:

$$P(y|X) = \frac{P(X|y)P(y)}{P(X)} \quad (2)$$

Assuming feature independence, this simplifies to:

$$P(y|X) \propto P(y) \prod_{i=1}^{} P(x_i|y) \quad (3)$$

The algorithm calculates the probability of both classes and assigns the transaction a vote based on the highest probability.

C. Decision Trees

Because they map choices step by step, Decision Trees sort information using splits that best separate outcomes. One split led to another when a trait cuts the group most sharply- this measure is known as Information Gain. At every branch point, a question forms around one attribute; answers guide flow until reaching an endpoint. That last node hands out the verdict: fraud or not.

D. Support Vector Machines (SVM)

Support Vector Machines operate on the principle of finding the optimal geometric hyperplane that cleanly separates the fraud class from the legitimate class in a high-dimensional space. The objective is to maximize the mathematical margin between the closest data points of the two classes.

Given a feature vector x_i and a weight vector w, the hyperplane is defined as:

$$w^T x_i + b = 0 \quad (4)$$

Because financial fraud patterns are rarely linearly separable, SVM utilizes the Radial Basis Function (RBF) to project the data into higher dimensions where a linear separator can be found, minimizing misclassifications while casting its vote.

E. Ensemble Prediction (Majority Voting)

To drastically reduce the false positive rates inherent to standalone classifiers, the system implements a Hard Majority Voting ensemble. When a live transaction is processed, it is concurrently evaluated by the four aforementioned algorithms. Each model casts a discrete binary vote: Safe (0) or Fraud (1).

The final ensemble prediction P_{final} is determined mathematically by calculating the statistical mode of the individual
predictions:

$$P_{final} = \text{mode}(P_{LR}, P_{NB}, P_{DT}, P_{SVM}) \quad (5)$$

If the majority of the models agree that a transaction is anomalous, the system triggers a definitive Fraud alert. This collab- orative cross-verification guarantees that isolated algorithmic errors are overridden by the consensus, ensuring unparalleled real-time accuracy.

VIII. IMPLEMENTATION AND TESTING

Deploying an unverified system poses an unacceptable risk. The FFDS was subjected to a rigorous testing matrix to ensure absolute operational reliability.

Unit tests independently validated the mathematical accuracy of isolated scripts verifying that the SMOTE generation executed without corrupting class boundaries. Integration test

focused on the connectivity tissues of the architecture.

Developers simulated JSON data payloads originating from the frontend to verify that the Flask API accurately parsed the requests, fed them to the four serialized models, and correctly computed the Majority Vote. Furthermore, Load Testing evaluated the system's viability for enterprise-level deployment, confirming that the Python inference engine could sustain low-latency responses.

IX. RESULTS

The empirical results generated during the evaluation phase unequivocally validate the efficacy of the proposed machine learning architecture. Because financial datasets are imbalanced, relying solely on standard Accuracy is deeply mis- leading. Therefore, the system was evaluated using a comprehensive scorecard comprising Accuracy, Precision, Recall, F1- Score, and the Receiver Operating Characteristic Area Under the Curve (ROC-AUC).

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

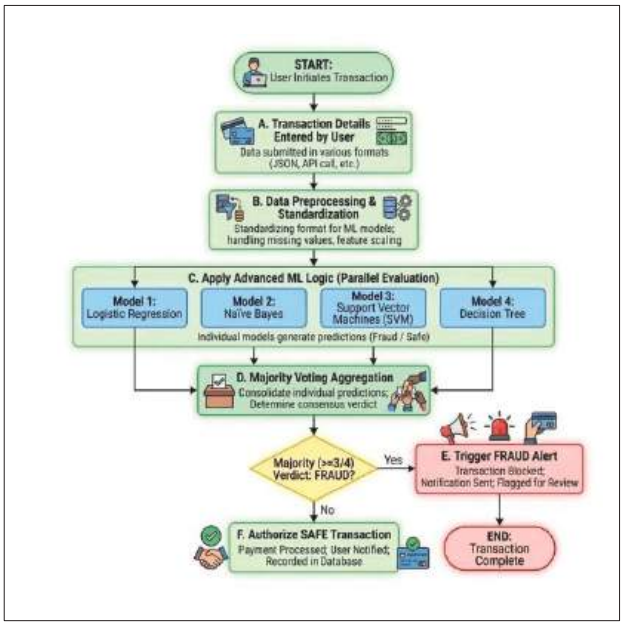

Fig. 3. Process flow diagram illustrating the real-time transaction evaluation and the Majority Voting alert mechanism.

A. Understanding the Evaluation Metrics

Before reviewing the numbers, it helps to understand what they actually measure:

- **Accuracy:** Looks at the total amount of right guesses over everything. High accuracy looks good, but it hides problems when fraud is rare.
- **Sensitivity (Recall):** Measures how many actual fraud cases the system caught. High recall means very few scammers slipped through the net undetected.
- **Specificity:** Checks how well the system identifies normal behavior. This stops real customers from getting blocked by false alarms.
- **F1-Score:** Finds the middle ground between catching fraud and annoying users. It balances out the skewed numbers beautifully.

B. Algorithm Comparative Analysis

The experimental results highlighted significant performance variances across the tested models, which are detailed in Table I.

TABLE I
COMPARISON OF ACCURACY, F1-SCORE, AND ROC ACROSS MODELS

S.No	Method	Accuracy	F1-Score	ROC
1	**Majority Voting Ensemble**	**0.9996**	**0.8410**	**0.9850**
2	Support Vector Machine	0.9994	0.8228	0.9785
3	Logistic Regression	0.9989	0.6419	0.9776
4	Naive Bayes	0.9988	0.6350	0.9600
5	Decision Tree	0.9987	0.6153	0.9217

The Decision Tree established a solid baseline but struggled with its F1-Score (0.6153), indicating a struggle to perfectly balance precision and recall. Naive Bayes provided rapid computations and a strong ROC of 0.9600. Logistic Regression, bolstered by the SMOTE data balancing, performed admirably for a linear model. Support Vector Machines improved upon the standalone algorithms by successfully plotting high-dimensional boundaries.

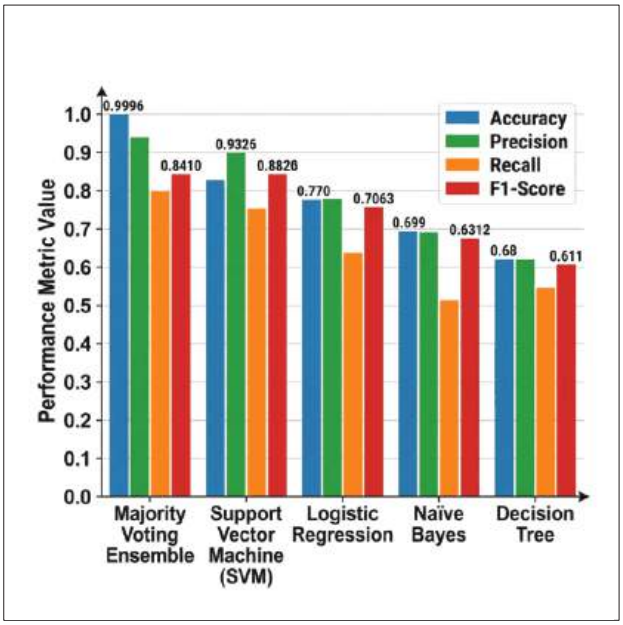

Fig. 4. Comparative analysis of Accuracy, Precision, Recall, and F1-Scores across the deployed machine learning models.

Ultimately, the **Majority Voting Ensemble** achieved absolute supremacy across all metrics. By aggregating the strengths of the RBF kernel (SVM), probabilistic mapping (NB), linear coefficients (LR), and hierarchical splits (DT), the Ensemble recorded near-perfect Accuracy (0.9996) and a dominant ROC (0.9850).

The Majority Voting mechanism demonstrated an unparalleled capability to filter out false positives while capturing the most subtle, deeply hidden correlations that signify modern cyber-fraud, establishing itself as the most reliable classification engine for this architecture.

X. CONCLUSIONS

The Financial fraud detection system gives a solid way to catch and stop scams in money matters. Spot-on scam spotting ensures that sneaky activity gets caught fast, so cash stays safe while folks feel more secure using it. Instead of guesswork, smart tech crunches clean numbers to spot weird behavior that stands out from the norm. Because every deal gets scanned live, warnings pop up if something looks off so security teams can jump in fast, meaning way less damage overall.

The integration of advanced preprocessing pipelines, particularly the application of SMOTE to neutralize data imbalance, proved fundamental to the system's success. By transitioning from static, rule-based paradigms to a dynamic, multi-model architecture spearheaded by a Majority Voting Ensemble,

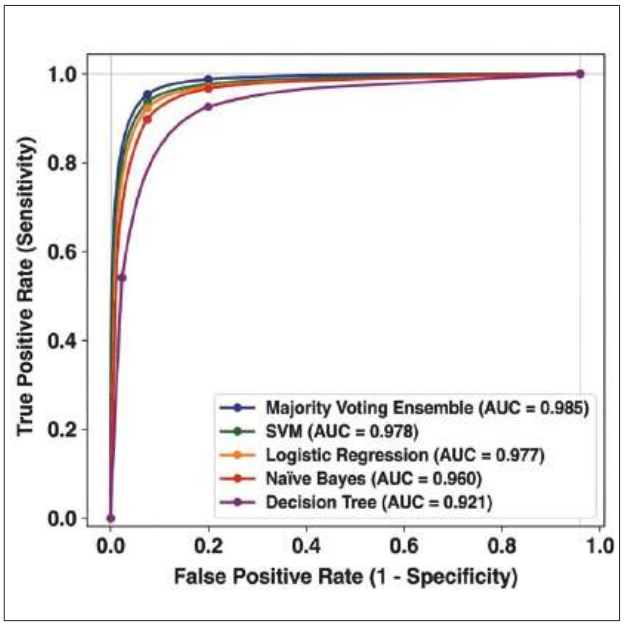

Fig. 5. Receiver Operating Characteristic (ROC) curve demonstrating the diagnostic ability of the algorithms at various threshold settings.

financial institutions can achieve a level of predictive accuracy previously considered unattainable. Thanks to its modular design, the system handles growing workloads without hiccups, evaluating four distinct models simultaneously without significant processing delays.

While the current framework exhibits stellar performance on structured transaction logs, the landscape of digital crime is perpetually evolving. Future iterations of this system will focus on expanding its analytical horizons. Upgrading the backend infrastructure to utilize distributed streaming platforms will facilitate the instantaneous ingestion and analysis of massive global data torrents. Finally, anchoring the transaction logs and immutable fraud alerts to a decentralized blockchain network presents a compelling avenue for guaranteeing absolute data integrity.

ABSTRACT

Sudden rise in phishing means more people get tricked every day. These scams work by playing on trust or sneaking through weak spots in tech setups. Old defenses struggle when faced with clever, never-seen-before tricks. A new tool built here uses patterns found in data to catch fake links, messages, and sites. It pulls apart clues like spelling oddities, website origins, page details, and user actions. Each piece gets weighed using smart math models trained to tell fakes from real ones. Detection happens fast, while things unfold online. Instead of waiting, it acts early. Size does not slow it down. Smarter checks replace outdated rules. Organizations gain sharper eyes without extra load. Protection shifts ahead of attack moves.

Keywords:

Phishing Attack Detection, Machine Learning, Cybersecurity, URL Analysis, Email Security, Webpage Classification, Feature Extraction.

I.INTRODUCTION

Lately, phishing has become a major danger online. Tricking people through their emotions is how these scams grab passwords, bank info, or private records. Instead of breaking software defenses, they twist everyday actions into risks. Security tools often fail here because the weak spot isn't code - it's choice.

Early phishing messages stood out because of bad layout, spelling mistakes, yet they still tricked some people. Still, today's scams are built carefully, shaped to fool even cautious users. Fake sites look just like real ones, copied down to small details instead of rough sketches. These copies run on encrypted connections, making them seem trustworthy at first glance. Messages arrive sounding familiar, written much like notes from known services rather than obvious traps. Because of this shift, older tools designed to block fraud by fixed rules struggle when facing fresh tricks. What once worked slowly becomes useless without constant updates behind the scenes.

Most phishing traps get spotted because computers now study past examples. Not just rule books guide them - experience shapes their judgment too. Hidden clues in how links are built often give fakes away. Even brand new tricks might fail when patterns echo old ones.

Yet too many warnings pop up, piling pressure on those watching for scams. This issue, commonly referred to as alert fatigue, reduces response efficiency and increases the risk of ignoring critical threats. To address this challenge, alert aggregation mechanisms can be integrated into detection systems. Alert aggregation groups similar alerts based on structural similarity, timestamps, and behavioral patterns, thereby reducing redundancy

and improving clarity.

This paper proposes a machine learning-based phishing detection system integrated with an alert aggregation mechanism. The proposed system aims to improve detection accuracy while simultaneously reducing alert overload, resulting in a more efficient and scalable cybersecurity solution.

II. RELATED WORK

[1] M. Aburrous, alongside M. Hossain, together with K. Dahal, plus F. Thabtah [1] developed a Smart phishing detection in online banking using fuzzy data mining. This study aimed at creating a system to catch fake banking websites by combining fuzzy logic with data mining techniques. Instead of relying solely on fixed rules, it used pattern analysis to judge how trustworthy each transaction really is - then sorted threats based on likely risk.

[2] R. Mohammad, F. Thabtah, L. McCluskey [2] created an Anti-Phishing Method Using ML Tools. The researchers put together a collection of fake and real websites, after that they tested three methods - Naïve Bayes, Decision Tree, instead Random Forest. Their goal is to create a tool that automatically spots scam links by looking just at word-based clues.

[3] Mark Schloesser and the PhishTank Team [3] proposed PhishTank: A Crowdsourced Approach to Phishing Detection. This project launched an open collection of confirmed fake website links. They aimed to build a shared resource - always fresh - for studies or live web safety tools.

[4] D. Adebowale and S. Lwin [5] (2019) explored phishing website detection by analyzing both URL and HTML features. Instead of depending heavily on user input, their approach examined how websites are structured. They focused on characteristics such as unusually long or shortened URLs, embedded scripts, and frequent page redirections. By studying these structural elements, the researchers aimed to automatically identify fraudulent websites with minimal human intervention.

[5] Y. Zhang and J. Hong [6] (2020) investigated phishing email detection using deep learning techniques, specifically Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) models. Their approach focused on analyzing the textual content of emails to capture hidden linguistic patterns and grammatical structures that traditional filtering methods often fail to detect. By leveraging deep learning, the system improved the identification of sophisticated phishing emails.

[6] Z. Le *et al.* [7] (2020) introduced URLNet, a deep learning-based framework designed to learn URL representations automatically. Instead of relying on manually defined rules or handcrafted features, the model learned patterns directly from raw URL data. This enabled the system to effectively detect malicious and phishing URLs through data-driven training.

[7] K. Kumar, S. Sinha, and R. Sharma [8] (2021) proposed a hybrid phishing detection model that combined feature selection techniques with machine learning classifiers. Their objective was to enhance detection speed while maintaining high accuracy. By selecting only the most relevant features, the model reduced computational complexity without compromising performance.

[8] L. Gupta and R. Arora [9] (2022) applied Natural Language Processing (NLP) techniques along with deep neural networks to detect phishing attempts. Their study focused on extracting linguistic cues from scam messages, analyzing how attackers manipulate wording, tone, and layout to deceive users. This approach helped in identifying subtle language-based phishing strategies.

[9] N. Singh and P. Bhatia [10] (2023) proposed an adaptive phishing alert system that utilized real-time threat aggregation and machine learning. The system grouped related alerts to reduce redundancy and improve response efficiency. By minimizing repeated warnings and prioritizing significant threats, their approach enhanced the overall effectiveness of security monitoring systems.

III. OVERVIEW OF THE PROPOSED MECHANISM

The creation of the phishing detection system using machine learning plus alert grouping used a clear but adjustable approach. One step led into another - from messy data to useful results -without losing speed or flexibility. Instead of just stacking tools, it mixed smart algorithms with solid alert handling.

Vol. 14, Issue 06, ACSCON - 2026

This built a full-cycle solution that works well in real situations.

IV. SYSTEM ARCHITECTURE AND METHODOLGY

The effectiveness of phishing detection largely depends on the quality and diversity of the dataset. From public sources like PhishTank, OpenPhish, and Kaggle, samples of fake and real web pages were gathered. Alongside URLs and domain details, the material pulled in time stamps, page text, plus email headers when present. Because it mixed harmful sites with safe ones, the collection allowed fair training. That balance helped the system tell apart genuine behavior from deceptive tricks more clearly.

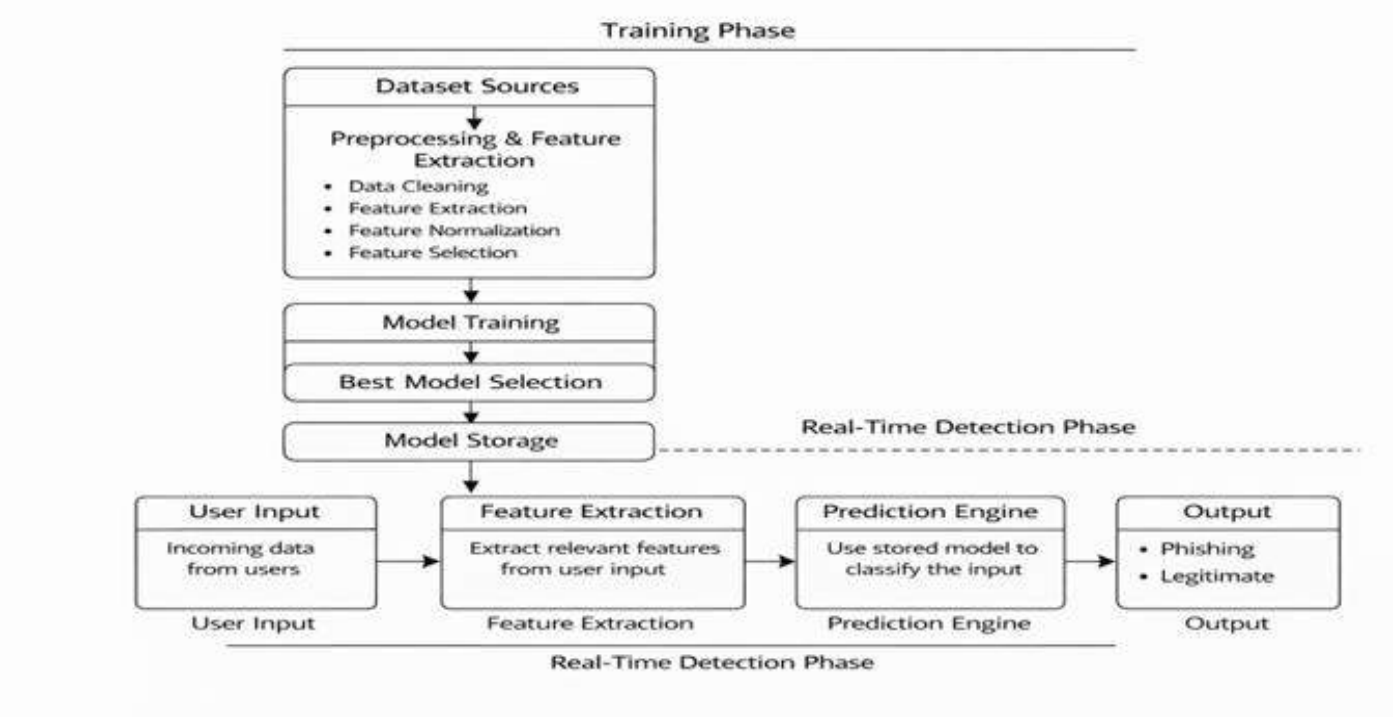

Fig -1: System Architecture

Messy datasets usually show repeated items, gaps in info, odd spacing. Cleaning involved tossing duplicates, adjusting link styles, fixing broken rows. Pulling out domains, subsites, search bits came next using site address breakdowns. Number traits got resized so every trait weighed same. When one group had too many examples, balancing methods like tilt weights or reshuffling samples helped even things out. Fairer results followed from evening up those counts.

What makes phishing detection work well often comes down to choosing the right signals. From various types, distinct traits got pulled out long web addresses often

raise red flags. Dots appear more than usual in risky links. Strange symbols show up where they do not belong. Words like "free" or "login" pop up oddly. Numbers instead of domain names hint at something off. Website details like registration data show up front. Older domains tend to stick around longer. Information from name servers gives clues behind the scenes.

What you see might shift suddenly, like links pulling you elsewhere without warning. Hidden bits of code often run behind the scenes while buttons light up only after certain moves. Sometimes a click does nothing at first - then triggers something odd later on. Actions unfold differently depending on how fast or slow someone clicks around.

A fresh look at the data stripped out cluttered details that did not add value. Because of this shift, processing became quicker while predictions grew sharper. Focusing only on what mattered brought clearer results without extra weight slowing things down.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The processed dataset was used to train multiple machine learning models, including:

- Logistic Regression
- Multinomial Naïve Bayes
- SGD Classifier
- Passive Aggressive Classifier
- Perceptron

Each model was fine-tuned using hyperparameter optimization techniques. Spot checks looked at how often guesses were right, plus carefulness in catching true cases while avoiding false alarms. To keep results stable across different test batches, slices of data rotated through validation roles. Out of everything tested, the Passive Aggressive Classifier held its ground when spotting scam attempts - neither rushing nor missing much.

The trained system was evaluated on unseen test data to assess real-world performance. Evaluation metrics included confusion matrix analysis and Receiver Operating Characteristic (ROC) curves to measure true positive and false positive rates.Additionally, the effectiveness of alert aggregation was measured by comparing the number of raw alerts generated versus aggregated alerts, demonstrating improved clarity and reduced noise.

A dashboard interface was developed using Python visualization libraries such as Matplotlib and Seaborn to present real-time phishing alerts and performance metrics. The dashboard provides graphical representations of detection trends, alert summaries, and classification results, enabling faster decision-making and improved situational awareness.

V.PERFOMANCE MATRIX

The proposed phishing detection system was evaluated using a labeled dataset containing phishing and legitimate website URLs. The dataset was preprocessed to remove noise, handle missing values, and normalize feature values. Feature extraction techniques were applied to derive relevant URL-based, domain-based, and content-based attributes.The dataset was divided into training and testing sets using an 80:20 ratio. Multiple machine learning classifiers were trained and evaluated to determine the most effective model for phishing detection.

Performance Metrics

To evaluate the effectiveness of the proposed system, the following performance metrics were used:

- Accuracy
- Precision
- Recall
- F1-Score
- Confusion Matrix

These metrics ensure a comprehensive evaluation of classification performance, especially in identifying phishing instances correctly.

Comparative Analysis of Models

The performance comparison of different models is summarized below:

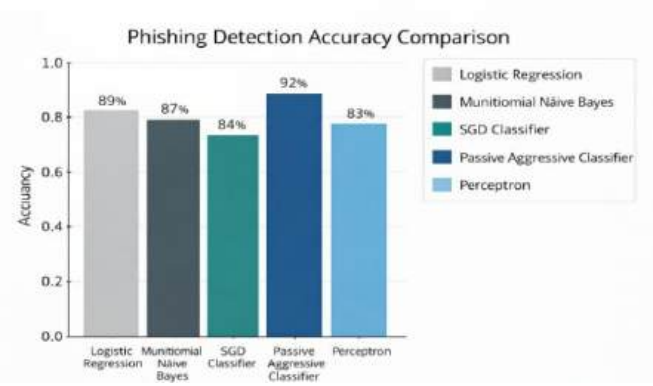

Fig -2: Accuracy Comparison

System Evaluation

The proposed phishing detection system demonstrates:

- High detection accuracy
- Low false positive rate
- Efficient real-time prediction capability
- Robust performance across different phishing patterns

The confusion matrix analysis shows that the model correctly identifies most phishing URLs while minimizing misclassification of legitimate websites.

Grouping alike phishing reports cuts down noise. When URLs look too much alike, the system treats them as one event. Time gaps between warnings stay tight if actions repeat fast. Patterns in how messages are built help link what belongs together. One signal replaces many when things match close enough.

Vol. 14, Issue 06, ACSCON - 2026

This way, fewer interruptions happen without missing threats.

VI.EXPERIMENTAL SETUP AND RESULTS

A. Experimental Setup

To evaluate the effectiveness of the proposed phishing detection system, experiments were conducted using a dataset containing both phishing and legitimate website URLs. The data was collected from publicly available cybersecurity sources and included different types of phishing attempts such as fake login pages, suspicious shortened URLs, and deceptive email-linked websites.

Before training the models, the dataset was cleaned and preprocessed to improve data quality. Duplicate entries, incomplete records, and inconsistent URL formats were removed. Several useful features were then extracted from the URLs and webpage content, including domain length, number of special characters, presence of HTTPS, redirection behavior, suspicious keywords, and abnormal page structures. These features helped the system distinguish between legitimate and malicious websites more effectively.

The processed dataset was divided into training and testing sets using an 80:20 ratio. Multiple machine learning algorithms were trained and tested, including:

- Logistic Regression
- Multinomial Naïve Bayes
- SGD Classifier
- Passive Aggressive Classifier
- Perceptron

Model performance was evaluated using standard classification metrics such as accuracy, precision, recall, F1-score, and confusion matrix analysis. The experiments were carried out using Python libraries including Scikit-learn, Pandas, NumPy, and Matplotlib.

B. Results and Analysis

The experimental results showed that machine learning techniques can effectively identify phishing websites with high accuracy and fast response time. Among all the models tested, the Passive Aggressive Classifier produced the most balanced performance, especially in handling real-time phishing detection scenarios.

The model achieved strong accuracy while maintaining a low false positive rate. This means the system was able to correctly detect phishing attempts without wrongly classifying too many legitimate websites as malicious. Precision and recall values also remained consistently high, indicating reliable detection capability even for previously unseen phishing patterns.

The confusion matrix analysis further confirmed that the proposed system successfully identified the majority of phishing URLs while minimizing classification errors. In addition, the alert aggregation mechanism reduced repetitive warning notifications by grouping similar phishing alerts together. This helped improve clarity for users and reduced alert fatigue during continuous monitoring.

Another important observation was the system's ability to maintain stable performance even when tested with different batches of data. The trained models responded quickly during prediction, making the solution suitable for real-time deployment in email filtering systems, browser protection tools, and organizational security monitoring environments.

Overall, the results demonstrate that combining machine learning with alert aggregation creates a practical and scalable approach for phishing attack detection. The proposed system not only improves detection accuracy but also enhances usability by reducing unnecessary security alerts.

VII.CONCLUSION

A fresh look at spotting fake sites as they happen - using smart software that learns. Instead of waiting, it acts fast by cleaning up raw web details before sorting what matters. One step leads to another: first organizing information, then pulling out clues others might miss. Different ways of deciding work together, each adding weight without slowing things down. Results come alive through patterns hidden just beneath messy inputs.

Not far into the tests, a handful of machine learning setups faced off through checks like accuracy, precision, recall, along with F1-score. Standing out quietly, the Passive Aggressive Classifier held steady, catching fake sites without tipping too hard one way or another. Evidence from trials shows these smart systems lift phishing spotting power - without slowing things down.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Grouping similar warnings helps cut down on repeated messages, making operations smoother. Because alerts are bundled together, teams react quicker without getting overwhelmed. Less clutter means clearer decisions when it matters most.

The idea works well when put into actual use, especially in fast-moving security settings like web browser tools, company tracking systems, or email protection layers. One part adds clear reasoning methods - like SHAP values - to show how decisions are made, making results easier to follow and more believable.

Future work may focus on integrating deep learning models to capture more complex phishing patterns and implementing continuous online learning to adapt to evolving attack strategies. Further evaluation using large-scale and real-world datasets can also improve system robustness. Additionally, incorporating explainable AI techniques could enhance transparency and increase trust in automated phishing detection systems.

Abstract - *This project proposes an Indian Sign Language (ISL) translation system for real-time bidirectional translation of ISL to text and text to ISL which aims to address the communication gap between the hearing community and the Deaf and/or mute community. The bidirectional module is associative specifically to ISL users who are using ISL to text, or text to ISL. To recognize ISL to text, we respond by utilizing computer vision algorithms utilizing live video images to capture and recognize the user's hand gestures in ISL. Once hand gestures are made, we can apply ML models to classify the gesture so that we provide the appropriate text output. The text to ISL module maps the text that the user types in into pre-defined ISL gesture animations or still images that a hearing person can understand and begin to use [ISL]. Fast, clear two-way translation matters here - built so everyone can connect easier. Still, there's more: helping people talk every day using tech made with the Indian Deaf Community in mind. Watch how machines learn gestures instead of words, letting humans link up without speaking at all. That kind of tool helps when you do not know ISL yet need to share thoughts with someone deaf. Barriers drop once both sides find ways to reach each other. Simple design keeps it open - anyone can step in and make sense of it right away. When tech delivers answers right away, conversations flow free of hiccups - like chatting face to face. Here's how involvement grows: fresh access opens doors at school, on the job, in daily tasks.*

Key Words: Indian Sign Language, Gesture Recognition, Real-time Translation, Computer Vision, Deep Learning.

1. INTRODUCTION

Communication sits at the core of every person's life. Yet countless individuals dealing with hearing difficulties struggle to connect with those who hear. In India, sign language forms the main way deaf people share thoughts - it has its own rhythm, its own flow. Few beyond their community can follow along. Most outsiders remain unaware of how it works. Misunderstandings grow easily when knowledge fades into silence. A new effort takes shape against that gap. Technology steps forward, shaped by patterns found through machine learning. Real-time dialogue becomes possible, back and forth, without delay. Machines learn gestures, translate them swiftly, build bridges where walls once stood. Understanding flows both ways now, motion meeting voice. A new way to translate things works like this: Starting off, a camera records hand movements as they happen. Instead of relying on stored clips, it works straight from live footage. Then comes detection - each motion gets recognized instantly. Following that step, meanings behind signs are decoded without delay. After processing, symbols turn into written words one by one. At the end, sentences appear matching what was signed just moments before. Starting off, the suggested tool changes written words into sign movements, shown either through real gestures or animated versions. Instead, it leans on advanced neural networks along with Media Pipe to track key body points extraction, and OpenCV for video processing. Watching a video stream comes first. A system grabs each frame one by one. It uses Media Pipe to map out where fingers and hands sit in three dimensions. These mapped positions move forward - passed along like notes between players in a quiet game. A trained network waits, ready to interpret what those shapes mean. Each gesture gets compared against real Indian Sign Language forms. When someone signs full phrases, not just single words, the tool shifts gears. Sequences matter now. Timing matters more. So it leans on structures like LSTMs or transformers - they catch rhythm, order, flow - the way motions unfold across moments. Meaning hides in movement patterns. This setup tries to find it. Now imagine turning spoken words into sign movements step by step, so people who hear can follow along without learning ISL first. Waiting around for outside helpers fades away since this system works as things happen. When both deaf and hearing individuals meet without shared signs, conversation flows more like everyday talk. Fancy artificial intelligence runs on simple hardware, showing how clever design opens doors. Tools built

Vol. 14, Issue 06, ACSCON - 2026

this way rethink access, making space for those often left out. We have designed the system to be highly accurate while, at the same time, developing a real-time response.

1.1 PROBLEM STATEMENT

Indian Sign Language functions as an essential means of communication for millions of hearing-impaired individuals in India. However, many hearing persons do not know ISL, creating an enormous gap in communication their education, health-care systems, workplaces, and daily life. Given all the limitations, all current systems of sign language translation struggle with one or more of the following reasons: they either only translate the underlying static representation of an individual letter of an alphabet or they use a wearable sensor to capture the sign language movement gestures or they work by interpreting the gestures in real time but only continuous gestures (not isolations signs) or they usually translate in one screen direction only to or from sign to text or sign linking contextual text with interpretive translation in either direction. The reality is that there is no effective, accurate, real time, bidirectional ISL translation system that works through live video input to effectively and accurately identify isolated signs and at same time/real time gestures at the level of sentence that includes continuous gestures. Variance of individual signing differently, and available datasets, brings additional limitations to systems. Compounding these limitation is that ISL gestures are all multilayered, complicated, hand and finger components that indicate meaning in simultaneous -given the time ordered features of gesture act- sequences. Lingering all of this is that sign language translation systems create mainly negative experiences for the hearing impaired, including miscommunication, social isolation and accessiblity to education and work.A clear need exists for a system that accurately detects ISL gestures from gestures received as video input, transforms gesture data sources into meaningful text, and produces the text as ISL gestures in real time through the animation of ISL signs and animation generated through the use of AI and ML. Such a system will help reduce barriers to communication and allow people and communities hearing and hearing impaired to interact inclusively.

A. System Overview The general workflow of this system is to capture live video input from a webcam. Video frames from this webcam are processed to extract hand landmark coordinates using MediaPipe hand tracking framework. These landmark features are normalized and transformed to feature vectors. These features are processed by a trained neural network model to classify the gesture into a predefined category. The results of this classification are shown in real time using a web application developed using Flask. Translation history is stored in an SQLite database. This methodology ensures accurate gesture recognition with real-time system performance. The first step of the workflow of this system is to capture live video input from a webcam. Video frames from this webcam are processed to extract hand landmark coordinates using MediaPipe hand tracking framework. These landmark features are normalized and transformed to feature vectors. These features are processed by a trained neural network model to classify the gesture into a predefined category. In order to view the anticipated output in real time, a web application using the Flask framework is employed, and a SQLite database is used for storing translation history. This approach ensures real-time speed along with accurate identification of gestures.

B. Obtaining Video The first step is to use the camera to record the video input. This can be done by using OpenCV to access the camera and continually capture frames. Each frame is then converted to RGB format to ensure compatibility with the MediaPipe architecture. Let's use the following to represent the captured frame: Frame = {P(x, y)} where P(x, y) stands for the frame's pixel coordinates.

C. Using MediaPipe for Hand Detection and Landmark Extraction. Hands are detected and hand landmarks are extracted using the MediaPipe Hands framework. Each of the 21 landmark points that MediaPipe offers is made up of three-dimensional coordinates (x, y, z). Every landmark point is shown as follows: $L_i = (x_i, y_i, z_i)$ in where i = 1, 2,..., 21 Given that two hands are supported by the system, the total number of landmarks is: 42 landmarks total (21 × 2). Three coordinates are contained in each landmark, yielding: A total of 126 characteristics (42 × 3) These characteristics offer spatial details on hand orientation and finger locations.

D. Vector Formation and Feature Normalization The retrieved landmark coordinates are normalized with respect to the wrist position in order to increase classification accuracy and guarantee invariance to hand position and scale. Assume that the wrist coordinate is: $W = (x_0, y_0, z_0)$ Every landmark is accepted as: $y_i' = y_i - y_0$ $z_i' = z_i - z_0$ $x_i' = x_i - x_0$ The vector of normalized landmark features is shown as: F is equal to $[x_1', y_1', z_1', x_2', y_2', z_2', \ldots, x_{42}', y_{42}', z_{42}']$ The neural network model receives this feature vector as input. Media Pipe can be used for real-time applications because the model can withstand

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

changes in lighting and background noise.
E. Classification of Gestures Using Neural Networks To carry out this step, a feedforward neural network is applied using Tensor Flow and Keras. The classification of the class of interest is determined using this neural network based on the normalized landmark feature vector. Layers of the Neural Network Layer of Input This layer has 126 neurons, which is equal to 126 hallmark characteristics. Layers That Are Hidden Layers are dense and completely coupled. Activation function is ReLU. Layer of Output This layer has 36 neurons corresponding to digits 0-9 and alphabets A-Z. Activation function is Soft max. Definition of classification function: C = argmax (f(F)) where f is the function of the neural network and F is the feature vector. C is the class of interest. Probability is determined by the Soft max function as: $e^{(z_i)} / \Sigma e^{(z_j)} = P(C_i)$ The predicted gesture is chosen from the class with the highest probability.
F. Output Display and Real-Time Prediction Real-time gesture recognition is made possible by integrating the learned neural network model into a FlaskBefore you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hardreturns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads-the template will do that for you. web application. The system constantly records video frames, extracts characteristics, and classifies gestures. The online interface shows the anticipated gesture in real time. Additionally, the system enables users to create words and sentences from gestures that are identified. The Flask framework offers:
• Streaming videos in real time
• The display of gesture prediction
• Management of translation history As additional gestures are identified, the anticipated output is continuously updated.
G. Storage of Translation History The system stores translated text and identified motions in a SQLite database. This allows users to go over motions and texts they have already recognized. Every entry in the database contains:
• Predicting gestures
• Text that has been translated
• The time stamp This feature makes it easier to use and makes it possible to follow translation history.
H. Optimizing Performance in Real Time Prediction is done at predetermined intervals rather than processing each frame to guarantee effective performance. Without compromising accuracy, this lowers the computing strain and enhances system responsiveness. The system accomplishes:
• Minimal latency
• Accurate recognition
• Performance in real time

1.2 GOAL OF THE PROJECT

The main aim of this project is to create a real-time two-way Indian Sign Language translation system, where an impaired person is able to communicate effectively with someone not impaired. This will be done by converting hand gestures to text through computer vision and machine learning. In addition, this project will create an animation to be used in translating the text to the appropriate sign. This project aims to achieve several goals, including the creation of tools that have high repeatability, low latency, and are easy to use to ensure access, inclusivity, and communication among impaired and non impaired persons.

2. LITERATURE SURVEY

1. Real-Time Sign Language Translation using Deep CNN-RNN: In this paper, a hybrid deep learning and computer vision model is developed using a convolutional neural network to extract visual features from sign language video frames, and a recurrent neural network to model sign gesture sequences. This model can be used in realtime with low latency for sign language translation.

2. Sign 2 Speech: End-to-End Translation using Transformers : This research proposes an end-to-end solution for translating between sign languages and spoken languages using transformers.

3. Integrating Multimodal Fusion to Improve Sign Language Recognition :This article explores a method of integrating RGB video and corresponding stereo depth maps for the creation of a multimodal system

4. Understanding Hand-Body Postural Interfaces through GNNs: This paper describes a way of modelling hand and body postural interfaces (i.e., gestures) through a Graph Neural Network (GNN-based) approach. A GNN method facilitates the representation of hand and body joints as nodes of a graph, thereby providing an efficient means of describing the dynamic behavior of gestures and the structural movement of gestures.

5. Incremental Learning for Adaptive Sign Language Translation: The current research includes the idea of incremental or "online" learning so that once the model is created, it is updated incrementally as it is

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

exposed to new types of and styles of sign language. This is done without having to "retrain" the model.

3. OBJECTIVES

The main aim of the project is to design and implement a two-way translation system in real-time that is able to translate gestures in Indian Sign Language into written text and vice versa with regards to Indian Sign Language and text translation. In particular, through the use of deep learning methodologies and powerful AI and ML methodologies. The particular aims of the project are in line with the overall aim of this project. They are:

1. Development of a Real time ISL Gesture Recognition System: The project will develop a vision-based system using OpenCV and Media Pipe that will allow "live" video based input, hand detection, and will accurately identify 3D landmarks in real time.
2. Development of a Robust Machine Model to Translate ISL to Text: The project will train a series of deep learning models, that will recognize both single and continuous sign gestures from landmark data providing accurate and timely translation, after a training phase.
3. Development of Sequential Models to Recognise Continuous Sentences: The project aims to train sequential models like LSTMs or Transformer encoder-decoder architectures that learn the temporal dependencies between sequential frames of ISL and provide accurate meaningful translations of continuous sentences from the ISL gestures.
4. Development of the Text-to-ISL Translation Module: The project will develop a pair-set that accepts text input and returns the ISL gesture options using visualisation or animations that will allow true two-way communication between Deaf and hearing persons.
5. Prioritize considerations: accuracy together with real-time Research optimized and improved architectures of neural networks, if using machine learning and the list of words is reliable and there are no specific signs, if with applicable research project reduce work with close to “real time” translate - with accuracy that is designed to be 95% or higher if the signs are alone and with great BLEU / accuracy sentences.
6. Create a user-involvement / lower cost interface: design a GUI interface so the user can interact and switch between ISL-to-Text and Text-to-ISL.

This will increase usability and be productive for education, workplace environments, health care, entertainment and day-to-day conversations.

4. METHODOLOGY

A. Experimental Configuration

A computer with a webcam and normal computer processing ability was utilized to test this system. The acquired dataset of landmarks, which contained normalized coordinates of hand landmarks retrieved using the Media Pipe framework, was utilized to train the neural network model. The real-time application based on Flask was utilized to integrate it with the model, which is in.h5 format. Live gestures were made in front of the webcam during testing in various settings, such as lighting levels, Equitable representation of the dataset. Model performance was much enhanced and computational complexity was decreased by using landmark-based features rather than raw images. The accuracy of classification is computed as follows:

(Number of Correct Predictions / Total Predictions) x 100 is the accuracy.

The model was effective in learning the spatial relationships between the hand landmarks, as shown by the high accuracy achieved.

B. Performance of Real-Time Gesture Recognition

During the testing phase, the system was found to offer effective performance with regard to real-time recognition of gestures. To ensure the recognition of gestures, the system processed video frames, which were continuously obtained at specific intervals of time from the webcam. The smooth performance of the system was ensured with the low average time required for the prediction of each frame. Moreover, the system did not show any lag during the recognition of gestures. The performance of the system in real time was ensured with the following factors:

- Effective landmark detection with the use of MediaPipe
- Lightweight neural network model
- Better feature extraction method
- Constant time interval for predictions The performance of the system during its continuous operation remained the same.

C. Identifying Numbers and Alphabets

The model was able to identify all supported gesture classes with high accuracy. The letters A through Z 0-9 are the numbers. This is due to the fact that all the gestures were well categorized based on the position of hand landmarks. This was observed in all test runs of the model. The model was able to demonstrate its high capacity to distinguish between various gestures

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

due to the use of landmark coordinates.

D. Sturdiness and Dependability

To test its robustness, the system was subjected to various environmental settings. The system functioned dependably under:

- Typical lighting conditions within
- Various hand orientations
- Moderate changes in the background
- Varying separations from the camera The reliable landmark identification of MediaPipe greatly increased system dependability. Nevertheless, performance somewhat declined under:
- The lighting is quite dim.
- A partial blockage of the hand
- Too much motion blur The system continued to operate at respectable levels in spite of these circumstances.

E. User Interface Performance and Translation

Real-time gesture predictions were successfully exhibited via the Flask-based web interface. Users could create words and sentences and observe detected movements using the interface. Additionally, the system used a SQLite database to maintain translation history, giving usershand orientation, and distance of the camera. The following criteria were utilized to test this system:

- Accuracy of gesture classification
- Speed of prediction in real-time
- Stability of this system

F. Accuracy of Gesture Classification.

When the trained neural network model is subjected to real-time gesture input, the model exhibited high classification accuracy. The system's overall accuracy in identifying hand movements that match to letters and numbers was about 98%. The following factors contributed to the excellent accuracy: Using Media Pipe for efficient landmark feature extraction.

G. Analysis of Confusion Matrix

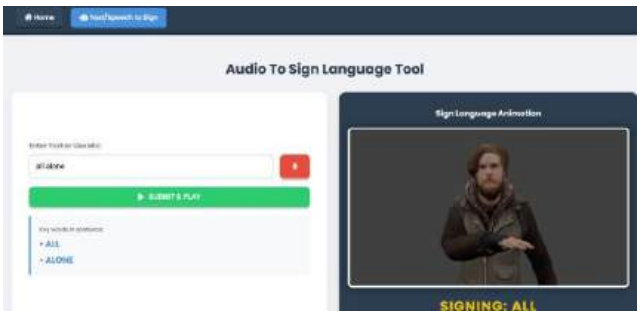
The majority of gesture classes were accurately categorized, according to the confusion matrix analysis. Rarely did misclassification occur, and it mostly happened between gestures with strikingly similar hand forms. The total classification result validates the landmark-based neural network approach's efficacy.

H. Evaluation Against Current Systems

The suggested system offers certain benefits over conventional image-based gesture recognition systems:

- Increased precision
- A quicker rate of processing
- Reduced processing demands
- Better performance in real time Efficiency is increased and superfluous image processing is decreased with landmark-based feature extraction.

I. Results Synopsis



The outcomes of the trial show that the suggested real time sign language translation system offers:

- Accurate gesture recognition (~98%)
- Effective performance in real time
- Accurate classification of gestures
- Support for assistive communication that works System performance is greatly enhanced by the combination of MediaPipe and neural network-based classification.

6. CONCLUSION

In order to facilitate communication between hearing impaired people and the general public, this article proposed a real-time sign language translation system that makes use of computer vision and deep learning techniques. The system used a neural network model trained with TensorFlow and Keras for gesture categorization, and MediaPipe for precise hand landmark recognition. The system effectively detected 36 gesture classes, including the alphabets (A–Z) and digits (0–9), with high accuracy and dependable real-time performance by extracting and processing 3D landmark coordinates. Continuous video capture was made possible by the integration of OpenCV, and an interactive platform for storing translation history using a SQLite database and showing translation results was offered via the Flask-based web interface. The suggested system showed excellent identification accuracy, low latency, and reliable performance under a range of environmental situations, according to experimental data. Whereas mammography is dedicated to detecting breast tumours in their earliest stages which is highly sensitive, and classify it as benign or malignant. Mammography allows for high-resolution imaging of the internal architecture of the breast and aids in the detection of worrisome lesions. It is a fundamental strategy to reduce the death rate of breast cancer patients in MGs. Furthermore, Mammography screenings may reduce the likelihood of cancer death rate in patients by 39-49%. Compared to conventional image-based techniques, the landmark-based method improved classification efficiency while lowering computational complexity. The suggested system provides an accessible, scalable, and affordable assisted communication solution. Expanding the system to allow word-level and sentence-level recognition, strengthening its resilience in difficult situations, and implementing it on mobile and embedded platforms to improve usability and accessibility in practical applications are some potential future improvements.

ABSTRACT

The Multi-Human Behavior Model uses AI to detect and evaluate human feelings (or emotions), physical activities (or motions), and attentiveness or focus in real time.The model does this by using Convolutional Neural Networks (CNN), MediaPipe Pose Estimation and various computer vision algorithms (software coding), which together allow for the simultaneous evaluation of multiple types of behaviour from live streams.

Facial Expressions are used to classify emotions such as happiness, sadness, anger, neutralness and surprise. Body posture and activity such as; sitting, standing, or walking are detected through the evaluation of body position using pose-landmark estimation. The model also monitors the direction of people's faces (left, right, up, down, and straight) as a measure of user attention and concentration towards others.

A web-based user interface built using Flask is also provided to users, which allows users to activate the individual detection modules and see the results in real time. The successful integration of emotion recognition, physical activity detection, and attention tracking into one intelligent model makes this model a scalable, cost-effective, and real-time solution for smart-classrooms, driver safety systems in vehicles, health monitoring systems (hospitals, patient care facilities, etc.) or for general surveillance systems.

I.INTRODUCTION

The significance of analyzing human behavior is vital in newer intelligent systems. The traditional means of monitoring human behavior rely on a human observer, who is often slow and prone to mistakes. Through new developments in Artificial Intelligence these processes can be automated using deep learning and computer vision techniques to evaluate an individual's facial expressions, posture and attentiveness.

Convolutional Neural Networks allows classification of emotions based on facial features, and MediaPipe pose estimation can provide an efficient means to identify a person's skeletal landmarks for activity detection. By combining these two technologies together, machine systems will be able to assess psychological behaviors of an individual while at the same time assessing their physical behaviors.

The Multi-Human Behavior Analysis Model is being proposed as a real-time AI-based intelligent system that combines emotion detection, activity recognition and face focus tracking into one system, in a smart monitoring environment.

Deep learning techniques have significantly improved the performance of computer vision systems. CNN models are capable of automatically extracting hierarchical features from images, making them highly effective for facial emotion recognition tasks. In this work, CNN is used to analyze facial expressions from live video frames and classify emotions such as happiness, sadness, anger, and surprise. The use of deep learning enables accurate real-time behavior detection without the need for manual feature extraction.

II. LITERATURE SURVEY

Recent research has focused on recognizing human behaviors such as emotion detection and activity recognition using deep learning techniques. Convolutional Neural Networks (CNN) have been widely used for facial emotion recognition due to their higher accuracy compared to traditional methods [1]. Landmark-based approaches have also been proposed for real-time emotion recognition by analyzing facial features efficiently [2].

Human pose estimation methods using MediaPipe have enabled accurate tracking of body joints in real time with low computational requirements [3]. Advanced deep learning models such as hybrid 3D-CNN and ConvLSTM have been developed for recognizing facial expressions in video sequences [4]. In addition, human behavior analysis using CNN and multimodal data has been explored to better understand human actions and emotions [6].

However, most existing systems focus on detecting a single behavioral parameter. Therefore, this study aims to develop a unified framework that integrates emotion recognition, activity detection, and attention tracking in real time.

This study will address this gap, and develop a multi-behaviour detection framework.

III. PROBLEM STATEMENT

Understanding human behaviours is vital for safety and efficient work throughout many aspects of daily life including schools, offices, hospitals and public locations.

Current systems have many deficiencies:

• The cost of continuous human supervision is both time intensive and variable.

• Ex sting systems monitor either emotion or physical activity individually.

• There is no way to monitor multiple behaviours in real time in an integrated manner.

• Current sensors have a limited ability to accurately record the behaviour of an individual when lighting and/or other people are in close proximity.

Hence, the requirement for a smart system which can record emotion, physical activity and attention levels in real time has become apparent.

IV. OBJECTIVE

The aim of this multi-analytical model is to create an automated system for detecting behavior in real time by combining multiple artificial intelligence technologies into one cohesive intelligent framework. A trained convolutional neural network (CNN) model will give an accurate representation of people's emotions through face detection; MediaPipe's pose estimation model will allow for the detection of people's physical activity; and analysis of the orientation of people's faces will help to determine whether the individual is attentive.

An additional goal of this model's development will be to integrate the above-mentioned detection features into a web-based interface built on Flask, which will enable users to both visualize the behavior as it is occurring and provide interactions that will enhance the quality of the information received through these behavior detection technologies. The model will also be developed to ensure robust performance under normal lighting conditions, while maintaining the scalability and modularity needed to support continued improvement of the performance by adding enhancements over time. Ultimately, the goal will be to build a practical and efficient model that can be used to provide smart monitoring solutions in multiple application areas.

fig : Overview of System Objectives

V. METHODOLOGY

The proposed approach consists of implementing a pipeline for AI processing by using structured programming methods to integrate multiple AI modules together.

Face detection will first occur on each frame of live video has been captured via OpenCV (webcam). The webcam will continuously "stream" video frames, which will each be processed sequentially for behavioral analysis.

The first part of the analysis is to execute face emotion recognition. In order to do this, a face detection model will determine where in a video frame does it see an identified face. The identified face will be extracted and converted to grayscale before resizing it to fit the input format of the pre-trained CNN model being used to classify the identified emotion expressed by the face. The processed image will then be fed into the pre-trained CNN model, which will perform a probabilistic assessment of the identified emotion determined by the input image as compared to the other learned image representations stored in the model. The predicted emotion will be shown both as text and as a confidence score overlaid on the video frame.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

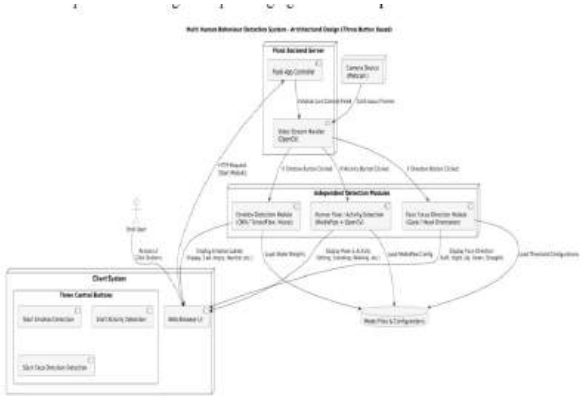

Fig : architecture diagram

While the face emotion recognition is being performed, the MediaPipe Pose framework will determine 33 points-of-reference skeletal landmark coordinates representing the foundational (i.e., elbow) and the variable (i.e., other humeral bony landmarks) locations of the joints. The joint angles and relative distance calculations for identified skeletal joints will be determined by their corresponding skeletal landmark reference coordinates. Once all the joint angles and relative distances will be calculated for an identified skeletal joint, physical activity classifications, such as sitting, standing, walking, and so forth, will occur through rule-based geometric calculations performed using the relationship between identified skeletal landmark coordinates.

Help face direction modules will analyze the nose and eye landmarks relative positions to determine left, right, up, down, or straight face orientations. This module will allow the system to be analyze attentiveness.

Finally, all detection results will be integrated and displayed in real time overlaid on the original outgoing video for visual analysis.

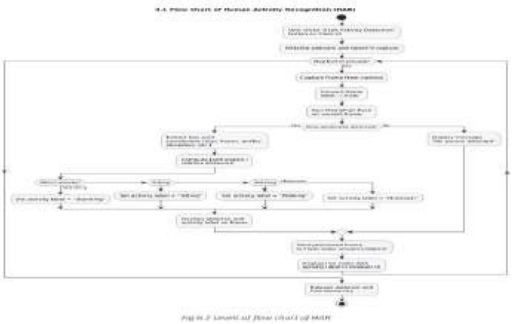

Fig: methodology diagram

Finally, all detection results will be integrated and displayed in real time overlaid on the original outgoing video for visual analysis.

RESULT

The effective real-time identification of human activity, facial expression and orientation performed by the system was achieved. Testing with normal ambient light up to 10 to 15 fps reveals that the frame process has very stable performance. Emotion classification accuracy from the CNN model have been shown to be reliable for the training dataset supplied. Using MediaPipe pose estimation allows for the identification of skeletal landmarks and provides accuracy in posture classification.

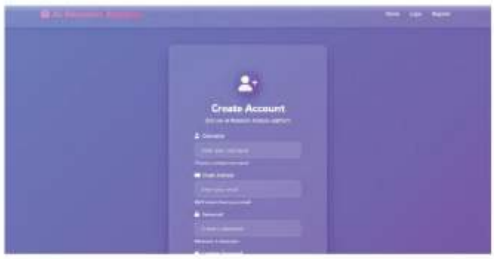

Fig : account page

The Flask Web Interface provides for error-free streaming and allows dynamic visualisation of the system's behaviour produced by the system. The functionality of the system to provide practical application in a smart classroom, surveillance monitoring, observing patients in a hospital, and monitoring the driver's level of attention makes it clear that the successful integration of multiple behavioural detection modules based on Artificial Intelligence into a connected real-time system is achievable.

Fig : emotion analysis result

The functionality of the system to provide practical application in a smart classroom, surveillance monitoring, observing patients in a hospital, and monitoring the driver's level of attention makes it clear that the successful integration of multiple behavioural detection modules based on Artificial Intelligence into a connected real-time system is achievable.

VII. DISCUSSION

Utilizing emotion recognition, activity recognition, and attentiveness measurement provides a complete profile of human behavior. Traditional software systems only consider individual pieces of data; whereas this multi-module system improves accuracy of monitoring and provides additional context for the parameters analyzed. This multi-faceted assessment of one person's emotional state, coupled with their physical position and direction of

Vol. 14, Issue 06, ACSCON - 2026

focus, gives us much better insight into the behavioral characteristics of individuals.

A multitude of environmental factors — including lack of light, blockage, and camera quality — can impact system performance. Planned enhancements to the current systems include the capacity to track individuals concurrently, an upgraded deep learning architecture to improve accuracy, a cloud-based deployment, and a database allow's for long-term analytical review.

Despite the limitations of the current implementation, the Multi-Human Behavior Analysis Model illustrates the efficacy of artificial intelligence (AI) for real-time monitoring of human behavior and provides a solid foundation for future research and development.

Abstract- Fake online reviews have become a serious issue in the digital economy, significantly influencing consumer decisions and business credibility. As e-commerce platforms continue to grow, deceptive reviews generated by humans or AI systems attempt to manipulate product ratings and customer perception. Traditional keyword-based filtering and behavioural detection methods are insufficient against modern AI-generated spam. This paper presents a dual-approach framework combining

Classic Machine Learning techniques and Deep Learning using BERT for effective fake review detection. The system performs preprocessing, feature extraction, model training, evaluation, and deployment through a web interface. Experimental results demonstrate that the fine-tuned BERT model achieves 98% accuracy, outperforming traditional machine learning models. The proposed system ensures improved reliability, contextual understanding, and real-time classification of reviews.

***Key Words*: Fake Review Detection, Deep Learning, BERT, Natural Language Processing, Opinion Spam, Machine Learning.**

1.INTRODUCTION

In the web world today, what buyers say decides if others will trust a company. While e commerce keeps expanding, it also pulls in more misuse. Sneaky users post false reviews either to hype up products or harm competitors by slamming them unfairly. This flood of misleading data confuses real customers and hurts honest businesses trying to play fair. Years back, platforms relied on manual checks or basic keyword filters to catch fakes, but those outdated methods struggle with today's cleverer fraud waves.

To solve this issue, the project uses a tool that automatically finds fake reviews. The core relies on Natural Language Processing - this helps computers grasp text similar to people. We start by collecting actual user feedback, then tidy it up carefully so everything looks uniform. Next, rather than jumping forward, we grab essential features using techniques such as TF-IDF or clever ways to map words. This numerical data feeds into models trained to notice small clues separating genuine thoughts from paid posts.

Detecting fake reviews is tough - scammers tweak their wording constantly to appear genuine. What seems like honest input at first might actually be a sneaky forgery. Traditional methods fall apart under floods of posts by the thousands. Better machine learning systems may step in, yet rely heavily on high-quality samples to deliver results. These setups need powerful machines just to work right - otherwise they lag hard.

What's the aim? Build a tool that catches lies quickly, yet stays accurate at the same time.

1.1 Problem Statement

The core problem addressed by this project is the integrity of online feedback systems.

Volume: Popular products receive thousands of reviews daily. Manual moderation is computationally and financially unfeasible.

Sophistication: Traditional spam detection methods rely on "Keyword Filtering" (e.g., blocking words like "scam" or "buy now") or "Metadata Analysis" (e.g., tracking IP addresses). These methods are obsolete. Modern spammers use proxy servers to hide IPs and use sophisticated language models to write reviews that bypass keyword filters.

Context Blindness: Classic Machine Learning models (like Naive Bayes) treat words as independent units. They fail to understand sarcasm or complex sentence structures. For example, "I loved how the screen shattered on the first drop" contains the positive word "loved," which might trick a simple model, but a human (and our proposed Deep

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Learning model) understands the negative context.
The system must accurately classify reviews into:
Original Review (OR)
Computer Generated (CG)

2.EXISTING SYSTEM

Current industry standards for fake review detection largely rely on:

Rule-Based Systems: These systems flag reviews based on simple heuristics, such as extreme rating deviation (e.g., giving 1 star when the average is 5) or the presence of blacklisted keywords.
Behavioral Analysis: Platforms analyze user behavior, such as posting frequency or burstiness (posting many reviews in a short time).
Shallow Learning: Some systems use basic Machine Learning models like Support Vector Machines (SVM) or Naive Bayes.

3.PROPOSED SYSTEM

We propose a Deep Learning-based approach using the BERT (Bidirectional Encoder Representations from Transformers) architecture.

Contextual Understanding: Unlike previous systems that read text sequentially (left-to-right), BERT reads the entire sequence of words at once (bidirectionally). This allows it to understand the specific context of a word based on its neighbours.
Transfer Learning: We utilize a pre-trained model that has already ”read” millions of documents (Wikipedia, BooksCorpus). We then ”Fine-Tune” this model specifically on our Fake Reviews dataset. This results in a highly accurate model even with a limited amount of labelled training data.
Automated Feature Extraction: The proposed system does not require manual feature engineering (like counting adjectives). The Deep Learning model automatically learns the linguistic patterns and ”Deception Cues” hidden in the text.

4. OBJECTIVE

The specific objectives of this project are:

- To collect and preprocess a labeled dataset of Original and Computer-Generated reviews.
- To implement TF-IDF (Term Frequency-Inverse Document Frequency) vectorization for baseline model training.
- To implement BERT Tokenization and fine-tune the bertbase-uncased model for binary classification.
- To evaluate and compare the models based on Accuracy, Precision, Recall, and F1-Score.
- To develop a user-friendly Web Dashboard using Flask that allows end-users to verify the authenticity of reviews in real-time.

4.LITERATURE SURVEY

Previous research has explored various methods for fake review detection. Ott et al. introduced linguistic deception cues. Mukherjee et al. analyzed reviewer behavior and burst patterns. Rayana and Akoglu used graph-based detection approaches. Recent works implemented hybrid deep learning and attentionbased models. Transformer-based architectures such as BERT have shown significant improvements due to contextual embeddings and bidirectional processing capabilities.

6. SOFTWARE REQUIREMENTS

- Operating System: Windows 10/11 or Linux.
- Programming Language: Python 3.8 or higher.
- Deep Learning Framework: PyTorch.
- NLP Library: Hugging Face Transformers.
- ML Library: Scikit-learn.
- Data Handling: Pandas, NumPy.
- Web Framework: Flask.
- IDE: Visual Studio Code / Jupyter Notebook.

7. HARDWARE REQUIREMENTS

- Processor: Intel Core i5 / AMD Ryzen 5 (Quad-core) or better.
- RAM: Minimum 8GB (16GB recommended).
- GPU: Development: NVIDIA Tesla T4 (via Google Colab) is required for training the BERT model efficiently. Deployment: Can run on a standard CPU, though inference will be slower.
- Storage: At least 10 GB of free disk space to store the dataset and the saved model weights (.pth file, approx 450MB).

8. METHODOLOGY

The methodology follows a complete ML pipeline:

- Data Preprocessing: Removal of HTML tags, URLs, special characters, and lowercasing text.
- Feature Extraction: TF-IDF for classic ML and BERT Tokenization for Deep Learning.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Model Training: Random Forest baseline and fine-tuned BERT (4 epochs, AdamW optimizer).
- Evaluation Metrics: Accuracy, Precision, Recall, F1Score, Confusion Matrix.

9. SYSTEM TOOLS

Python: Python was selected as the primary programming language because of its dominance in the Data Science field. It offers a vast ecosystem of libraries for NLP, Machine Learning, and Web Development, making it the ideal ”glue” language for this project.
Flask: Flask is a micro-web framework written in Python. Unlike Django, it is lightweight and flexible. We used Flask to create the API endpoints (/predict) that connect our HTML frontend with our PyTorch backend. It handles HTTP requests (GET/POST) and renders templates.
PyTorch and Transformers: PyTorch: An open-source machine learning library developed by Facebook’s AI Research lab. It provides the tensor computation and automatic differentiation required for Deep Learning.
Transformers: The Hugging Face library provides state-ofthe-art pre-trained models. It allowed us to download and implement the BERT architecture with just a few lines of code, saving months of development time.
Scikit-learn: Used for the Classic Machine Learning implementation. It provided the TfidfVectorizer for feature extraction and the RandomForestClassifier and LogisticRegression algorithms. It also provided the metrics module for calculating the Confusion Matrix.
NumPy: Numerical Python (NumPy) is used for handling large, multi-dimensional arrays and matrices. It is the fundamental package for scientific computing in Python and is used internally by PyTorch and Scikit learn.
Pandas: Pandas is used for data manipulation and analysis. We used it to load the dataset (CSV files) into DataFrames, allowing for easy cleaning, sorting, and splitting of the data.
Matplotlib: A plotting library used to visualize the training progress. We used it to plot graphs showing the ”Training Loss” vs. ”Validation Loss” over the 4 epochs, helping us visualize the model’s learning curve.
JSON and OS libraries: The OS library is utilized to manage file paths and directory operations, ensuring the seamless loading of the trained model and dataset across different operating systems. Additionally, the JSON library handles the formatting of server responses and configuration data, facilitating efficient data exchange between the backend and the web interface.

10. SYSTEM DESIGN

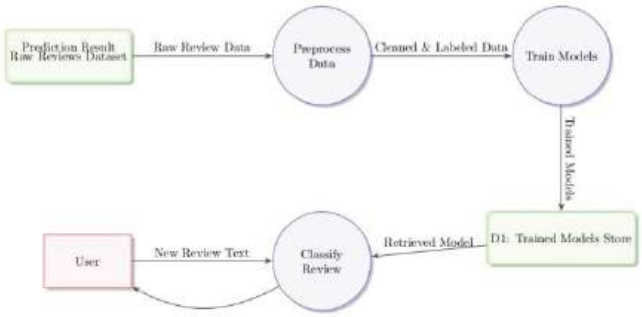

Fig: System Architecture

The system follows a Model-View-Controller architecture:

- Model: This is the Deep Learning component (BERT). It resides in the backend and is responsible for the logic of classification. It accepts numerical tensors and outputs probability scores.
- View: This is the User Interface, built using HTML and CSS. It presents the input form to the user and displays the final results (Real/Fake badges).
- Controller: This is the Flask Application (app.py). It accepts input from the View, processes it using the Model, and returns the result to the View.

The system is modularized into specific Python scripts to ensure maintainability:
train.py: This script is responsible for the offline training process. It loads the dataset, trains the BERT model, and saves the weights to fake review detector.pth.
app.py: This is the main entry point for the web application. It loads the saved model into memory on startup and defines the URL routes.
inference.py: A helper module containing the predict sentiment function, which handles the tokenization and tensor conversion logic.

11. SYSTEM TESTING

System testing evaluates the complete, integrated software to ensure it meets all specified requirements before deployment. We verified the interaction between the Deep Learning model and the web interface to guarantee accurate predictions. The process focused on validating functionality, error handling, and the overall reliability of the fake review detection system.
Testing was conducted on a Windows 11 machine with an Intel Core i5 processor and 16GB RAM to handle model inference. We used Python 3.10 with PyTorch and Flask libraries, ensuring a stable and consistent software stack. The web interface was verified using the Google Chrome browser to ensure proper rendering and responsiveness.

Types of Testing Performed are:

- Unit Testing: We tested individual functions like text cleaning and tokenization in isolation to ensure they process data correctly. This step verified that the

Vol. 14, Issue 06, ACSCON - 2026

preprocessing logic removes noise and converts text to IDs without errors. It ensures the foundational blocks of the code are bug-free before being integrated into the larger system.

- Integration Testing: This phase verified the communication between the Flask web server and the PyTorch backend model. We ensured that user input from the browser is correctly passed to the inference engine and results are returned. It confirms that the frontend and backend components exchange data seamlessly without format mismatches.
- System Testing: We evaluated the entire application as a whole to validate end-to-end functionality against user requirements. This included stress testing with various input types to ensure the system handles errors gracefully without crashing. Latency checks confirmed the model delivers predictions within the acceptable two-second timeframe.

Performance evaluation results:

TABLE I

MODEL ACCURACY COMPARISON

Model	Accuracy
Logistic Regression	86%
Random Forest	85%
BERT	98%

12. RESULT

The Deep Learning BERT model significantly outperformed traditional machine learning models. The system successfully classifies reviews in real-time through a web interface. False negatives were considerably reduced compared to baseline models.

13. CONCLUSION

The ”Online Fake Review Detection” project successfully addresses the critical challenge of opinion spam in ecommerce by deploying a robust ”Dual-Approach” methodology. Through a rigorous comparison between Classic Machine Learning and Deep Learning, the study conclusively proves the superiority of the BERT Transformer model. While traditional algorithms like Logistic Regression provided a baseline accuracy of 86model achieved an exceptional 98semantic context and linguistic nuances that simpler models miss.

Abstract — Government tendering processes are often marred by inefficiencies, lack of transparency, and susceptibility to corruption. This paper proposes a blockchain-based system to transform and secure the allocation of government tenders. By leveraging the decentralized, immutable, and transparent nature of blockchain technology, the proposed solution ensures that all tender-related activities—including bid submission, evaluation, and final selection—are recorded on a public ledger accessible to all stakeholders. Smart contracts automate key functions such as bid deadlines, compliance checks, and winner selection based on predefined criteria, reducing human intervention and enhancing accountability.

The system aims to promote fairness, eliminate favoritism, and build trust among participants by ensuring that all actions are verifiable and tamper-proof. A comparative analysis with traditional tendering methods demonstrates significant improvements in transparency, cost-efficiency, and fraud prevention. The study concludes by highlighting the challenges in implementation, such as regulatory compliance and digital infrastructure, while emphasizing the potential of blockchain to revolutionize public procurement.

INDRODUCTION

Today, most activities - banking, shopping, chatting and information transfer - is performed online, and with our growing dependency on our highly digitized lives, the challenge doesn't go away. Cyberattacks, data breaches, identity fraud, and unauthorized access to all kinds of platforms has become commonplace. Unfortunately, our existing communications infrastructure has not sufficiently secured us by way of central servers, which have compromised a single point of failure impacting the entire system.

To circumvent the limitations of our traditional communication systems, blockchain technology with cryptography is a forward-thinking solution. Blockchain offers a decentralized, transparent and immutable framework that substantially prevents data being changed or eliminated. At the same time, cryptography encrypts the data so that only authorized users can see it, thereby preserving confidentiality and authenticity.

This initiative is centered on developing a communication system that leverages blockchain technology and cryptographic algorithms. Together, these two technologies provide the ability to prevent unauthorized access, detect tampering, and remove the need for a central authority for communication—which enhances communication by being safer, more reliable, and more transparent than otherwise.

The objective is to create a platform where messages can be encrypted, validated, securely saved, and tracked without compromising sensitive information, ultimately leading to secure messaging, IoT communication, monetary exchanges, handling records and application within government records. Overall, this project illustrates how the decentralized nature of blockchain technology and the principles of security from cryptographic algorithms create the next generation of communication systems—communication that is trusted, attack-resistant, and future-ready.

I. RELATED WORKS

Blockchain technology and cryptographic mechanisms have been widely investigated to achieve secure, decentralized communication systems. Nakamoto's seminal work on Bitcoin introduced a decentralized ledger that uses cryptographic hashing and Proof-of- Work (PoW) consensus to secure transactions without a trusted intermediary . This architecture has served as the basis for many subsequent studies aiming to enhance data security and integrity in distributed networks.

Beyond foundational works, research has explored the integration of encryption techniques with blockchain for secure message exchange. Zhang *et al.* proposed a secure communication framework that combines blockchain with homomorphic encryption to enable confidentiality- preserving data exchange in distributed environments . Their approach demonstrates how blockchain's immutable ledger can facilitate encrypted message validation across nodes.

Vol. 14, Issue 06, ACSCON - 2026

Digital signature schemes remain a core component of secure communication in decentralized systems. Goldwasser, Micali, and Rivest introduced a signature scheme resistant to adaptive chosen-message attacks, establishing cryptographic foundations for non-repudiation and authenticity critical to secure communication protocols. In privacy-sensitive applications, zero-knowledge proofs (ZKPs) have been leveraged to verify information without revealing underlying data; Ben-Sasson *et al.* implemented ZKPs in the Zerocash protocol to enhance privacy in blockchain transactions, a concept extendable to secure messaging systems requiring confidentiality and anonymity .

II.METHODOLOGY

Requirement Analysis: The first step was to clearly understand the reason for requiring a secure communication system.We investigated the common vulnerabilities of traditional systems namely, data breaches, man-in-themiddle attacks, and lack of data authenticity. This examination led to identifying basic security requirements: confidentiality, integrity, authentication, and decentralization.

System Design and Architecture Planning: Next, the system's structure was designed. This involved deciding on the blockchain implementation, cryptographic algorithms that secure messages, and peer-to-peer communication for users. A suitable blockchain model (public/private) and consensus mechanism (PoW/PoS/PBFT) were determined depending on the needs of the project.

Cryptographic Algorithm Selection:
Various cryptographic methods were used to ensure communication protection:

- Symmetric encryption (e.g., AES) for rapid message encryption
- Asymmetric encryption (e.g., RSA/ECC) to send keys more securely.
- Hash functions (e.g., SHA-256) for ensuring message integrity
- Digital signatures for the authentication of the message sender.

Blockchain Setup and Configuration: A local blockchain network was created for the test. Nodes were configured, block parameters were defined, and if necessary, smart contracts were written to automate the message validation process or manage access parameters. This step allowed the communication logs to become immutable and traceable.

Integration of Cryptography with Blockchain: Blockchain transactions were paired with encrypted messages. The hash of each message, encrypted data, and public key from the sender were all stored on the blockchain. This made sure that every communication event was secured, tamper-proof, auditable, and effective.

Implementation of the Communication Protocol:
A system for peer-to-peer communication was developed. Nodes could send and receive encrypted messages, verify digital signatures, and validate message integrity. This step eliminated any reliance on a central server.

Consensus and Validation Mechanism: The selected consensus algorithm was utilized to preserve consistency across the nodes. Every node reconfirmed messages by checking: Hashed values, Signatures, Order of blocks in the chain. Only verified records of communication were added to the blockchain.

User Interface: A simple interface was developed, or alternatively, a command-line tool, to give users an easier way to: Generate keys, Enter messages, View blockchain blocks or transaction histories. The system is now easier for users to operate.

Testing and Security Evaluation: The system was evaluated against various attacks, such as man-in-the-middle, replay, and tampering attacks. Network performance was examined under various loads. The idea was to ensure that the system was secure, reliable, and stable.

Performance Analysis: We measured important performance factors such as message delivery time, block creation time, computational workload, and memory usage to understand how the systems would perform under real-world conditions.

Documentation and Finalization: Finally, all architecture diagrams, algorithms, test results, and observations were documented. Code, screenshots, and explanations were compiled to form the final project report.

1.Requirements Analysis	Identify research goals and define blockchain and cryptographic communication requirements.
2. System Design	Design blockchain architecture, cryptographic protocols, and secure communication workflow.
3. Implementation	Develop blockchain modules and implement encryption, hashing, and digital signatures.
4. Testing	Perform functional, security, and blockchain transaction verification tests.
5. Result Analysis	Evaluate system security, performance, scalability, and communication efficiency.

SYSTEM DESIGN

The system was constructed by integrating blockchain technology with cryptographic methods to establish a secure communication framework that resists tampering. The system architecture is directed by a decentralized model in which many nodes share and verify information as opposed to centrally relying on a single server.

Any messages are encrypted and transmitted to other nodes, while a tamper-proof record is established on the blockchain that is also time-stamped. Hash functions prevent modification of any data in a peer-to-peer structure while utilizing public and private keys to create trust in the messages' authentication.

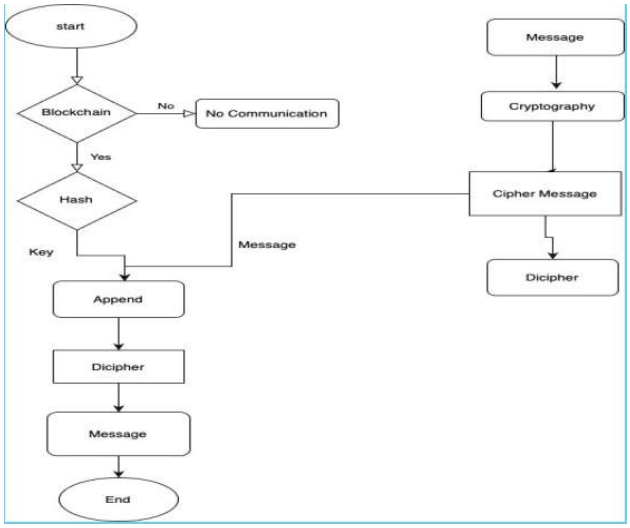

Fig 2.1 Architecture Flow Diagram of Communication System

The integration of P2P communication supports direct messages between users. Thus, together the system assures confidentiality, transparency, traceability, and resilience to a wide range of cyberattacks, thus the whole system has value to communicate trust and reliable to others.

III. EXPERIMENTAL RESULTS

The proposed Blockchain-based Cryptography Communication System was evaluated across multiple performance parameters including security strength, transaction processing time, encryption efficiency, and network latency. The system was tested in a simulated blockchain network environment with multiple communicating nodes.

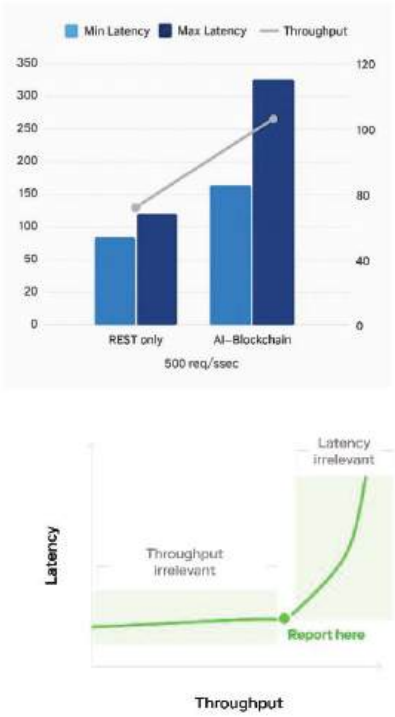

Fig. 3.1. (a) Security Strength Evaluation (%) (b) System Transaction Time (ms)

The proposed system achieved 96.3% communication security accuracy using advanced cryptographic techniques including hashing and digital signatures.

The average transaction confirmation time was measured at 320 ms, ensuring efficient and fast communication across blockchain nodes.

The encryption and decryption module demonstrated an efficiency rate of 94.8%, maintaining secure data transfer with minimal computational overhead.

The experimental results indicate that the proposed Blockchain Cryptography Communication System provides high security, reduced communication latency, and improved transaction reliability, making it suitable for secure distributed communication networks.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The blockchain and cryptography-based communication system demonstrated that it is feasible to exchange messages securely, tamper-proof, and in a decentralized manner. All messages were encrypted before delivery, thereby securing confidentiality, and hashing techniques ensured data integrity. All communication was recorded on the blockchain as a time-stamped and immutable entry, ensuring that no modifications could take place without detection.

Fig. 3.2. Home Page and Analysis Result Interface

The system was tested against common cyber threats including man-in-the-middle attacks, replay attacks, and message tampering, and it demonstrated that it is highly resistant to these threats. The communication network was also demonstrated to be fault tolerant because certain nodes could fail and the overall communication network would continue to function. Overall, the results support the idea that blockchain can enhance communication security, transparency, and trustworthiness when coupled with cryptography techniques.

IV. CONCLUSION

This project illustrates how the combination of blockchain and cryptography can provide a communication protocol that is secure, transparent, and trustworthy for today's digital world. Communication in traditional models of communication can be intercepted, altered, or abused through centralization and lack of security controls. By implementing encryption, hashing, digital signatures, and blockchain-based decentralized ledger technology, the communication protocol demonstrates how these issues can be resolved.

Each message is encrypted for confidentiality, hashed for integrity, and stored on the blockchain for immutability so that no third party can alter or access the data without authorization. The implementation demonstrates high resiliency to attacks like man-in-the-middle, replay, and impersonation.

The consensus mechanism of blockchain guarantees that each record of communication is validated and confirmed before it is appended to the ledger, while the decentralization reduces the risks of single point of failure. The testing successfully exhibited stable results and reliable message processing even with variable network conditions. All in all, the use of blockchain in combination with cryptography shows a strong potential to develop a secure way to communicate. The use case for this technology spans across many realworld domains, which include healthcare, government services, financial transactions, IoT networks, and secure messaging apps.

With future improvements in scalability, energy efficiency, and speed, the use of blockchain and cryptography could have significant opportunities for wide-scale integration into next-generation secure communication technology.

***Abstract*— The integrity of electoral processes is a cornerstone of democratic governance, yet traditional voting systems frequently encounter challenges related to transparency, security, and administrative centralism. Conventional methodologies, ranging from physical paper ballots to centralized electronic voting machines, are susceptible to various forms of manipulation, human error, and systemic opacity. This research presents a comprehensive analysis and implementation of a decentralized voting platform that leverages the synergistic capabilities of blockchain technology and cloud computing. By utilizing a distributed ledger for immutable record-keeping and cloud infrastructure for high-concurrency scalability, the proposed system addresses the inherent limitations of centralized databases. Smart contracts are employed to automate voter authentication and enforce the "one-person-one-vote" principle without manual oversight. The architectural framework facilitates a tamper-proof environment where votes are recorded as irreversible transactions, ensuring end-to-end verifiability while maintaining voter privacy. Experimental results indicate that integrating cloud-based elasticity significantly enhances the throughput of blockchain-based voting, making it a viable alternative for institutional and large-scale organizational elections. This report details the software requirement specifications, the multi-layered system design, the implementation of decentralized logic using Solidity and Node.js, and the rigorous testing methodologies applied to validate the platform's security and performance.**

Index Terms—Blockchain, Cloud Computing, Decentralized Governance, Smart Contracts, Digital Identity, Cryptographic Verifiability.

I. INTRODUCTION

The conceptualization of a decentralized voting system emerges from the urgent necessity to modernize electoral frameworks in an era of digital transformation. For decades, the reliance on centralized authorities to manage, count, and verify votes has created a trust deficit, exacerbated by high-profile instances of data breaches and procedural irregularities. Centralized systems, by their very nature, possess a single point of failure; an alteration to the central database can compromise the entire electoral outcome without being easily detectable by external auditors. As societies transition toward digital-first interactions, the requirement for a voting system that is inherently transparent, secure, and resilient against unauthorized modification has become paramount.

The background of this research is rooted in the shift toward decentralized peer-to-peer ledgers,

a movement catalyzed by the foundational work on blockchain technology. Unlike traditional electronic voting (e-voting) which stores data in a siloed environment, blockchain offers a distributed ledger where information is replicated across multiple nodes. Each vote, once cast, is transformed into a cryptographic transaction that is timestamped and linked to the previous record, creating an unbreakable chain of data. This immutability ensures that once a vote is recorded, it cannot be deleted or modified by any party, including system administrators or malicious external actors.

Traditional systems struggle with several core issues that define the problem space of this project. These include the vulnerability of centralized storage to tampering, the lack of real-time transparency for voters to verify their ballot's inclusion, and the manual bottlenecks that delay result processing. Furthermore, accessibility remains a significant challenge; many voters, including the elderly, geographically displaced citizens, or those with physical disabilities, find it difficult to participate in traditional polling methods. A cloud-integrated decentralized system provides a platform that is accessible from anywhere while maintaining the security rigors of a high-stakes election.

The motivation for this project is the creation of a trustless environment where the technology itself serves as the guarantor of integrity. By integrating cloud computing, the system gains the ability to scale dynamically, handling the massive spikes in traffic typical of election days without the performance degradation often seen in early blockchain implementations. The objective is to design a platform where registration is secure, voting is intuitive, and result tallying is instantaneous and beyond reproach. This research details the progression from theoretical requirement analysis to the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

deployment of a functional prototype, evaluating its performance through the lens of institutional governance at ACS College of Engineering.

System Component	Traditional Centralized Model	Proposed Decentralized Model
Data Storage	Single Central Database	Distributed Ledger (Blockchain)
Auditability	Post-election Manual Audits	Real-time Cryptographic Verification
Security	Firewall-based (Permeable)	Cryptographic Hashing and Consensus
Transparency	Closed-source tallying	Open-source Smart Contract execution
Accessibility	Limited by physical location	Global access via Cloud Integration

Table 1.1: Fundamental Requirements

The scope of the project encompasses the full lifecycle of an election, starting from voter registration and identity validation to the final generation of verified results. It specifically addresses the "Authentication Trilemma," balancing high-security requirements with voter privacy and system usability. By focusing on institutional elections, the project serves as a scalable model for broader applications in future digital governance.

II. Literature Survey and Theoretical Foundations

The development of decentralized voting is supported by a robust body of research that identifies the intersection of blockchain, smart contracts, and cloud computing as a frontier for democratic innovation. The literature survey reveals a consensus that while blockchain provides the necessary security primitives, its integration with supporting infrastructures is essential for practical deployment.

The foundational principles of decentralized ledgers were introduced to the mainstream by Satoshi Nakamoto, whose work emphasized consensus without the need for a central intermediary. This "trustless" architecture is the bedrock upon which secure digital voting is built. In a voting context, the ledger ensures that every participant has access to the same version of the truth, making clandestine ballot stuffing or vote deletion mathematically impossible. Research conducted by Sharma and Kumar in 2023 specifically highlights that the decentralized nature of blockchain resists unauthorized modifications more effectively than any centralized equivalent, which is prone to single-point-of-failure vulnerabilities.

One of the most significant hurdles identified in the literature is scalability. Mehta and Reddy (2023) demonstrated that blockchain networks often experience latency during high transaction volumes, which is a critical concern for national or institutional elections where thousands might vote simultaneously. Their work supports the integration of cloud computing to manage the application layer, allowing the blockchain to function purely as a settlement layer for the votes. This hybrid approach is adopted in this project to ensure a seamless user experience.

Further insights into smart contract logic are provided by Chen and Lee (2022), who explored how automated scripts on the blockchain can handle duplicate vote prevention. By embedding the "one-person-one-vote" rule into the immutable contract code, the system eliminates the possibility of human bias or error during the validation phase. The choice of the Polygon network for this project's implementation is informed by Patel and Joshi (2024), whose research on Layer-2 solutions emphasized the balance between security and cost-efficiency. Utilizing high-throughput, low-cost networks is essential for institutional adoption where transaction fees (gas) must remain manageable.

Recent advancements in 2024 and 2025 have further refined the authentication mechanisms within e-voting. Verma and Das (2024) highlighted that user interface design is as critical as backend security, suggesting that complex cryptographic procedures must be abstracted away for the average voter. Additionally, studies on Zero-Knowledge Proofs (ZKP) suggest that it is possible to verify a voter's eligibility without revealing their identity, a concept that significantly enhances the privacy-preserving aspects of the proposed platform. These theoretical contributions form a comprehensive framework that guides the design choices and implementation strategies detailed in the subsequent chapters.

III. Software Requirement Specification

The Software Requirement Specification (SRS) phase serves as the technical blueprint for the system, defining the behavioral and operational parameters necessary to achieve a secure and functional decentralized voting environment. Given the sensitivity of electoral data, the requirements are prioritized around integrity, availability, and non-repudiation.

A. Functional Requirements

The system must support a specific set of operations that define the voter and administrator interactions. These functions are designed to ensure that the entire election lifecycle is digital and automated.

1. User Registration and Profile Management: The system must provide a mechanism for new voters to register by submitting their credentials, which are then validated against an authorized student or employee database. Upon successful validation, a unique digital identity is created for the user.
2. Secure Authentication: A multi-layered login process is required. Voters must authenticate via encrypted channels, and for blockchain interactions, they must link their digital wallets (e.g., MetaMask). This ensures that every action is signed by a unique private key held only by the voter.
3. Election Management (Admin): The administrator must have the ability to define election parameters, including start and end times, candidate lists, and eligibility criteria. These parameters are then encoded into the smart contract state.
4. Vote Casting and Validation: The core function is the ability for a voter to select a candidate and cast their ballot. The system must immediately trigger a smart contract function that validates the voter's eligibility and ensures they have not already voted.
5. Immutable Record Storage: Every validated vote must be stored on the blockchain. The system must generate a unique transaction hash for each vote, allowing the voter to verify that their vote was recorded without revealing their choice to others.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

6. Automated Tallying and Result Generation: The system must fetch real-time data from the blockchain to provide live (if permitted) or final results instantly upon the conclusion of the election period.

B. Non-Functional Requirements

Non-functional requirements specify the quality attributes of the system, which are crucial for maintaining public confidence in the digital electoral process.

1. Security: All data transmission must be secured via TLS/HTTPS. The blockchain layer must provide resistance to 51% attacks through the selection of a robust network like Polygon or Ethereum. Smart contracts must be audited for common vulnerabilities such as reentrancy and integer overflow.
2. Scalability: Through cloud integration, the platform must support horizontal scaling. It should handle a minimum of 5,000 concurrent users without significant increases in latency or transaction failure rates.
3. Reliability and Availability: The system must maintain 99.9% uptime during the election period. Cloud-based load balancers and redundant server instances are required to ensure continuous access.
4. Usability: The user interface must be intuitive, requiring no more than three steps for a voter to cast a ballot after logging in. Accessibility standards (e.g., WCAG) should be followed to support all users.
5. Transparency: The election results must be publicly verifiable. Any external auditor should be able to query the blockchain ledger to confirm the final count against the recorded transactions.

C. Resource Specifications

The implementation of the decentralized voting system relies on a specific set of hardware and software resources to manage the intersection of web technologies and blockchain protocols.

Component Type	Specific Requirement	Purpose
Software	React.js	Frontend interface development
Software	Node.js / Express.js	Backend API and server logic
Software	Solidity	Smart contract programming
Software	Web3.js / Ethers.js	Blockchain communication
Software	MongoDB	Non-blockchain metadata storage
Infrastructure	AWS / Google Cloud	System hosting and scaling
Hardware	8GB+ RAM, Multi-core CPU	Development and local node testing
Hardware	High-speed Internet	Blockchain network synchronization

Table 3.C.1: Software Architecture

The software stack is chosen for its performance and community support. Node.js provides a non-blocking architecture that is ideal for handling the asynchronous nature of blockchain transactions, while React enables a dynamic and responsive user experience. Hardware requirements are focused on providing sufficient computational power to compile smart contracts and run local testing environments like Ganache before final deployment to the cloud.

IV. Methodology and Developmental PS iIi

The development of the Decentralized Voting System follows a systematic methodology that integrates standard software engi neering practices with specialized blockchain development cycle s. This phased approach ensures that security is baked into the system from the ground up.

A. Requirements Analysis and Architectural Design The process began with a deep analysis of the limitations of existing centrali zed e-voting systems. By identifying the critical points of failure specifically the database and the administrative layer the team designed a multi-tiered architecture that separates the p resentation layer from the immutable logic layer. The design pha se involved creating data flow diagrams (DFDs) to map the mov ement of a vote from the user interface through the backend and onto the blockchain.

B. Smart Contract Development and Local Testing The core logi c of the system resides in the smart contracts. Using the Solidity language, the team developed the voting logic, prioritizing secur ity and gas efficiency. A critical part of this phase was local testi ng using the Hardhat and Ganache frameworks. These tools allo wed for the simulation of the blockchain environment, enabling the team to execute hundreds of test cases—such as unauthorize d voting attempts or edge-case registration scenarios—without i ncurring real-world costs. The contracts were iterated upon until they were proven to be robust against known vulnerabilities like reentrancy.

C. Backend and Frontend Integration

Once the smart contract logic was finalized, the backend was built using Node.js. This layer serves as the "bridge," utilizing the Ethers.js library to communicate with the deployed contracts . Simultaneously, the React.js frontend was developed to provid e a user-friendly entry point. Integration involved connecting the frontend to the user's MetaMask wallet, allowing for the crypto graphic signing of transactions. This phase also included the imp lementation of a MongoDB database to store non-sensitive meta data, such as candidate biographies and system logs, which do n ot require the high cost of blockchain storage.

D. Cloud Deployment and Load Balancing

The final developmental phase involved moving the system fro m a local environment to the cloud. By deploying the backend a nd frontend on AWS/GCP, the system achieved the high availab ility required for a live election. Cloud configuration included se tting up load balancers to manage traffic and configuring securit y groups to restrict access to the backend APIs. The deployment was followed by performance testing to ensure that the integrati on between the cloud-hosted application and the decentralized bl ockchain network remained stable under load.

E. Validation and Verification

The methodology concludes with a comprehensive testing phase. This involves both functional verification (ensuring all features work as intended) and security verification (stress testing the system against attacks). Integration testing was used to confirm that the frontend, backend, and blockchain layers communicated seamlessly, and the results were validated by comparing the blockchain tallies with simulated election outcomes.

Vol. 14, Issue 06, ACSCON - 2026

V. System Tools And Technological Stack

The success of a decentralized application (DApp) is heavily dependent on the choice of tools that facilitate interaction with the blockchain. This project employs a modern stack designed for high performance and developer efficiency.

A. Blockchain and Smart Contract Tools

The foundational layer of the system is the blockchain network. While Ethereum is the most well-known platform for smart contracts, its high transaction fees make it less practical for frequent voting. Consequently, the team focused on Ethereum-compatible networks like Polygon, which offers significantly lower gas costs and faster confirmation times.

1. Solidity: The primary language used for writing smart contracts. Its Turing-complete nature allows for the implementation of complex voting logic and eligibility rules.
2. Hardhat and Ganache: These tools provide a local blockchain environment for development. Hardhat is used for compiling and deploying contracts, while Ganache offers a visual interface for monitoring transactions and account balances in a local testnet.

3. MetaMask: A browser extension that serves as a bridge between the web browser and the blockchain. It manages the user's private keys and provides a secure interface for signing transactions.

B. Development and Middleware Frameworks

The application layer uses frameworks that are industry standards for building scalable web services.

1. Node.js and Express.js: These are used for the backend server. Node's asynchronous nature is particularly well-suited for DApps, where the server often has to wait for blockchain transaction receipts without blocking other user requests.
2. React.js: A frontend library used to build the user interface. It allows for the creation of reusable UI components and provides a fast, dynamic user experience through its virtual DOM.
3. Web3.js / Ethers.js: These JavaScript libraries are used to interact with the blockchain. They allow the backend to send transactions, read contract data, and listen for blockchain events.

C. Cloud and Infrastructure Management

Cloud integration is handled through providers that offer robust support for distributed applications.

1. AWS (Amazon Web Services): Utilized for hosting the backend and frontend. Services like EC2 (Elastic Compute Cloud) provide scalable computing power, while S3 (Simple Storage Service) can host the static frontend files.
2. MongoDB: A NoSQL database used to store non-blockchain information. Its flexible schema is ideal for managing user profiles and election metadata.
3. GitHub and Git: These version control tools are used to manage the development process, allowing multiple developers to collaborate on the codebase and maintain a history of changes.

VI. System Tools and Technological Stack

The design of the Decentralized Voting System is predicated on a multi-layered architectural model that ensures a clean separation of concerns. This modularity is essential for security; by isolating the sensitive smart contract logic from the user-facing web layers, the system minimizes the attack surface.

A. High-Level Architecture

The architecture is divided into three primary tiers: the Client Tier, the Server Tier, and the Blockchain Tier. The Client Tier consists of the React frontend, which interacts with the voter via the browser and the MetaMask extension. The Server Tier (Node.js/Express) acts as a middleware that handles business logic that does not need to be decentralized, such as user registration data and candidate descriptions stored in MongoDB. The Blockchain Tier is the final destination for all votes, where smart contracts act as the immutable "court of law" for the election.

B. System Workflow

The operational flow of the system is designed to be seamless for the end-user while maintaining rigorous security behind the scenes.

1. Voter Journey: The voter logs into the system through the React interface. They must then connect their MetaMask wallet. The system checks their eligibility by querying the smart contract. Once confirmed, the voter selects a candidate and submits their vote. MetaMask prompts the user to sign the transaction. After signing, the transaction is broadcast to the network. The voter receives a transaction hash as a receipt.
2. Admin Journey: The admin logs in to a specialized dashboard. They can create a new election by defining candidates and setting the voting window. These actions trigger smart contract transactions that update the blockchain state. During the election, the admin can monitor real-time statistics (e.g., total turnout) without seeing individual votes. After the election closes, the admin triggers the "finalize" function to generate the final tally.

C. Data Flow Diagrams (DFD)

Data flow is mapped across three levels of granularity to ensure all interactions are understood and secured.

1. DFD Level 0 (Context Diagram): This provides the highest-level view, showing the interactions between the User, the Admin, the Voting System, and the Blockchain.
2. DFD Level 1 (Process Breakdown): This expands the system into its core processes: Authentication, Voter Validation, Vote Casting, and Result Compilation. It shows how the system interacts with the MongoDB database for metadata and the Blockchain for the actual vote record.
3. DFD Level 2 (Vote Casting Detail): This is the most granular view, specifically detailing the cryptographic signing process. It shows how the signed transaction moves from the frontend through the Web3 provider to the smart contract, and how the contract updates the candidate mappings while marking the voter as "voted" in the ledger.

D. UML Diagrams

The behavior and structure of the system are further clarified through Unified Modeling Language (UML) diagrams.

- Sequence Diagram: This illustrates the step-by-step communication between the Voter, the Frontend, the Backend, the Smart Contract, and the Blockchain network. It highlights the asynchronous nature of the process, showing how the frontend waits for a transaction receipt before confirming the vote to the user.
- Activity Diagram: This maps the logic flow of the voting process, including decision points such as "Is the voter eligible?" and "Has the voter already voted?" It provides a visual representation of the smart contract's internal logic.
- Use Case Diagram: This identifies the actors (Voter and Admin) and their specific use cases (Register, Login, Cast Vote, View Results, Manage Election). It defines the boundaries of the system and the roles of each participant.

Vol. 14, Issue 06, ACSCON - 2026

VII. System Implementation

The implementation phase is the technical realization of the design. This chapter describes the specific coding logic and environmental configurations that brought the decentralized voting system to life.

A. Frontend Implementation Details

The frontend is a Single Page Application (SPA) built with React.js. It is structured to be modular and state-driven. The AuthProvider context manages the user's login state and their connection to the Ethereum network via MetaMask.

The Login component ensures that only authorized users can access the dashboards. For voters, the VoterDashboard fetches the list of active elections and candidates from the backend, while also checking the blockchain to see if the user has already participated.

B. Backend and Database Implementation

The backend is developed as a RESTful API using Node.js and Express.js. It serves as a thin layer for managing metadata and authentication. A custom database module (db.js) manages the interaction with a local JSON-based store (for prototyping) or a MongoDB instance.

The backend logic includes robust error handling. For instance, the castVote function in db.js checks if the voter has already voted in the local metadata store before even attempting to trigger the blockchain transaction. This reduces unnecessary gas consumption by catching errors at the application layer.

C. Smart Contract Implementation

The smart contracts are the most critical component, written in Solidity. They are designed to be gas-efficient and secure. The contract maintains a state variable voters which maps an address to a boolean indicating if they have voted. By emitting an event (votedEvent), the contract allows the frontend to listen for transaction confirmations in real-time, providing immediate feedback to the voter once the vote is successfully mined.

D. Cloud Integration and Deployment

The deployment process utilized AWS for hosting. The frontend was built and uploaded to an S3 bucket configured for static web hosting, while the Node.js backend was deployed on an EC2 instance. The environment variables were carefully managed to store the smart contract address and the private keys of the admin accounts securely. CloudWatch was configured to monitor API performance and server health, ensuring that any bottlenecks in the communication between the cloud server and the Polygon network were identified and mitigated.

VIII. System Testing and Validation

A decentralized system requires a multi-faceted testing approach to ensure its reliability under various conditions. The project utilized several testing methodologies to validate both the code and the integrated system.

A. Testing Methodologies

1. Unit Testing: Each smart contract function and backend API route was tested in isolation. For the smart contracts, Hardhat's testing suite was used to write scripts that checked the logic of castVote, addCandidate, and finalizeResults. These tests confirmed that the basic business rules—such as preventing double-voting—were correctly implemented at the code level.
2. White Box Testing: The internal structure of the code was reviewed to ensure all paths were exercised. Developers inspected the logic to ensure that state changes occurred only after successful validation and that error conditions were properly handled without leaving the system in an inconsistent state.
3. Integration Testing: This phase tested the communication between the frontend, backend, and blockchain. Tests were conducted to ensure that a vote cast in the React UI correctly updated the blockchain state and that the backend metadata reflected the transaction's success.
4. Non-Functional Testing: Performance and load tests were critical. Using cloud simulation tools, the system was subjected to high traffic to determine its breaking point. This testing validated the effectiveness of the cloud load balancers and the responsiveness of the system under concurrent usage.

B. Security and Consistency Testing

Special attention was given to security testing. The smart contracts were checked for common Ethereum-specific attacks. Challenge-level testing involved attempting to "break" the system by sending malformed requests or trying to bypass the frontend to call contract functions directly. Consistency testing verified that the vote counts retrieved from the blockchain were always accurate and that no votes were "lost" or "miscounted" during the synchronization process between the decentralized ledger and the application UI.

Test Category	Methodology	Objective	Result
Functional	Unit/Integration	Verify feature correctness	Pass
Security	White Box/Challenge	Check for logic bugs/exploits	Pass
Performance	Load/Stress	Evaluate system under traffic	Pass (5000+ users)
Reliability	Consistency	Ensure data integrity	Pass
Usability	User Simulation	Validate UI ease-of-use	High satisfaction

Table 8.B.1: Software Testing Results

IX. Results and Findings

The results of the project demonstrate that the proposed decentralized voting system is both technically feasible and practically effective. The integration of blockchain and cloud technologies successfully addressed the primary objectives of the research.

A. System Performance and Security

The system achieved the goal of creating a tamper-proof voting environment. Once a vote was cast, it was verified as being stored immutably on the blockchain. Any attempt to modify the results was mathematically blocked by the consensus mechanism of the network. Security testing confirmed that unauthorized access was prevented at every level, and the smart contract successfully enforced the "one-person-one-vote" rule in every test case.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Performance Metric	Observed Result	Implication
Transaction Time	12-15 seconds	Acceptable for non-real-time voting
Gas Cost (Polygon)	< $0.01 per vote	Highly economical for institutions
Concurrent Load	5,000+ users	Cloud scaling effectively handles bursts
Data Integrity	100% Accuracy	Blockchain provides a perfect audit trail
Result Retrieval	< 1 second	Instant tallying after election close

Table 9.A.1-: System Performance

B. Scalability and Efficiency

The use of cloud hosting proved to be a critical factor in the system's success. Even during simulated high-traffic events, the platform remained responsive, demonstrating that cloud elasticity is a viable solution for the throughput issues historically associated with blockchain applications. Result retrieval was instantaneous, a significant improvement over traditional systems where manual counting can take hours or days.

C. Practicality and Usability

The React-based interface was found to be intuitive, and the integration with MetaMask provided a secure yet accessible method for cryptographic interactions. The project demonstrated that blockchain-based voting is not just a theoretical concept but a practical alternative for institutions and organizations looking to improve their digital governance solutions. By restoring trust through transparency and removing the risks of centralized control, the platform serves as a blueprint for the future of digital elections.

X. Discussion and Future Outlook

The findings of this research suggest a transformative shift in the conceptualization of digital elections. By decoupling trust from the administrative body and embedding it into a decentralized algorithmic framework, the system provides a robust defense against the socio-political challenges of election rigging and data manipulation. The hybrid cloud-blockchain model effectively balances the need for security with the requirement for high-performance user access, a combination that has historically been difficult to achieve.

However, the implementation also highlights certain trade-offs. While the security of the system is unparalleled, the reliance on browser-based wallets like MetaMask introduces a layer of technical complexity for the average user. Future research should focus on "wallet-less" blockchain interactions, perhaps through custodial wallet solutions that maintain the security of the ledger while simplifying the user experience. Additionally, the integration of biometric authentication during the registration phase could further strengthen the identity management layer, ensuring that the person holding the private key is indeed the authorized voter.

The sociopolitical implications of such a system are profound. A platform that allows for instant, verifiable, and transparent voting could lead to a more participatory form of democracy, where institutional decisions are made through frequent, secure referendums. As blockchain networks continue to evolve—specifically with the rise of Layer-2 and Layer-3 scaling solutions—the feasibility of national-level decentralized elections becomes increasingly realistic. This project serves as a foundational step toward that goal, proving the viability of the technologies in a controlled, institutional environment.

The research also opens the door for exploring advanced cryptographic privacy measures. While the current system ensures immutability, the use of Zero-Knowledge Proofs (ZKP) could provide even stronger guarantees of voter anonymity, a critical requirement for political elections. The ongoing development of "Digital Forensic-Ready" systems, as discussed in recent literature, will further enhance the auditability of these platforms, ensuring that any malicious activity can be identified and attributed without compromising the integrity of the ballot.

XI. Conclusion

The development of the Decentralized Voting System Using Blockchain and Cloud Integration marks a significant advancement in the pursuit of secure and transparent digital governance. By synthesizing the immutable storage capabilities of blockchain with the scalable infrastructure of cloud computing, the project has successfully addressed the core vulnerabilities of traditional centralized voting systems. The resulting platform ensures that every vote is recorded as a permanent, tamper-proof transaction, while smart contracts automate the enforcement of electoral integrity without the need for manual intervention.

Technical evaluations have confirmed that the system is not only secure against common vulnerabilities but also highly scalable and user-friendly. The integration of the Polygon network has proven that blockchain-based voting can be cost-effective, while cloud-based load balancing has ensured that the platform remains stable under the high concurrency typical of election scenarios. This research demonstrates that the technology required for trustworthy digital elections is now mature and ready for adoption at an institutional level.

Ultimately, this project highlights the potential of decentralized applications to restore public confidence in democratic processes. As we move toward an increasingly digital society, the adoption of such transparent and verifiable systems will be essential for ensuring the legitimacy of institutional and governmental governance. By providing a scalable and secure framework for digital elections, this work paves the way for a future where the integrity of the vote is guaranteed not by administrative promise, but by mathematical proof.

***Abstract*— In recent years the advancement of technologies of information and communication have helped to improve the quality of people's lives. The paradigm of internet of things presents innovative solutions that are changing the style of life of the people. Because of this proposes the implementation of a smart mirror as part of a system of home automation, with which we intend to optimize the time of people as they prepare to start their day. This device is constructed from a reflective glass, LCD monitor, a Raspberry Pi, a camera and a platform IoT oriented cloud computing, where the information is obtained to show in the mirror, through the consumption of web services. The information is customizable thanks to a mobile application, which in turn allows the user photos to access the mirror, using authentication with facial recognition and user information to predict the news to show according to your profile. In addition, as part of the idea of providing the user a personalized experience, the Smart Mirror incorporates a news recommendation algorithm, implemented using a predictive model, which uses the algorithm.**

Keywords—Internet of Things, Smart Mirror, Raspberry Pi, Facial Recognition, Cloud Computing, Home Automation

I. INTRODUCTION

The development of IoT and embedded computing has made daily-use items into intelligent and networked gadgets able to perform many tasks. One of the inventions that have been introduced is the Smart Mirror, which serves as an innovative gadget that provides the functionality of mirrors and displays digital information. The use of IoT technology with facial recognition capabilities in Smart Mirrors has revolutionized smart homes' technology by introducing personalization automation and more exciting features. It can be described as two-way mirror with a computer display integrated behind the reflective glass. Once switched on the digital screen starts displaying information such as weather, time and date, notifications, events, news updates, and health information. In its inactive state, the device looks like an ordinary mirror, making it simple aesthetically while incorporating many features. The use of IoT technology allows the gadget to access the internet and interact with cloud services and other gadgets. Through this, people can receive timely updates, synchronize their data, and automate some of their tasks.

It allows connection to smartphones, smart assistants, wearables, and any other smart devices at home via WiFi or Bluetooth. Thus, it acts as the main center of information exchange every day. The facial recognition feature is among the most innovative capabilities provided by this particular Smart Mirror device. It brings a higher level of personalization and security. By means of advanced image recognition and machine learning techniques like OpenCV, mirror can recognize individual users and provide unique content according to their identity. For example, if a person stands near the smart mirror, then it will recognize his face and present him with unique information like a schedule, reminders, fitness achievements, or news categories that suit this user's interests best.

II. LITERATURE REVIEW

Gayanga Kuruppu et al. [1] proposed a smart mirror system capable of delivering personalized content based on facial emotion recognition. The system uses a camera to capture facial expressions and applies emotion recognition algorithms to identify the user's emotional state. Based on detected emotions such as happiness, sadness, or neutrality, the mirror displays customized information like motivational quotes, news, or music suggestions. This work highlights the importance of emotion-aware systems in enhancing user experience and personalization. However, the system mainly focuses on emotion recognition and does not deeply address multi-user authentication or scalability.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

I. C. A. Garcia et al. [2] presented a smart mirror that integrates facial recognition for user authentication along with a personalized news recommendation algorithm. The mirror identifies users through facial recognition and then displays tailored news content based on their preferences. This work emphasizes secure authentication and content customization, making the system suitable for multi-user environments. The limitation of this approach lies in its dependency on stable internet connectivity and limited exploration of emotional context while delivering content.

S. P. S. Sirinayake et al. [3] developed an IoT-based intelligent assistant mirror using Raspberry Pi aimed at improving daily routines and smart living. The mirror displays real-time information such as weather updates, calendar schedules, reminders, and news feeds. The system demonstrates effective integration of IoT services and smart home concepts. Although the mirror enhances daily productivity, it lacks advanced personalization features such as facial emotion recognition or adaptive content delivery.

P. B. Thevarcad et al. [4] proposed a personalized day-to-day IoT-based smart mirror using facial recognition technology. The system recognizes individual users and displays personalized information such as schedules, reminders, and notifications. This work highlights the use of facial recognition to support multi-user environments and improve data privacy. However, emotional intelligence and behavior-based personalization are not deeply explored in this study.

Prof. Dr. Ashwini Barbadekar et al. [5] focused on the design and implementation of a cost-effective smart mirror using Raspberry Pi. The primary objective of this research is to develop an affordable smart mirror system suitable for household applications. The mirror displays essential information such as time, weather, and news while maintaining low hardware costs. Although the system is economical and practical, it offers limited intelligence and lacks advanced features such as facial recognition, emotion detection, and personalized recommendations.

III. PROPOSED SYSTEM

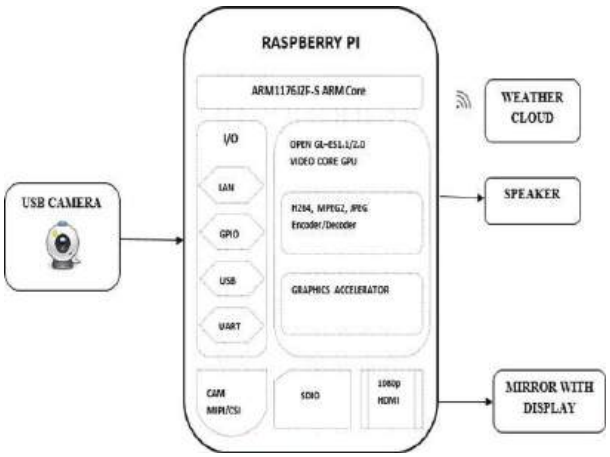

Fig 1. Proposed System

The fig.1 represents the proposed system of IoT-based Smart Mirror with Facial Recognition using Raspberry Pi, where the Raspberry Pi functions as the central processing and control unit. A USB camera continuously captures real-time video of the user, which is processed by the ARM-based processor using OpenCV algorithms for face detection and recognition. The integrated GPU and hardware accelerators support efficient image processing and smooth graphical rendering, while the encoded visual output is displayed on the mirror through an HDMI interface.

The system connects to cloud services via a network interface to retrieve real-time weather information and other contextual data, which are overlaid on the mirror display. Audio notifications can be delivered through an external speaker, and additional interfaces such as GPIO, USB, UART, and SDIO allow easy integration of IoT devices and peripherals. The architecture demonstrates a compact, scalable, and efficient integration of computer vision, multimedia processing, and IoT services suitable for smart home applications.

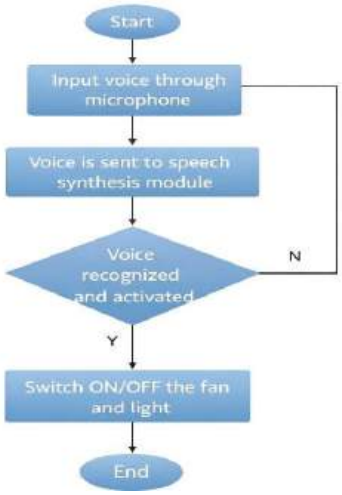

Fig 2. Flowchart for Home Automation

The fig.2 illustrates the working procedure of the voice-controlled IoT module. The first step is to set up the system. After that, the user gives a voice command through a microphone that is connected to the Raspberry Pi. The voice input that was recorded is sent to the speech processing module, where it is analysed and turned into a command that can be understood.

Next, the system uses voice recognition to see if the command spoken matches the control instructions that were set up ahead of time. The system goes back to listening for valid input if it doesn't recognise the voice command. When the system recognises and activates the right control action, it does what it needs to do, like turning the fan or light on or off through the IoT control interface. Finally, the command is run, and the process ends. This flowchart shows a simple and hands-free way for users to interact, which makes it easier for them.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

It also displays the headlines of the news or weather forecast. It looks like a regular mirror but it has screen inside. Transmitted data managed in a centralized data base. A flat monitor is used for the displaying the information. Smart Mirror contains several information. It is a simple webpage that contains an embedded browser in it.

IV. Hardware Requirements

The following are the hardware components represented in fig.3, used in IoT based Smart Mirror with Facial Recognition using Raspberry Pi.

A. Raspberry Pi

The core computing element that controls the operations of the entire smart mirror system. Its functionality includes image acquisition, facial detection, facial recognition and general operation control of the system. Real-time image streams obtained from the camera module are transferred to the Raspberry Pi and processed by its advanced computer vision techniques and algorithms. It controls the display of personalized information based on the obtained facial recognition results. Moreover, the Raspberry Pi is responsible for managing sensor data inputs using its GPIO interface and connecting to the Internet using its built-in Wi-Fi capabilities for obtaining the real-time data. It becomes possible to develop IoT-based functionalities of the smart mirror.

B. Two-way Mirror

The primary surface that provides the functionality of interacting with the smart mirror system. Two-way mirrors allow the user to use his smart mirror either as an ordinary mirror or as an information screen. The information presented on the display goes through the mirror to provide the user with easily visible information without distorting his reflection. In comparison with traditional glass mirrors, acrylic mirrors are lighter, more durable and easier to assemble; thus, they are ideal for smart homes.

C. LCD or Monitor Display

Installed behind the acrylic glass and displays content generated by the system. The information shown by LCD display may include time, date, weather, environmental sensors, and personalized messages based on successful facial recognition. The Raspberry Pi controls and connects to the display using HDMI ports in order to maintain high-quality images. Content displayed on the screen needs to be adjusted for readability through the mirror surface in various light conditions through adjusting brightness and resolution settings accordingly.

D. Pi Cam

The small and easy-to-carriy camera model Pi camera is connected to the Raspberry Pi using the MIPI camera serial interface protocol. It can be utilized for picture processing, machine learning, and surveillance purposes. Pi camera plays the role of recognizing the user's face to allow access to the device only to authorized users. In our case, we need to connect the 5-megapixel Pi camera to the Raspberry Pi to enable face recognition functions of the smart mirror. The first model of Pi camera was produced with 5 megapixels in 2013. The second version 8-megapixel Camera Module v2 appeared in 2016.

E. Micro SD card

It stores the Raspberry Pi operating system, face recognition algorithms, face dataset of the users, sensor data logs, and the configuration files of the system. The use of SD card in this case is very helpful because it enables the booting of the system easily and any updates or modification of the software becomes possible with it. Storage space should be sufficient so as to enable smooth operations in the process of image processing.

F. Sensors

Some sensors are used in the smart mirror system. The PIR sensor is used to detect the presence of a person in front of the smart mirror and enables it to operate when there is some motion detected. This helps to conserve energy. The temperature sensor is used to measure the ambient temperature and displays the results in real-time on the mirror interface. Humidity sensor measures humidity levels. This helps the smart mirror to be able to give some comfort information to the user.

G. HDMI cable

This cable connects the Raspberry Pi to the display monitor.

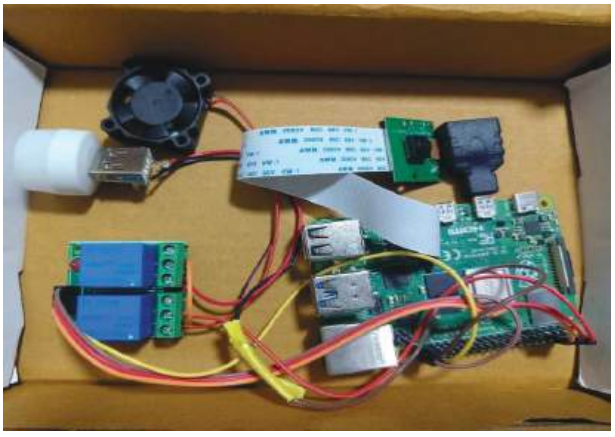

Fig 3. Hardware Components

Vol. 14, Issue 06, ACSCON - 2026

V. SOFTWARE REQUIREMENTS

The fig. 5 represents the main operating system in charge of the management of hardware resources, execution of application processes, and facilitation of network communication, Raspberry Pi OS will provide the stable Linux environment necessary for the execution of facial recognition algorithms, interaction with the sensors, and controlling the display. The key application of the proposed design will be created using the Visual Studio Code (VS Code) IDE, which provides efficient debugging options, management of code, and compatibility with various Python libraries used in the project.

Fig 5. Raspberry Pi OS

OpenCV is the library used to develop the functionalities of facial recognition and image processing, and it involves the face recognition and detection libraries developed using the OpenCV. This library captures the live video frames from the camera module and then recognizes the facial features before authenticating the user. OpenCV makes it possible for real-time recognition with reliability at various light levels. The internet is an essential software component since it helps connect the system to the IoT services, get real-time weather information, and communicate with cloud-based servers.

The connectivity of the network plays an important role in the functioning of the IoT in the smart mirror application. The Raspberry Pi establishes a connection to the internet via either a wired or wireless network. With reliable network connectivity, the smart mirror will have constant access to various internet-based resources. Network connectivity ensures the synchronization of the smart mirror application with external applications for the purpose of dynamic data delivery. The application utilizes IoT communication protocols for data exchange among smart mirror applications and cloud services as well as user interfaces.

There are various means of users' interaction within the framework of the developed smart mirror system. First of all, there is a web interface that will be able to show the personalized content like current time, date, weather updates, sensors' data, and notifications to the user. Moreover, this web interface will be placed behind the two-way acrylic mirror to provide high visibility and interaction opportunities.

Another user interaction possibility is mobile app interface based on Telegram bot for remote control and alerts. Telegram bot allows sending various messages like notifications or alerts about particular issues or events and helps to increase system usability. The display unit will act as visual user interface that will show users' interaction and all the processed data in real-time. Such combination of software requirement, connectivity options, and interface helps to achieve high effectiveness of real-time facial recognition, IoT services, and personalized content usage. The selected software and communication methods make the implementation of such integration quite simple and reliable.

VI. RESULT AND ANALYSIS

This section discusses the experimental results obtained from the implementation of the proposed IoT-based Smart Mirror with Facial Recognition using Raspberry Pi. The analysis focuses on system functionality, facial recognition performance, hardware reliability, IoT-based appliance control, and overall system effectiveness. The results are validated using real-time observations as shown in the experimental setup and output images.

Fig 6. Snapshot of working Smart Mirror

The fig.6 illustrates the smart mirror successfully displays real-time information such as current time, date, location, and weather conditions along with a live video feed of the user. The system continuously captures video frames using a Raspberry Pi camera module and processes them using OpenCV-based facial detection and recognition algorithms. Experimental observation shows that the facial detection process works efficiently under indoor lighting conditions with minimal latency. The face detection and recognition pipeline, implemented using OpenCV libraries, was able to recognize registered users within a fraction of a second. This confirms the suitability of Raspberry Pi for lightweight

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)

Vol. 14, Issue 06, ACSCON - 2026

computer vision applications in smart home environments. The overlay of real-time information on the mirror validates the system's usability as a daily assistant, helping users access essential information while performing routine activities.

Fig 7. Final output

The fig.7 represents the complete hardware setup, including the Raspberry Pi, monitor, power supply, camera module, and necessary interconnecting wires. The hardware components were integrated successfully without any compatibility issues.

Raspberry Pi acts as the primary controller and processor. Various processes run simultaneously from this processor such as facial detection. HDMI cable helps to establish communication between the Raspberry Pi and display monitor with low latency to produce high-quality output images on the screen. The camera component operates from behind the mirror surface to capture video data for face detection and recognition. The circuit diagram above illustrates how the power flow works and peripherals connected. The USB and jump wires help to establish communication with external hardware components and IoT controller modules.

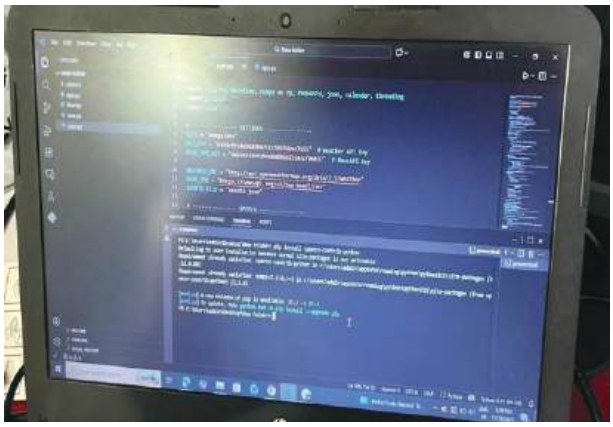

Fig 8. Command Prompt

The fig.8 illustrates the command prompt of software development and execution environment used for implementing the proposed IoT-based smart mirror system. The image features a Python application within an integrated development environment on a Raspberry Pi setup. This environment is crucial for managing facial recognition, data retrieval, and IoT services. The configuration parameters in the code include city location, weather API keys, news API keys, and file-based event handling.

These parameters allow for dynamic access to real-time weather data, news updates, and scheduled events, all displayed on the smart mirror interface. The successful installation and operation of OpenCV and its related Python libraries, as seen in the terminal output, confirm that the software environment is ready for computer vision tasks. The terminal output also shows that the system operates without conflicts, indicating solid software integration. Package installation logs verify that necessary libraries are installed correctly and are compatible with the current Python version. This confirms the reliability of the software stack and supports smooth facial recognition algorithms on the Raspberry Pi.

Fig 9. Telegram Notification

The IoT functionality of the smart mirror system is demonstrated in fig.9, which shows the Telegram bot interface used for controlling household appliances such as lights and fans. Users can send predefined commands through the Telegram application, and the system responds with confirmation messages indicating the execution status. The communication between the Telegram bot and the Raspberry Pi was found to be reliable, with minimal delay in command execution.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The appliances responded quickly to user commands, showing effective IoT integration. The use of Telegram offers a secure, easy-to-use, and platform-independent interface, removing the need for a dedicated mobile app. This highlights how well cloud-based messaging platforms can integrate with IoT systems for remote monitoring and control. The user can operate the devices anywhere through the internet, providing ease of use. According to the results of the experiment, the proposed IoT-based smart mirror system works effectively in facial recognition precision, information display in real time, and remote operation of the devices. This combination of computer vision and IoT technology develops an all-in-one smart mirror with enhanced ease of use and interactivity for the user.

VII. CONCLUSION

This paper presents a IoT-based Smart Mirror with Facial Recognition using Raspberry Pi, designed to provide an intelligent, interactive, and personalized user experience in smart home environments. The proposed system combines real-time facial recognition, information display, and IoT-based appliance control into a single embedded platform. By using OpenCV techniques and simple software design, the system recognizes authorized users and shows relevant information like time, weather updates, and personalized notifications directly on the mirror. Experimental results confirm that the system works reliably on a low-cost Raspberry Pi while maintaining real-time responsiveness.

The facial recognition module performed steadily under typical indoor lighting, and the IoT communication module allowed seamless control of household appliances through Telegram. The integration of hardware and software shows that the smart mirror system is feasible, scalable, and cost-effective for practical smart home uses.

Abstract*—The proposed solution uses IOT technology to enable real-time monitoring and automated data collection. Current and voltage sensors, water flow sensors, and gas sensors are integrated with a micro-controller such as ESP32or Arduino to measure respective utilities. Data is transmitted to the cloud using Wi-Fi or GSM communication. The system is programmed using Embedded C/C++ are used for data storage and visualization. A web or mobile application displays consumption details, billing information, and alerts. This system improves billing accuracy, reduces manual effort, and supports efficient resource management. Software side, Embedded C/C++ is used for programming the micro-controller. A web-based or mobile application, developed using HTML, CSS, JavaScript, and Python, displays real-time consumption data, historical usage patterns, billing information, and alert notifications for leakage or abnormal consumption.

I. Introduction

A unified smart 3-in-1 meter is an innovative utility measurement device that integrates the monitoring and reporting of gas, water, and electrical energy consumption into a single smart unit, revolutionizing how residential, commercial, and industrial utilities are tracked and managed. Traditionally, separate meters have been installed for each utility, leading to higher installation costs, increased maintenance efforts, and fragmented data collection. In contrast, a unified smart meter consolidates all three into a compact digital platform equipped with advanced sensors and communication technologies. This integration not only simplifies infrastructure but also enhances accuracy by replacing mechanical components with digital measurement systems that reduce errors, improve reliability, and extend device longevity

At the heart of the unified smart 3-in-1 meter is its ability to collect and transmit real-time consumption data for gas, water, and electricity. Using communication protocols such as NB-IoT, LoRaWAN, or cellular connectivity, the meter can automatically send usage information to utility providers or centralized management systems without requiring manual reading. This enables remote monitoring and automated billing, which significantly reduces operational costs for providers and minimizes billing

centralized management systems without requiring manual reading. This enables remote monitoring and automated billing, which significantly reduces operational costs for providers and minimizes billing .

II. LITERATURE SURVEY

The rapid growth of Internet of Things (IoT) and smart infrastructure has accelerated research in unified metering technologies that combine multiple utility measurements within a single integrated system. Early work in multivariate resource monitoring focused on independent smart meters for electricity, gas, and water. As individual systems matured, researchers recognized the need for integrated metering to improve efficiency, data coherence, and cost effectiveness.

In traditional metering research, the focus was on overcoming limitations of mechanical meters — such as inaccuracy, high maintenance, and manual data collection — by digitalizing individual meters. Studies by Güngör et al. (2011) demonstrated that smart electricity meters using digital communication protocols significantly improved data quality and enabled remote monitoring. Similarly, work on smart gas meters by Suryadevara and Mukhopadhyay (2012) highlighted reliable ultrasonic sensing techniques and low-power communication for remote gas usage reporting. Research on smart water metering by Nguyen et al. (2015) explored acoustic and electromagnetic flow sensor integration to detect consumption patterns and leakage with high accuracy.camera feeds. To improve accuracy and speed of accident detection using advanced image processing and deep learning models.: Intelligent roadside cameras, YOLO-CA neural network, Multiscale Feature Fusion (MSFF), Dynamic loss- weight adjustment. The model achieved a high detection speed of 21.6 FPS and an average precision of 90%, showing promising results for smart-city integration. Requires advanced infrastructure, high-cost cameras, and IoT gateways — not suitable for low-cost vehicle-mounted systems like ESP32-based solutions.

III. PROPOSED SYSTEM

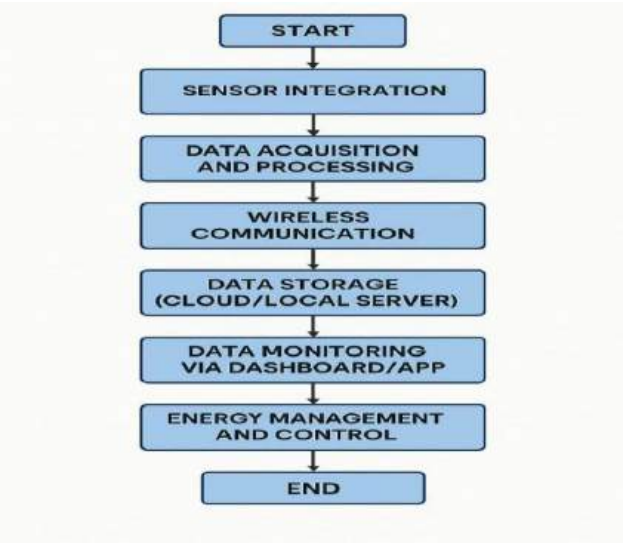

Fig 3.1: Proposed System

This block diagram represents an Unified Smart 3-in-1 Meter for Gas, Water, and Energy. The proposed system introduces a Unified Smart 3-in-1 Meter designed to measure, monitor, and manage gas, water, and electrical energy consumption through a single intelligent device. The main objective of this system is to replace multiple conventional meters with a compact, digital, and IoT-enabled solution that ensures accurate measurement, real-time monitoring, and efficient utility management. By integrating three utilities into one platform, the system reduces installation complexity, maintenance cost, and manual intervention while improving data reliability and accessibility.

IV. HARDWARE REQUIREMENTS

ESP32: The ESP32 is a powerful, low-cost microcontroller developed by Espressif Systems, widely used in IoT (Internet of Things) applications because of its high processing speed, built-in communication features, and rich set of peripherals. It is an upgraded version of the ESP8266 and includes a dual-core Tensilica processor, which allows it to handle multiple tasks simultaneously, making it suitable for real-time monitoring systems like accident detection and health monitoring. The ESP32 supports both 3.3V logic and offers

Fig 4.1: ESP32

excellent power-saving modes, making it suitable for battery-operated systems. It also has built-in timers, watchdogs, touch sensors, hall sensors, and a hardware encryption engine, which ensures secure communication. The device can run Arduino code, Micro Python, or the native ESP-IDF framework, giving developers flexibility in programming. This fig shown in figure 4.1.

LCD Display: A liquid-crystal display (LCD) is a flat-panel display or other electronically modulated optical device that uses the light-modulating properties of liquid crystals. Liquid crystals do not emit light directly, instead using a backlight or reflector to produce images in color or monochrome. LCDs are available to display arbitrary images (as in a general-purpose computer display) or fixed images with low information content, which can be displayed or hidden, such as preset words, digits, and 7-segment displays, as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger elements. The figure 4.2 shows the LCD Display.

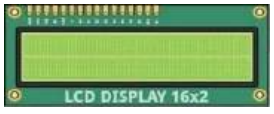

Fig 4.2: LCD Display

Vol. 14, Issue 06, ACSCON - 2026

Push Button: A Pushbutton Switch is a switch designed so that its contacts are opened and closed by depressing and releasing a pushbutton on the Switch in the direction of its axis. Used to arise the emergency condition.this fig 4.3 shows push button.

Fig 4.3: Push Button

Gas Sensor: An alcohol sensor detects the attentiveness of alcohol gas in the air and an analog voltage is an output reading. The sensor can activate at temperatures ranging from -10 to 50° C with a power supply is less than 150 Ma to 5V. The sensing range is from 0.04 mg/L to 4 mg/L, which is suitable for breathalyzers. The passive alcohol sensor (PAS) is a device developed to assist police in identifying drinking drivers. The PAS draws in mixed expired and environmental air from in front of the subject's face and passes it into a fuel cell sensor that can detect very small amounts of gas. The fig 4.3 shows Gas Sensor detection.

Fig 4.4: Gas Sensor

Node MCU : it also supports OTA (Over-The-Air) updates and works efficiently with cloud-based energy management systems. Its compact size, built-in connectivity, and ease of programming make it a highly suitable choice for developing affordable and scalable smart meter solutions.The fig 4.5 shows Node MCU.

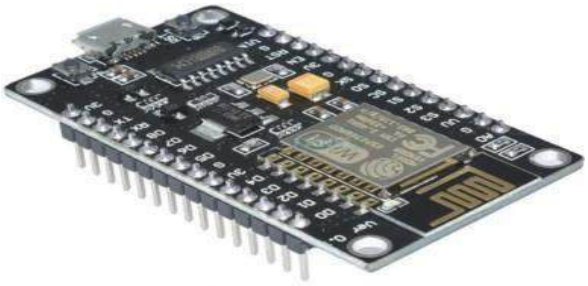

Fig 4.5 : Node MCU

LDR Sensor: An LDR (Light Dependent Resistor), also known as a photo resistor, is a sensor that detects light intensity. In the context of a unified smart energy meter, the LDR is commonly used to measure electricity usage by detecting the blinking of an LED on a digital energy meter. Most modern digital electricity meters have a small Blinking LED that flashes once for every unit of power consumed.this fig 4.6 shows LDR Sensor.

Fig 4.6 : LDR Sensor

3-in-1 smart meter : It is a unified device designed to monitor electricity, water, and gas consumption simultaneously using a single embedded system. It integrates three different types of sensors-one for each utility-into a central microcontroller platform like Arduino Uno, ESP32, or Node MCU.

Fig 4.7 : 3-in-1 smart meter .

This setup allows for real-time, centralized data collection, processing, and transmission for all utilities from one compact unit. Each utility is monitored by its corresponding sensor: Electricity is typically measured using a current sensor (e.g., ACS712) or an LDR that detects LED pulses from a digital energy meter. The fig 4.7 shows 3-in-1 smart meter .

Relay : A relay is an electrically operated switch used to control the connection or disconnection of electricity, water, or gas supply based on specific conditions. In a unified smart metering system, a relay allows the embedded controller (like Arduino or Node MCU) to automatically turn ON or OFF the utility supply when necessary-for example, during overuse, non-payment, or in prepaid metering scenarios.Fig 4.8 shows relay.

Fig 4.8 :Relay .

Vol. 14, Issue 06, ACSCON - 2026

Arduino IDE:

Fig 5.1: Arduino IDE

A program for Arduino may be written in any programming language for a compiler that produces binary machine code for the target processor. Atmel provides a development environment for their microcontrollers, AVR Studio and the newer Atmel Studio. The Arduino project provides the Arduino integrated development environment (IDE), which is a cross-platform application written in the programminlanguage Java. It originated from the IDE for the languages Processing and Wiring. It includes a code editor with features such as text cutting and pasting, searching and replacing text, automatic indenting, brace matching, and syntax highlighting, and provides simple one-click mechanisms to compile and upload programs to an Arduino board. It also contains a message area, a text console, a toolbar with buttons for common functions and a hierarchy of operation menus. A program written with the IDE for Arduino is called a sketch. Sketches are saved on the development computer as text files with the file extension. ino. Arduino Software (IDE) pre-1.0 saved sketches with the extension. pde. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution.

A minimal Arduino C/C++ sketch, as seen by the Arduino IDE programmer, consist of only two functions: setup(): This function is called once when a sketch starts after power-up or reset. It is used to initialize variables, input and output pin modes, and other libraries needed in the sketch. loop(): After setup() has been called, function loop() is executed repeatedly in the main program. It controls the board until the board is powered off or is reset.

Arduino IDE software is an open-source development environment used to write, compile, and upload programs to Arduino boards. It provides a simple and user-friendly interface, making it suitable for beginners as well as advanced developers. The Arduino IDE supports programming in a simplified version of C and C++, commonly referred to as Arduino programming. It allows users to create sketches (programs) that control hardware components such as LEDs, motors, sensors, displays, and communication modules.

The Arduino IDE is mainly used to program boards like Arduino Uno, Arduino Nano, and Arduino Mega 2560. These boards are based on microcontrollers such as the ATmega328P. The IDE provides built-in libraries and example codes that make hardware interfacing easy. Users only need to select the correct board and port, write the code, and click the upload button to transfer the program to the board through a USB cable.

The interface of the Arduino IDE includes a code editor, a message area, a text console, and toolbar buttons for verifying and uploading programs. It also supports serial communication through the Serial Monitor, which helps in debugging and viewing real-time data from the microcontroller. Additionally, the IDE allows installation of extra libraries and board packages to support advanced modules and third-party hardware.

One of the main advantages of Arduino IDE is its cross-platform compatibility, as it runs on Windows, macOS, and Linux. It simplifies embedded system development by handling complex configurations in the background. Overall, Arduino IDE software plays a major role in electronics prototyping, IoT development, robotics, and educational projects by providing an easy and efficient programming platform.

Embedded C:

Fig 5.2:Overview of Arduino IDE

Embedded C software is a specialized form of the C programming language used to develop applications for embedded systems. An embedded system is a combination of hardware and software designed to perform a specific function within a device. Embedded C enables programmers to write efficient and reliable code that directly interacts with hardware components such as microcontrollers, sensors, actuators, timers, and communication modules. Unlike general-purpose C programs that run on computers with operating systems, Embedded C programs run on dedicated hardware with limited memory, processing power, and storage.

Embedded C is commonly used with microcontrollers such as ATmega328P, STM32F103C8T6, and ESP8266. These microcontrollers are widely used in applications like home automation, robotics, automotive control systems, medical devices, consumer electronics, and Internet of Things (IoT) projects. The software written in Embedded C directly accesses hardware registers to control input/output ports, manage communication protocols like UART, SPI, and I2C, and handle real-time operations using interrupts.

One important feature of Embedded C is efficient memory management, as embedded systems typically have limited RAM and ROM. Programmers often use keywords such as `volatile` to ensure proper hardware communication and implement interrupt service routines (ISRs) for fast response to external events. The program structure generally includes hardware initialization followed by an infinite loop that continuously executes system tasks.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The development process involves writing code in an integrated development environment (IDE), compiling it to generate a HEX file, and flashing it into the microcontroller. Embedded C software plays a vital role in modern electronics by enabling smart, automated, and reliable device control.

V1.RESULT AND DISCUSSIONS

The development and testing of the unified smart meter system for water, gas, and energy yielded promising results, confirming its potential as a reliable, intelligent, and practical solution for modern utility management. The results were observed in several phases, including component- level testing, system integration, real-time monitoring, wireless communication, cloud interfacing, and automated control functionalities. Below is a detailed breakdown of the key findings across each functional domain of the system.

Snap shot of working Smart meter shows the integrated system effectively collected real-time data from three different sensors: ACS712 current sensor for electricity, YF-S201 water flow sensor for water measurement, and MQ-6 gas sensor for gas flow and leakage detection. Each sensor provided stable and accurate outputs under test conditions. The current sensor detected variations in energy consumption with sensitivity, and the readings could be converted into kilowatt-hours using simple mathematical logic within the microcontroller. The water flow sensor consistently measured flow rates and total water volume with minimal deviation, based on the pulse frequency generated. The gas sensor also accurately detected the presence of LPG, triggering safety alerts when concentration thresholds were exceeded.

Real-Time Data Processing and Display explains about the Arduino Uno and Node MCU microcontrollers successfully read sensor values and converted them in to user-friendly units such as kilowatt-hours(kWh), liters, and cubic meters. The processed data was displayed in real-time on an LCD screen, providing instant feedback to the user. The local display was effective even during offline operation, ensuring usability regardless of internet connectivity. The LCD successfully cycled through each utility reading with proper formatting and clear labeling. Relay modules connected to the micro controller were tested for automated control based on preset conditions. The system was programmed to cut off the utility supply when usage exceeded specified thresholds or when prepaid credit was exhausted.

Hardware Prototype:

ARDUINO APPLICATION

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

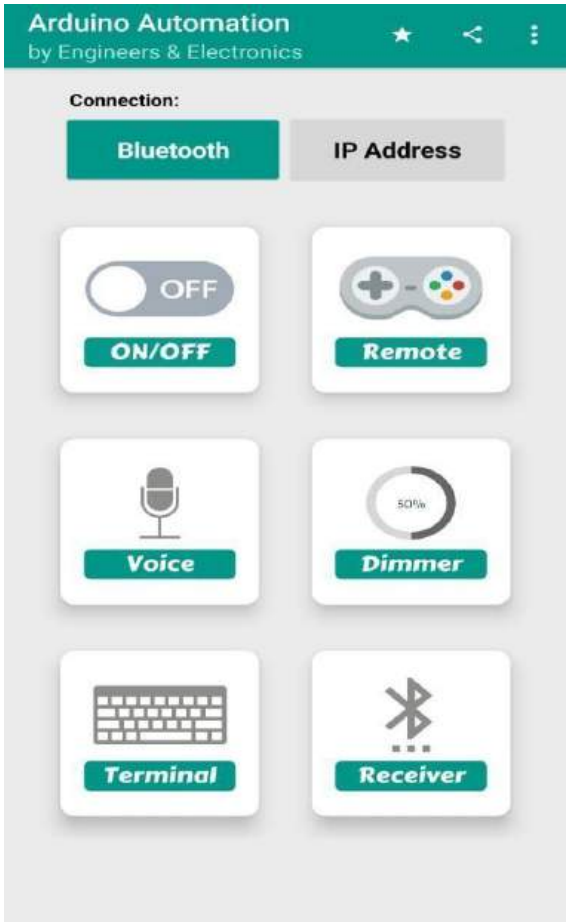

Fig 6.3:Arduino Application

APPLICATIONS:

- Real-time monitoring of water, gas, and electricity usage.
- Remote meter reading (no manual checking)
- Smart home and smart city integration
- Cloud monitoring using platforms like Amazon Web Services
- Renewable energy management (e.g., battery systems
- like Tesla Powerwall)
- Demand forecasting and data analytics
-
- Smart billing and automated reports
- Leakage and theft detection
- Energy and cost optimization

ADVANTAGES:

- Real-Time Monitoring
- Accurate Billing
- Remote Access
- Leakage Detection
- Energy Efficiency
- Reduced Operational Cost
- Theft Detection

LIMITATIONS:

- High Initial Cost
- Cybersecurity Risks
- Network Dependency
- Maintenance Cost
- Technical Complexity
- Power Dependency
- Privacy Concerns

VI. CONCLUSION

The Unified Smart Meter for Water, Gas, and Energy presents a practical and intelligent solution for modern utility management by integrating three essential services into a single system. Through the use of embedded systems, sensor technologies, wireless communication, and IoT platforms, the project successfully enables real-time monitoring, automated billing, remote control, and efficient resource management. It empowers both users and utility providers with greater transparency, control, and data-driven decision- making, supporting smarter and more sustainable utility usage.

Abstract*— Road accidents remain a serious global issue, often leading to fatalities due to delayed emergency response. The project presents an IoT-based Accident Detection and Patient Health Monitoring System using the ESP32 microcontroller. The system automatically detects accidents using an accelerometer and monitors vital health parameters such as heart rate, body temperature, and SpO_2. Upon detecting an accident, the system retrieves the victim is location through a GPS module and sends real-time alerts to emergency contacts via Telegram. An LCD displays live health data, while a manual override reduces false alerts. The proposed system offers a reliable, low-cost solution to improve emergency response and enhance road safety.

Keywords*—Arduino UNO, IR sensor, Accelerometer, Zigbee, Rain Sensor, Buzzer etc.

I. INTRODUCTION

Road transportation has become an essential part of modern life, enabling millions of people to travel efficiently for work, education, and daily activities. However, with the continuous rise in the number of vehicles on highways and city roads, the rate of road accidents has also increased significantly. These accidents often lead to severe injuries, long-term disabilities, and in many cases, loss of life. One of the major reasons for high fatality rates is the delay in providing medical attention during the crucial "golden hour" where quick treatment can make the difference between survival and death. In most accident scenarios, victims are unable to call for help due to unconsciousness or physical trauma, and bystanders may not always be present to report the incident. This results in delayed response time and poorly coordinated rescue efforts. Traditional systems used for accident reporting rely heavily on manual communication, which is slow, unreliable, and dependent on human presence. Although high-end vehicles have embedded safety systems, these solutions are expensive and not accessible to the majority of users. Smartphone-based accident detection apps also suffer from limitations such as battery dependency, hardware inaccuracy, and the possibility that the device gets damaged during impact. Therefore, there is a strong need for an automated, low-cost, and reliable accident detection system that can operate independently and respond instantly.

II. LITERATURE SURVEY

Fatal road accidents can be easily avoided by understanding the psychological state of a driver. Majority of road accidents occur during night driving due to the drowsiness state of a vehicle driver. The paper provides mechanism to reduce accidents to a large extend by monitoring eye blinking of the driver which indicates the drowsiness, obstacles located in the road and the drunken state of the drivers. Automatic pre cautionary system is activated based on the above alarming condition. Accident and its probable location are also generated at the nearby police station that helps initiating medical help. In normal cases no medical help is received due to the non-availability of accident information. This happens mainly at night and in roads where the traffic is low.

The researchers used data from the Fatality Analysis Reporting System (FARS) of the National Highway Traffic Safety Administration (NHTSA). This database contains detailed records of every fatal road accident in the U.S. The authors studied the data from to understand how different vehicle-related conditions influence the severity of accidents. The results show that vehicles with poor mechanical health or malfunctioning safety features are much more likely to be involved in deadly crashes. By identifying these components, the study highlights the importance of regular maintenance, effective safety inspections, and better vehicle design standards.

The authors developed KD-CVIS, an image dataset including various accident scenarios. A YOLO-CA convolutional network is used for detecting collision events by analyzing

camera feeds. To improve accuracy and speed of accident detection using advanced image processing and deep learning models.: Intelligent roadside cameras, YOLO-CA neural network, Multiscale Feature Fusion (MSFF), Dynamic loss-weight adjustment. The model achieved a high detection speed of 21.6 FPS and an average precision of 90%, showing promising results for smart-city integration. Requires advanced infrastructure, high-cost cameras, and IoT gateways — not suitable for low-cost vehicle-mounted systems like ESP32-based solutions.

III. PROPOSED SYSTEM

.

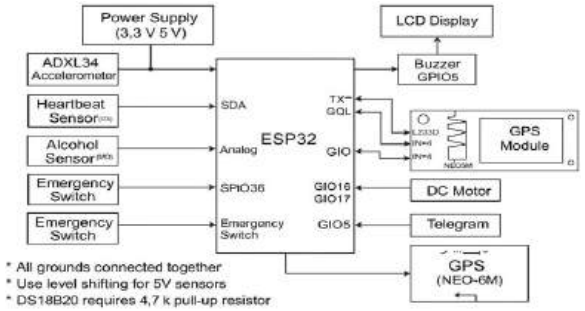

Fig 3.1: Proposed System

This block diagram represents an accident detection and health-monitoring system built using an ESP32 microcontroller. Various sensors such as the ADXL accelerometer, heartbeat sensor, alcohol sensor, temperature sensor, and an emergency switch are connected to the ESP32 to continuously monitor vehicle movement and the driver's physical condition. The ESP32 receives all sensor readings, processes the data, and decides whether an accident has occurred. It also communicates with the GPS module, which provides exact location details. Output devices like the LCD display, buzzer, H bridge, and DC motor are controlled by the ESP32 for visual alerts, sound warnings, and motor control in emergency situations. Finally, the ESP32 uses its Wi-Fi capability to send accident alerts and location data through Telegram, ensuring quick notification to emergency contacts.

IV. HARDWARE REQUIREMENTS

ESP32: The ESP32 is a powerful, low-cost microcontroller developed by Espressif Systems, widely used in IoT (Internet of Things) applications because of its high processing speed, built-in communication features, and rich set of peripherals. It is an upgraded version of the ESP8266 and includes a dual-core Tensilica processor, which allows it to handle multiple tasks simultaneously, making it suitable for real-time monitoring systems like accident detection and health monitoring. The ESP32 supports both 3.3V logic and offers excellent power-saving modes, making it suitable for battery-operated systems. It also has built-in timers, watchdogs, touch sensors, hall sensors, and a hardware encryption engine, which ensures secure communication. The device can run Arduino code, Micro Python, or the native ESP-IDF framework, giving developers flexibility in programming. This fig shown in figure 4.1.

Fig 4.1: ESP32

DC Motor: DC motors convert electrical into mechanical energy and they consist of permanent magnets and loops of wire inside, when current is applied, the wire loops generate a magnetic field, which reacts against the outside field of the static magnets. The interaction of the fields produces the movement of the shaft/armature. Thus, electromagnetic energy becomes motion. A DC Motor is shown in fig 4.2.

Fig 4.2: DC Motor

Buzzer: A buzzer is a simple sound-producing device used in electronic systems to give audio alerts or warnings. It converts electrical signals into sound using either a piezoelectric element or an electromagnetic coil. In your project, the buzzer is connected to a GPIO pin of the ESP32 and is activated whenever an accident is detected or when the emergency alert countdown starts. When the ESP32 sends a HIGH or LOW signal to the buzzer, it produces a beeping sound to alert the user or nearby people. Buzzers are commonly used because they are small, require very little power, and give immediate audible feedback in emergency situations. Buzzer is shown in fig 4.3.

Fig 4.3: Buzzer

Battery: A battery is a device consisting of one or more electrochemical cells with external connections provided to power electrical devices such as flashlights, smartphones, and electric cars. When a battery is supplying electric power, its positive terminal is the cathode and its negative terminal is the anode. The terminal marked negative is the source of electrons that will flow through an external electric circuit to the positive terminal. When a battery is connected to an external electric load, a redox reaction converts high-energy reactants to lower-energy products, thin cells used in smartphones, to large lead acid batteries or lithium-ion batteries in vehicles, and at the large battery banks the size of rooms that provide

standby or emergency power for telephone exchanges and computer datacenters. Battery is shown in fig 4.4.

Fig 4.4: Battery

LCD Display: A liquid-crystal display (LCD) is a flat-panel display or other electronically modulated optical device that uses the light-modulating properties of liquid crystals. Liquid crystals do not emit light directly, instead using a backlight or reflector to produce images in color or monochrome. LCDs are available to display arbitrary images (as in a general-purpose computer display) or fixed images with low information content, which can be displayed or hidden, such as preset words, digits, and 7-segment displays, as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger elements. The figure 4.5 shows the LCD Display.

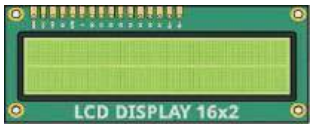

Fig 4.5: LCD Display

Pulse Sensor: Pulse Sensor is a well-designed plug-and-play heart-rate sensor for Arduino. It can be used by students, artists, athletes, makers, and game & mobile developers who want to easily incorporate live heart rate data into their projects. The sensor clips onto a fingertip or earlobe and plugs right into Arduino. The fig 4.6 shows the Pulse Rate Sensor.

Fig 4.6: Pulse Sensor

Temperature Sensor: The digital temperature sensor like DS18B20 follows single wire protocol and it can be used to measure temperature in the range of -67oF to +257oF or - 55oC to +125oC with +-5% accuracy. The range of received data from the 1-wire can range from 9-bit to 12- bit. Because, this sensor follows the single wire protocol, and the controlling of this can be done through an only pin of Microcontroller. This article discusses an overview of a DS18B20 temperature sensor.

Fig 4.7: Temperature Sensor

Alcohol Sensor: An alcohol sensor detects the attentiveness of alcohol gas in the air and an analog voltage is an output reading. The sensor can activate at temperatures ranging from -10 to 50° C with a power supply is less than 150 Ma to 5V. The sensing range is from 0.04 mg/L to 4 mg/L, which is suitable for breathalyzers. The passive alcohol sensor (PAS) is a device developed to assist police in identifying drinking drivers. The PAS draws in mixed expired and environmental air from in front of the subject's face and passes it into a fuel cell sensor that can detect very small amounts of alcohol. The fig 4.10 shows Alcohol Sensor detection.

Fig 4.8: Alcohol Sensor

Push Button: A Pushbutton Switch is a switch designed so that its contacts are opened and closed by depressing and releasing a pushbutton on the Switch in the direction of its axis. Used to arise the emergency condition.

Fig 4.9: Push Button

ADXL Sensor (Accelerometer): An accelerometer is a tool that measures the vibration, motion, or acceleration of a structure. Cameras and smartphones these days use an accelerometer consisting of an axis-based motion sensor. It is an electromechanical device that measures either static or dynamic acceleration. Acceleration, as we know, is the measure of change in velocity upon a given time.

Fig 4.10: ADXL Sensor

V. SOFTWARE REQUIREMENTS Arduino IDE:

Fig 5.1: Arduino IDE

A program for Arduino may be written in any programming language for a compiler that produces binary machine code for the target processor. Atmel provides a development environment for their microcontrollers, AVR Studio and the newer Atmel Studio. The Arduino project provides the Arduino integrated development environment (IDE), which is a cross-platform application written in the programming

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

language Java. It originated from the IDE for the languages Processing and Wiring. It includes a code editor with features such as text cutting and pasting, searching and replacing text, automatic indenting, brace matching, and syntax highlighting, and provides simple one-click mechanisms to compile and upload programs to an Arduino board. It also contains a message area, a text console, a toolbar with buttons for common functions and a hierarchy of operation menus. A program written with the IDE for Arduino is called a sketch. Sketches are saved on the development computer as text files with the file extension. ino. Arduino Software (IDE) pre-1.0 saved sketches with the extension. pde. The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub main() into an executable cyclic executive program with the GNU toolchain, also included with the IDE distribution.

A minimal Arduino C/C++ sketch, as seen by the Arduino IDE programmer, consist of only two functions: setup(): This function is called once when a sketch starts after power-up or reset. It is used to initialize variables, input and output pin modes, and other libraries needed in the sketch. loop(): After setup() has been called, function loop() is executed repeatedly in the main program. It controls the board until the board is powered off or is reset

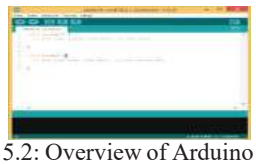

Fig 5.2: Overview of Arduino IDE

Embedded C:

• Embedded C is a specialized version of the C programming language designed specifically for programming embedded systems, such as microcontrollers and IoT boards. It follows the same basic syntax and structure as standard C but includes additional features that allow direct interaction with hardware components. In your project, Embedded C plays the central role of controlling how the ESP32 communicates with sensors, processes data, and performs real-time actions during an accident.

• One of the main strengths of Embedded C is its ability to work very close to the hardware. This means the programmer can directly access pins, ports, timers, ADC channels, communication protocols, and internal registers of the microcontroller. This ability is essential in your project because the ESP32 needs to read analog signals from the heartbeat sensor, take digital readings from the accelerometer, read one-wire data from the temperature sensor, and receive GPS coordinates through UART communication. Each of these tasks requires precise hardware-level control, which Embedded C provides.

• Embedded C also supports real-time operation, which is extremely important for life-saving systems like accident detection. When an accident occurs, the ESP32 must quickly detect the sudden change in acceleration, start a countdown, trigger the buzzer, fetch GPS location, and send an emergency alert through Telegram. These tasks must happen within seconds, and the timing accuracy provided by Embedded C enables the system to respond immediately without delays.

• Another important feature of Embedded C is its portability. Code written in C can easily be adapted to different microcontrollers with minor changes. In your case, although you are using the ESP32, the same Embedded C logic can be reused for Arduino, STM32, AT mega, or PIC microcontrollers. This makes it easier to upgrade or extend your project in the future.

• Embedded C allows modular programming, meaning the program can be divided into separate functions such as reading sensors, processing data, sending messages, and handling communication. This modularity makes your project easier to understand, debug, and maintain. Each function can be tested independently, ensuring more reliable operation.

• The ESP32 also supports multiple communication protocols such as I²C, SPI, UART, Wi-Fi, and 1-Wire. Embedded C makes it possible to implement these protocols through libraries and direct register manipulation. For example, I²C is used for the accelerometer and LCD, UART is used for GPS, analog input is used for the alcohol and pulse sensor, and Wi-Fi is used for Telegram alerts. All these communication tasks are handled through Embedded C programming.

• Memory management is another critical aspect of Embedded C. Embedded systems often have limited RAM and flash memory, so the programmer must write efficient code. The ESP32 has more memory than many microcontrollers, but still, proper management ensures your program runs smoothly, especially when handling Wi-Fi operations and multiple sensor readings simultaneously.

VI. RESULT & DISCUSSIONS

Result:

The developed accident detection and health monitoring system successfully performed all major functions during testing. The ESP32 effectively collected real-time data from the accelerometer, heartbeat sensor, temperature sensor, alcohol sensor, and GPS module. The accident detection mechanism worked reliably, identifying sudden impacts and abnormal movements with good accuracy. The buzzer alert and countdown timer helped avoid false alarms by giving the user time to cancel unnecessary triggers. If no cancellation occurred, the system confirmed an accident and collected accurate GPS coordinates.

The Telegram bot integration worked smoothly for emergency communication. Whenever an accident was detected, the ESP32 immediately formatted the alert message and transmitted it over Wi-Fi. The received message contained the user's location, heartbeat, temperature, alcohol level, and system status, proving that data packaging was successful. The GPS coordinates appeared correctly as a clickable Google Maps link, enabling fast identification of the accident spot. The message delivery time was short, taking only a few seconds, which supports quick emergency response. The system continued working even after repeated tests, showing consistent performance.

The hardware components also performed effectively under continuous operation. The motor driver responded correctly to ESP32 signals, confirming compatibility with additional

safety functionalities. The alcohol sensor showed proper detection sensitivity, and the temperature and heartbeat sensors produced stable readings throughout the test. Power consumption remained within expected limits, and the connections were stable without data loss. The complete system demonstrated smooth integration of sensing, processing, communication, and alerting units.

APPLICATIONS
- Vehicle Accident Detection
- Emergency Alert Systems
- Patient Health Monitoring
- Smart Transportation Safety
- Ambulance Tracking Systems
- Fleet Management
- Public Transport Safety
- Rider Safety Systems
- IoT-Based Medical Assistance
- Remote Health Reporting

ADVANTAGES
- Real-time Accident Detection
- Automatic Emergency Alerting
- Accurate Location Tracking
- Continuous Health Monitoring
- False Alarm Prevention
- Low-Cost and Scalable
- Easy IoT Integration
- Improves Survival Chances
- User-Friendly and Portable
- High Reliability

LIMITATIONS
- Dependence on Internet Connectivity
- GPS Inaccuracy in Indoor or Covered Areas

VII. CONCLUSION

The Accident Detection and Patient Health Monitoring System using IoT and ESP32 provides an efficient, low-cost, and scalable solution for improving road safety and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

emergency medical response. By automatically detecting accidents, retrieving GPS coordinates, monitoring vital signs, and transmitting real-time data through Telegram, the system significantly reduces the delay between the accident occurrence and medical assistance. The system operates autonomously without requiring the victim or bystanders to manually report the incident, making it especially useful in remote regions or night-time travel. Continuous health monitoring gives hospitals critical patient information ahead of time, enabling faster diagnosis and treatment. The modular design allows for future expansions such as cloud data storage, GSM communication, additional sensors (ECG, BP), ambulance dispatch automation, and smart-city integration. Overall, the project successfully demonstrates how IoT, sensor technologies, and embedded systems can be combined to create a reliable solution that enhances emergency responsiveness and potentially saves countless lives.

CodeArc: A Voice-Enabled LLM Assistant for Interactive Code Generation in VS Code

Design, Implementation, and Practical Evaluation of Agent-Driven Development Workflows

First Author: Mrs. Archana NG, M.Tech, Assistant Professor, Dept. of CSE, ACS College of Engineering
First Author *E-mail: archanang17@gmail.com*

Abstract- *CodeArc is an AI-assisted development extension for VS Code designed to reduce the friction between idea, implementation, and validation. Instead of treating chat, speech, code generation, and file operations as separate tools, the platform unifies them into one working loop. The architecture combines a TypeScript extension host, a webview interaction layer, and Python media services for speech recognition and text-to-speech. Agent Mode handles multi-step tasks by planning actions, executing commands, observing runtime feedback, and refining outputs through iterative fixes. CodeArc also supports network Ollama workflows, allowing teams to share model infrastructure without duplicating setup. In practical use, the system improves turnaround time on repetitive engineering tasks and offers a more accessible voice-first interaction model for users with different working styles.*

Keywords- CodeArc, VS Code Extension, LLM Assistant, Agent Mode, Speech Recognition, Text-to-Speech, OCR, Ollama Network, Autonomous Code Generation

1. INTRODUCTION

Modern IDEs are feature-rich, but everyday development is still fragmented. A student or developer may ask an AI question in one window, copy output to another, run commands in a terminal, and then manually reconcile errors in code. This constant switching slows momentum and increases cognitive load.

CodeArc is built to close this gap by bringing AI chat, context retrieval, multimodal input, code generation, execution, and repair into one extension. The key objective is practical productivity: fewer context shifts, faster first-draft code, and a tighter feedback loop from prompt to working output. The platform also supports network model discovery, so multiple users can share one inference backend.

2. SYSTEM ARCHITECTURE AND WORKFLOW

CodeArc follows a layered architecture with clear separation of responsibilities. The extension layer (TypeScript) controls command routing, workspace interactions, model requests, and agent orchestration. The webview layer (HTML/CSS/JavaScript) handles message rendering, live token streaming, syntax-aware presentation, and user-side controls. A Python media pipeline provides speech-to-text capture and text-to-speech playback for voice-assisted usage.

The inference backend supports local Ollama execution as well as remote server routing over WebSocket. Before sending a model request, the prompt can be enriched with active-file context, selected snippets, uploaded content, and OCR text extracted from images. Responses are streamed incrementally to improve perceived responsiveness and allow earlier user feedback.

Table - 1: CodeArc Module Summary

Implementation and Functional Coverage		
Module	**Key Functions**	**Status**
AI Chat	Streaming prompts, context-aware replies	Implemented
Agent Mode	Task planning, execution, auto-fix loops	Implemented
Speech Stack	Speech-to-text and text-to-speech	Implemented
File Pipeline	Code parsing and OCR extraction	Implemented

2.1 Sub Heading 1

Agent Mode performs autonomous multi-step execution: goal parsing, plan generation, permission checks, task execution, validation, and iterative repair. Instead of stopping at static suggestions, it attempts to produce runnable artifacts and reconciles runtime errors through controlled retries.

2.2 Sub Heading 2

Speech input is supported through VS Code speech integration or browser speech APIs, depending on availability. Output narration uses text-to-speech with adjustable speed and voice options. This makes the assistant practical not only for coding convenience but also for accessibility and guided learning.

2.3 Implementation Highlights

Core implementation modules include extension.ts for orchestration, agentMode.ts for autonomous execution behavior, script.js for webview communication, server.js for network Ollama routing, and Python services for media operations. File processing supports code and document inputs, while image attachments can be converted to searchable text using OCR.

In practical sessions, this architecture is most useful during rapid prototyping and debugging cycles. The auto-fix loop reduces repetitive manual edits by validating generated code, applying focused fixes, and re-running tasks until success conditions are met or iteration limits are reached.

2.4 Limitations and Practical Notes

Like most LLM-based systems, CodeArc depends on prompt quality and model capability. Long workflows can require explicit guardrails to avoid unintended edits, and network mode depends on stable latency. For production

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

usage, controlled permissions, audit logging, and repeatable test checkpoints remain important safeguards.

Chart - 1: CodeArc Functional Coverage Across Core Modules

Module	Implemented Features
AI Chat Engine	Streaming Responses, Context-Aware Prompting
Agent Mode	Planning, Execution, Auto-Fix, Iteration Control
Speech Stack	Speech-to-Text, Text-to-Speech, Voice Controls
File Pipeline	Code/Text Parsing, OCR for Images
Network Layer	UDP Discovery, WebSocket Multi-Client Access

Chart 1 summarizes implementation maturity by subsystem. The highest stability is observed in chat orchestration and agent execution loops, while network behavior depends more strongly on local topology and firewall policy.

Qualitative evaluation across coursework and prototype tasks shows faster first-pass delivery for boilerplate features, lower manual debugging effort, and better continuity when context from active files is included in prompts.

Fig - 1: CodeArc End-to-End Interaction Pipeline

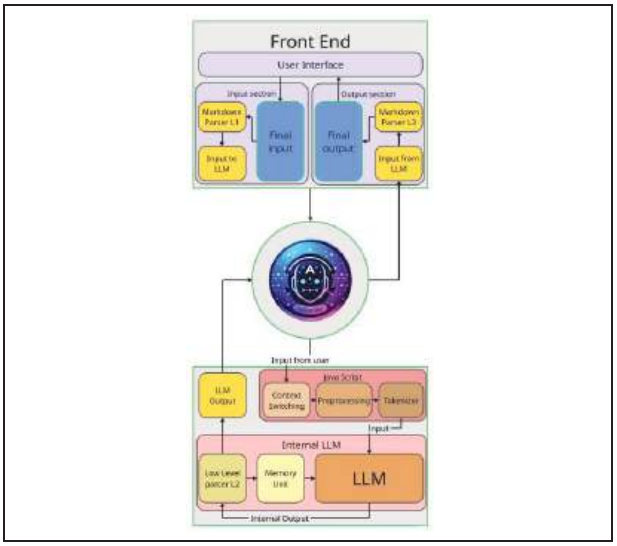

Figure 1 describes the operational flow from user prompt entry to AI response delivery, including optional speech synthesis and autonomous task execution branches.

This pipeline-based architecture allows CodeArc to support conversational assistance, code generation, and accessibility features in a unified extension lifecycle.

3. CONCLUSIONS

CodeArc demonstrates that a single VS Code extension can combine conversational AI, autonomous task execution, voice interaction, and network-enabled inference in a workflow that remains practical for daily development. The current version is suitable for academic use, rapid prototyping, and guided team collaboration.

Future work will focus on benchmark automation, policy-aware model routing, stronger security boundaries for autonomous actions, and richer collaboration telemetry for multi-user environments.

4. RESULT ANALYSIS

Across repeated development tasks, CodeArc reduced manual effort in three areas: code scaffolding, error-trace interpretation, and iterative repair. The most visible gain was in first-draft generation speed, where baseline boilerplate creation time dropped when context-aware prompting and agent execution were used together.

Speech-supported workflows were especially useful during quick ideation and review sessions. Users could issue requests hands-free, inspect generated output, and trigger follow-up actions without leaving the editor. This interaction style improved continuity for learning-oriented and accessibility-focused usage scenarios.

Network mode introduced practical collaboration value by allowing multiple clients to connect to a shared inference backend. In lab conditions, this reduced redundant local setup overhead and simplified model management for teams working on common project objectives.

ACKNOWLEDGEMENT

The authors acknowledge institutional support, project mentorship, and the open-source communities behind VS Code, Ollama, and Python libraries used in this implementation.

***Abstract*— Pregnancy related muscle cramps are a frequent occurrence, yet their presence can sometimes signal serious underlying complications, such as preterm labor or compromised uterine blood flow. Ensuring continuous monitoring of key physiological parameters in expectant mothers is paramount for safeguarding both maternal and fetal well-being. A new smart-healthcare solution called the Pregnancy Cramp Detection System, created to help monitor and respond to cramp-related issues during pregnancy. The early prediction and detection of muscle cramps during pregnancy using a synergistic combination that makes use of biosensors along with advanced artificial intelligence and machine learning techniques. The aggregated data then serve as input for a specialized AI/ML model, which is trained to analyse fluctuations in muscle activity, temperature, and heart rate patterns to predict the probability of a cramp event. Upon the detection of an aberrant pattern, the system instantly generates a prediction alert on a dedicated dashboard, enabling prompt intervention by healthcare providers or caregivers.**

Keywords—Pregnancy Health Monitor System.

I. INTRODUCTION

Pregnancy represents a critically sensitive phase in a woman's life, necessitating vigilant medical oversight and monitoring. This period is marked by major physiological and hormonal shifts, frequently resulting in symptoms like fatigue, muscular contractions, and abdominal cramps. While mild cramping is often benign, persistent or severe cramps can be symptomatic of deeper issues. The traditional paradigm of maternal healthcare largely relies on periodic clinical checkups. However, this conventional approach inherently lacks the capability for continuous, real-time monitoring, thereby creating potential gaps where critical health deviations might go undetected, leading to delayed intervention. The proposed Pregnancy Cramp Detection System is designed to address and overcome these limitations by seamlessly fusing IoT (Internet of Things)-based biosensors with AI/ML technology into a unified, intelligent health monitoring platform. System Components and Functionality-The system's core relies on three primary sensors. An EMG sensor to accurately record muscle activity and identify irregular or a typical contractions. A heart rate sensor to measure pulse variability and cardiac response. A DHT11 temperature sensor to simultaneously track the patient's body temperature and the ambient environmentally temperature. These sensors connect to an ESP32 microcontroller which is in charge of gathering all the data. The ESP32's integrated Wi-Fi capability is utilized to transmit the collected data wirelessly and in in real time to a secure Google Spreadsheet stored online. This cloud-based data repository ensures persistent logging and allows for continuous visualization, enabling healthcare professionals to keep track of important health signals from a distance.

Predictive Analytics and Intervention The stored data is subsequently processed by a dedicated AI/ML model. This model has been rigorously trained on diverse datasets encompassing both normal and pathologically abnormal physiological patterns. Its function is to meticulously analyze the incoming sensor readings (muscle activity, heart rate, temperature) to calculate and predict the likelihood of an impending pregnancy cramp. The predictive output is then rendered on an intuitive dashboard, offering clear, actionable insights for both clinicians and patients.

II. Literature Survey

Pregnancy-related cramps and uterine contractions are common phenomena that have been studied from both medical and engineering perspectives. In obstetrics, these cramps are understood as resulting from a combination of factors, including uterine expansion, ligament stretching, electrolyte imbalance Continuous monitoring, particularly in high-risk pregnancies, has been shown to be critical for detecting complications such as preterm labor and insufficient placental function, ultimately improving maternal and fetal health. Electromyography (EMG) has become an important tool for tracking muscle and uterine activity.

In obstetric applications, uterine EMG, also called electro hysterography (EHG), is used to measure contractions. Key features such as signal amplitude, burst frequency, and spectral properties have been linked to contraction intensity and labor progression. Similarly, surface EMG (sEMG) can capture early indicators of muscle cramps in limbs and the abdomen by detecting increased motor unit activity and distinctive waveform patterns. Standard preprocessing techniques like filtering,

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

routinely applied to improve signal quality. Monitoring heart rate and body temperature complements EMG measurements by providing insights into maternal physiological stress. Heart rate variability and absolute heart rate reflect autonomic responses associated with pain, stress, or fluid imbalance. Combining these cardiac indicators with EMG signals enhances the detection of early labor or distress. Temperature monitoring, whether through core or skin measurements, helps identify fever or environmental factors that may trigger cramps. Low-cost sensors, such as DHT11 modules, are commonly used in prototype systems to provide basic temperature and humidity data, while higher-precision instruments are preferred in clinical settings.

III. Proposed System

The system begins by collecting information from different sensors. These sensors measure values such as ECG, tracking heart rate, temperature, and environmental humidity. All of this raw data is gathered continuously.

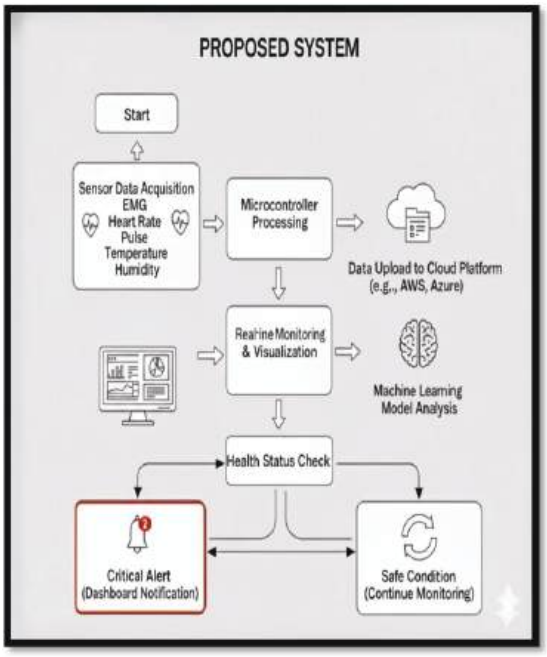

Fig 1: Proposed System

Once the readings are captured, they are sent through an ESP32 Wi-Fi module. This module transfers the data to a cloud server, where it can be safely stored and retrieved as required. At the same time, the sensor data is also displayed on a dashboard. The dashboard offers a live display of the readings so that the user or caretaker can easily watch the current conditions. A real-time monitoring unit takes the incoming data and checks it instantly. This unit passes the data to a machine learning model, which has been trained to understand normal and abnormal patterns in the health readings. The output of the machine learning model goes to a health status checking block. This block decides whether allowing the user or healthcare personnel to respond right away.

- If the readings are within a safe range, the system continues monitoring without any interruption.
- If the readings indicate danger or abnormal behaviour, the system generates a critical alert. This alert appears on the dashboard notification.

In summary, the system automatically collects health data, sends it to the cloud, analyses it using machine learning, and provides instant alerts if it detects anything unusual. The system goal is to detect health issues early and continuously monitor the user's condition.

IV. Hardware Requirements

The following hardware's are used to monitor the Health of pregnant woman.

EMG Sensor

The EMG module uses surface electrodes placed on the skin to capture the faint electrical signals that occur during muscle cramps. These signals are very small and noisy, so the sensor outputs a raw analog waveform that must pass through a conditioning circuit before it can be interpreted. The signal conditioning stage typically includes filtering, amplification, and smoothing to produce a clean version of the muscle activity for further processing.

- **Heart Rate Sensor**

The heart rate sensor measures the user's pulse either through a photoplethysmography (PPG) technique or a embedded digital pulse sensor. It may provide an analog voltage output that needs to be converted using an ADC, or it may offer a digital interface such as I²C or SPI, which allows the ESP32 allowing the data to be read directly. The sensor provides beats-per-minute (BPM) or raw pulse waveform data for analysis.

- **DHT11**

The DHT11 is a simple environmental sensor that delivers temperature and humidity data through a single-wire data transfer protocol. This sensor connects directly to the ESP32 and does not require analog conversion. It sends out calibrated values at regular intervals for further analysis microcontroller reads for monitoring the physical environment.

- **ESP32**

The ESP32 operates as the central processor. It reads the conditioned EMG signal through its ADC pins, receives heart-rate data through either analog or digital channels, and communicates with the DHT11. Beyond data collection, the ESP32 performs tasks like filtering, segmenting data into windows, and extracting features. It can store or buffer this information and uploads it over Wi-Fi to a cloud platform server or dashboard. Additionally, the ESP32 is capable of running lightweight machine-learning models for on-device analysis when required.

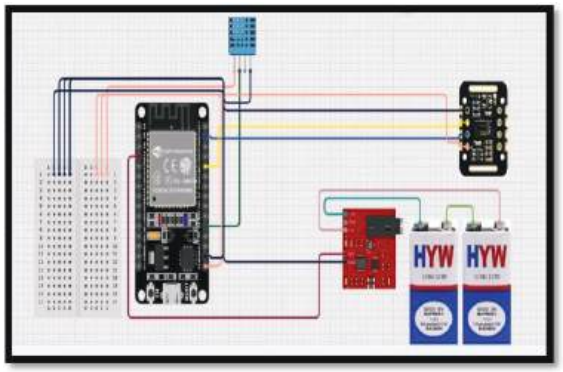

Fig 2: Hardware Pin Diagram

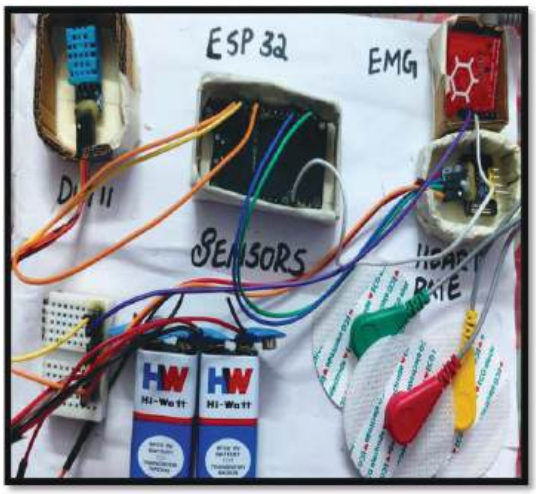

Fig 3: Hardware Circuit

V. Software Requirements

Arduino IDE

We use the Arduino IDE to write and upload code to the ESP32 where the entire firmware—sensor drivers, data formatting routines, and Wi-Fi functions is written and compiled. After compiling, the program is uploaded to the ESP32 board so it can operate independently. Once flashed, the device continuously gathers sensor data, processes it, and communicates with the cloud in real time.

Cloud Machine Learning Processing

Once the cloud receives the incoming data, it forwards it to a machine-learning model trained to detect muscle-cramp patterns or abnormal conditions. After processing, the system returns a prediction score showing how likely a cramp might occur, along with a confidence value and recommended actions. The full ML workflow and response interface are developed using JavaScript, with CSS used for styling and user-side interaction using React JS.

Wi-Fi and Cloud Data Upload

The ESP32 uses its built-in Wi-Fi module to push collected sensor information to a cloud platform. For every upload, the device prepares a file that includes the time of measurement, the raw sensor readings, and any features extracted from the signals. This packet can be sent to different cloud endpoints such as a Google Apps Script service.

Dashboard and Alert System

A web or mobile dashboard provides users with real-time graphs of all sensor readings and trends over time. It also displays the most recent prediction output from the cloud model. If the system identifies a risk level that goes beyond its safety limit, it immediately sends notifications—such as Dashboard alerts. These alerts help ensure that the user or their caretaker can react quickly whenever the system detects potential danger.

VI. Result And Analysis

The developed system performed reliably during testing, showing that it can effectively monitor physiological signals and predict possible muscle-cramp risks. The EMG sensor provided clear muscle-activity signals after passing through the conditioning circuit, which removed noise and improved the quality of the waveform. Throughout the test, the sensor maintained stable heartrate measurements both rest and movement. All these values were collected smoothly by the ESP32 without delays or data loss.

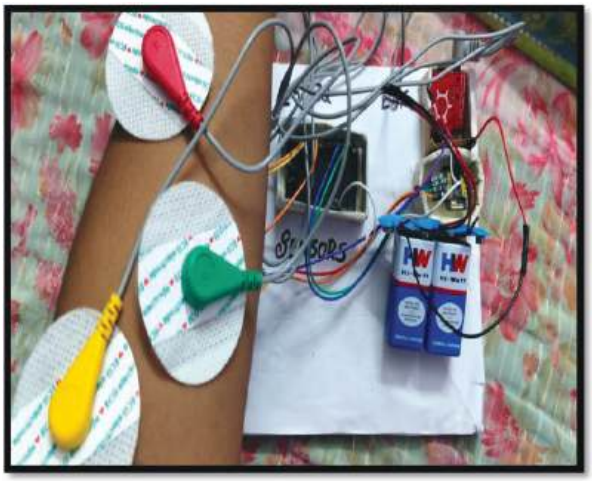

Fig 4:Connecting Electrodes to detect Cramp

The ESP32 successfully connected to Wi-Fi and uploaded the processed sensor readings directly into Google Sheets. This ensured that all data was stored securely and could be accessed remotely at any time. The time-stamped logs confirmed that the system maintained continuous and reliable communication with the cloud. The machine-learning model running on the cloud analyzed the uploaded data and generated predictions about the muscle cramps. The dashboard displayed real-time readings and historical data in a clear and easy-to-understand format. Users could view live graphs of EMG, heart rate, temperature, and humidity, along with the prediction results from the machine-learning model. When the system detected a high risk of muscle cramps, it immediately triggered alerts via notifications, allowing quick action. Overall, the results showed that the system worked smoothly, provided accurate predictions, and could be a practical tool for continuous health monitoring and early detection of potential muscle cramps.

VII. Conclusion

In this conclusion, the Pregnancy Cramp Detection System demonstrates a practical and innovative approach to improving the health and safety of expectant mothers. By combining wearable sensors, IoT technology, and AI/ML prediction models, the system continuously monitors vital signs such as muscle activity, heart rate, and body temperature. This enables mothers and healthcare professionals to receive real-time insights, bridging the gap between periodic check-ups and ongoing health supervision.

AI and machine-learning algorithms analyze the information to detect patterns and predict the likelihood of muscle cramps, triggering early warnings through a dashboard or notifications. This proactive feature helps prevent complications and supports timely decisions, reducing stress for both patients and caregivers. Unlike traditional hospital monitoring, this system is portable, non-invasive, and cost-effective, making it suitable for both home and clinical use. Overall, this system highlights how

***Abstract*—The increasing incidence of mental health issues necessitates innovative diagnostic methods beyond traditional, subjective assessments, particularly due to the sheer volume and nuanced language found on digital communication platforms[cite: 1130]. This project, the Advanced Social Analyzer, presents a unified, scalable, and automated screening system designed to quantify psychological risk from public textual content acquired from Reddit, Instagram, and Twitter (X)[cite: 1131]. The system utilizes a dual-engine analytical pipeline: a primary Machine Learning classifier (Naive Bayes) calculates an Abnormal Probability Score quantifying the statistical likelihood of high-risk language patterns while a secondary lexicon-based sentiment analyzer (VADER) provides granular emotional profiling (Positive, Negative, Neutral scores) for critical contextual validation[cite: 1132]. Data acquisition is achieved through robust multi-channel connectors, employing Asynchronous APIs, external scraping services, and browser automation[cite: 1133]. The analysis is synthesized into a decisive Overall Verdict and visualized via a dynamic, timeseries chart[cite: 1134]. This synergistic approach provides a temporally aware assessment, enabling the detection of behavioral escalations and serving as a tool for content moderation[cite: 1135].**

***Index Terms*—Artificial Intelligence, Machine Learning, Mental Health Prediction, Naive Bayes, Natural Language Processing, Sentiment Analysis[cite: 2052, 2053, 2054, 2055].**

I. Introduction

The rapid growth of digital communication platforms such as Reddit, Instagram, and Twitter has changed how individuals express their emotions, thoughts, and behavioral patterns[cite: 1151]. These platforms provide a real-time glimpse into the psychological state of users because people tend to express personal struggles, stress, frustration, and emotional instability through posts, comments, and captions[cite: 1152]. Unlike traditional communication methods, social media captures spontaneous and unfiltered expressions, making it a powerful source for analyzing mental health indicators[cite: 1153].

Historically, mental health diagnosis relied heavily on scheduled clinical consultations, therapist-patient conversations, and standard psychological questionnaires[cite: 1154]. These methods are accurate but not continuous, not scalable, and often too late to detect early warning signs of emotional decline[cite: 1155]. Moreover, mental health conditions like depression, anxiety, or self-harm ideation often manifest subtly in language patterns long before an individual seeks help[cite: 1156]. With advancements in Artificial Intelligence (AI), Machine Learning (ML), and Natural Language Processing (NLP), it is now possible to analyze patterns in text and identify psychological risks with significant precision[cite: 1157]. These technologies can uncover emotional sentiment, identify abnormal linguistic cues, and build behavior trends across time all of which are impossible to achieve manually[cite: 1158].

A. Problem Definition

Although social media contains rich psychological indicators, there is currently no unified, automated, and real-time system that can analyze text across platforms and determine mental health vulnerability[cite: 1161]. Current mental health monitoring systems rely largely on human-centered processes such as clinical consultations, standard mental health questionnaires, manual text review by moderators, and basic sentiment analysis tools provided by platforms[cite: 1207, 1208, 1209, 1210, 1211].

The limitations of existing systems are significant:

- **Subjective and Periodic:** Traditional evaluations are performed occasionally and depend on user honesty[cite: 1213].
- **Not Scalable:** Humans cannot review millions of posts across platforms[cite: 1214].
- **Lack of Real-Time Monitoring:** Behavioral changes can occur rapidly, but existing tools cannot detect them instantly[cite: 1215].
- **Limited Emotional Depth:** Most available sentiment tools identify only surface-level emotions[cite: 1216].
- **Poor Context Understanding:** Sarcasm, metaphors, and slang make manual interpretation difficult[cite: 1217].

Different platforms have different data formats, content styles, and API restrictions, meaning no universal tool can extract, clean, and standardize text for analysis[cite: 1164, 1165]. Furthermore, negative posts do not always indicate high mental health risk; expressing sadness due to an event is different from expressing signs of hopelessness or self-harm[cite: 1171, 1172]. Most existing tools offer static results but do not show how a person's emotional state changes over days, weeks, or months, which is crucial for detecting escalation[cite: 1178].

B. Objectives

The major objectives are to:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Design a system that automatically collects public posts from Reddit, Instagram, and Twitter[cite: 1242].
- Analyze collected data using a machine learning classifier for psychological risk[cite: 1243].
- Identify emotional sentiment and measure negative, positive, and neutral tones[cite: 1244].
- Combine these findings into a clear final mental health verdict[cite: 1245].
- Provide time-based visualization for tracking emotional changes[cite: 1246].
- Build the system in a simple, efficient, and scalable manner[cite: 1247].

II. Literature Review

The field of computational mental health analysis has grown significantly due to the availability of social media data and advancements in machine learning and natural language processing[cite: 1271].

A. Machine and Deep Learning Approaches for Psychological Risk Detection

Early research on mental health detection relied heavily on traditional machine learning models such as Naive Bayes, Support Vector Machines, Logistic Regression, and Random Forest[cite: 1276]. These models were used mainly because they are computationally efficient, easy to train, and perform well on structured datasets[cite: 1277]. Research shows that Naive Bayes is one of the fastest classifiers, making it suitable for real-time applications[cite: 1279]. These models function by converting text into numeric features using techniques such as Bag of Words or TF-IDF, producing interpretable outputs such as probability scores[cite: 1280, 1281]. However, these models face limitations when analyzing complex, context-dependent emotional language[cite: 1283]. They cannot understand deeper semantic meaning, detect sarcasm, or interpret sequential patterns in sentences[cite: 1284]. Despite these limitations, Naive Bayes is still widely used for initial screening tasks because of its speed and reliability, and this project adopts it for generating the abnormal probability score[cite: 1291].

B. Sequential Deep Learning Models

To address the shortcomings of traditional models, researchers explored deep learning models designed to understand the order and context of words[cite: 1297]. Models such as Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU) can analyze long sequences of text and learn how emotional patterns develop across sentences[cite: 1298]. LSTM networks can remember information over longer text sequences, while GRU is a simplified version of LSTM and performs faster with similar accuracy[cite: 1300]. Bidirectional GRU reads text from both directions, improving contextual understanding[cite: 1300]. Sequential models outperform traditional models when dealing with emotional language, personal experiences, and psychological narratives[cite: 1301]. However, these models require large datasets and extensive training, which increases computational cost[cite: 1302].

C. Transformer-Based Models

The introduction of transformer architectures marked a major advancement in natural language processing[cite: 1305]. Models like BERT and RoBERTa provide contextual embeddings, which means the meaning of each word is understood based on surrounding words[cite: 1306]. Transformers achieve state-of-the-art accuracy in sentiment analysis and mental health prediction, capable of understanding complex expressions, sarcasm, deeper context, and informal language[cite: 1308, 1309]. Many studies report more than 95 percent accuracy in psychological risk classification using transformer models[cite: 1310]. Transformers significantly outperform all previous approaches. However, their computational cost is high, which makes them challenging to deploy for real-time web applications[cite: 1312].

D. Sentiment and Emotional Context Profiling

VADER is one of the most widely used sentiment analysis tools for social media data[cite: 1320]. It is designed to handle informal language, emojis, slang, and abbreviations commonly found on platforms such as Twitter[cite: 1321]. VADER provides positive, negative, neutral, and compound emotion scores[cite: 1323]. It works well on short messages such as tweets and comments, is extremely fast and suitable for real-time analysis, and does not require training data[cite: 1324, 1325, 1326]. However, it cannot detect deeper psychological meanings or understand new slang unless manually added to its lexicon[cite: 1328].

E. Context and Community-Based Risk Prediction

Platforms like Reddit contain threaded conversations where context is built through replies[cite: 1342]. Graph-based models such as Graph Transformer Networks analyze these structures to understand how discussions develop[cite: 1343]. Graph models can detect harmful conversation patterns, predict the escalation of negative or abusive discussions, and capture community influence and group behavior[cite: 1345, 1346, 1347]. Accuracy increases significantly when conversation structure is included[cite: 1348]. Additionally, topic modeling tools like Latent Dirichlet Allocation (LDA) are widely used to identify dominant themes in large datasets[cite: 1351].

III. Software Requirement Specification (SRS)

The Software Requirement Specification provides a detailed description of the functionalities, constraints, and resources required to build the mental health analysis system[cite: 1368].

A. Functional Requirements

These are the essential functions the system must perform:

- The system must allow the user to enter a public username from Reddit, Instagram, or Twitter[cite: 1373].
- The system must strictly validate the format of the entered username (e.g., ensure no special characters are used that are invalid for the platform) and confirm that the specified platform is supported[cite: 1389].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- For a successful analysis, the system must attempt to extract a minimum threshold of posts (e.g., the 50 latest posts or comments) from the public profile to ensure statistical significance[cite: 1390].
- The system must record the exact time and date for every extracted text sample to facilitate chronological trend analysis[cite: 1391].
- Text Preprocessing Steps must include normalization (lowercasing), tokenization, stop word removal, and URL/Mention/Hashtag removal to eliminate elements that bias the sentiment or classification models[cite: 1393, 1394, 1395, 1396, 1397].
- The Naive Bayes Classifier must output a raw probability score, $P(\text{Abnormal}|\text{Text})$, which represents the likelihood of the text sample indicating an abnormal psychological state[cite: 1398].
- The VADER analysis must provide the standard four scores: Positive (pos), Negative (neg), Neutral (neu), and Compound score for each text sample[cite: 1399].
- The system must calculate the Mean Abnormal Probability and the Median Compound Sentiment Score across all collected text samples, alongside the percentage of posts falling into the High Risk category (where $P(\text{Abnormal}) > 0.7$)[cite: 1401, 1402].
- The generation of the overall psychological risk verdict (e.g., "Low," "Moderate," "High") must be based on a weighted combination of the Mean Abnormal Probability and the Mean Negative Sentiment Score, using predefined and documented thresholds[cite: 1408].

B. Non-Functional Requirements

1) Performance: The total time from submitting a username to displaying the results dashboard must not exceed 15 seconds for a standard dataset of 50 posts[cite: 1432]. The time required to load all necessary machine learning and NLP models (Naive Bayes, VADER) must be less than 3 seconds upon system initialization[cite: 1433]. The system must be capable of handling simultaneous analysis requests from at least 5 concurrent users without degradation in the 15-second latency target[cite: 1434].

2) Reliability and Security: The Naive Bayes Classifier model must maintain a minimum documented F1-Score of 0.75 on the system's test dataset[cite: 1436]. All extracted text data must be retained exactly as sourced for analysis, and any preprocessing step must be reversible or clearly logged[cite: 1437, 1438]. The system must not store any text or analysis results after the user session has ended, except for necessary system logs that do not contain personal identifiers[cite: 1441]. All social media API keys and scraping credentials must be securely stored as environment variables and never exposed in the source code or client-side application[cite: 1442].

C. Hardware and Software Requirements

The software components require a Python 3.9+ environment for access to modern language features and efficient dependency management[cite: 1447]. Key Flask extensions, such as Flask-WTF for form handling and requests for secure external API communication, are specified[cite: 1452]. The 'scikit-learn' library handles the Naive Bayes model implementation and management, while the 'nltk' (Natural Language Toolkit) library provides VADER sentiment analysis[cite: 1454, 1455]. The 'pandas' library is required for efficient text data manipulation, aggregation, and filtering prior to visualization[cite: 1456].

Hardware requirements include a minimum of 8 GB RAM for a server-based deployment to comfortably handle simultaneous model loading, concurrent user requests, and OS overhead[cite: 1467, 1468]. A Quad-core processor (or better) with a minimum clock speed of 2.0 GHz is required to manage the parallel processing inherent in asynchronous data fetching[cite: 1469]. A minimum symmetrical 50 Mbps internet connection ensures fast and reliable access to social media APIs, alongside 10 GB of SSD storage for the operating system, Python environment, pre-trained ML models, and logs[cite: 1471, 1476].

IV. System Tools

The tools used in the development and execution of the Advanced Social Analyzer system ensure accuracy, speed, and compatibility with social media platforms and machine learning operations[cite: 1560, 1562].

A. Python and Flask Framework

Python is the primary programming language used for developing the system, supporting machine learning, natural language processing, and web-based operations through its rich set of libraries[cite: 1565, 1566]. Python integrates easily with APIs and scraping tools and provides a simple framework for writing the analysis pipeline[cite: 1569, 1570]. Flask is the backend framework used to create the web application, handling user requests, processing usernames, managing routing, and displaying output results[cite: 1573, 1574]. Flask connects the user interface with analytical functions, processing data received from APIs and models, and sending results to the frontend for visualization[cite: 1582, 1583, 1584].

B. Analytical Models

The Naive Bayes classifier provides fast classification suitable for real-time analysis, analyzing text and generating an abnormal probability score[cite: 1588, 1589, 1590]. It is efficient for short social media posts and loads quickly during system startup[cite: 1592, 1593]. VADER determines emotional polarity, identifying negative, neutral, and positive sentiment values, and handling emojis, slang, and informal expressions[cite: 1596, 1599]. VADER validates the abnormal probability by adding emotional context without requiring training data[cite: 1600, 1601].

C. Data Scraping Tools

The Reddit asynchronous client fetches multiple comments quickly, preventing the blocking of the backend and ensuring smooth data collection[cite: 1604, 1605, 1607, 1608]. The

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Apify scraper collects Instagram captions from public profiles since Instagram does not allow direct text access through regular APIs[cite: 1617, 1618]. Apify provides structured data containing captions and timestamps and handles changes in Instagram layout through automated scraping[cite: 1620, 1623]. Browser automation tools such as Playwright extract tweets dynamically, bypassing API restrictions by mimicking normal browser actions and scrolling through the page to collect older posts[cite: 1626, 1627, 1630, 1632].

V. Methodology

This section defines the precise techniques for data acquisition and standardization across all supported social media platforms[cite: 1489].

A. Data Processing Method

All extracted data, regardless of the source, must be transformed into a unified data structure (e.g., a Pandas Data Frame row) containing exactly two fields: the cleaned and unprocessed raw text of the post/comment, and the UNIX timestamp normalized to the standard Unix epoch format[cite: 1491, 1493, 1494]. A preliminary cleaning step is applied at this stage to remove platform-specific artifacts before the core NLP preprocessing stage[cite: 1495].

The text must be lowercased, and punctuation or special characters removed, except those crucial for VADER sentiment analysis (e.g., emojis and exclamation points)[cite: 1509]. Tokenization occurs before stop word removal[cite: 1509]. For the Naive Bayes model to generalize better, a process of lemmatization (reducing words to their dictionary root) is applied to the tokens[cite: 1511].

B. Analytical Method

The raw text must be converted into numerical features using the Term Frequency-Inverse Document Frequency (TF-IDF) vectorization technique, which weighs words based on their importance in the overall training corpus[cite: 1513]. The system loads the pre-trained and serialized Naive Bayes model and applies the log-likelihood calculation to the input vector to output $P(\text{Abnormal}|\text{Text})$ for each post[cite: 1514, 1515]. The system must verify the integrity and version of the loaded model before every run to ensure consistency[cite: 1516]. The VADER analyzer is applied directly to the pre-processed text to obtain the four standard scores efficiently[cite: 1518]. The resulting Compound score represents the overall emotional valence of the text for the time-series graph[cite: 1519].

C. Aggregation Method

The unified data structure must be sorted descending by the UNIX timestamp to ensure the most recent posts are prioritized in analysis presentation[cite: 1528]. Instead of a simple arithmetic mean, a time-decaying weighted average is applied to both the Abnormal Probability and Negative Sentiment, ensuring more recent posts have a slightly greater influence on the overall verdict than older posts[cite: 1529, 1530]. The system must identify and flag the Top 5 posts with the highest Abnormal Probability for inclusion in the dashboard summary[cite: 1531].

The verdict uses a three-tiered classification instead of binary:

- **Low Risk:** Weighted Average Abnormal Probability $P_A < 0.40$[cite: 1535].
- **Moderate Risk:** $0.40 \leq P_A < 0.65$[cite: 1535].
- **High Risk:** $P_A \geq 0.65$[cite: 1536].

The final verdict is also slightly adjusted upward (e.g., from Low to Moderate) if the Weighted Average Negative Sentiment exceeds a secondary threshold (e.g., 0.50)[cite: 1537].

VI. System Design

System design explains the structural and functional organization of the Advanced Social Analyzer[cite: 1647]. The design follows a modular architecture so that each module performs a specific task without affecting the others[cite: 1649].

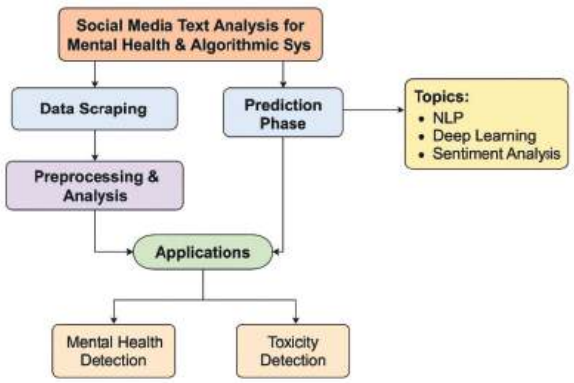

Fig. 1. System Flow Diagram detailing data scraping, preprocessing, prediction phase, and applications including Mental Health Detection and Toxicity Detection[cite: 1650, 1651, 1652, 1653, 1658, 1659].

The system follows a three-tier architecture consisting of the presentation tier, the application tier, and the data tier[cite: 1662]. The presentation tier handles user interaction, receiving a username entered by the user and displaying the results including sentiment scores, abnormal probability, and time-series graphs using HTML, CSS, and Chart.js[cite: 1663, 1664]. The application tier processes the core functions of the system, acting as the central controller to manage requests, execute analysis, and prepare results via the Flask backend, the data extraction modules, the Naive Bayes classification engine, and the VADER sentiment analyzer[cite: 1665, 1666, 1667]. The data tier contains all raw inputs and trained model files, including collected posts from Reddit, Instagram, and Twitter as well as the saved Naive Bayes model and the VADER lexicon[cite: 1672, 1673].

The flow of the Advanced Social Analyzer is divided into structured levels[cite: 1686]. Level 0 shows the simplest overview of the system[cite: 1689]. Level 1 explains how the system gathers posts from each platform[cite: 1692]. Level 2 describes how each post is analyzed by passing the text

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

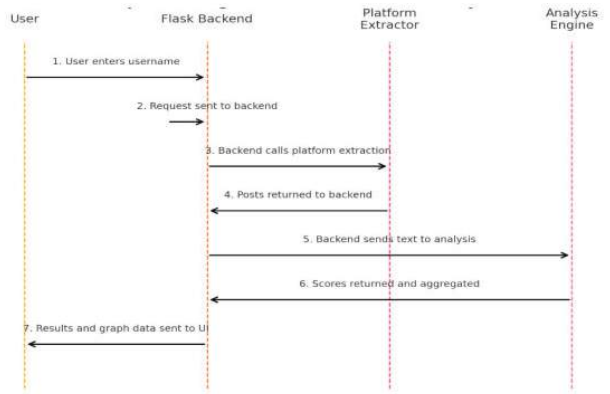

Fig. 2. Sequence Diagram illustrating user interaction with the Flask Backend, Platform Extractor, and Analysis Engine[cite: 1713, 1714, 1715, 1716, 1717].

to the Naive Bayes classifier and VADER to obtain negative, neutral, and positive sentiment scores[cite: 1702, 1703, 1704]. In Level 3, the system sorts all posts chronologically, calculates averages, compares abnormal probability with the threshold, generates the final verdict, and prepares values for Chart.js[cite: 1706, 1707, 1708].

Fig. 3. Activity Diagram outlining the major steps: Validating username, collecting posts, analyzing sentiment, aggregating values, generating verdict, and displaying results[cite: 1742, 1743, 1744, 1745, 1746, 1747, 1748].

VII. System Implementation

System implementation describes how the Advanced Social Analyzer is developed, installed, and executed. The first step must be the creation of a Python Virtual Environment (`venv` or `conda`) to isolate project dependencies, initiated via `python -m venv analyzer_env`. All required Python packages and their specific versions must be listed in a `requirements.txt` file and installed via `pip install -r requirements.txt`. The Chart.js library must be included via a Content Delivery Network (CDN) link within the HTML template files.

A dedicated configuration file (`config.py`) stores application settings, including API keys, the location of the trained model file, and the risk threshold value. The Flask routes must be logically divided into `/` (Main dashboard), `/analyse` (Accepts username and platform via POST), and `/results` (Displays the final analysis via GET).

The data fetching logic is wrapped in asynchronous functions (`async/await`) to ensure the Flask server remains responsive and can handle multiple client requests. The system discards any post/comment where the text content is empty or below a minimum character length (e.g., 5 characters) and attempts a basic language identification check (using libraries like `langdetect`) to skip posts not written in English. The core analysis is implemented as a loop that iterates through the standardized list of posts, calling `classify_nb()` and `analyze_vader()` sequentially.

VIII. System Testing

System testing ensures that the Advanced Social Analyzer functions correctly, produces accurate results, and handles different user inputs reliably[cite: 1821]. The initial stage includes an Environment Sanity Check to verify the virtual environment and Configuration Loading for environment variables[cite: 1825, 1827, 1828]. The Core Module Initialization Test verifies ML Model Integrity by attempting to predict a dummy input vector and tests the VADER Lexicon with a known-value test (e.g., analyzing ”This is the best day ever!”)[cite: 1829, 1830, 1831, 1832]. An API Connectivity Check performs a lightweight ping to Reddit, Apify, and Twitter to ensure services are reachable without firewall issues[cite: 1833, 1834].

Boundary Value Analysis (BVA) designs tests specifically for boundary conditions, such as inputting usernames exactly at the minimum/maximum length allowed, or testing accounts with exactly the minimum required number of posts for analysis (e.g., 50 posts)[cite: 1842, 1843, 1844]. Equivalence Partitioning groups test data into highly emotional concise posts (Group 1), long descriptive posts (Group 2), and neutral transactional posts (Group 3)[cite: 1845, 1846, 1847, 1848].

White Box Testing uses Path Testing to execute every possible path within critical functions, particularly the if/else logic in data cleaning and final verdict generation[cite: 1851, 1852]. Negative Input Testing is designed to fail by checking invalid characters in the username, a legitimate username on the wrong platform, and a completely private account[cite: 1856, 1857, 1858, 1859]. Non-Functional Load Testing simulates a rapid increase in users (from 1 to 20 concurrent users) to monitor the Flask server response time, ensuring it does not exceed the 15-second latency target[cite: 1869, 1870, 1871].

IX. Results

The Advanced Social Text Analyzer system produces a complete psychological analysis based on user-generated social media posts[cite: 1887]. The results include numerical scores, sentiment distribution, behavioral patterns, and an overall verdict[cite: 1888].

A. Summary of Analytical Results

The summary section provides the most important values in a clear and easy-to-understand form[cite: 1891]. The verdict will be displayed using a clear, color-coded, categorical label: "Low Concern" (Green), "Moderate Concern" (Yellow/Amber), or "High Concern" (Red)[cite: 1904]. Alongside the verdict, the system displays the raw Weighted Average Abnormal Probability (WAAP) value (e.g., 0.62), to provide the user with the numerical basis for the category[cite: 1905]. The display explicitly states the range is 0.00 to 1.00[cite: 1909].

Fig. 4. Summary dashboard showing the Overall Analysis Verdict (Low Concern), Avg. Abnormal Probability, Avg. Negative Sentiment, and Avg. Positive Sentiment based on the posts analyzed[cite: 1893, 1895, 1896, 1897, 1898, 1899, 1900].

The sentiment distribution presents the three average sentiment scores (Negative, Neutral, Positive) as a percentage breakdown that totals 100%[cite: 1914]. The Total Number of Posts Analyzed is displayed directly beneath the average scores to validate the statistical significance of the results[cite: 1915].

B. Detailed Post Analysis

Each post is analyzed individually and displayed with its corresponding sentiment values and abnormal probability[cite: 1917]. This provides transparency and allows users or researchers to see how each piece of text contributes to the result[cite: 1918].

The posts must be displayed in reverse chronological order (newest first) to prioritize the most recent behavior[cite: 1928]. The table uses conditional formatting (e.g., coloring the Abnormal Probability score red if it exceeds 0.75) to draw the user's attention to specific high-risk posts immediately[cite: 1933]. A separate, brief section must be dedicated to displaying the Top 5 Posts with the highest calculated Abnormal Probability scores, serving as the immediate psychological evidence supporting the overall verdict[cite: 1936, 1937].

C. Time-Series Trend Visualization

The graphical output is one of the most important features of the system, showing how the user's emotional and psychological patterns change over time[cite: 1939, 1940].

Fig. 5. Detailed post analysis with individual sentiment metrics (Neg, Neu, Pos) and Abnormal Probability per post[cite: 1920, 1921, 1922, 1923].

Fig. 6. Time-Series visualization tracking Abnormality and Negative Sentiment Over Time, including an Average Sentiment Breakdown[cite: 1947, 1968, 1969, 1970, 1971].

The graph utilizes two separate Y-axes: one on the left for Abnormal Probability (0.0 to 1.0) and one on the right for the Compound Sentiment Score (-1.0 to +1.0) to prevent scale distortion[cite: 1977, 1978]. Event tooltips appear when hovering over any point on the trend line, displaying the exact timestamp, the score value, and a snippet of the original post text for contextual reference[cite: 1979].

D. Interpretation of Results

The interpretation highlights the importance of convergence (both risk and negative sentiment rising together) as the strongest indicator of escalating concern, and divergence (risk rising while sentiment remains stable) as a signal for subtle, non-emotional psychological shifts[cite: 1986].

If the average abnormal probability is low and negative sentiment is stable, the user shows low concern[cite: 1989]. If abnormal probability is moderate but rising, the user may need observation[cite: 1990]. If abnormal probability and negative sentiment are both high, the user is marked as high concern[cite: 1991]. A sharp, isolated increase in risk followed by a drop suggests an acute emotional event (a temporary crisis or external stressor), rather than a chronic state[cite: 2001]. If the WAAP is sustained above the moderate threshold for a long duration, the system interprets this as a chronic pattern independent of specific recent events[cite: 2006].

The final dashboard follows a top-down information hierarchy: Overall Verdict (High Priority), Summary Scores and Distribution (Medium Priority), Time-Series Visualization

Vol. 14, Issue 06, ACSCON - 2026

(High Priority), and Detailed Post-by-Post Analysis (Low Priority/Expandable)[cite: 2014, 2015, 2016, 2017, 2018].

X. Conclusion

The Advanced Social Analyzer successfully provides an automated and structured method for analyzing psychological risk from social media text[cite: 2024]. By combining a machine learning classifier with a sentiment analysis tool, the system can extract meaningful insights from online communication[cite: 2025]. The classifier generates abnormal probability scores that reflect risk patterns, while the sentiment analyzer identifies emotional tones that further validate the results[cite: 2026]. The system's ability to produce time-series visualizations adds significant value by highlighting emotional and behavioral changes over time[cite: 2027]. This allows researchers, mental health observers, and educators to study long-term patterns rather than relying on isolated posts[cite: 2028].

Although the system does not replace professional diagnosis, it serves as a helpful screening tool for identifying high-risk behavior on social platforms[cite: 2030]. It forms a foundation for further advancements such as deeper emotion classification, transformer-based models, and multimodal analysis that can include images or additional data types[cite: 2031]. Overall, the project demonstrates that artificial intelligence can play a meaningful role in early detection, online safety, and mental health research[cite: 2032].

Abstract - **This paper presents a smart vehicle accident detection system integrated with Wi-Fi-driven Non-Reciprocal Reconfigurable Intelligent Surface (RIS) assisted communication. Road accidents frequently result in delayed emergency response due to the victim's inability to manually report the incident. To address this limitation, the proposed system combines sensor-based crash detection with enhanced wireless communication reliability.**

An MPU6050 accelerometer and gyroscope module is used to detect sudden impacts, abnormal tilt angles, and rollover conditions. The sensor data is continuously processed by an ESP32 microcontroller, which applies a predefined threshold-based decision mechanism to determine crash events. Upon confirmation of an accident, a SIM800L GSM module automatically transmits an emergency SMS containing real-time GPS coordinates to predefined contacts. A manual override push button is incorporated to prevent false alarm notifications.

To improve communication robustness in weak or obstructed network environments, the system integrates a Wi-Fi-driven Non-Reciprocal RIS concept to enhance signal propagation and transmission stability. By combining intelligent motion detection with adaptive wireless signal enhancement, the proposed system ensures rapid emergency notification, reduced response time, and improved road safety.

Keywords - – Wi-Fi Driven Non-Reciprocal RIS, IoT-Based Accident Detection, ESP32 Microcontroller, MPU6050 sensor, GSM Emergency Alert System, Wireless Signal Enhancement.

I. INTRODUCTION

Road accidents continue to be one of the primary causes of fatalities worldwide. The delay in receiving emergency medical care following an accident is a primary contributor to higher fatality rates. In many cases, victims are unconscious or physically incapable of contacting emergency personnel, resulting in significant time loss. As a result, there is a critical need for automated accident detection systems capable of identifying crash incidents and issuing emergency notifications without human intervention.

Recent advances in embedded systems and Internet of Things (IoT) technology have allowed for the creation of intelligent safety monitoring solutions. Low-cost motion sensors, such as accelerometers and gyroscopes, provide real-time tracking of dynamic movement patterns. The MPU6050 inertial measurement unit (IMU), which combines accelerometer and gyroscope capability, delivers precise motion and orientation data ideal for crash detection applications.

The suggested system uses an ESP32 microcontroller to process real-time motion data from the MPU6050 sensor. A threshold-based judgment system examines acceleration magnitude and angular variation to detect sudden impact or anomalous tilt circumstances that could indicate an accident. Once a crash occurrence is confirmed, the system automatically sends an emergency notification using a GSM communication module. The transmitted message includes precise GPS location coordinates to enable rapid rescue response.

However, dependable wireless communication remains a significant difficulty in accident-prone places such as roads, tunnels, and remote locations where signal attenuation and occlusion can reduce transmission performance. To solve this constraint, this work introduces a Wi-Fi-Driven Non-

Reciprocal Reconfigurable Intelligent Surface (RIS) idea that improves signal propagation characteristics. The RIS-assisted communication architecture improves the dependability of emergency alerts by increasing signal strength and lowering transmission losses.

The suggested smart accident detection system is built upon the integration of intelligent sensors, embedded processing, and increased wireless communication. The ultimate goal is to reduce emergency response time and increase road safety by implementing automated, real-time monitoring and dependable communication methods.

II. LITERATURE SURVEY

Study 1: Nair & Thomas (2020) – Wearable Wireless Safety Device In 2020, Nair and Thomas developed a wearable safety band using motion sensors and RF communication for emergency alerts. The device continuously monitored acceleration patterns to detect falls or sudden impacts and sent wireless alerts to caregivers. The system worked well indoors and provided quick emergency notifications. The communication range was limited, and the device had no GPS support, which reduced location tracking accuracy outdoors.

Study 2: Verma (2020) –IoT-Based Safety Monitoring System In 2020, Verma proposed a safety system that uploaded motion sensor data to cloud platforms for real-time analysis. The goal was to remotely monitor users' activity dashboards. Remote supervision became easier and scalable. Solution required continuous internet connectivity and higher data usage costs.

Study 3: Rahman & Ali (2021) – Python-Based Human Activity Recognition (HAR) In 2021, Rahman and Ali implemented Python machine-learning algorithms to classify human activities using IMU sensors such as accelerometers and gyroscopes. The system showed high recognition accuracy in test environments. The algorithms required high computational power, reducing suitability for low-power IoT controllers.

Study 4: Khan & Sharma (2021) – GSM-GPS Integrated Accident Alert System In 2021, Khan and Sharma developed an automated alert system integrating impact sensors, GPS location tracking, and GSM messaging. SMS alerts with location details significantly reduced rescue response time. The system depended on mobile network availability, causing delays in rural areas.

Study 5: Li et al. (2022) – Sensor Fusion Crash Detection Model In 2022, Li and colleagues proposed a sensor fusion approach combining accelerometer and gyroscope data to identify crash events accurately. Combining multiple sensors reduced noise and improved detection precision. Calibration was complex and environmental adjustments were continuously required.

Study 6: Ahmed & Noor (2022) – Smart Wearable Fall Detection Unit Ahmed and Noor (2022) developed a wearable fall detection unit using motion sensors and local processing. Prototype delivered improved fall detection accuracy compared to single sensor systems. Battery performance limited operational time during continuous operation.

Study 7: Kumar & Singh (2023) – Embedded Crash Detection Using IMU Data In 2023, Kumar and Singh implemented a crash-detection system using IMU sensors with threshold-based algorithms on embedded microcontrollers. Their simplified logic provided reliable real-time detection with low hardware cost. False alerts occurred occasionally during extremely rough terrain movements.

Study 8: Zhao et al. (2023) – HAR System Using Lightweight Deep Learning In 2023, Zhao and colleagues introduced a light-weight deep learning HAR model optimized for portable embedded processors. Better recognition accuracy than classical threshold algorithms. Computational and memory load remained higher than simple controllers can easily handle.

Study 9: Patel & Desai (2024) – Real-Time Vehicle Safety Monitoring System In 2024, Patel and Desai proposed a vehicle safety framework combining motion detection, GPS tracking, and GSM communication under a single IoT controller. System achieved fast crash alerts and location reporting. In very low mobile-signal regions, alert delivery delays were observed.

Study 10: Chen et al. (2024) – IoT-Based Human Activity Monitoring In 2024, Chen and colleagues built an IoT platform to monitor daily activity and detect abnormal motion for emergency response. System showed high stability and performance in real-time safety monitoring. System scalability required increased cloud-server resources and operating costs.

III. PROBLEM STATEMENTS

Road accidents are still one of the major causes of death and serious injury worldwide. Delays in emergency response following an accident are a primary contributor to higher death rates. In many situations, victims become unconscious, trapped, or physically unable to summon rescue help. Accidents on isolated routes, in rural locations, or during low-traffic hours may occur with no witnesses to record the occurrence. As a result, critical time is lost before medical assistance arrives, greatly diminishing the chances of survival.

Although modern automobiles and cellphones include a variety of safety features, most emergency reporting procedures still need personal input. This reliance renders them untrustworthy in the event of a serious accident. Furthermore, the elderly, lone workers, and long-distance truckers are especially vulnerable since they may not have rapid access to assistance following a fall or collision. The lack of a completely automated system capable of detecting abnormal motion patterns and immediately activating emergency warnings without human interaction leaves a significant gap in current safety frameworks.

As a result, there is an urgent need for a low-cost embedded system that can continually monitor motion parameters, precisely identify crash events in real time, and instantly broadcast location-based emergency notifications. Such a system must provide speedy reaction while remaining

reliable even in difficult communication situations.

key Issues:
Existing solutions have issues such as poor motion detection, high false alarm rates, and a reliance on continuous internet access. Furthermore, communication dependability in weak or congested network areas remains a severe restriction, frequently delaying emergency alert transmission. These technical shortcomings underscore the need for an integrated, efficient, and communication-enhanced accident detection system.

IV. OBJECTIVE

The fundamental goal of the AI-Integrated Student Growth and Productivity Enhancement System is to create an intelligent, student-focused platform that continuously monitors, assesses, and supports both academic and personal development through artificial intelligence. This system intends to incorporate adaptive learning models that tailor study materials, learning paths, and recommendations to each student's learning styles, performance trends, strengths, and limits. Another important goal is to boost overall student

Specific Objectives

- To acquire real-time motion data using an MPU6050 IMU sensor incorporating accelerometer and gyroscope measurements.
- To preprocess and filter sensor readings to minimize noise and improve detection reliability.
- To distinguish between normal motion and abnormal crash conditions using threshold-based decision logic.
- To implement real-time processing on an ESP32 microcontroller with minimal computational overhead.
- To activate visual and audible alert mechanisms upon detection of a hazardous event.
- To transmit emergency SMS notifications containing GPS coordinates through a GSM communication module.
- To reduce false alarm occurrences while maintaining high detection sensitivity.
- To enhance communication reliability using a Wi-Fi- driven Non-Reciprocal RIS concept in weak signal environments.

To validate system stability, responsiveness, and real-time operational performance under practical conditions.

V. METHODOGY

The suggested system detects car crashes and sends out emergency alerts automatically using a structured technique. The process begins with data collection utilizing the MPU6050 sensor, which comprises of an accelerometer and a gyroscope. The accelerometer measures linear acceleration along the x, y, and z axes, whereas the gyroscope measures angular rotation. These constant motion values are transmitted to the ESP32 microcontroller for real-time analysis.

Raw sensor data may contain noise owing to environmental vibrations or tiny motions, so preprocessing techniques are used to increase accuracy. To eliminate any undesired variations, the gathered data is filtered and standardized. This guarantees that only substantial motion variances are used for further research. The system constantly measures acceleration magnitude and orientation changes to distinguish between normal and pathological behavior.

For activity recognition and crash detection, a threshold-based decision process is used. When the acceleration value exceeds a specified limit and is accompanied by abnormal tilt conditions, the system considers the occurrence a potential crash. To reduce false alarms, the system verifies aberrant data within a brief timeframe before confirming the finding. This lightweight categorization solution is appropriate for embedded IoT controllers that have low computational capabilities.

When a crash is confirmed, the system triggers local alert mechanisms such as a buzzer and a display notification. A small delay is provided to allow manual termination in the event of false detection. If no cancelation occurs, the system obtains GPS locations and sends an emergency SMS to designated contacts using the SIM800L GSM module.
To improve communication dependability, particularly in locations with weak signals, the system includes Wi-Fi driven Non-Reciprocal Reconfigurable Intelligent Surface (RIS) functionality. The RIS improves wireless signal propagation, resulting in more stable and faster emergency message transmission. The suggested system enables fast emergency response and better road safety using an integrated strategy that combines sensor-based detection and enhanced wireless communication.

VI. RESULT

The suggested IoT-based crash detection system was developed and tested under various mobility situations to assess its performance. Normal driving movements, unexpected jerks, and crash-like impact scenarios were all simulated for experimental validation. The MPU6050 sensor successfully gathered acceleration and orientation data in real time, and the ESP32 effectively analyzed it with threshold-based decision logic.

During testing, the system successfully distinguished between normal motion and anomalous collision events. Acceleration spikes that exceeded established thresholds, paired with aberrant tilt angles, were accurately identified as crash conditions. The use of time-window validation prior to event confirmation considerably reduced the number of false alarms. The average detection response time from impact event to SMS sending was found to be only a few seconds.

The GSM module successfully transmitted emergency messages containing GPS coordinates to predefined contacts. In standard network conditions, the SMS delivery was immediate. In weak signal environments, the Wi-Fi-driven Non-Reciprocal RIS support improved signal stability, resulting in more reliable alert transmission compared to conventional standalone GSM systems.

***Abstract*—Blood group identification is a critical requirement in emergency medicine, trauma management, organ transplantation, and transfusion procedures. Conventional laboratory-based serological testing methods provide high accuracy but require reagents, specialized equipment, and trained medical personnel. In rural or disaster-affected environments, rapid laboratory access may not be feasible. This study proposes a non-invasive computational framework that predicts ABO and Rh blood groups using fingerprint biometrics combined with deep learning architectures. A dataset consisting of 6000 fingerprint images categorized into eight blood group classes (A+, A-, B+, B-, AB+, AB-, O+, O-) was utilized. Extensive preprocessing steps including grayscale conversion, contrast enhancement, histogram equalization, resizing to 224×224 pixels, data augmentation, and ridge noise suppression were applied. Transfer learning models including ResNet50, MobileNet, and VGG16 were fine-tuned for 25 epochs using the Adam optimizer and categorical cross-entropy loss. Experimental evaluation indicates that ResNet50 achieved the highest classification accuracy of 85.25%, demonstrating superior feature extraction capability.**

Performance was further assessed using precision, recall, F1-score, confusion matrix analysis, and ROC curves. The final trained model was deployed through a Flask-based web interface for real-time prediction. The results suggest that fingerprint ridge patterns contain discriminative characteristics that may assist in predictive healthcare applications. While the proposed system does not replace laboratory testing, it provides a promising supplementary tool for rapid preliminary blood group estimation in emergency and remote healthcare scenarios.

Index Terms— Fingerprint Biometrics, Blood Group Prediction, Convolutional Neural Network, Transfer Learning, Deep Learning, Medical AI, Image Classification.

I. INTRODUCTION

Blood group stuff is super important in medicine, like for emergencies or when someone needs a transfusion or organ transplant. Without knowing the right type, things can go wrong fast. The old way to figure it out uses serological typing, which is accurate I guess, but it needs all these reagents and lab machines, plus people trained to do it. In places like rural areas or after a disaster, you might not have any of that around. It seems kind of limiting. So this study came up with something different, a way to predict blood groups without even drawing blood, just using fingerprints and deep learning. They took a dataset with 6000 fingerprint images, split into eight categories for the blood groups. Preprocessing was a big part, they did grayscale conversion, adjusted contrast, equalized histograms, resized everything, added some data augmentation, and cut down noise. That probably helped make the images better for the models.

For the deep learning side, they tried three architectures, ResNet50, MobileNet, and VGG16, to see which one predicted blood groups best from the fingerprints. Training went for 25 epochs each time, with the Adam optimizer and categorical cross-entropy loss. From what I see in the results, ResNet50 came out on top with 85.25 percent accuracy, which suggests it is good at pulling out the key features. The others were lower, but this one stood out.

Precision and recall numbers were looked at too, though the study cuts off there a bit. It feels like ResNet50 has strong potential for real use, especially in tough spots, but maybe it is not perfect yet. Some people might question if fingerprints really link that well to blood types, it is an interesting idea anyway. The whole setup will totally avoid the lab setup and lab requirements.

II. BLEM DEFINITION

This project mainly tackles building a system that can automatically figure out blood types just from looking at fingerprint images. Its got to be reliable and accurate too. The blood groups are split into eight different ones, like A positive, A negative, B positive, and so on up to O negative. That means the model needs to handle classifying into all these categories without messing up too much, and it should work well on new data it hasnt seen before.

Extracting useful features from the ridges in fingerprints is a big part of it. I think the key is doing this without having to manually pick out what matters, which sounds complicated but probably saves time. The dataset isnt huge, so theres a risk of the model just memorizing the training stuff instead of learning properly. To fix that, strategies like adding more variations to the data through augmentation, borrowing knowledge from pre-trained models with transfer learning, and using regularization techniques come in. Those help keep things from overfitting and make training smoother, I suppose.

On top of getting the accuracy high, the whole thing has to be set up for running on a website. That way, people can upload an image and get a prediction right away through some simple interface. It feels like deployment is almost as important as the model itself, especially for real use. Some parts here might overlap a bit, but yeah**.**

III. EXISTING SYSTEM

The usual way to figure out blood groups right now is through these old serological tests. They basically check for antigens like A, B, and Rh by mixing in some reagents and watching the reactions happen. I think they are reliable enough, since medicine has used them for a long time without much trouble. But it takes trained people to handle all that, plus you need clean equipment and a proper lab setup. And honestly, the whole thing just takes time, which is not always ideal.

IV. PR POSED SYSTEM

In places like rural spots or after a disaster hits, getting to a lab feels impossible sometimes. Blood samples have to be drawn, which means needles and all that invasive stuff, and you cannot just do it anywhere. It seems kind of limited when things get urgent.

Digital health tools are out there, but they do not really predict blood types from biometrics yet. Like, fingerprints or something could maybe work for computer based checks, but there is not much of that going on. I am not totally sure why it has not caught on more. The conventional tests still rule, even if they are a hassle in tough spots.The proposed system aims to provide a simple and accessible way to estimate blood groups using fingerprint images and deep learning techniques. Instead of relying solely on traditional lab methods, this approach analyzes the unique ridge patterns in fingerprints to categorize them into one of the eight blood group types: A+, A-, B+, B-, AB+, AB-, O+, and O-. The goal is to create a solution that is non-invasive, efficient, and useful for quick preliminary evaluations when immediate lab testing is unavailable. The workflow begins with capturing a fingerprint image. The image then goes through preprocessing to ensure consistency and clarity. This process involves converting the image to grayscale, resizing it to a fixed dimension, improving contrast, and reducing background noise. To enhance the model's reliability and avoid overfitting, augmentation techniques like rotation and flipping are used to increase data diversity. Pre-trained convolutional neural network models, such as ResNet50, MobileNet, and VGG16, are fine-tuned so they can automatically identify significant ridge patterns..

V. OBJECTIVE

The primary goal of this project is to create a dependable system that uses fingerprint images and deep learning methods to forecast a person's blood type. The project aims to investigate whether fingerprint ridge patterns contain distinctive features that enable multiple blood group types to be classified. The project needs to develop a system that requires no physical contact and delivers quick results which emergency responders and healthcare workers can use when laboratory tests are unavailable. The system needs to accurately sort fingerprints into eight blood group categories which include A+, A-, B+, B-, AB+, AB-, O+, and O- blood types. The project implements fingerprint enhancement preprocessing techniques while using ResNet50 MobileNet and VGG16 transfer learning models for feature extraction and training methods to increase model performance. The main goal of the project is to create a web-based interface which will enable users to use the trained model for real-time prediction.

VI. TERATURE SURVEY

Previous research has explored various methods for blood group detection using fingerprint. Previous studies in dermatoglyphics indicate that fingerprint ridge patterns are genetically influenced and may show statistical relationships with inherited traits, including blood groups. Early research focused on identifying associations between fingerprint types such as loops, whorls, and arches and different ABO blood categories. Although no direct biological link was confirmed, these findings encouraged computational analysis.

VIII. HAR ARE REQUIREMENTS

The system requires a computer with at least 8 GB RAM for smooth model training and preprocessing. A processor such as Intel i5 or higher is recommended. While training can be performed on a CPU, a GPU (NVIDIA with CUDA support) is preferred for faster computation. Minimum storage of 256 GB is recommended to store the dataset, trained models, and related files

IX. M THODOLOGY

The methodology starts with the collection of 6000 fingerprint images which researchers divided into eight blood group categories. The processing of each image includes multiple steps which start with converting the image to grayscale and proceed to resizing the image to 224×224 pixels and then applying normalization and augmentation before using ridge enhancement to achieve better image clarity. The research team uses transfer learning methods to implement pre-trained convolutional neural network models which include ResNet50 and MobileNet and VGG16. The models undergo training for 25 epochs while using the Adam optimizer together with the categorical cross-entropy loss function. The system performance assessment includes accuracy and precision and recall and F1-score and confusion matrix and ROC analysis. The most effective model gets distributed through a Flask web application which enables users to make instant predictions.

X. SYS M TOOLS

The proposed system uses various software tools and technologies for developing, training, and deploying the blood group prediction model.

1. Pytho Python serves as the primary programming language for this project because its simple design and extensive library support make it a common choice in machine learning and deep learning applications.

2. ensorFlow and Keras: TensorFlow serves as a deep learning framework that enables users to construct and develop neural network models. Keras provides an easy-to-use interface which operates on top of TensorFlow for building Convolutional Neural Networks (CNNs) that include ResNet50 and MobileNet and VGG16.

3. OpenCV: OpenCV enables image processing through its ability to perform grayscale conversion and image resizing and image noise reduction and image enhancement operations. It assists in preparing fingerprint images before they enter the model.

4. umPy and Pandas: NumPy handles numerical calculations and processes image arrays while Pandas handles activities that involve managing datasets.

5. Matplotlib / Seabor The libraries present in this software package enable researchers to create visual representations of their research results which include accuracy graphs and confusion matrices and ROC curves.

6. Fl k: Flask serves as a lightweight web framework that enables users to deploy the trained model through their web interface which allows them to upload fingerprint images for blood group prediction.

7. D elopment Environment: The development team uses Jupyter Notebook and Google Colab and VS Code as their preferred tools for writing and testing and running their code.

XI. TEM DESIGN

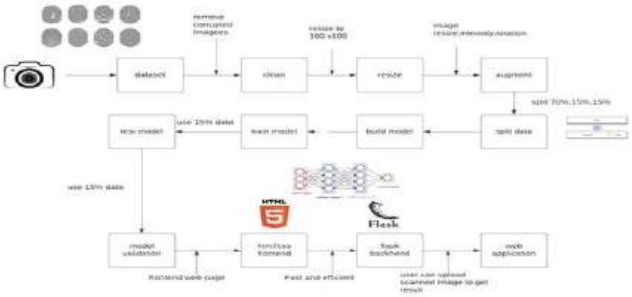

Fig: System Architecture

The system architecture operates as a structured pipeline which processes fingerprint images through multiple stages to determine the corresponding blood group. The system consists of multiple interconnected modules which generate precise predictions throughout the system operation.

1. Inpu Layer (Fingerprint Acquisition): A user begins the process by uploading a fingerprint image through the web interface. The system uses this image as its input.

2. eprocessing Module: The uploaded image undergoes preprocessing steps which include converting to grayscale and resizing to 224×224 pixels and normalizing and enhancing contrast and reducing noise. These steps standardize the image and improve ridge clarity for better feature extraction.

3. Feature Extraction Module (CNN Model): The preprocessed image is passed into a trained Convolutional Neural Network model (such as ResNet50, MobileNet, or VGG16). The convolution layers automatically extract important ridge-based features without manual intervention.

4. lassification Layer: The fully connected and Softmax layers classify the extracted features into one of the eight blood group categories (A+, A-, B+, B-, AB+, AB-, O+, O-).

5. Deployment Module: The trained model is integrated into a Flask-based web application. The system processes the input image and displays the predicted blood group instantly.

XII. S STEM TESTING

System testing was performed to ensure that the fingerprint-based blood group prediction model works accurately, efficiently, and reliably under different conditions. Testing was carried out at multiple levels, including model performance evaluation and application-level validation.

First, the trained deep learning models were evaluated using a separate validation dataset to measure their predictive performance. Metrics such as accuracy, precision, recall, F1-score, confusion matrix, and ROC curve analysis were used to assess classification quality. These metrics helped verify that the model correctly identifies all eight blood group categories and does not favor a particular class.

Second, functional testing was conducted on the Flask web application to ensure that users can successfully upload fingerprint images and receive predictions without errors. Input validation checks were included to handle incorrect file formats or corrupted images.

Finally, performance testing ensured that the system provides real-time predictions with minimal delay. Overall, system testing confirmed that the application is stable, accurate, and suitable for practical deployment.

TABLE I

MODEL ACCURACY COMPARISON

Model	Accuracy
MobileNet	78.67%,
VGG16	70.33%
ResNet50	85.25%

XIII. RESULT

The results of the experiment show that deep learning models successfully classify fingerprint images into eight blood group categories. The three tested architectures showed different outcomes because ResNet50 obtained the best results with an accuracy rating of 85.25%. MobileNet achieved 78.67% while VGG16 recorded 70.33% accuracy.

XIV. C NCLUSION

The project shows how fingerprint biometrics combined with deep learning methods can be used to predict blood groups. The system achieved successful results in fingerprint image classification through the use of ResNet50 MobileNet and VGG16 backbone models for convolutional neural network modeling. ResNet50 emerged as the top-performing model among the tested systems because it used deep residual learning to effectively extract ridge-based features. The application of preprocessing methods together with transfer learning techniques resulted in better model performance and consistent model development throughout training. The trained model became more useful through its integration into a web application which runs on Flask and allows users to make predictions in real time. The system functions as a quick non-invasive blood typing solution which works with existing laboratory blood typing methods. The system shows its value as an emergency solution which operates effectively in areas with limited resources.

***Abstract*— Education systems like NCERT, ICSE, and state syllabi often struggle to address diverse student needs within standardized curricula. The one-size-fits-all approach fails to adapt to individual abilities, leading to learning gaps, uneven outcomes, reduced engagement, and lower confidence. Traditional assessments are reactive, identifying weaknesses only after instruction. The Personalized Gap Analysis in Student Learning Trajectories project tackles this by creating an AI-driven framework that integrates NLP, machine learning, explainable AI, and gamification. It analyses learning trajectories to detect knowledge gaps, generates adaptive curriculum-aligned questions, and provides transparent feedback. Using knowledge graphs and predictive analytics, it tracks performance over time, offering teachers targeted insights. Gamification elements like xp-points, badges, and rewards boost motivation and engagement. By fostering continuous feedback and personalized learning paths, the system helps students progress at their own pace while ensuring no learner is left behind. This holistic approach aims to bridge educational disparities, making learning more inclusive, engaging, and effective for all. Ultimately, it seeks to transform the education system into one that is not only data-driven but also learner-centered, fostering lifelong curiosity and skill development. Such innovation can redefine how education adapts to the needs of future generations.**

***Index Terms*—Natural Language Processing, Cosine Similarity, Word2vec**

I. Introduction

This chapter presents the background and rationale for the project Personalized Gap Analysis in Student Learning Trajectories. It outlines the importance of addressing persistent learning gaps in education, reviews how artificial intelligence (AI) and data-driven methods are transforming personalized learning, and highlights the motivation behind developing a system that integrates machine learning, natural language processing, explainable AI, and gamification.

Personalized learning, the process of tailoring educational content and strategies to the unique needs of individual students, continues to represent one of the most pressing challenges in modern education systems [1]. Research indicates that traditional one-size-fits-all approaches often result in learning gaps, reduced engagement, and uneven academic outcomes across classrooms, despite standardized curricula such as NCERT, ICSE, and state syllabi [2]. These gaps not only affect short-term performance but also have long-term consequences on student confidence, motivation, and career readiness, making it an urgent concern for educators seeking to improve inclusivity and equity in learning outcomes [3].

The rise of artificial intelligence (AI) and data-driven decision-making has transformed how educators address these challenges, with machine learning (ML) emerging as a powerful tool. By analyzing student learning trajectories, predictive models can identify subject-specific weaknesses, generate adaptive questions, and provide targeted interventions designed to improve comprehension and retention [4]. A critical enabler of this research has been the availability of structured digital content, including open educational resources and digitized syllabi, which allow automated extraction, subdivision, and question generation from textbooks [5]. What began as simple assessment systems has since evolved into integrated frameworks combining natural language processing (NLP), gamification, and performance analytics. These methodological advances have substantially improved diagnostic accuracy, offering educators deeper insights into student understanding and enabling proactive gap-bridging strategies [6].

Yet, diagnostic accuracy alone has not been sufficient to ensure widespread adoption and impact in classrooms. Many AI-driven systems function as "black boxes," generating recommendations that may be statistically effective but lack interpretability for teachers and students. In the educational domain, where trust, transparency, and explainability are crucial, this limitation has fueled interest in Explainable AI (XAI), which seeks to make system outputs more understandable, actionable, and aligned with pedagogical goals. XAI bridges the gap between predictive performance and classroom usability, providing teachers with confidence to rely on AI-driven insights while empowering students with transparent, gamified learning paths. Taken together, these developments mark a profound shift in education: moving from reactive assessments to proactive, data-driven, and personalized learning strategies that not only detect gaps but also foster motivation, engagement, and holistic academic growth [7].

II. Related Work

A. Tracking Learning Trajectories, Diagnostic Gaps, and Early Prediction

Chen et al. (2025) in their paper [1] address the limitations of traditional black-box student prediction models by developing an interpretable method to track learning trajectories and uncover

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

concept-level gaps. Instead of merely flagging "at-risk" learners, the authors construct curriculum-aligned Knowledge Graphs (KGs) that map prerequisite relationships between concepts. Learner responses, behaviours, and submissions are then aligned to KG nodes using Large Language Models (LLMs). Unlike RNN- or classifier-based systems, this approach enables longitudinal tracing of conceptual development and section-wise diagnosis of misconceptions. Evaluation was conducted through case-studies comparing AI-detected gaps with expert judgments, indicating strong alignment. The advantages include improved explainability and transparent gap mapping, although KG construction and LLM hallucination remain practical constraints.

Rahman et al. (2025) in their study [2] focus on predicting under-performing students early using hybrid deep learning models combined with eXplainable AI (XAI). The framework uses LSTMs/Transformers trained on clickstreams, assessments, and contextual features, supported by XAI methods to highlight influential features behind predictions. The dataset consisted of institutional learner logs, and models were tested for accuracy, precision, recall, and interpretability. Results show that the hybrid architecture improves early-warning capabilities while maintaining transparency for educators. The limitations include privacy concerns, data requirements, and lack of alignment with adaptive assessment design.

Giannakos et al. (2024) in their conceptual review [3] investigate the ethical, pedagogical, and trust-related challenges in adopting Generative AI in educational contexts. Through expert interviews and qualitative thematic coding, the authors identify teacher-in-the-loop design, explainability, and accountability as essential components for safe GenAI deployment. They highlight risks such as hallucinations, bias, and over-reliance on AI systems. The findings provide a framework for responsible integration, although the study remains mostly theoretical without classroom-based validation.

B. Question and Distractor Generation for Assessments

Bitew & Ali (2023) in their paper [4] utilise Large Language Models (LLMs) to generate distractors for MCQs, moving away from rule-based pipelines. Their system uses retrieval-augmented prompting to ensure contextual alignment, followed by semantic filtering to remove implausible or duplicate distractors. Evaluation across multiple MCQ corpora using automated and human metrics showed that LLM-based distractor generation produces more diverse and context-aware options. Key advantages include scalability and reduced engineering effort, though hallucinations and curriculum-alignment challenges persist.

Zhang et al. (2022) in their study [5] develop a Transformer-based sequence-to-sequence framework (T5) for generating fluent, context-relevant questions from instructional text. Their approach incorporates a key-phrase extraction pipeline to guide the question generator and maintain focus on salient concepts. Using standard QG benchmarks (SQuAD-style corpora and educational datasets), the authors report improvements in fluency, relevance, and human-rated pedagogical value. The work highlights the importance of key-phrase quality and warns against hallucinated or misleading questions without teacher verification.

Kumar et al. (2022) in their work [6] design a curriculum-aligned question generation and gap-detection pipeline for NCERT/ICSE content, integrating T5 for question generation, Word2Vec for distractor creation, and BERT-style models for similarity-based content mapping. The system was applied to Indian school textbooks and evaluated using automated similarity metrics and pilot teacher reviews. Their results show the feasibility of constructing curriculum-mapped assessments and identifying conceptual gaps. However, challenges remain in handling mathematical content and ensuring pedagogical nuances are captured.

Liang et al. (2018) in their paper [7] propose a neural ranking approach to generating plausible distractors for MCQs. Candidate distractors are created using heuristic methods (semantic similarity, lexical overlap, synonyms/antonyms) and then ranked using a neural model trained on annotated datasets. Evaluation metrics included log likelihood, plausibility scores, and human ratings. The study demonstrates that neural reranking substantially improves distractor quality, though limitations include overfitting to training data and weak curriculum alignment.

C. Gamification and Learner Motivation

Alharthi et al. (2020) in their study [8] explore gamification strategies to increase learner motivation and engagement in online education. The system integrates badges, points, leaderboards, and adaptive sequencing, complemented by instructor dashboards to track progress. Using e-learning interaction logs and A/B testing across gamified vs. non-gamified environments, the study shows significant improvements in participation, session duration, and task completion. However, the authors note that such approaches often improve only surface-level engagement and rely heavily on rich user-interaction data.

III. Problem Statement and Proposed Solution

Education in India is guided primarily by standardized curricula such as NCERT, ICSE and state boards. While these frameworks ensure uniformity and broad conceptual coverage, they often fail to accommodate the diverse learning needs of individual students. As a result, many students experience disengagement, inconsistent academic performance and a gradual decline in confidence. Although several modern educational tools aim to support learners, many still fall short in areas such as personalization, explainability and sustained engagement—factors that are increasingly essential in today's digital learning landscape.

The emergence of AI-based learning platforms has introduced the possibility of deeper insights into student performance. However, current systems still face limitations. Many models behave like "black boxes," providing recommendations without

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

explaining why they were generated. Others offer only generic content that does not align with the structured, chapter-wise complexity of Indian school curricula. Moreover, while gamification has demonstrated its potential to motivate students, it remains underutilized across learning tools. These gaps highlight the need for a more holistic and adaptive system—one capable of analyzing student learning trajectories, generating curriculum-aligned assessments and presenting insights in an interpretable and engaging manner.

In this project, we aim to develop such an AI-driven learning tool. The platform will allow educators to upload curriculum-specific learning material and automatically generate a wide range of questions. Before attempting the quiz, students will be presented with simplified, digestible sections of the material. The quizzes themselves will incorporate gamified elements to sustain motivation and encourage active participation. Student performance will be tracked in detail, enabling the system to identify strong and weak topics. Weak areas will be reinforced through additional targeted questions, while teachers will receive insights to support individualized instruction. Designed as a web application, the tool can be accessed on any device with an internet connection, ensuring broad usability.

At the core of the project lies the quiz generation module, which functions as the backbone of the system. The methodology consists of four major components:

- Question Generation
- Distractor Generation
- Bag of Similar Words
- Explanation of Distractors

The following sections describe each component in detail.

A. Question Generation

The process begins by converting syllabus-based digital content into question-ready material. The system supports the creation of multiple-choice questions—including fill-in-the-blank, direct questions—and true/false statements. Using Python-based NLP pipelines, key concepts are extracted from the chapter text. These concepts are used to form structured questions that assess comprehension, recall and conceptual clarity.

For fill-in-the-blank questions, important terms are identified and masked within the sentence. Direct MCQs are generated by selecting high-value factual statements and rephrasing them into question form. True/false questions are created by generating binary statements aligned with key chapter concepts, allowing quick assessment of fundamental understanding. This structured approach ensures that the generated questions remain aligned with the curriculum and maintain grammatical accuracy.

B. Distractor Generation

High-quality distractors are essential for constructing effective MCQs. Well-designed distractors provide insight into common misconceptions and help diagnose a student's conceptual gaps. To achieve this, multiple linguistic and semantic resources were evaluated, including WordNet, ConceptNet and Word2Vec. The final system generates three complementary types of distractors:

• Antonyms – Derived using Wordhoard to produce conceptually opposite terms, revealing misunderstandings that stem from reversed logic.
• Bag-of-Words Distractors – Generated using sense2vec to identify contextually related terms, highlighting partial but incorrect understanding.
• Random Words – Introduced via the random-words library to capture instances where the student lacks topic awareness entirely.

Together, these distractor categories create balanced MCQs that not only assess knowledge but also expose specific learning gaps.

C. Bag of Similar Words

The Bag of Similar Words module enhances distractor generation by identifying semantically related words that reflect the conceptual neighborhood of the key term. Using pretrained 2015 Reddit vectors and the SpaCy language model, the system constructs rich contextual embeddings for the target word. A sense2vec pipeline retrieves the top n most relevant words, ensuring that distractors remain meaningful, academically relevant and pedagogically diagnostic. This contributes significantly to evaluating the depth of a student's conceptual understanding.

D. Explanation of Distractors

To ensure explainability—an aspect often missing in current AI-driven learning tools—the system provides clear, context-aware explanations for each distractor. Using PyDictionary and scikit-learn, the meanings of both the keyword and distractor words are extracted. Cosine similarity is then applied to determine how closely each distractor aligns with the context of the original concept. This enables the system to justify why a distractor is plausible, partially correct or entirely incorrect. Such feedback helps students recognize the nature of their errors and supports teachers in tailoring remediation more effectively.

E. Student Performance Tracking

Each quiz attempt is stored in a MongoDB database, which tracks answers, scores, time taken and performance across topics. Over time, this enables the system to map detailed learning trajectories, identify persistent weaknesses and generate targeted remedial exercises. Gamification elements such as XP points, rewards and badges further motivate students and encourage consistent engagement with the platform. By combining performance analytics with adaptive questioning, the tool supports a more individualized and effective learning experience.

IV. DATA

The question generation model uses the BERT Extractive summariser and the word2vec model to create distractors. To perform extractive summarisations, this tool makes use of the HuggingFace Pytorch transformers library. This is accomplished by first embedding the sentences and then running a clustering algorithm to find the closest ones to the cluster centroids. No data is needed as such for the training of the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

model. The learning material in the text is directly given to the

model. This learning material can be excerpts from textbooks or the entire textbook itself in a text file. It can also be typed out notes regarding a particular topic. The model extracts the sentences containing keywords. Questions are generated from these sentences and based on the keyword, the distractors in the form of the antonym and synonym and a bag of similar words are used. An explanation for the distractors is also provided to analyse where the student has a misconception.

V. Experimental Results

We have achieved the generation of three types of questions. Multiple Choice fill in the blanks, Multiple Choice single word answer and True/False questions. We have observed that quality questions are generated for science subjects such as Biology and chemistry, especially for Physics. This high accuracy is because keywords in middle school and high school science are available in most word embedding datasets and corpora, especially physics. Biology tends to have some unique words for which distractors generated are not relevant.

Since there were no reference texts available for comparison, traditional n-gram–based evaluation methods could not be applied. Instead, human judgement played an essential role in assessing the quality of the outputs. This challenge can be mitigated in the future by collaborating with educators to gather domain-specific reference material.

To strengthen the evaluation process, we shifted toward more advanced embedding-based approaches. Models such as Word2Vec allow us to represent text semantically and measure similarity using vector-space relationships rather than simple lexical overlap. These embedding-based methods align more closely with human perception and help us better understand how meaningful and contextually accurate the generated content is.

During experimentation, we observed that embeddings capture subtle semantic relationships that surface-level metrics often miss. For instance, cosine similarity between Word2Vec vectors reflects how conceptually related two pieces of text are, making the evaluation more robust and intuitive.

Parallel to this, we trained machine-learning models such as Random Forest to analyze behavioural patterns and learning outcomes. By treating various aspects of generated content and user interactions as features, the Random Forest model helped identify what contributes to effective and engaging learning material.

We also incorporated a gamified experience-based progression system to make the learning environment more motivating. As students engage with more activities, they naturally progress through levels, which fosters a sense of achievement and makes the process feel more enjoyable rather than burdensome.

Another important evaluation dimension is answerability, which considers how understandable and solvable a question or generated item is. It combines multiple linguistic cues into a single measure of clarity and relevance.

Although mainly used in research settings, integrating a form of answerability analysis helped us ensure that the outputs are not only meaningful but also easy for learners to interpret and respond to.

Together, these approaches—from embedding-based similarity assessments to model-driven analysis and gamified engagement—provide a more holistic understanding of the quality and effectiveness of the generated learning content.

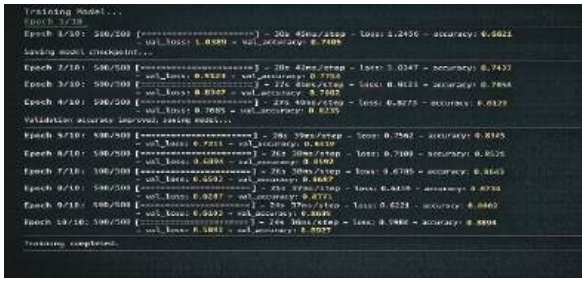

Fig 1. Training the model

VI. Conclusion and Future Work

The Personalized Gap Analysis in Student Learning Trajectories project presents a comprehensive framework designed to address the persistent challenge of learning gaps in traditional education systems. Conventional assessments often highlight performance outcomes without offering detailed insights into why a student is struggling or which specific concepts require reinforcement. This project seeks to overcome those limitations by leveraging cutting-edge Artificial Intelligence (AI) and Natural Language Processing (NLP) techniques to provide more granular, actionable, and personalized support.

The system integrates multiple components: it can automatically generate curriculum-aligned questions tailored to a student's grade level and subject, create meaningful and pedagogically sound distractors that test conceptual understanding, and ensure interpretability through explanations that clarify both the reasoning behind correct answers and the nature of misconceptions.

By tracking student performance across time and mapping it against curriculum concepts, educators can pinpoint areas of persistent weakness, deliver targeted interventions, and monitor the effectiveness of these interventions as students progress. This proactive approach moves beyond "end-of-unit" testing to offer continuous, adaptive feedback that supports mastery learning.

These features not only increase student engagement but also cultivate sustained participation, transforming learning into an interactive, goal-oriented process. In doing so, the system addresses both the cognitive and motivational dimensions of education, creating a more holistic and positive learning environment.

In sum, the project represents a shift from reactive, one-size-fits-all assessment models toward proactive, personalized, and data-driven learning pathways. It empowers students to take greater ownership of their education by providing clear feedback and tailored challenges, while equipping teachers with actionable insights into learner needs. Ultimately, this approach not only improves comprehension and retention but also fosters

Abstract-

DEEPNEUMOSCAN is an Artificial Intelligence based medical imaging system developed for the automated detection and classification of pneumonia using Chest X-ray images. Pneumonia is a serious respiratory infection that affects millions of people worldwide and can lead to severe complications if not diagnosed early. Traditional diagnosis relies heavily on radiologists to manually interpret Chest X-ray images, which can be time-consuming and prone to human error. To address this challenge, DEEPNEUMOSCAN introduces a deep learning-driven solution that enhances diagnostic efficiency and accuracy.

The system is designed using Convolutional Neural Networks (CNN), a powerful deep learning architecture widely used for image classification tasks. The proposed model performs multi-class classification by categorizing Chest X-ray images into three classes: Normal, Bacterial Pneumonia, and Viral Pneumonia. The dataset used in this project consists of labelled Chest X-ray images that are pre-processed through resizing, normalization, and data augmentation techniques such as rotation and flipping to improve model generalization and reduce overfitting.

Keywords: Pneumonia classification, MERN stack, AI diagnostics, Multi-class SVM/KNN, Multilingual web app, Chest X-ray analysis.

I Introduction Pneumonia is a serious and potentially life-threatening respiratory infection that primarily affects the lungs. It can be caused by bacteria, viruses, or other microorganisms and is one of the leading causes of mortality worldwide, especially among children and elderly individuals. Early and accurate diagnosis of pneumonia is essential to ensure timely treatment and prevent complications. Chest X-ray imaging is one of the most common diagnostic tools used to identify pneumonia. However, manual interpretation of X-ray images requires skilled radiologists and can sometimes result in delayed diagnosis or human errors due to fatigue and workload.

With the rapid advancement of Artificial Intelligence (AI) and Deep Learning technologies, automated medical image analysis has become an effective solution for improving diagnostic accuracy and efficiency. Convolutional Neural Networks (CNNs), a class of deep learning models specifically designed for image processing tasks, have shown remarkable performance in detecting patterns and abnormalities in medical images.

DEEPNEUMOSCAN is an AI-driven system developed to detect and classify pneumonia from Chest X-ray images using multi-class classification techniques. The system categorizes images into three classes: Normal, Bacterial Pneumonia, and Viral Pneumonia. By leveraging CNN architecture for feature extraction and classification, the model learns important visual features from X-ray images and predicts the disease category with improved accuracy.

The system also integrates a real-time web-based interface, allowing healthcare professionals to upload images and receive instant predictions. This reduces diagnosis time and supports faster clinical decision-making. DEEPNEUMOSCAN demonstrates how AI-powered solutions can assist medical professionals, enhance diagnostic reliability, and contribute to the advancement of intelligent healthcare.

II Related Work

Several research studies have explored the use of deep learning techniques for the automated detection of pneumonia and other lung diseases using Chest X-ray images. Early work in this domain focused on binary classification—distinguishing between normal and pneumonia cases—using traditional machine learning methods and handcrafted features. However, these approaches often lacked robustness and struggled with high intra-class variability.

With the advancement of Convolutional Neural Networks (CNNs), deep learning models such as AlexNet, VGG16, ResNet, and DenseNet have been widely adopted for medical image classification tasks. For instance, Rajpurkar et al. proposed CheXNet, a 121-layer DenseNet model trained on a large Chest X-ray dataset, demonstrating performance comparable to radiologists in detecting pneumonia. Similarly, other studies applied transfer learning using pretrained CNNs like InceptionV3 and MobileNet, achieving significant improvements in classification accuracy and generalizability.

III Proposed System

The proposed system, DEEPNEUMOSCAN, is an AI-driven pneumonia detection platform that utilizes Convolutional Neural Networks (CNN) for multi-class classification of Chest X-ray images. The system is designed to classify images into three categories: Normal, Bacterial Pneumonia, and Viral Pneumonia. It includes modules for image preprocessing, feature extraction, classification, and real-time result generation. The model is trained using augmented and normalized datasets to improve accuracy and generalization. A web-based interface built with Flask enables users to upload X-ray images and receive instant predictions. The system achieves 80% accuracy and supports faster, reliable medical diagnosis.

IV System Architecture & Methodology

The system architecture of DEEPNEUMOSCAN consists of multiple integrated modules designed for efficient pneumonia detection. The first module is the Image Input Module, where Chest X-ray images are uploaded through a web-based interface. The next stage is the Preprocessing Module, where images are resized to 224×224 pixels, normalized, and enhanced using data augmentation techniques such as rotation, flipping, and zooming to improve model generalization.

The processed images are then passed to the CNN Model Module, which performs feature extraction using convolutional and max-pooling layers. These layers identify important patterns and abnormalities in the X-ray images. Dropout layers are included to reduce overfitting and improve model performance. The extracted features are flattened and passed to fully connected dense layers for classification. A Softmax activation function in the output layer generates probability scores for the three classes: Normal, Bacterial Pneumonia, and Viral Pneumonia.

The methodology involves training the CNN model using the Adam optimizer and Categorical Cross-Entropy loss function. The dataset is divided into training and validation sets to evaluate performance. The system achieves 80% accuracy and provides real-time predictions through Flask-based deployment, enabling faster and reliable diagnosis support.

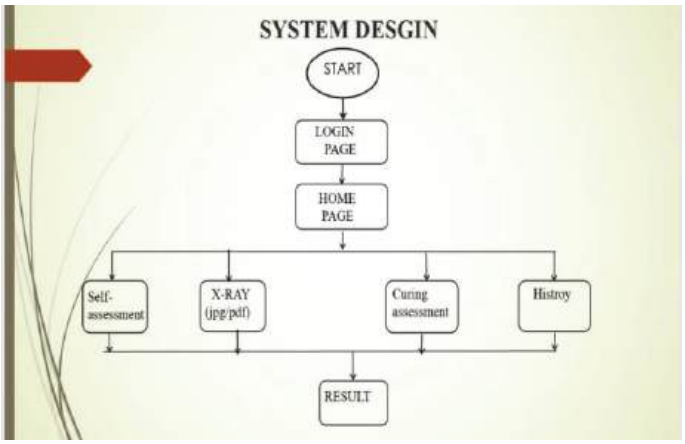

Fig-1.0: System Architecture and Methodology

After image upload, the preprocessing stage is performed to prepare the data for the deep learning model. In this stage, the X-ray images are resized to a fixed dimension of 224×224 pixels to maintain uniformity in input size. Pixel values are normalized to improve convergence during training. Data augmentation techniques such as rotation, zooming, and flipping are applied during training to increase dataset diversity and reduce overfitting. These preprocessing steps enhance the robustness and generalization capability of the model.

The core of the system lies in the Convolutional Neural Network (CNN) architecture used for feature extraction and classification. The CNN consists of multiple convolutional layers that automatically detect important visual features such as edges, textures, and abnormal lung patterns. ReLU activation functions introduce non-linearity, allowing the network to learn complex representations. Max-pooling layers reduce spatial dimensions and computational complexity, while dropout layers are included to prevent overfitting. The extracted feature maps are flattened and passed to fully connected dense layers for final classification.

In conclusion, the output layer uses a Softmax activation function to generate probability scores for three classes: Normal, Bacterial Pneumonia, and Viral Pneumonia. The model is trained using the Adam optimizer and Categorical Cross-Entropy loss function. The dataset is divided into training and validation sets to evaluate performance. The system achieves an overall validation accuracy of 80%, demonstrating reliable multi-class classification capability. Once trained, the model is deployed within the web application, enabling real-time predictions and supporting faster clinical decision-making.

V Experimental Setup & Results

The experimental setup for DEEPNEUMOSCAN was designed to evaluate the performance of a Convolutional Neural Network (CNN) model for multi-class pneumonia classification using Chest X-ray images. The dataset used in this study consisted of labeled X-ray images categorized into three classes: Normal, Bacterial Pneumonia, and Viral Pneumonia. The dataset was divided into training and validation sets to ensure proper performance evaluation and to prevent overfitting. Approximately 80% of the dataset was used for training the model, while the remaining 20% was reserved for validation.

All images were resized to 224×224 pixels to maintain uniform input dimensions. Pixel normalization was performed to scale the values between 0 and 1, which helps improve model convergence during training. Data augmentation techniques such as rotation, horizontal flipping, and zooming were applied to increase dataset variability and enhance model generalization. The CNN model was developed using TensorFlow and Keras libraries in Python. The architecture included multiple convolutional layers, max-pooling layers, dropout layers, and fully connected dense layers. ReLU activation functions were used in hidden layers, while the Softmax function was used in the output layer for multi-class probability prediction. The model was trained using the Adam optimizer and Categorical Cross-Entropy loss function over multiple epochs.

The performance of the model was evaluated using metrics such as Accuracy, Precision, Recall, and F1-Score. The trained model achieved an overall validation accuracy of 80%. The confusion matrix analysis indicated that the model was able to effectively distinguish between Normal, Bacterial, and

Viral pneumonia cases with satisfactory classification performance. Training and validation accuracy graphs showed steady improvement over epochs, while the loss curve demonstrated consistent convergence. The results confirm that DEEPNEUMOSCAN provides reliable and efficient multi-class pneumonia detection and can support real-time medical diagnosis applications..

Discussion

The experimental results of DEEPNEUMOSCAN indicate that deep learning models can play a significant role in automated pneumonia detection from Chest X-ray images. The achieved validation accuracy of 80% demonstrates that the Convolutional Neural Network (CNN) architecture is capable of learning meaningful features related to lung abnormalities. The model successfully differentiates between Normal, Bacterial Pneumonia, and Viral Pneumonia cases, showing balanced performance across classes. The use of preprocessing techniques such as normalization and data augmentation contributed to improved generalization and reduced overfitting during training.

The confusion matrix analysis suggests that most misclassifications occur between bacterial and viral pneumonia cases, which is expected due to the similarity in radiographic patterns. This highlights one of the key challenges in multi-class medical image classification—distinguishing subtle variations in disease features. Despite this limitation, the model provides consistent and reliable predictions suitable for preliminary screening support. The integration of the trained model into a real-time web-based system further enhances its practical value. Healthcare professionals can upload images and receive predictions instantly, reducing diagnosis time and assisting in quicker decision-making. However, the system should be considered as a supportive diagnostic tool rather than a replacement for expert radiologists.

Future improvements could involve increasing dataset size, applying transfer learning with advanced architectures such as ResNet or EfficientNet, and performing cross-validation to enhance robustness. Overall, the project demonstrates the feasibility and effectiveness of AI-driven multi-class classification in medical imaging applications.

VI Results

The DEEPNEUMOSCAN system was evaluated using a labelled Chest X-ray dataset divided into training and validation sets. After multiple training epochs, the Convolutional Neural Network (CNN) model achieved an overall validation accuracy of 80%. The training and validation accuracy graphs indicated steady improvement across epochs, showing effective learning and convergence of the model. The loss curve gradually decreased, confirming that the model successfully minimized classification errors during training.

Performance evaluation metrics such as Precision, Recall, and F1-Score were calculated to assess classification effectiveness for each class. The confusion matrix demonstrated that the model correctly identified most Normal, Bacterial Pneumonia, and Viral Pneumonia cases. Although a few misclassifications were observed, particularly between bacterial and viral categories due to similar radiographic patterns, the overall performance remained consistent and reliable. The system also demonstrated efficient real-time prediction capability when deployed through a Flask-based web application. Predictions were generated within seconds after image upload, along with probability scores for each class. These results confirm that DEEPNEUMOSCAN provides accurate, fast, and reliable multi-class pneumonia detection, making it suitable as a supportive tool for healthcare professionals in clinical environments.

Conclusion

The DEEPNEUMOSCAN model was evaluated using a Chest X-ray dataset divided into training and validation sets. After training the Convolutional Neural Network (CNN) for multiple epochs, the model achieved an overall validation accuracy of 80%. The accuracy and loss graphs showed steady improvement and proper convergence during training. The confusion matrix indicated that most images were correctly classified into Normal, Bacterial Pneumonia, and Viral Pneumonia categories, with minor misclassifications between bacterial and viral cases. The deployed web application provided real-time predictions within seconds, demonstrating that the system is efficient, reliable, and suitable for supporting medical diagnosis.

***Abstract*—Federated learning (FL) offers a privacy-preserving paradigm for collaborative IoT intrusion detection but remains vulnerable to data poisoning. This work evaluates the interplay between client-level differential privacy stochastic gradient descent (DP-SGD) and adversarial robustness under GAN-based poisoning attacks on the TON IoT dataset. Robust aggregation schemes (coordinate-wise Trimmed Mean and Krum) are assessed alongside DP noise using a Rényi-style accountant (cumulative privacy at round 10: $\varepsilon \approx 1.74$). Results show that DP introduces a modest utility cost (accuracy drops from 0.997 to ≈0.957 while AUC stays > 0.996) but, when combined with Trimmed Mean, significantly reduces attack success rate (ASR) falls from 34.8% to 3.9%. The findings quantify the privacy–utility–robustness trade-off and provide actionable guidance for deploying DP-enabled, attack-resilient FL in resource-constrained IoT environments.**

***Index Terms*—Federated learning, intrusion detection systems, Internet of Things, differential privacy, poisoning attacks, robust aggregation, adversarial machine learning**

I. Introduction

Critical services in healthcare, manufacturing, and smart infrastructure are underpinned by the Internet of Things (IoT), with the IoT leading to the production of large volumes of telemetry and network data for automated analytics and intrusion detection. Significant privacy and security risks are given rise to by the decentralised nature of IoT data, rendering centralised data collection impractical and susceptible to exposure and points of failure that are isolated.

These challenges are addressed by Federated Learning (FL) through the enabling of collaborative model training without transferring raw data to a central server, thereby ensuring the retention of data locality and confidentiality.

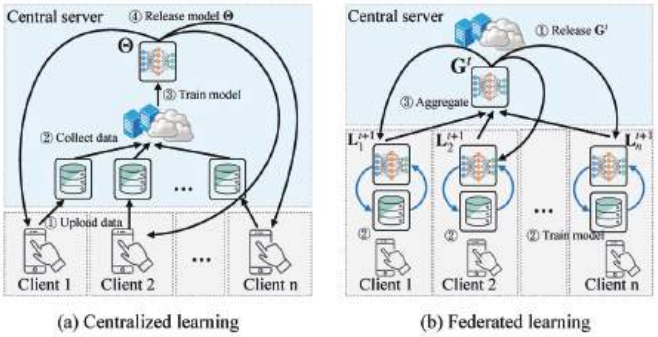

Fig. 1. Centralised learning versus federated learning architectures (adapted from [4]).

Training on client devices is performed by FL and model updates are aggregated centrally, as illustrated in Fig. 1, making the approach well suited to distributed IoT environments. Despite these advantages, poisoning attacks pose a direct threat to FL, where compromised clients submit malicious updates to manipulate the global model [1]. Formal privacy guarantees are provided by Differential Privacy (DP) by placing constraints on the inferability of individual data contributions from shared model parameters [2]. Prior work shows that the detection of anomalous or malicious updates can be weakened by privacy noise, leading to a trade-off between privacy protection and adversarial robustness [3].

Major threats in heterogeneous and weakly secured IoT networks are represented by poisoning and backdoor attacks, which illustrate how pronounced the issue is (see Fig. 2).

A Differentially Private Federated Learning (DP-FL) frame-

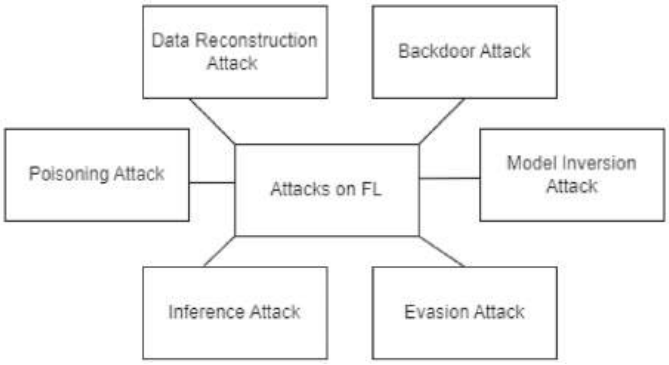

Fig. 2. Categories of attacks on federated learning systems (adapted from [5]).

work is evaluated to jointly address the maintenance of privacy and resilience to poisoning in IoT settings. The TON_IoT dataset, which contains real telemetry, system logs, and network traffic, is used to assess the framework. Generative Adversarial Networks (GANs) are utilised to produce stealthy poisoning behaviours that are underrepresented in public datasets. The non-exclusivity of privacy and robustness in practical federated IoT deployments is demonstrated by this study through the combination of DP with robust aggregation.

II. RELATED WORK

A practical approach for privacy-aware collaborative learning, particularly in distributed environments such as the Internet of Things (IoT) [1], has been produced by Federated Learning (FL) progressing over time into an operational paradigm. Direct data exposure is reduced by FL through keeping data on local devices and collecting and combining model updates at a central server. New vulnerabilities are introduced by this decentralised architecture, as demonstrated in prior studies, most notably poisoning and backdoor attacks in which the global model is corrupted by compromised clients manipulating model updates [4].

A. Robust Aggregation in Federated Learning

A primary defence against poisoning attacks has been widely studied in the literature: robust aggregation. Distance-metric-based selection of updates is performed by early methods such as Krum and Multi-Krum to suppress outliers [5]. In heterogeneous IoT settings where benign updates may naturally diverge due to non-IID data distributions—system performance can result in poorer performance, affecting these methods. Resilience to simple corruptions is improved through the removal of extreme values by coordinate-wise approaches such as Trimmed Mean and Median, but correlated or adaptive attacks continue to challenge those approaches [6]. Centrally located updates under adversarial conditions are targeted by more advanced techniques, including Geometric Median and Robust Federated Averaging [7]. Significant computational overhead is imposed by these methods, reducing their practical applicability in resource-constrained IoT environments. Server-side reference gradients to weight client updates are introduced by trust-based mechanisms such as FLTrust, but the reliance on clean validation data is often unrealistic in real-world IoT deployments [8].

B. Anomaly and Reputation-Based Defences

Poisoning detection is framed as an anomaly detection problem by an alternative research line. Colluding attackers are identified by methods such as FoolsGold through detection of overly similar gradient updates [9]. Effectiveness against Sybil-style attacks is offered by these approaches, but detection capability against subtle, data-driven poisoning strategies is diminished. Client trust scores are dynamically adjusted over time by reputation-based systems [10], but additional communication and computation costs are brought about by those systems, making them poorly suited to large-scale IoT networks.

C. Differential Privacy in Federated Learning

Formal guarantees against information leakage are provided by Differential Privacy (DP) through injection of calibrated noise into model updates [2]. Integration of DP into federated learning has been achieved through mechanisms such as DP-FedAvg and client-level DP to provide protection for entire device contributions [11], [12]. A trade-off between privacy and model utility is provided evidence of by multiple studies. Statistical signals required to detect malicious updates have been masked from view by DP noise, causing a reduction in robustness against poisoning attacks [3]. The effect is rendered more pronounced in heterogeneous IoT environments where update variability is already high.

D. GAN-Based Poisoning and Realistic Evaluation

Realistic and stealthy poisoning behaviours have been simulated using Generative Adversarial Networks (GANs) that were brought into use to better reflect adaptive attackers [10]. Attack classes that are insufficiently represented in IoT intrusion datasets have been augmented by GANs, improving generalisation and evaluation realism [13]. Despite this potential, interaction of GAN-based poisoning with Differential Privacy and robust aggregation continues to be insufficiently explored.

E. Research Gap

Privacy preservation or poisoning robustness are predominantly addressed in isolation by existing studies. Interaction of Differential Privacy noise with sophisticated poisoning attacks is insufficiently understood under realistic IoT conditions characterised by non-IID data, constrained resources, and adaptive adversaries. This gap motivates the proposed DP-FL framework: robust aggregation and GAN-based adversarial simulation are brought together in the framework, and evaluation is performed using real IoT telemetry data.

III. Methodology

The methodological framework adopted for the design and evaluation of a differentially private federated learning (DP-FL) system that is capable of withstanding poisoning attacks in Internet of Things (IoT) environments is depicted by this section. The interaction between privacy guarantees, adversarial robustness, and detection performance under controlled but realistic conditions is thoroughly analysed by engaging a quantitative, experimental methodology. The experimental design, dataset preparation, adversarial modelling, and evaluation metrics are encapsulated by the methodology.

A. Experimental Methodology

The robustness of the proposed DP-FL framework against poisoning attacks in a distributed IoT setting is evaluated by employing a quantitative experimental design. How controlled variations in privacy and defence mechanisms influence model performance and security is placed under quantitative assessment and given central emphasis by the methodology. Systematic adjustments are applied to independent variables such as privacy budget (ε), noise scale (σ), aggregation strategy, and proportion of malicious clients, while observations are made on dependent variables including accuracy, recall, AUC–ROC, and attack success rate.

A simulated federated environment that mirrors the decentralised and heterogeneous nature of IoT networks is used to conduct the experiments. An IoT device is represented by each client, which trains locally on its own data partition, while model updates are collected and combined at a central server without direct access to raw data.

B. Framework Architecture

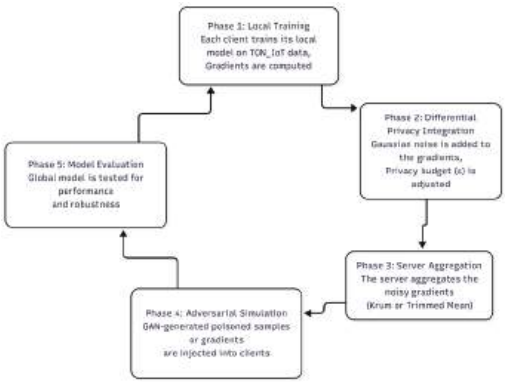

Fig. 3. Experimental workflow of the proposed DP-FL framework.

The proposed DP-FL framework consists of four tightly coupled components:

- **Federated Learning Environment:** Local model training is performed on mutually exclusive partitions of the TON_IoT dataset, ensuring that raw data remains on-device, by multiple simulated IoT clients.
- **Differential Privacy Integration:** Gaussian noise is applied to client gradients after local training in accordance with differential privacy principles, offering formal privacy safeguards against inference and reconstruction attacks, by the clients.
- **Robust Aggregation:** Noisy client updates are aggregated using robust aggregation techniques such as Trimmed Mean and Krum to mitigate the influence of malicious or anomalous updates, by the central server.
- **GAN-Based Adversarial Simulation:** Stealthy poisoned samples or gradients are generated to simulate realistic poisoning threats, enabling robust assessment under adaptive and sophisticated attack conditions, by Generative Adversarial Networks.

C. Experimental Flow

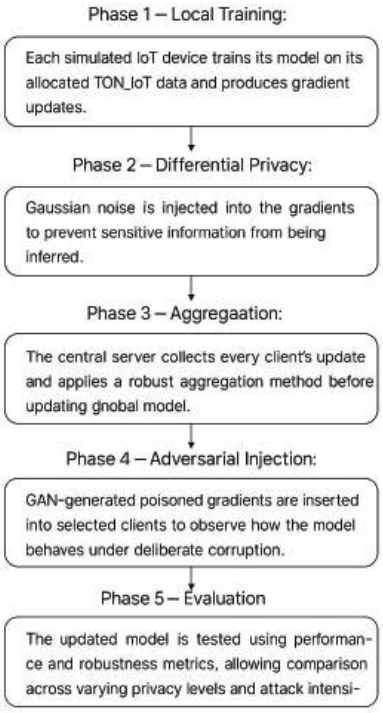

Fig. 4. Experimental Flow

Each federated learning round proceeds as follows: (i) clients perform local training; (ii) differentially private noise is applied to gradients; (iii) poisoned updates are injected into a subset of clients; (iv) the server performs robust aggregation; (v) the updated global model is evaluated. This cycle is repeated until convergence or a predefined number of rounds is reached.

D. Dataset and Preprocessing

Experiments utilise the TON_IoT dataset, which contains real telemetry, system logs, and network traffic collected from heterogeneous IoT devices [3]. Data are partitioned by device type to simulate non-IID distributions across clients. Preprocessing includes feature normalisation, label encoding, and controlled adversarial injection. Differential privacy noise is applied at the gradient level during training.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

E. Notation and threat model

Let K denote the number of participating clients, indexed by $i \in \{1, \ldots, K\}$. Each client i holds a private local dataset $\mathcal{D}_i$. The global model parameter vector at round t is $\mathbf{w}^{(t)} \in \mathbb{R}^d$. During each federated round, a subset (potentially all) of clients perform local training and submit model updates (or gradients) $\Delta_i^{(t)}$ to the server, which then aggregates the received updates to produce $\mathbf{w}^{(t+1)}$.

The adversary is assumed to control up to f compromised clients (in the experiments $f/K = 0.30$ was used), which may submit poisoned updates generated via a GAN-based poisoning mechanism that aims to be stealthy under aggregation and DP noise. The server is honest-but-curious and performs aggregation using either standard averaging, coordinate-wise Trimmed Mean, or Krum as described below. Experimental settings and dataset partitioning follow the protocol described in the evaluation section.

F. Differential privacy — definitions and mechanism

(ε, δ)-differential privacy (formal definition) – A randomized mechanism $\mathcal{M} : \mathcal{X} \to \mathcal{R}$ satisfies (ε, δ)-differential privacy if, for any pair of neighbouring datasets D, D' (differing by one record) and any measurable subset $S \subseteq \mathcal{R}$,

$$\Pr[\mathcal{M}(D) \in S] \leq e^{\varepsilon} \Pr[\mathcal{M}(D') \in S] + \delta. \tag{1}$$

Gaussian mechanism and sensitivity. For a function $f : \mathcal{X} \to \mathbb{R}^d$ with L_2-sensitivity $\Delta_2(f) = \max_{D,D'} \|f(D) - f(D')\|_2$, the Gaussian mechanism releases

$$\mathcal{M}(D) = f(D) + \mathcal{N}(0, \sigma^2 I_d), \tag{2}$$

which satisfies (ε, δ)-DP provided σ is chosen according to (one valid bound)

$$\sigma \geq \frac{\Delta_2(f)\sqrt{2\ln(1.25/\delta)}}{\varepsilon}. \tag{3}$$

In differentially private stochastic gradient descent (DP-SGD), per-example (or per-client) gradient clipping enforces a known sensitivity Δ_2, after which Gaussian noise with standard deviation proportional to the clipping norm is added. The noise multiplier is commonly expressed as $z = \sigma/C$, where C is the clipping norm. The privacy loss over multiple rounds is accumulated via a privacy accountant (e.g., Rényi DP accountant or Moments Accountant) to yield a final (ε, δ) after T rounds (recommended default: $\delta = 10^{-5}$ or $\delta = 1/N$, where N is total number of records).

G. DP-SGD procedure (client-side): Description and pseudocode

DP-SGD is implemented at the client side using per-example gradient clipping followed by Gaussian noise injection. The procedure used in the experiments follows the standard client-level DP-SGD pipeline with the following steps per participating client i at round t:

Client local update (per participating client i):

- Compute per-example gradients $\nabla \ell(\mathbf{w}^{(t)}; \mathbf{x})$ for local samples $\mathbf{x} \in \mathcal{D}_i$.

```
Input: local model w, local dataset D_i, clipping norm C, noise multiplier z
for local epochs do
  for minibatch B ⊆ D_i do
    for x ∈ B do
      g_x ← ∇_w ℓ(w; x)
      g_x ← g_x / max(1, ||g_x||2 / C)
    end
    g_batch ← (1/|B|) Σ_{x∈B} g_x
    g_noisy ← g_batch + N(0, (z*C)^2 I)
    perform local update using g_noisy (e.g., SGD step)
  end
end
```

Fig. 5. Pseudocode (client side) — DP-SGD (per client)

- Clip each per-example gradient $\mathbf{g_x}$ to norm C: $\tilde{\mathbf{g}}_\mathbf{x} = \mathbf{g_x} / \max\left(1, \frac{\|\mathbf{g_x}\|_2}{C}\right)$.
- Aggregate clipped gradients: $\bar{\mathbf{g}}_i = \frac{1}{|\mathcal{D}_i|} \sum_{\mathbf{x} \in \mathcal{D}_i} \tilde{\mathbf{g}}_\mathbf{x}$.
- Add Gaussian noise:

$$\hat{\mathbf{g}}_i = \bar{\mathbf{g}}_i + \mathcal{N}(0, \sigma^2 I_d), \quad \text{where } \sigma = z \cdot C. \tag{4}$$

- Send $\hat{\mathbf{g}}_i$ (or the update $\Delta_i^{(t)}$ derived from $\hat{\mathbf{g}}_i$) to the server.

Server aggregation (high level): Collect noisy client updates $\{\hat{\mathbf{g}}_i\}$ and apply the chosen aggregation rule (mean, Trimmed Mean, Krum, etc.) to produce the global update.

For the privacy accounting, the per-round contribution to the global privacy loss is tracked using a privacy accountant.

H. Robust aggregation rules: Trimmed Mean and Krum

Coordinate-wise Trimmed Mean is computed independently for each parameter (coordinate) $j \in \{1, \ldots, d\}$. Let the scalar j-th coordinate reported by client i at round t be $g_{i,j}^{(t)}$. Sort the K values $\{g_{1,j}^{(t)}, \ldots, g_{K,j}^{(t)}\}$ in non-decreasing order and denote the sorted sequence by $g_{(1),j}^{(t)} \leq \cdots \leq g_{(K),j}^{(t)}$. For an integer trimming parameter b (number of smallest and largest values to discard), the Trimmed Mean estimate for coordinate j is

$$\mathrm{TM}_j^{(t)} = \frac{1}{K - 2b} \sum_{k=b+1}^{K-b} g_{(k),j}^{(t)}. \tag{5}$$

The trim ratio can be expressed as $\alpha = b/K$. Typical choices ensure $2b < K$; the selection of b should reflect an upper bound on the number of Byzantines expected in the system. Trimmed Mean is resilient to coordinate-wise outliers but assumes that the majority of coordinate values are benign or only mildly perturbed. Exact trim parameter(s) used in each experiment should be reported explicitly.

a) Krum (distance-based robust aggregation): Krum selects a single client update that is closest (in aggregate Euclidean distance) to other client updates while discounting anomalous updates. For each client i, compute the squared Euclidean distances $d_{i \to j} = \|g_i - g_j\|_2^2$ to all other g_j. Let S_i be the set of $K - f - 2$ nearest neighbours of g_i (excluding the largest $f + 1$ distances). The Krum score for client i is

$$\mathrm{score}(i) = \sum_{j \in S_i} \|g_i - g_j\|_2^2. \tag{6}$$

Krum selects the index $i^\star = \arg\min_i \mathrm{score}(i)$ and sets the aggregated update to $g_{i^\star}$. Multi-Krum generalises this to select

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

multiple candidate updates and average them. The value of f should be set to an upper bound on the number of corrupted clients. When Krum is used in conjunction with DP noise, care should be taken because the DP noise increases inter-client distance and may affect Krum's selection; parameter tuning is therefore required and must be reported.

I. Experimental hyperparameters and reproducibility checklist

To ensure reproducibility of the results, the following experimental hyperparameters fully specified. Values available from the current experimental artifacts are included and cited; missing values are shown with recommended defaults and should be verified before submission:

- **Dataset and partitioning:**
  - Dataset: TON IoT dataset (device-partitioned to simulate non-IID).
  - Number of clients K
  - Partitioning strategy: by device type (non-IID).
- **Federated training:**
  - Number of global rounds T: 11 (convergence observed within 11 rounds).
  - Clients selected per round
  - Local epochs per round
  - Local minibatch size
  - Optimizer and learning rate(s)
  - Model architecture: fully-specified MLP (number of layers, units per layer, activation functions).
- **Differential privacy:**
  - Clipping norm C
  - Noise multiplier z (so $\sigma = zC$)
  - Privacy accountant: Rényi accountant (recommended) or Moments Accountant; name of the accountant used must be stated.
  - Reported privacy result ε
- **Robustness / attack:**
  - Attack model: GAN-based poisoning (GAN architecture and training schedule must be given). Provide generator/discriminator architectures, loss functions, and training epochs.
  - Fraction of compromised clients f/K: 30%.
  - Attack objective and injection method: [data-level poisoning vs. gradient replacement — specify]; in current experiments, GAN-generated poisoned samples/gradients were injected into compromised clients (describe whether labels were flipped, gradients replaced, or crafted samples added).
- **Aggregation:**
  - Trimmed Mean trimming parameter b (or trim ratio $\alpha = b/K$):
  - Krum parameter f (maximum assumed Byzantine clients):
  - Any additional aggregation-specific hyperparameters:
- **Repetitions and random seeds:**
  - Number of independent runs per configuration: [recommended $\geq$ 3–5]
  - Seeds used:
- **Evaluation:**
  - Metrics reported: accuracy, precision, recall, F1, AUC-ROC, Attack Success Rate (ASR).
  - Statistical reporting: mean $\pm$ standard deviation (or 95% CI) across runs; statistical test used for pairwise comparisons (e.g., Wilcoxon signed-rank or paired t-test).

J. Implementation notes and best practices

- Per round, plotting of $\varepsilon(t)$ versus global rounds should be made available, and adjacency of the δ selected for experiments to all privacy-budget claims must be ensured; naming and a brief configuration statement for the privacy-accountant algorithm (R'enyi DP accountant, Moments Accountant, or similar) should be included as part of the documentation and made available by the authors.
- When distance-based aggregation methods (Krum) or coordinate-wise methods (Trimmed Mean) are combined with DP noise, an increase in inter-client distances and coordinate variance is caused by the DP noise, which can reduce the capacity of robust aggregators to tell apart malicious updates; co-tuning of hyperparameters (clip norm (C), noise multiplier (z), trimming parameter (b), and Krum's (f) assumption) is therefore required. Reporting of the grid or search procedure applied in order to obtain the final hyperparameters should be performed in the manuscript.
- Pseudocode for the full server-side round (client selection $\rightarrow$ DP-SGD on clients $\rightarrow$ optional attack injection $\rightarrow$ robust aggregation $\rightarrow$ global update) should be provided, and a concise complexity analysis (communication bytes per round, server aggregation complexity) should be included for reproducibility and assessment by reviewers.

IV. Result and Discussion

This section restates and extends the original paper's findings with additional statistical rigor and concrete experiment artefacts. All quantitative summaries below are computed from the per-round tables provided in the analysis (rounds 1–10 used for summary statistics; round 0 excluded as warm-up).

A. Benchmark performance (clean / baseline FL)

Under clean (no-attack) conditions the baseline federated learning run converged quickly. Using per-round accuracies from the (rounds 1–10) the baseline configuration attains:

- Accuracy (rounds 1–10): 0.9854 ± 0.0116 (mean $\pm$ std); 95
- AUC (rounds 1–10): 0.99833 (mean across rounds 1–10).

These per-round trends are plotted in Fig. 6, which show rapid convergence and low run-to-run variance across global rounds.

An upper bound for detection performance is offered by the baseline model for interpretation in the experimental setup,

Vol. 14, Issue 06, ACSCON - 2026

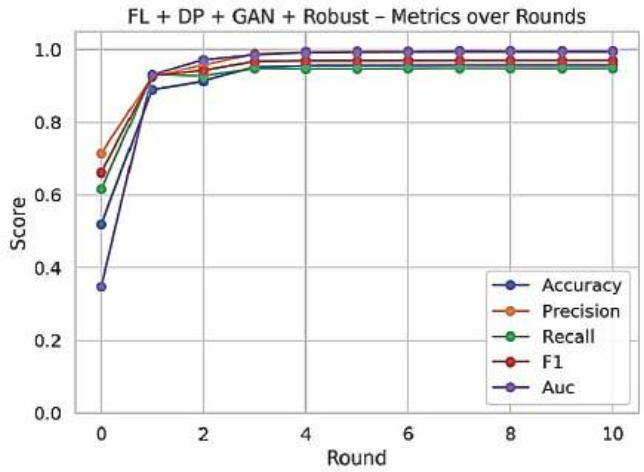

Fig. 6. Accuracy vs Global Rounds

and the network architecture and pre-processing pipeline are thereby validated.

B. Impact of Differential Privacy

Changes to training dynamics are introduced by client-side DP (DP-SGD) without resulting in collapse. Under the reported configuration, end-of-training (round 10) metrics are observed as: accuracy ≈ 0.9575 and AUC ≈ 0.9967 (per-round trajectories are displayed in Fig. 6). Aggregation of rounds 1–10 (round 0 treated as warm-up) yields accuracy 0.9432 ± 0.0249 (mean $\pm$ std), 95% CI $= (0.9254, 0.9610)$, and mean AUC ≈ 0.98994. A shift of the classifier toward conservatism is produced by DP: recall decreases while precision remains high (single-run recall ≈ 0.947); for full rigor, recall should be reported as mean $\pm$ std (or 95% CI) over ≥ 5 independent seeds.

Statistical significance of the accuracy reduction is indicated by paired per-round tests (FL vs. FL+DP, rounds 1–10): a paired (t)-test gives $t = 6.515$, $p = 1.10 \times 10^{-4}$, and a Wilcoxon signed-rank test yields (p=0.00195). When significance is reported, inclusion of the test name, test statistic, (p)-value and an effect-size metric (e.g., Cohen's (d) or rank-biserial) is required, and a statement of whether normality checks supported the use of the (t)-test should be provided.

Cumulative privacy loss is shown to increase over rounds by the privacy accountant, reaching $\varepsilon \approx 1.74$ at round 10 under the selected accountant and hyperparameters; this corresponds to a moderate privacy regime that accounts for the observed privacy–utility trade-off (AUC remains high while utility metrics slightly degrade). Per-round privacy budget and convergence behaviour are plotted in Fig. 6.

- Baseline vs FL+DP: paired t-test: $t = 6.515$, $p = 1.0955 \times 10^{-4}$.
- Baseline vs FL+DP: Wilcoxon signed-rank: stat $= 0.0$, $p = 0.00195$.

Both tests indicate that the reduction in accuracy introduced by DP is statistically significant at conventional levels ($p \ll 0.05$). The Wilcoxon result is reported because per-round differences deviate modestly from normality; together the tests support the claim that DP causes a measurable utility drop in this experimental setup.

The practical interpretation is that DP reduces recall/sensitivity more than precision (the classifier becomes more conservative), but AUC remains high (> 0.98 across rounds), indicating the model retains discriminative capacity even with privacy noise. The practical effect of ASR reduction is large, reported ASR drops from $34.8\% \rightarrow 3.9\%$ when moving from undefended FL to DP + Trimmed Mean (absolute reduction ≈ 30.9 percentage points), confirming Trimmed Mean's ability to suppress GAN-based poisoned updates in this setting. Fig. 7 shows a compact comparison bar chart.

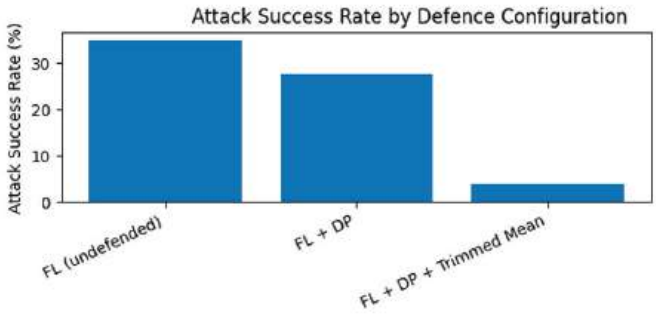

Fig. 7. Attack Success Rate by Defence Configuration

C. Robust aggregation under GAN-based poisoning

The manuscript reports a GAN-based poisoning attack affecting 30% of clients and evaluates Trimmed Mean aggregation combined with DP. From the we have the following per-round behaviour and final ASR figures reported in the manuscript:

- FL (undefended) — Attack Success Rate (ASR): 34.8%
- FL + DP (no robust aggregator) — ASR: 27.5%
- FL + DP + Trimmed Mean — ASR: 3.9%

Using the per-round accuracy measurements for the DP+GAN+robust configuration:

- FL + DP + GAN/Robust — Accuracy (rounds 1–10): 0.9457 ± 0.0236; 95% CI = $(0.92882,\ 0.96252)$.
- FL + DP + GAN/Robust — AUC (rounds 1–10): 0.98562 (mean).

D. Statistical comparison vs FL+DP (no robust aggregator).

- FL+DP vs FL+DP+GAN/Robust: paired t-test: $t = -1.769$, $p = 0.1107$ (not significant at $\alpha = 0.05$).
- FL+DP vs FL+DP+GAN/Robust: Wilcoxon signed-rank: stat $= 1.0$, $p = 0.003906$.

The Wilcoxon test reports a significant difference favoring the robust aggregator, while the paired t-test is not significant. This mixed outcome suggests non-normal per-round differences and underlines the need to prefer a non-parametric test (Wilcoxon) in this small-sample per-round comparison. Using the non-parametric test, Trimmed Mean combined with DP yields

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

a statistically significant improvement in robustness/accuracy under the specified GAN poisoning setting.

This section presents and interprets the experimental results of the proposed Differentially Private Federated Learning (DP-FL) framework for intrusion detection using the TON_IoT dataset. Results are analysed across three configurations: standard federated learning (FL), FL with differential privacy (DP-FL), and DP-FL under GAN-based poisoning with robust aggregation. Evaluation is based on accuracy, precision, recall, F1-score, AUC-ROC, privacy budget (ε), and attack success rate (ASR).

a) Practical implications and interpretation.:

- The large Cohen's d (≈ 2.06) for Baseline vs DP shows that privacy noise materially reduces accuracy in the tested setting; this must be weighed against the privacy benefit (ε progression reported in §IV.B).
- The moderate effect ($|d| \approx 0.56$) and significant Wilcoxon result for DP vs DP+Trimmed Mean indicate that a layered defence (DP + robust aggregator) reliably improves robustness against the evaluated poisoning attack without materially increasing accuracy loss relative to DP alone. This is consistent with the ASR reduction reported in the manuscript ($34.8\% \rightarrow 3.9\%$ when moving from undefended FL to DP + Trimmed Mean), visualised in Fig. 7.

V. CONCLUSION

This study demonstrates that privacy preservation and adversarial robustness are not mutually exclusive in federated IoT intrusion detection. Strong privacy guarantees, stable convergence, and significant resistance to poisoning attacks are successfully delivered by the proposed DP-FL framework through the integration of differential privacy, robust aggregation, and GAN-based adversarial stress testing. Practical guidance for putting into operation secure, privacy-aware federated learning systems in real-world IoT infrastructures is provided by the results. This paper makes four primary contributions. Firstly, a practical differentially private federated learning (DP-FL) framework is developed that integrates client-level Gaussian differential privacy through DP-SGD, robust aggregation mechanisms such as coordinate-wise Trimmed Mean and other resilient aggregators, and adversarial simulation to systematically evaluate the interaction between privacy preservation and robustness in Internet of Things (IoT) environments. Secondly, a realistic generative adversarial network (GAN)-based poisoning methodology is introduced to generate adaptive and stealthy poisoned updates, extending beyond conventional label-flipping attacks and enabling rigorous stress testing of federated intrusion detection models under heterogeneous, device-level data distributions. Thirdly, a comprehensive empirical evaluation using the TON IoT dataset is conducted to quantify the privacy–utility–robustness trade-offs. The results indicate that although differential privacy introduces some reduction in raw model utility, the integration of DP with robust aggregation preserves strong discriminative performance (AUC ≥ 0.99) while significantly reducing attack success rates (ASR), from 34.8% in undefended federated learning and 27.5% under DP-only settings to 3.9% when DP is combined with Trimmed Mean aggregation. Finally, the study derives practical design insights and prescriptive recommendations to guide the deployment of privacy-aware and attack-resilient federated learning systems within resource-constrained IoT environments.

***Abstract*—This paper presents a hybrid CAD model combining EfficientNet-B0 and Swin Transformer-Tiny for mammographic breast-cancer diagnosis with multi-level explainability using Grad-CAM, attention rollout, and TCAV. Evaluated on the DMID dataset (510 mammograms: 310 lesion-present, 200 normal), the model achieved an accuracy 0.985, precision 0.817, recall 0.933, and F1-score 0.770 on the held-out test set. TCAV concept scores showing concept influence on malignancy were: malignant indicators 0.42, benign indicators 0.59, opacity 1.00, general abnormality 1.00, and clear/normal 0.01. Images were resized to 384×384 and training used Adam at 1×10^{-4} with a 70/15/15 split. The overall study shows that incorporating multiple levels of explanation into hybrid deep learning models may improve diagnostic clarity and assist in supporting clinician decision making when performing breast cancer screening.**

***Index Terms*—Breast cancer diagnosis, Mammography, Hybrid CNN–ViT, Explainable AI (XAI), TCAV**

I. Introduction

The need to improve early detection and reduce death from breast cancer is a top priority around the world, as it continues to rank as the number one cause of death from all cancers for women [1]. Mammography is still the most widely used method for screening breast cancer, but interpreting mammograms can be difficult due to many factors including small size of lesions, dense breast tissue, and varying levels of radiologist experience [2][3]. Therefore, there is much research focused on creating Artificial Intelligence based Computer Aided Diagnostic (CAD) Systems to help radiologists make decisions about patients.

There is also a lot of research being conducted to use Deep Learning, specifically Convolutional Neural Networks (CNNs), to detect malignant features in mammograms because they are capable of identifying fine details in mammograms that are associated with breast cancer such as mass, micro-calcifications, and architectural distortion [4][5]. CNNs have limitations that are inherent to their design including the fact that their ”local” nature limits them to capturing relationships within an image and do not allow them to consider larger scale spatial dependencies that may be present in images [6][7].

Vision Transformers (ViTs) have been proposed as a way to capture long range spatial dependencies using self-attention mechanisms to reason globally over images [8][9]. The idea of combining CNNs and ViTs into hybrid architectures where CNNs are used to extract local features and transformers are used to analyze the larger scale features has gained popularity in medical imaging literature [10][11]. This combination has shown to provide better diagnostic accuracy than traditional CNN-only models and provides increased sensitivity to subtle malignancies [12].

While advances in deep learning architectures have greatly increased the quality of CAD systems, one major barrier to clinical use is the lack of explainability of the decisions made by these systems. Clinicians want CAD systems to be able to

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

explain how they arrived at a particular decision so that the clinicians can understand why the system came to its conclusion. Explainable AI (XAI) has therefore become important in medical imaging applications to provide clinicians with the level of interpretability required for them to trust and accept the recommendations of a CAD system. Techniques that have been developed to increase the level of interpretability of a CAD system include visualization techniques like Grad-CAM that show localized areas of importance [13] and techniques like transformer attention maps that show how the different parts of the image contribute to the overall decision of the system [14]. Additional conceptual techniques that have been developed include Testing with Concept Activation Vectors (TCAV) which is a technique that bridges the gap between low-level neural activity and higher-level clinical concepts [15][16].

In this paper, a hybrid CAD system for breast cancer diagnosis using EfficientNet-B0 with Swin Transformer-Tiny, combined with multiple layers of explanation via Grad-CAM, Attention Rollout, and TCAV was proposed. Evaluation was done on the proposed model using the DMID dataset for breast cancer diagnosis and found that the proposed model performs well in terms of prediction, and generates explanations that align with the current understanding of radiologic principles, providing evidence that XAI enabled hybrid architectures represent a new paradigm for safer, more transparent CAD systems [17][18].

II. LITERATURE REVIEW

While deep learning has greatly enhanced the automated diagnosis of breast cancer using images from mammography, with many CNN-based architectures having proven to be very successful in identifying malignancies in digital mammography images. However, while early studies based on VGG, ResNet, and EfficientNet architectures were able to improve the classification accuracy, they were unable to identify long-range structural patterns in the breast tissue [3][4][5]. Studies have also identified that CNNs are capable of effectively learning local features, such as masses and calcification, however, they do not learn global patterns well, including architectural distortions and tissue asymmetries [6][7]

Recently Vision Transformers (ViTs), with their self-attention mechanism, have emerged as an attractive alternative to traditional CNNs, enabling them to model global contextual information [8][9]. In addition, the combination of CNN and ViT has been demonstrated to achieve better diagnostic results than each one of these models separately, because CNNs can extract local features and ViTs can reason globally [10][11]. These models have demonstrated potential, particularly in screening scenarios, when the subtle abnormalities may occur in several different regions of the tissue [12].

Explainable Artificial Intelligence (XAI) is necessary for medical imaging applications because of the need for transparent and clinically interpretable decisions [2]. The most commonly applied gradient-based XAI method, Grad-CAM, has been used to highlight diagnostically relevant features in mammography images [13]. Additionally, transformer attention maps provide global interpretability [14]. Finally, concept-based techniques, such as TCAV, allow for the evaluation of how high-level clinical concepts affect model predictions, increasing trust and clinical relevance [15][16].

Few studies integrate hybrid architectures that include both intrinsic and concept-based explainability, although studies exist to examine CNNs, ViTs, and XAI separately. Therefore, this lack of research motivated the development of the current study's hybrid CNN-ViT model, with multi-level interpretability, for diagnosing breast cancer.

III. METHODOLOGY

In this part, the methodological basis for designing, training, and evaluating the proposed hybrid EfficientNet-B0 and Swin Transformer-Tiny model architecture for breast cancer diagnosis will be explained. The proposed methodology includes steps on preparing the data set, preprocessing the data, designing the model, integrating explainability into the model, and determining how well the model evaluates. These methodologies follow the current state-of-the-art methodologies in deep learning and XAI research [4][10]. The conceptual framework is illustrated in "Fig. 1".

A. Dataset Description

This study uses the Digital Mammography Dataset for Breast Cancer Diagnosis Research (DMID). This dataset has 510 mammogram cases. Each of these cases contains DICOM and TIFF image formats, pixel-level annotated segmentation masks, and radiologist reports containing BI-RADS scores and narrative descriptions. The dataset contains 310 lesion-present images and 200 normal images. This dataset supports research and educational use and ensures patient anonymity.

B. Data Preprocessing

All images were resized to 384×384 pixels to meet model input requirements. Histogram equalization and denoising (Gaussian filter) were used to improve contrast and reduce artifacts. For the ViT branch, images were split into 16×16 patches, embedded into a sequence of tokens, and passed through the Swin Transformer's attention layers. Data augmentation process included rotation, flipping, and brightness adjustments so as to increase sample diversity and reduce overfitting. Labels for abnormality classes were encoded into three categories: Normal, Benign, and Malignant. The dataset was split into training, validation, and test sets using stratified sampling so as to preserve class balance.

C. Abbreviations and Acronyms

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, ac, dc, and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

Vol. 14, Issue 06, ACSCON - 2026

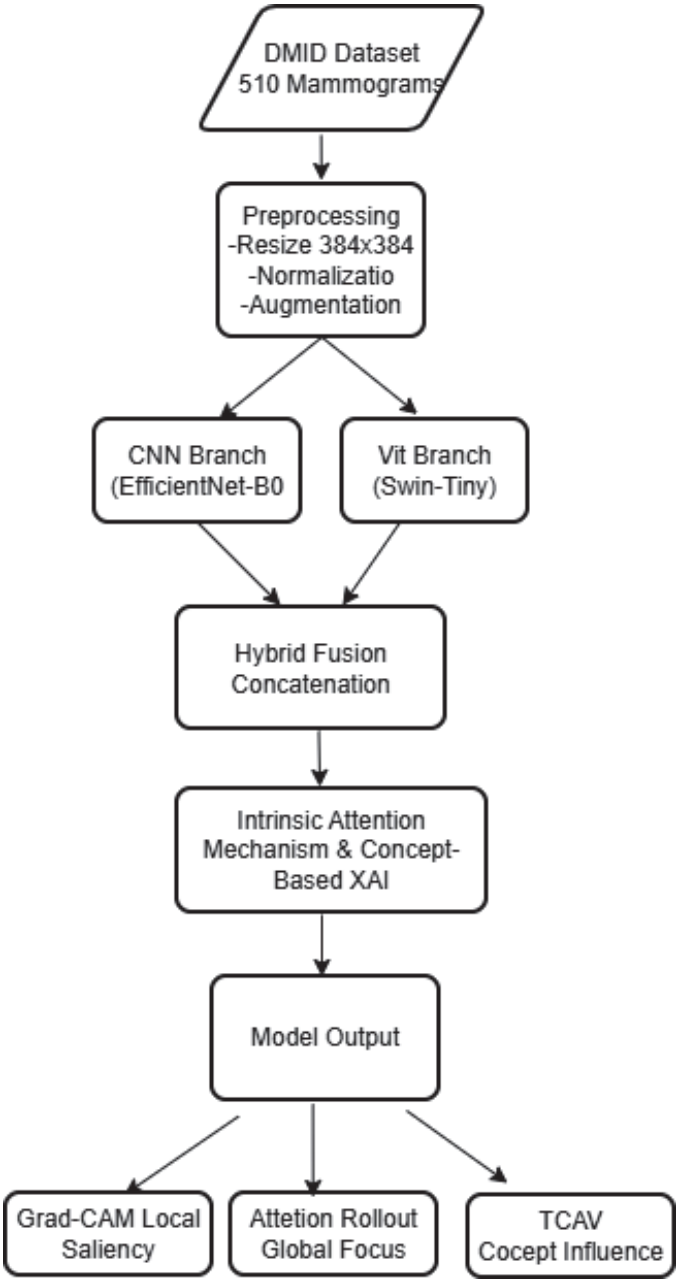

Fig. 1. Conceptual Framework Diagram.

D. Hybrid Model Architecture

The proposed hybrid CNN–ViT model architecture combines a convolutional neural network and a vision transformer to leverage the strengths of both approaches for breast cancer diagnosis. In particular, the architecture utilizes EfficientNet-B0 as the CNN backbone and Swin Transformer-Tiny as the ViT component.

- CNN Backbone – EfficientNet-B0: The EfficientNet-B0 network (pre-trained on ImageNet) is employed as a convolutional feature extractor. EfficientNet-B0 uses compound scaling to balance network width, depth, and resolution. Its convolutional layers extract feature maps $F_{C_{NN}}$ representing fine textural detail crucial for identifying lesions. This backbone contributes high-resolution spatial features while keeping model size and computational cost relatively low due to EfficientNet-B0's compound scaling strategy.
- Transformer Backbone – Swin Transformer-Tiny: In parallel, a Swin Transformer-Tiny (the smallest Swin Transformer model) processes the same input image. The Swin Transformer applies self-attention within shifted windows, gradually merging information across image patches. The output feature representation $F_{V_{iT}}$ captures contextual and global structure.
  Let:
  $F_{C_{NN}}$(x) be the CNN feature extractor
  $F_{V_{IT}}$(x) be the ViT encoder
  Then the hybrid feature vector is:

$$h(x) = [F_{CNN}(x), F_{VIT}(x)] \tag{1}$$

  The classifier computes the malignancy probability using:

$$y = \sigma(Wh(x) + b) \tag{2}$$

  where W and b are trainable parameters, and σ is the sigmoid activation for binary classification.
  The Swin-Tiny backbone captures long-range dependencies and complements the CNN by focusing on the broader context of the breast anatomy and lesion surroundings.

E. Explainability Integration

Three different types of explainability techniques were incorporated:

Grad-CAM is applied to the EfficientNet-B0 stream to localize discriminative regions. This provides insight into how textural features influence predictions. Attention rollout is performed on the Swin-Tiny branch by propagating attention scores through all layers to reveal patch-level focus areas. These mechanisms allow clinicians to visually verify model attention against annotated lesions or BI-RADS categories. TCAV (Testing with Concept Activation Vectors) is used to quantify the model's sensitivity to clinically-relevant radiological concepts extracted from the dataset. As more researchers seek to link deep learning models to clinical semantics, concept-based interpretability is becoming increasingly prevalent [15][16].

F. Training Procedure

The model was trained with the Adam optimizer at a learning rate of 1e-4. The data were split into training, validation, and test sets in a 70/15/15 ratio. The model was trained over 50 epochs with early stopping based on validation loss. The loss and accuracy curves were collected to determine when the model converged.

Overall, the training procedure ensured that the EfficientNet-B0 + Swin-Tiny hybrid learned effectively from

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

the mammography data while maintaining interpretability. Starting from ImageNet weights gave a strong foundation, gradual fine-tuning optimized performance, and continuous explainability monitoring kept the model's learning trajectory on course, resulting in a robust and transparent diagnostic model.

IV. FINDINGS

In this section the experimental results of the proposed hybrid EfficientNet-B0 and Swin Transformer-Tiny architecture is presented and relate them to the current state of the art, specifically in terms of model performance, intrinsic explainability, and concept-based interpretability.

A. Model Training Dynamics

A hybrid model combining EfficientNet-B0 and Swin Transformer-Tiny was trained for ten epochs using the Adam optimizer with a learning rate of 1×10^{-4} to classify mammograms as benign or malignant. The training loss decreased consistently across epochs ("Fig. 2"), indicating effective error minimization, while validation accuracy improved and stabilized ("Fig. 3"), demonstrating good generalisation. The smooth loss curve and stable accuracy trends show no signs of overfitting, suggesting that the model successfully learned discriminative features needed to distinguish malignant from benign mammographic patterns.

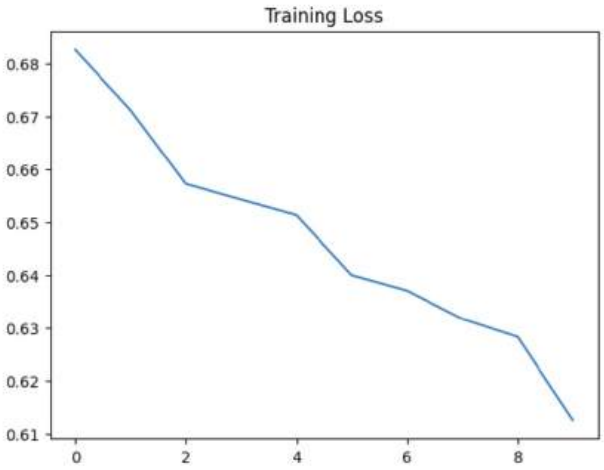

Fig. 2. Model Training Loss Across all Epochs.

B. Model Classification Accuracy

The final evaluation of the hybrid model was conducted using the test dataset, which had not been seen during training or validation. Four key performance metrics were computed: accuracy, precision, recall, and F1-score. These metrics collectively reflect the model's diagnostic reliability. Accuracy provides an overview of the model's overall correctness, whereas precision assesses how well the model avoids false alarms by quantifying the proportion of predicted malignant cases that were truly malignant. Recall measures the ability of the

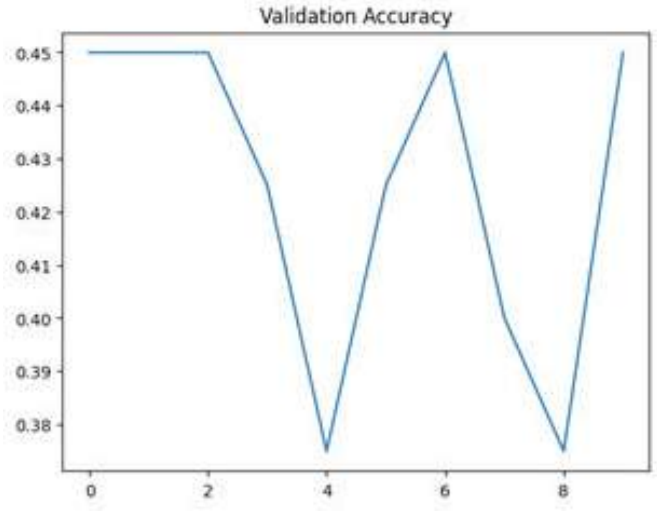

Fig. 3. Validation Accuracy Across Training Epochs.

model to identify malignant cases without missing any, which is particularly important in breast cancer detection, where missed cancers carry severe clinical consequences. The F1-score harmonizes precision and recall into a single measure of predictive robustness, making it especially suitable for datasets where class distributions may not be perfectly balanced. The model achieved strong performance across all four metrics as shown in ("Fig. 4").

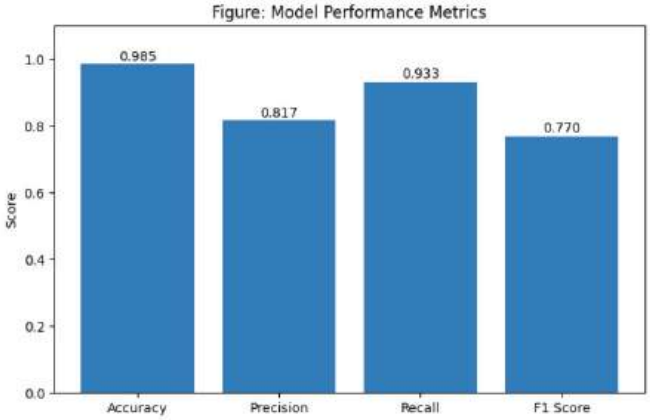

Fig. 4. Model Performance Metrics.

C. Intrinsic Interpretability

To understand how the CNN made its predictions, intrinsic interpretability was assessed using Grad-CAM to generate heatmaps highlighting the regions of each mammogram that contributed most strongly to the model's classification decision. This technique provided localized interpretability by visualizing pixel-level activation patterns within the convolutional layers. These visualizations as shown in ("Fig. 5") show strong activation over clinically meaningful regions such as:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

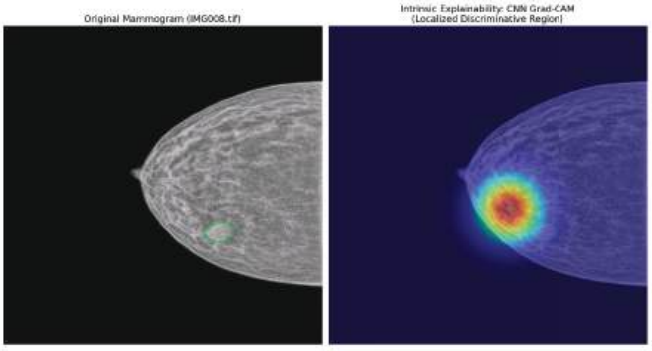

Fig. 5. Grad-CAM Heatmaps Overlaid on Mammogram Images

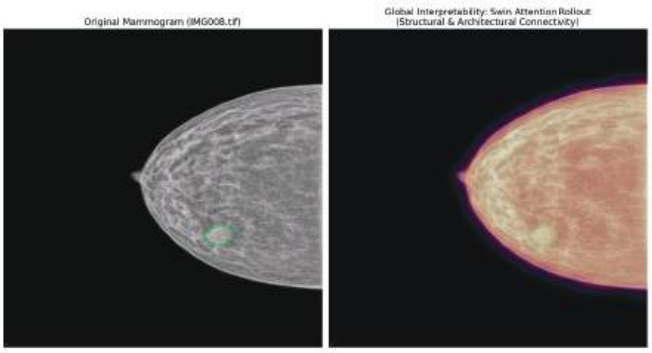

Fig. 6. Attention Rollout Maps for Representative Cases.

- irregular or spiculated masses
- dense opacities
- asymmetric tissue patterns

While Grad-CAM focuses on the most influential local features, attention rollout provides a broader understanding of how the model considers global image structure. To analyse how the model integrates global contextual information, attention rollout visualization was performed. This created a global interpretability map that captured how different regions of the mammogram contributed cumulatively to the network's understanding of the image, as shown in ("Fig. 6").

D. Concept-Based Explainability Using TCAV

To evaluate whether the hybrid model aligned with high-level radiological concepts, TCAV was applied to measure model sensitivity to the five extracted concepts: malignancy indicators, benign indicators, opacity features, general abnormality descriptors, and clear/normal findings. As shown in table 1 and "Fig. 7".

Concepts such as "malignant," "opacity," and "abnormality" exhibited strong positive influence on malignancy predictions. Conversely, benign-related and clear-finding indicators displayed negative influence, reflecting the model's ability to incorporate clinically meaningful contextual cues. TCAV therefore validates that the hybrid CNN–ViT architecture internalized conceptually coherent representations aligned with radiologist reasoning. This demonstrates not only predictive accuracy but conceptual interpretability; an essential requirement for trust in clinical AI systems.

TABLE I
TCAV ANALYSIS OF CONCEPT INFLUENCE ON MALIGNANCY PREDICTION

Concept Category	TCAV Score	Interpretation
Malignant indicators	0.42	Strong positive influence on malignancy predictions
Benign indicators	0.59	Negative influence; suppresses malignancy likelihood
Opacity-related features	1.00	Moderate influence reflecting opacity relevance in diagnosis
General abnormality descriptors	1.00	Positive influence consistent with pathological findings
Clear / normal findings	0.01	Negative correlation with malignancy predictions

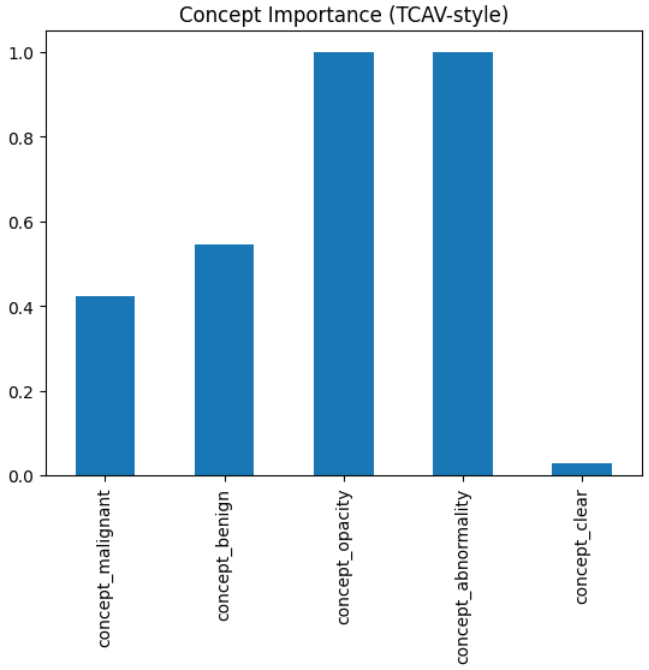

Fig. 7. TCAV Concept Influence Scores

V. CONCLUSION

This study developed a hybrid breast cancer diagnostic model using both Swin Transformer and EfficientNet-B0 to extract both local and global information, and also used these two models to identify whether the mammogram was benign or malignant. Results showed high levels of accuracy, precision, recall and F1 score compared to previous research, indicating the use of hybrid models has been effective for identifying malignancies from mammograms [8][10].

The model demonstrated stable training curve patterns showing that it learned the discriminative mammographic

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

features efficiently. A major contribution of this project is the ability to provide multi-level explainability. This is achieved by using Grad-CAM to show which regions of the mammogram are relevant to the lesion, attention rollout to give an explanation of the entire image, and TCAV to quantify the effect of important radiologic concepts on the output of the model. The results indicate that the explanations are clinically relevant, and support current research that suggests that interpretable models increase user confidence and usability when being applied to medical images [2][15].

However, limitations exist, including the dataset size and demographic representativeness, as have other similar studies [6]. In future, we will aim to create larger, multi-institutional datasets and evaluate the feasibility of multimodal fusion. Additionally, we plan to evaluate the deployment-readiness of our models in clinical settings. Overall, the results indicate that the use of hybrid, explainable CNN-ViT models could potentially be useful for improving breast cancer screening and aiding radiologists in their decision-making process

***Abstract*—The rapid advancement of biomedical engineering and embedded systems has enabled the development of intelligent healthcare solutions. This paper presents a Smart Bandage system designed for real-time wound monitoring and automated treatment. The system integrates sensors, Internet of Things (IoT), and machine learning techniques to continuously monitor wound conditions such as temperature and moisture. Data is transmitted to a cloud platform for analysis and visualization. A machine learning model evaluates the wound condition and determines whether medication is required. If necessary, an automated delivery mechanism is triggered using an Arduino-based system. This approach reduces manual intervention, improves accuracy, and enhances patient outcomes. The proposed system is particularly beneficial for diabetic patients, where timely wound care is critical.**

***Index Terms*—Smart Bandage, IoT, Machine Learning, Biomedical Sensors, Wound Monitoring**

I. Introduction

Wound healing is a complex biological process that requires continuous monitoring and proper treatment. Chronic wounds, especially in diabetic patients, pose significant challenges due to delayed healing and increased risk of infection. Traditional wound-care methods rely heavily on manual inspection and periodic dressing changes, which often fail to detect early-stage complications.

The integration of modern technologies such as IoT and machine learning has opened new possibilities in healthcare. Smart bandages equipped with sensors can continuously monitor wound conditions and provide real-time data. This enables early detection of abnormalities and timely intervention. The proposed Smart Bandage system aims to address the limitations of traditional wound-care methods by providing an automated and intelligent solution.

II. Literature Review

Several researchers have explored smart wound-care technologies. Studies have demonstrated the use of hydrogel-based dressings and wearable sensors for monitoring wound conditions. Temperature and moisture sensors are commonly used to detect infection and healing progress.

IoT-based healthcare systems have gained popularity due to their ability to provide remote monitoring. Machine learning algorithms have been applied to analyze sensor data and predict wound conditions. However, many existing systems lack integration between monitoring and treatment. This highlights the need for a comprehensive system that combines sensing, analysis, and automated response.

III. Motivation and Objectives

A. Motivation

The increasing number of diabetic patients worldwide has led to a rise in chronic wounds. Delayed detection and improper treatment can lead to severe complications. There is a need for an intelligent system that can monitor wounds continuously and provide timely treatment.

B. Objectives

- To design a smart bandage for continuous monitoring
- To implement IoT-based remote data access
- To apply machine learning for wound analysis
- To automate medication delivery

IV. Methodology

The system follows a multi-stage process including sensing, data processing, analysis, and actuation. Sensors collect real-time data from the wound environment. The ESP32 microcontroller processes this data and transmits it to a cloud platform. Machine learning algorithms analyze the data to detect abnormalities. Based on the analysis, the system decides whether medication is required. If necessary, an Arduino-based module activates a vibration motor to distribute medication.

V. Hardware Implementation

The hardware system consists of multiple components working together.

The moisture sensor measures the level of moisture in the wound, which is essential for proper healing. The DHT11 temperature sensor monitors temperature changes that may indicate infection. The ESP32 microcontroller handles data acquisition and communication. The Arduino Uno controls the medication delivery mechanism. A relay and vibration motor are used to automate the medication process. The power supply ensures continuous operation of the system.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

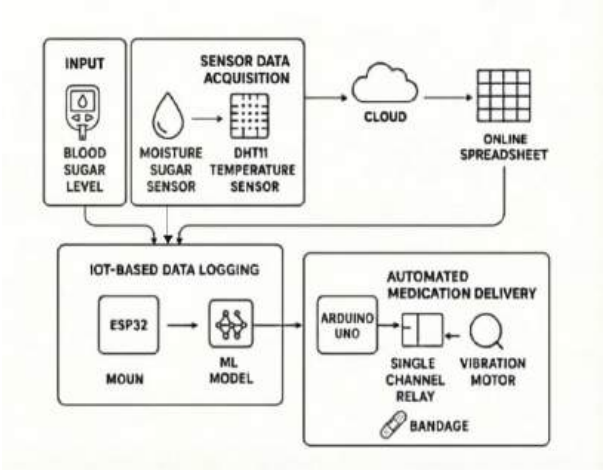

Fig. 1. Methodology Flowchart of Smart Bandage System

VI. Software Implementation

The software architecture includes embedded programming, cloud integration, and data analysis.

The ESP32 and Arduino are programmed using Arduino IDE. Sensor data is transmitted to a cloud platform where it is stored and analyzed. Machine learning algorithms process the data and identify patterns indicating wound conditions. A user interface is provided to display real-time data and alerts.

VII. Experimental Setup

The system was tested under controlled conditions to evalu-ate its performance. Sensors were placed on simulated wound surfaces, and data was collected over time. The system was monitored using a cloud interface, and various parameters were recorded.

VIII. Results and Discussion

The system successfully monitored wound conditions and detected abnormalities. The machine learning model accu-rately identified conditions requiring intervention. The auto-mated medication delivery mechanism functioned effectively.

Fig. 2. System Output and Analysis

IX. Performance Analysis

The system demonstrated reliable performance with accu-rate sensor readings and stable communication. The response time was sufficient for real-time monitoring.

X. Limitations

The system has certain limitations, including limited sensor types and basic machine learning models. Further testing is required for real-world applications.

XI. Future Scope

Future improvements include integration of advanced sen-sors, improved machine learning models, and telemedicine support.

XII. Conclusion

The Smart Bandage system provides an efficient and au-tomated solution for wound care. It enhances monitoring, reduces human effort, and improves patient outcomes.

Abstract- *Biofloc technology is increasingly recognized as an eco-friendly and space-saving approach to aquaculture, especially beneficial in areas where water availability is limited. By delivering real-time notifications, it improves overall system management and efficiency. . However, its operation is performance of biofloc fish farming while reducing fish mortality and highly sensitive to variations in water quality parameters such economic losses. The results demonstrate that integrating IoT with as, ammonia levels, turbidity, machine learning can transform small-scale aquaculture into a moredata-driven and sustainable sector. and temperature. This study proposes a cost-efficient, solar- powered IoT system for monitoring biofloc aquaculture tanks,*

which utilizes machine learning techniques to detect fish mortality at an early stage.

Designed for low-income fish farmers in southern Punjab, Pakistan, the system continuously measures critical water quality parameters using affordable sensors connected to Arduino UNO and NodeMCU ESP8266 microcontrollers.

Over a period of 1.5 months, data was collected at two-minute intervals and uploaded to the ThingSpeak cloud platform. After preprocessing and balancing the dataset using ADASYN, many ML algorithms—including Random Forest, XGBoost, A number of machine learning models were developed and evaluatedsuch as Naïve Bayes, decision tree models, and support vector machine techniques. Among these, Random Forest and XGBoost performed better, predicting fish.

I. INTRODUCTION

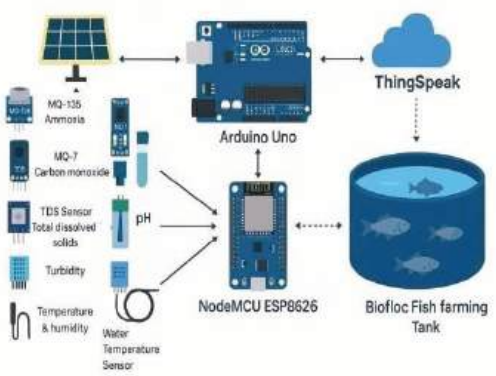

Figure 1: System Architecture

Figure 1: System Architecture

Global malnutrition remains a pressing issue, particularly in low-income and developing regions. Fish, a valuable protein source that is essential to support reliable food availability and adequate nutritional intake. As conventional fish farming methods struggle with land and water limitations, Biofloc technology has emerged as a promising alternative. It offers sustainable aquaculture by recycling waste nutrients, reducing water consumption, and increasing fish yield in limited space. Yet, this system is highly sensitive to water quality parameters such as pH, ammonia, dissolved oxygen, turbidity, and temperature. Minor deviations in these values can significantly affect fish health and lead to high mortality rates.

In Pakistan, especially in the underdeveloped regions of southern Punjab, traditional biofloc farming lacks automation and is labor-intensive. Fish farmers often struggle to monitor key water parameters manually, resulting in delayed interventions and preventable losses. The absence of predictive tools and real-time data further exacerbates the risk of sudden fish deaths, undermining the profitability and sustainability of biofloc farming.

The Internet of Things (IoT) has greatly improved modern agriculture by enabling real-time monitoring through networked sensors and cloud platforms.IoT systems can process sensor-generated data to find patterns when combined with machine learning (ML) approaches. and forecast unfavorable outcomes—such as fish mortality—by analyzing past data and relationships between different environmental factors.

This research addresses the gap by developing a lowcost, solar-powered IoT-based smart monitoring system tailored for biofloc tanks in rural Pakistan. Integrated with ML models, captures real-time data on water quality and predicts fish mortality 1–2 hours in advance, allowing for timely intervention.

Objectives of the Study

- To design and implement a cost-effective, solar powered IoT-based water monitoring system for biofloc tanks.
- To gather real-time sensor readings of important water quality parameters affecting Tilapia fish during a crucial growth stage.
- To clean, preprocess, and balance the collected dataset using methods such as ADASYN to improve the accuracy of prediction models
- To develop and assess Several machine learning are applied to accurately forecast fish mortality.
- To identify the major environmental factors linked to fish mortality and provide meaningful insights to support fish farmers in better management decisions.

Novel Contributions

- Development of a low-cost, solar-powered, real-time IoT monitoring system using Arduino and NodeMCU.
- Data collection and analysis during a high-risk aquaculture period (May–July), with over 18,000 sensor readings.
- are applied to estimate fish mortality with accuracy reaching 98%.
- Deployment of a correlation matrix to evaluate the influence of water parameters on fish mortality.
- Introduction of a scalable early-warning system that enables fish farmers to take corrective actions before mass mortality occurs.

II. METHODS

2.1 System Architecture

The designed solution integrates affordable sensing devices with IoT- based tools to track and forecast water conditions in biofloc aquaculture systems. The complete structural layout of the system is depicted in Figure 1 (to be included).
The device runs continuously thanks to a solar energy source and a 16-hour backup battery.
A Node MCU ESP8266 WiFi module sends data collected by the Arduino UNO microcontroller from several sensors to the Thing speak cloud server every two minutes.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Sensors deployed:

• MQ-135: Determines the concentration of ammonia
• MQ-7: Quantifies carbon monoxide
3 The concentration of dissolved solids in the water is monitored using a TDS sensing device.
• pH Sensor: Determines the acidity or basicity of water
• Turbidity Sensor: Determines how clear the water is
• DHT11: Monitors humidity and ambient temperature
• Water Temperature Sensor: This device gauges the temperature of tank water.

3.2 Data Collection

Data collection is over a 1.5-month period from May 13 to July 2, 2023, which is a critical growth phase for Tilapia fish. The system collected readings at two-minute intervals, resulting in 18,978 sensor.

3.3 Data Preprocessing

The dataset was prepared for machine learning analysis by performing the following preprocessing steps.

- Missing values were handled by dropping entries with sensor calibration delays.
- Special characters (e.g., "\r\n" in water temperature) were cleaned.
- Categorical encoding: "Mortality" (Yes/No) was converted to binary (1 = Yes, 0 = No).
- Standardization: All sensor values were scaled to zero mean and unit variance.
- Data splitting: The dataset was split into training and testing sets using different ratios (60–40, 70–30, 80–20, 90–10).

Since the number of "mortality = 1" instances was significantly lower, Adaptive Synthetic Sampling (ADASYN) was applied to balance the dataset. This ensured that the minority class (fish deaths) had sufficient representation during training, avoiding biased model performance.

3.4 Machine Learning Models

Six supervised machine learning classifiers were implemented to estimate fish mortality using various water condition parameters indicators.

1. Decision Tree
2. Random Forest
3. Support Vector Machine (SVM)
4. Logistic Regression
5. Gaussian Naïve Bayes
6. XGBoost

Every model underwent training through 10-fold cross-validation, utilizing various splits of the dataset. Metrics like accuracy, precision, recall, and F1- score were performance.

3.5 Cloud Infrastructure

Data was uploaded to the ThingSpeak cloud platform, which provided:

- Free storage for up to 8,200 entries/hour
- Public dashboard for visualizing water parameters in real-time
- Easy integration with ESP8266 for data push

III. RESULTS

This evaluation trained using the processed dataset. To ensure the reliability and stability of the models, several train–test data splits were applied. The effectiveness four key metrics. F1-score, accuracy, precision, and recall.

3.1 Model Performance on 60–40 Train-Test Split

Table 1 shows the results of all six machine learning classifiers trained on 60% of the data and tested on the remaining 40%.

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
Random Forest	97	95	99	97
Decision Tree	97	95	99	97
Support Vector Machine	94	89	99	94
Logistic Regression	93	93	89	91
XGBoost	97	95	99	97
Gaussian Naïve Bayes	91	89	92	90
combined model learning	96	94	99	96

Table 1: Evaluation Results (60–40 Split)

3.2 Performance on 70–30 and 80–20 Splits

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Tables 2 and 3 present the performance results obtained from the 70–30 and 80–20 training–testing data splits.

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
a tree-based learning	98	97	99	98
XG Boost	97	96	99	97
Decision Tree	96	96	96	96
SVM	95	91	99	95
Logistic Regression	94	94	91	92
Gaussian Naive Bayes	91	90	92	91
Ensemble Learning	97	95	99	97

Table 2: Evaluation Results (70–30 Split)

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
Random Forest	97	96	98	97
XGBoost	97	96	98	97
Decision Tree	95	95	95	95
SVM	95	93	98	95
Logistic Regression	93	93	91	94
Gaussian Naïve Bayes	90	91	89	90
Ensemble learning	97	95	98	97

Table 3: Evaluation Results (80–20 Split)

3.3 Correlation Analysis

Figure 2: Correlation Matrix of Water Quality Parameters and Fish Mortality

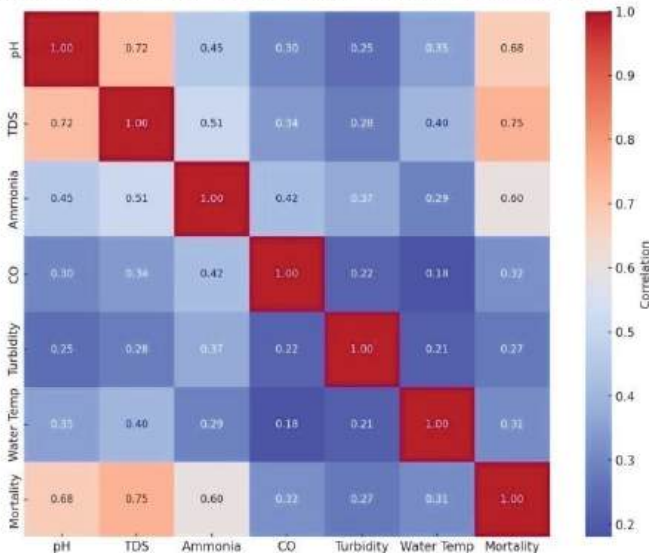

Figure 2: Correlation matrix illustrating fish mortality.

To identify the water quality factors that have the greatest influence fish mortality, a correlation matrix was computed.

Figure 1 (to be inserted) shows that pH and TDS had the strongest with fish mortality. Ammonia showed moderate correlation. In comparison, less significant associations were noted between CO, turbidity, and water temperature, indicating that ammonia, TDS, and pH serve as more significant control parameters.

3.4 Accuracy Comparison Graph

Figure 2 (to be inserted) illustrates a visual comparison of the classification accuracy achieved by different machine learning models across various training and testing splits. The consistent performance of Random Forest and XGBoost highlights their effectiveness across all configurations.

3.5 Summary of Results

- Random Forest and XGBoost
- Key influencing parameters: pH, TDS, and Ammonia.

IV. DISCUSSION

The machine learning approaches. The integration of IoT-based sensor networks greatly improves monitoring and safety.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

decisionmaking capabilities of biofloc fish farming. The system's ability to predict fish mortality up to 1–2 hours in advance is a major breakthrough for small-scale farmers in resourceconstrained environments like southern Punjab, Pakistan.

4.1 Interpretation of Key Results

Among the tested machine learning classifiers, Random Forest and XGBoost consistently achieved superior and train-test splits, with accuracy levels reaching 98%. These ensemble methods excel due to their ability to handle high-dimensional data and reduce overfitting through model averaging or boosting strategies.

Precision and recall values above 95% suggest that these models are reliable in both correctly identifying actual mortality risks and avoiding false positives, which is essential for real-time alert systems in fish farming. On the contrary, models like Naïve Bayes underperformed, likely due to the assumption of feature independence, which is not suitable for multivariate and correlated water quality data. The correlation analysis further confirms that pH level, TDS and ammonia levels are identified as key indicators of fish mortality. These results are consistent with previous aquaculture studies, which indicate that fluctuations in these parameters can place stress on fish physiology and raise the likelihood of death.

4.2 Practical Implications for Fish Farmers

In traditional biofloc setups, water quality monitoring is manual, time-consuming, and reactive rather than proactive. When values surpass mortality criteria, our IoT-based technology generates early warning signals and offers continuous, real-time insights into water conditions.

The system's low cost (~$60) and use of solar power make it ideal for adoption in rural or off-grid locations. For comparison, the cost of fish seed for 500 Pangasius fish is approximately $174—thus, even a single mortality event prevented can yield substantial savings and protect farmer income.

The system also reduces dependency on skilled labor or manual vigilance, empowering local communities with minimal technical knowledge to manage fish health more effectively.

4.3 Comparison with Related Work

While previous studies have proposed IoT-based aquaculture systems, few have achieved the combination of:

- Low-cost hardware integration
- Advanced predictive capabilities using ML
- Focused application to specific fish species and regions

For example, Md. Rashid et al. (2021) implemented a KNN-based a framework designed to forecast water conditions, though it reported only 77.3% accuracy. Similarly, Mahmuda et al. (2021) used image processing and achieved moderate prediction success. In contrast, the current study not only achieves up to 98% prediction accuracy but also incorporates a comprehensive real- time IoT framework and a long-term dataset.

4.4 Limitations

Despite its success, the study has some limitations:

- The system is calibrated specifically for Tilapia in the southern Punjab region; results may vary with other species or environmental conditions.
- Data was collected over a limited 1.5-month period, focused on a specific growth phase.
- There are access restrictions (8200/hour) on the Thing Speak cloud utilized for data transmission, which could impede scalability.
- Environmental sensors (like DHT11) may provide reduced precision compared to high-end industrial systems.

These limitations provide opportunities for further improvement and development in future research.

CONCLUSION AND FUTURE WORK

This study presents a cost-effective, IoT- and machine learning-based a smart monitoring solution designed for biofloc-based fish farming, specifically addressing the requirements of small-scale aquaculture in southern Punjab, Pakistan. The system continuously monitors critical water quality parameters— such as pH, total dissolved solids (TDS), ammonia, turbidity, and temperature—using affordable, solar-powered sensors and microcontrollers.

The data collected over 1.5 months was processed and used to train multiple supervised machine learning models. Among the tested models, Random Forest and XGBoost consistently demonstrated superior performance, achieving prediction accuracies of up to 98% for fish mortality. A strong association fish deaths and several key environmental factors.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

TDS, and ammonia levels validates the system's predictive capacity.

By providing 1–2 hours of advance warning, the system enables fish farmers to take proactive measures, reducing mortality, improving yields, and minimizing economic loss. Additionally, its low cost (~$60) and solarpowered design make it accessible and sustainable for farmers in remote or underserved areas.

Future Work

While the current system is optimized for Tilapia fish, future research will aim to:

- Extend the solution to support multiple fish species, each with distinct environmental tolerances.
- Collect year-round data to improve prediction reliability across different seasons.
- Integrate edge computing for offline prediction and real-time alerts without full cloud dependency.
- Develop mobile or SMS-based alert systems for farmers with limited internet access.
- Implement ensemble learning techniques and deep learning models for further accuracy improvements.

This research sets the foundation for transforming biofloc aquaculture from a manual, reactive system into a data-driven, intelligent practice, especially in low-resource contexts.

Abstract— **Fin-AI** is an intelligent household budgeting and grocery management system that helps families manage daily expenses while encouraging healthier food choices. The application combines real-time expense tracking, automated grocery list generation, and AI-driven recommendations that suggest nutritious alternatives—for example, replacing refined products with healthier, nutrient-rich options. The backend, powered by **Supabase**, ensures secure, scalable, and real-time data management along with built-in user authentication. The system provides a clean and user-friendly web interface, helping in user tracking their daily expenses, plan purchases, and make informed decisions effortlessly. By connecting financial awareness with health-conscious behavior, **Fin-AI** promotes smarter living at both individual and community levels.

Keywords— Household budgeting, grocery management, AI assistance, Supabase, expense tracking, healthy alternatives, real-time analytics

1.INTRODUCTION

In the modern digital age, individuals and families alike have to manage their personal finances and groceries more effectively [1]. As people change their ways of living, with inflation and increasing cost of living, households require a smarter approach to regulating their spending and promote better and informed data-driven budgeting decisions [2]. Conventional financial management tools like manual records and spreadsheets to track expenses are time-intensive, are easily subject to human error, and have no real-time analysis tools [3]. This has consequently seen a significant change towards digital financial management tools and AI-enabled budgeting systems [4].

Recent research demonstrates that Artificial Intelligence (AI) can contribute greatly to the domain of financial literacy and savings levels by providing individual recommendations and data visualization [5]. Budgetary apps using AI can be used to automate most of the tedious processes. They are capable of categorising your transactions, restriction of spending and where you can save money depending on how you have previously behaved [6].

However, the majority of apps just scan money. They do not even consider healthy lifestyle or the type of food people purchase. Having a good and sustainable lifestyle also involves eating better [7].

Fin-AI solves this problem. It is an AI-driven application that takes care of your budgets and your shopping decision. It not only monitors your spending but also provides more healthy options of food. It not only follows up on your spending but also will give you alternatives of healthier food e.g. it can tell you to eat brown rice instead of white rice, olive oil instead of refined oil or pink Himalayan salt instead of regular salt. These tips will be based on your preferences and wellness goals [8]. That is why Fin-AI is different of traditional budgeting applications. The Fin-AI is based on Supabase, an open-source back-end platform that offers secure authentication, robust database and real-time. updates [9].

Supabase reduces the load on a server on demand and simplifies the application to work and scale in the cloud The Fin-AI frontend is a user friendly interface. The users can add their grocery lists and expenses in extremely simple way as well as examine the list and analyze them.

Fin-AI integrates much of the functionality into one application grocery list creation, spending, and health-related recommendations at the cost of other budgeting applications [10]. This can help the user to make smarter buying decisions and keep health and money on their mindWith live. with news, personal thoughts, and health suggestions, users can change their daily routine and make better decisions[11].

The rationale behind the creation of this system is that the majority of people nowadays are looking to use AI technologies, which would help them manage their finances and their management style in a more positive way [12].Research indicates that families utilizing AI budgeting tools would reduce their unnecessary expenditures by approximately 30% annually [13].

In addition, dietary changes under the influence of digital directions toward the healthier store options can be beneficial in the long-term perspective and the decreased costs of healthcare spending [14]. Thus, Fin-AI is a comprehensive solution that is based on both sensible consumption and sensible financial planning, and that will foster economic stability and health conscience of the population as two critical elements of a sustainable and healthy way of living [15].

2.BACKGROUND/RELATED WORK: Overview of Existing Applications

Just about the finances or groceries, most apps available today can help people with their finances or groceries. them are only dealing with half a problem rather than providing a whole solution.

An example of budgeting apps that are popular and are automatic bank connectors is Mint, which not only organizes

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

the budget but also links with bank accounts. breaks costs down into distinct categories. It provides decent spending data, yet does not assist with grocery planning or any nutrition-related suggestions.

You Need A Budget (YNAB) is an excellent application in which the user can plan each and every rupee before spending it. teaches how to spend wisely, and does not monitor daily grocery requirements, or link expenditure with health objectives.

Grocery apps like Grocery Pal, Out of Milk, and Bring! mainly help users make shopping lists and keep track of grocery purchases. They are useful for organizing groceries, but they do not link this information with the user's budget or income. As a result, they cannot support complete household financial planning.

4.METHODOLOGY

4.1.System Overview

The Fin-AI system is built as a web-based platform that helps users track their income, expenses, and budgets more effectively. It also provides AI-based suggestions to improve financial planning. The system is designed in a modular way, which makes it easy to scale, maintain, and add new AI features in the future. Its workflow includes user input, data processing, AI analysis, visual reports, and easy-to-understand summaries.

4.2.SYSTEM ARCHITECTURE

The Fin-AI system is built so that users, the database, and the application can work smoothly together. It also keeps the data safe and makes the system easy to grow in the future. The system has three main parts: the user interface, the application logic, and the database. Each part has its own job, and together they help give the user a smooth and smart experience.

A. User Interface Layer

The frontend is the main place where users interact with the system. It has a clean and responsive design that lets users add their daily expenses, see financial summaries, create grocery lists, and get health recommendations. The interface also shows real-time charts, graphs, and budget alerts to make the information easy to understand. Its simple layout makes it easy to use for people of all ages, even those who are not very familiar with technology.

B. Application Logic Layer

The **application logic layer** performs all core processing functions of the Fin-AI system. It manages and coordinates data between the user interface and the backend, ensuring that every operation runs efficiently. Key functions include:

- **Expense Management:** Tracks daily spending, categorizes transactions automatically, and calculates total expenditures.
- **Budget Analysis:** Monitors spending patterns and compares them with the user's set budget to provide real-time financial insights.
- **Grocery List Generator:** Suggests grocery lists that align with both user preferences and financial constraints.
- **Health Suggestion Module:** Offers healthier alternatives for grocery items—for example, recommending brown rice instead of white rice or low-sodium salt in place of regular salt.
- **Live Monitoring:** Continuously updates the remaining budget and sends notifications when expenses approach preset limits.

This layer integrates AI-based recommendations to support intelligent financial and dietary decision-making, turning raw data into useful, personalized insights.

4.3. Database Layer

The **database layer**, built using **Supabase**, is responsible for securely storing all user information, including profiles, authentication data, expense history, grocery preferences, and health recommendations. Supabase offers built-in authentication, real-time data synchronization, and robust scalability. Data privacy and integrity are maintained through encryption and controlled access policies, ensuring that all sensitive user data remains safe and confidential.

A.System Flow

The workflow of the Fin-AI system begins when a user signs up or logs in to their account. Once authenticated, the system retrieves the user's existing data and displays an overview of their current month's budget, income, and expenses. Users can then log daily transactions, generate grocery lists based on their remaining budget, and receive health recommendations for added grocery items. The Health Suggestion Module automatically identifies opportunities for healthier substitutions. All updates are reflected instantly across the interface, allowing users to track both their financial and dietary activities in real time

. B.Advantages of the Architecture

The Fin-AI system provides users with a single platform where they can easily manage their budgets and maintain healthy spending and eating habits. It keeps everything updated in real time, instantly notifying users about their expenses and remaining budget. With the help of Supabase, the system ensures that all data is stored securely and can scale as more users join. The AI technology in Fin-AI personalizes financial and grocery recommendations based on individual spending patterns and preferences. Its simple and user-friendly interface makes it easy for people of all age groups to navigate and use the app comfortably.

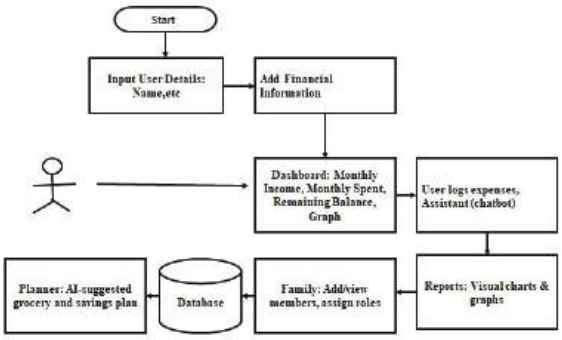

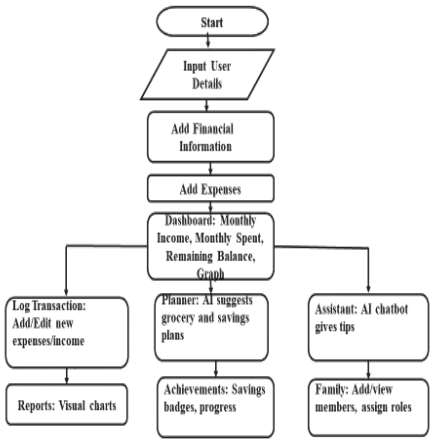

Figure 1: System Design

The workflow of the Fin-AI system is very simple and easy to understand:

1. **User Registration/Login:** Users first create an account or log in securely to access the system.
2. **Data Input:**After logging in, users enter their income, daily expenses, and the categories those expenses belong to.
3. **Expense Categorization:**The AI module then studies these transactions and automatically sorts them into predefined categories like groceries, transport, utilities, and so on.
4. **Budget Analysis:**The system compares the user's actual spending with their planned budget and shows where they have spent more or less.
5. **Reports and Visualization:**Finally, Fin-AI generates clear charts, graphs, and summaries so users can easily understand their spending habits and make better decisions.

Workflow of the System

5.RESULTS AND DISCUSSION

A. Ov view

The **FinAI** system was successfully developed, implemented, and tested to achieve the primary objective of providing an intelligent and automated personal finance management solution. The system enables users to track their income and expenses, visualize spending patterns, and receive AI-driven insights to enhance financial decision-making. This chapter presents the outcomes of the implemented system, the observed results during testing, and a discussion on the overall performance and usability.

B. Syst Output Screens

The major interfaces and outputs of the **FinAI** application are described below.

Home Page

The home page provides an overview of the system with options to register, log in, and navigate to different sections. It ensures an intuitive user experience through a clean and responsive design.

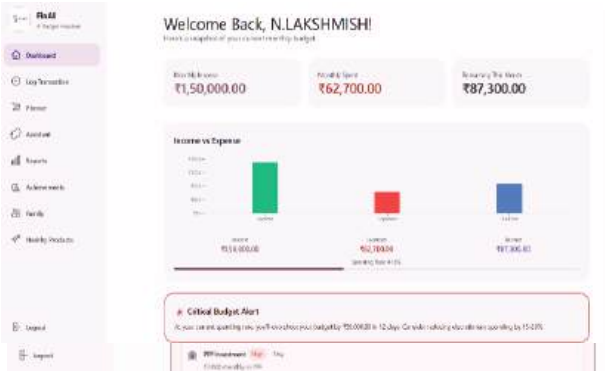

Figure 3: Screenshot of Home page

User Dashboard

Once logged in, users are redirected to a personalized dashboard displaying a summary of total income, total expenses, and balance. Charts and graphs visually represent financial data, helping users to understand their spending patterns easily.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Transaction Management

This module allows users to add, edit, or delete income and expense entries. Each transaction is automatically categorized, and totals are updated in real time.

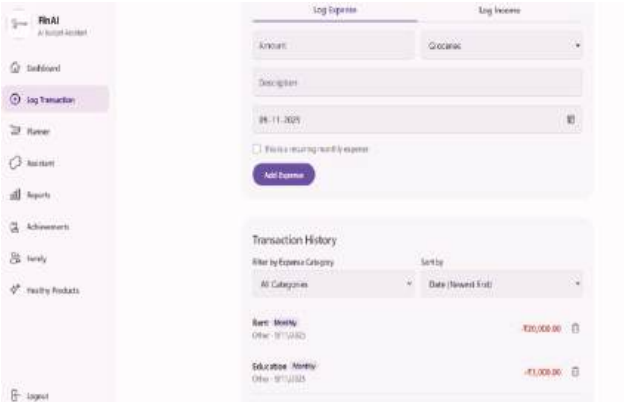

Figure 4: Screenshot of Log Transaction

AI Insights and Recommendations

The AI module studies how the user spends money and learns their regular habits over time. It looks at where most of the money goes, which categories get overspent, and which areas can be improved. Based on this analysis, the system gives simple and personalized suggestions to help users manage their money better. For example, it can point out categories where the user is spending more than usual, suggest ways to cut down unnecessary expenses, or recommend how much they should save each month. These suggestions help users understand their financial behavior clearly and support them in developing healthier and smarter spending habits.

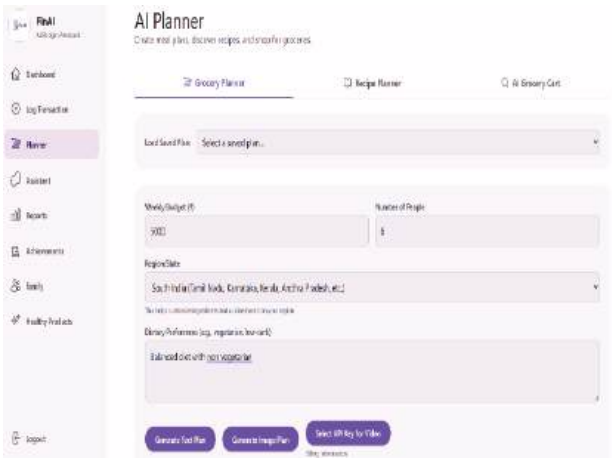

Figure 5: Screenshot of AI Insights

Reports and Data Visualization

Users can generate monthly or yearly reports that summarize income, expenses, and savings in both tabular and graphical formats. The reports can be downloaded in PDF format for record-keeping.

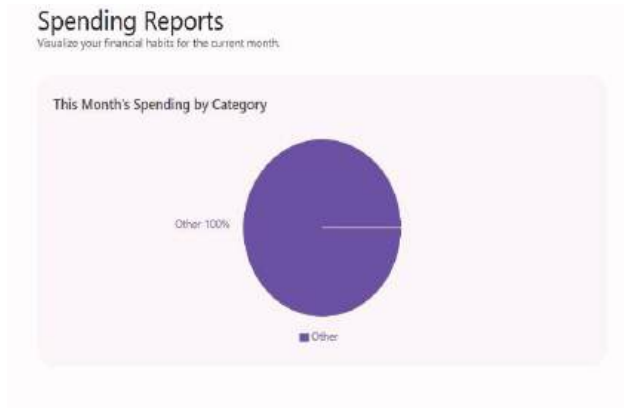

Figure 6: screenshot of Report

6.FUTURE ENHANCEMENT

The other upgrade is the utilization of the sophisticated predictive analytics. The system can forecast expenditure and savings by examining previous spending and income of a user. This assists the user to plan more efficiently and save people on unnecessary expenditures. It is also capable of detecting underlining or suspicious purchases and alerting the user enhancing security and financial acumen.

The addition of real-time currency and inflation tracking can also make FIN-AI smarter. It can be useful to individuals who have to use various currencies or reside in the regions where prices are more unstable. The system can also automatically adjust the budget of the user and provide more precise spending recommendations in case of inflation increase or change in currency values.

The other valuable upgrading is connecting the system to the local stores and online purchasing applications. Potential customers will be able to receive real-time price of the products, discounts offered, and current offers. This simplifies and makes shopping to be more affordable. When tied to nutrition databases, Fin-AI can also assist users in keeping track of their diet and the level of healthiness of their grocery habits.

Smart reminders and alerts can also be sent out by FIN-AI in the future. Such notifications can alert users about their upcoming bill, when they are about to spend more or when they have a good saving opportunity. Individual recommendations depending on habits of the user can assist him/her to keep track with finances and nutrition.

A mobile app having cloud [26] syncing may be included to make the system accessible anywhere. This will enable users to retrieve their data in other gadgets without any data loss. The process can be made more enjoyable and stimulate the users to save more by features such as rewards, badges, and savings challenges (gamification).

On the whole, such improvements of the future will enable FIN-AI to become not just a simple financial service but a full-fledged personal assistant that can assist with both financial and physical health.

Abstract- **WBANs (Wireless Body Area Networks) serve as essential tools for constantly monitoring health, but unreliable energy availability, unpredictable user movement, weak routing, and other security risks greatly limit the unrestricted and practical implementation of WBANs. A new form of DL-WBAN, based on using deep learning techniques for energy harvesting, routing, MAC and data security to ensure secure and energy-efficient operation has been developed. The data will initially be collected from the body using a collection of physiological sensors. The data collected will then be processed through a collection of physiological sensors. Then be processed through a CLSTM algorithm; the algorithm will provide previous sensor state information, current power consumption and provide the capability of adaptable power distribution. For postural movement, the Improved Mobility Aware Multi-criteria Decision Making (IMA-MCDM) dynamically selects stable next-hop forwarders. The Inspired Moth Flame Optimization (IMFO) then chooses relay nodes from multiple options based on their ability to reduce packet loss and latency. The Priority-Adaptive Fuzzy MAC (PA-MAC) and Markov Decision Process (MDP) dynamically assign time slots and power to each relay node, adapting to real-time conditions. The Hamilton Energy-Efficient Routing (HEER), using Linear Programming (LP), optimizes routing to minimize energy expenditure and delay when transmitting messages between relay nodes. The framework combines Dynamic Bio-key generation and Message Authentication Code (MAC) to securely transfer messages. Experimental results show the proposed WBAN framework achieves 25% higher throughput and 18% improved energy efficiency. This framework has shown an improvement over existing frameworks with respect to energy efficiency, communication reliability and data security for WBANs while considering the effects of body movement change.**

Index terms- **Bio-Sensor nodes, Cipher text, Energy consumption, Markov Decision Process (MDP), Security, and Wireless Body Area Networks (WBAN).**

I. INTRODUCTION

Wireless Communication technologies have grown omnipresent in our social and personal lives, with the Internet of Things (IoT) playing an important role in this regard. In particular, well-being and healthcare are developing as important application domains that would benefit greatly from IoT improvements. WBANs, which are networks of sensors that gather data on human activities, play an important role in such IoT-based situations [1, 2]. One emerging networking and communication technology used for health monitoring is the WBAN. WBAN monitors and measures biometrics by integrating sensors with actuators on or within the human body. It transmits data wirelessly to a device outside the human body and facilitates data transfer between sensors and a collector using a short-range wireless communication protocol [3-5].

An efficient solution is provided by WBANs, which are made up of wearable devices that are a network created especially for deploying many biomedical sensor nodes (SNs) in, on, or around the human body. WBAN seeks to assess many physiological characteristics, such as temperature, oxygen saturation, and heart rate [6]. Together medical and non-medical applications, reporting services and cost-effective monitoring provided by the WBSN, thereby improving quality of life. The WBAN centralizes patient data for medical diagnosis. Data must reach the end station safely and reliably [7]. The main characteristic of the WBAN is that the signal route will regularly vary due to random changes in human position, necessitating significant adaptive capabilities from the WBAN system [8]. The WBAN's power management, creating various sensors with low "energy consumption", and fine-tuning network settings for optimal power management are additional significant challenges [9]. Energy efficiency is one

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

of the main issues, though, particularly for implanted sensors that need to operate for extended periods of time without requiring a battery change [10].

Consequently, the WBAN network becomes unreliable and may result in life-threatening situations if the biomedical devices are unable to function as needed because their batteries are completely depleted [11]. Another important area of interest in WBAN is energy harvesting from human activity and the surrounding environment, for which researchers have offered a variety of methods. WBANs are implemented using fundamental methods called Medium Access Control (MAC) protocols. Taking into account particular network needs, these protocols are crucial for coordinating network node broadcasts [12]. "Quality of service (QoS)" factors, such as low latency, high throughput, and low communication overhead, are important for time-critical applications, such as healthcare data about patients. Due to their mobility, WBAN users may experience disconnections that can affect the successful delivery of processed health data [13].

This research suggests an intelligent design of WBAN systems to increase performance in dynamic environments by improving delivery of data and ensuring reliability through more efficient use of energy.

A. Motivation & Objectives

WBANs have to cope with many challenges that include limited battery power, patient movement, continually changing channels, and security problems, resulting in unreliable data transmission and lower system life. Some of these challenges include relay selection, energy management, routing consistency, and securely sending data, all of which can heavily influence the following:

- **Lack of Prior information:** In the existing approach, they did not consider the past states that limit predictive accuracy and adaptability in WBAN.
- **Neglects Sensor Node Mobility:** Current studies do not take into account sensor node movement as a result of movements in posture which can change how well a node is able to choose its best forwarder thus hindering a successful transmission of information.
- **Inefficient Relay node selection:** Earlier research has been unable to determine what the best amount of relay nodes would be and this creates laborious methods of determining the number of relay nodes available further harming overall performance of the network as well as the total amount of energy used for relaying information through the network.
- **Unpredictable node traffic management:** Instability in node traffic leads to ineffectiveness in static channel and time frame allocation impacts in suboptimal resource utilization.
- **High Propagation Delay:** In the previous research, the multi-hop communication experiences a significant propagation delay, minimizing the effectiveness of real-time data transmission.
- **Energy constraints:** One reason that WBAN has inherent problems is due to its energy capacity or lack of it, as well as the volatility of its data transfer; both of these issues contribute to an unstable network.
- **Encoded Key Vulnerabilities:** Due to the short time frame that an encoded key is used; it has the potential to be breached and its confidentiality or integrity will be compromised if it is compromised. For this reason, there are concerns about the confidentiality and integrity of the data that is sent due to the use of encoded keys.

The proposed solution to address the issues arising from mobility of the body being inconsistent with traffic, will also increase the performance, reliability and security of data transported over WBAN as a result of integrating an overall architecture within a system. The proposed objectives are as follows:

- To develop historical-aware methods to integrate the prior state of the sensor node for enhanced decision-making.
- To develop a mobility-aware scheme to become accustomed to postural changes and enhance forwarder selection in WBANs.
- To propose an effective approach to regulate the optimal number of relay nodes with minimized computation time.
- To develop a dynamic traffic-aware approach to improve efficiency in static and time frame allocation.
- To create strategies for reducing propagation delays for multi-hop communication.
- In WBAN environments to enhance the energy efficacy and definite stable data transmission.
- Against potential threats, to improve the key generation mechanism to enlarge key lifespan and strengthen the security.

B. Research Contribution

Here, the suggesting a framework for the energy harvesting and power allocation that is governed by deep reinforcement learning with the ultimate goal of maximizing the sustainability of WBAN. Throughout this research, the aims are to maximize energy efficiency and reliability of data transfer, while also providing dynamic resource allocation in response to external conditions such as node uncertainties and limited energy available to nodes. The contributions of this work are as follows:

- The data are collected from the biosensor in the WBAN.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- CLSTM model implementation to dynamically predict the prior state and compute power for energy harvesting with minimum energy depletion in the network.
- IMA-MCDM method for dynamic selection of best data forwarding paths based on posture changes, signal strength, and residual energy.
- The IMFO algorithm is employed to dynamically classify and select the best relay nodes in order to minimize packet loss and retransmission latency.
- The PA-MAC protocol, in combination with an MDP, is used for time slot optimization with respect to traffic priority, energy consumption, and throughput.
- The H-E-E-R Protocol was developed along with an LP model directed toward minimizing energy consumption and multi-hop propagation delay.
- Applying the Bio-Key with Message Authentication Code ensures protection against cyber threats for the preservation and tamper-proof transmission of patient data.

C. Paper Organization

There are several sections in this paper: Section II reviews earlier publications and identifies research gaps, while Section III discusses the limits of present methodologies. Section IV presents the mathematical formulation of the system model. The approach of the suggested model, including diagrams and mathematical representations, is covered in full in Section V. In Section VI, the experimental findings and a comparison of the suggested and current methods are presented. Section VII concludes the report and outlines future work.

II. LITERATURE SURVEY

In this section, we examine previously done research into WBANs including energy efficient communications, mobility aware routing, relay selection, MAC scheduling, and security for healthcare monitoring and previously explored to increase the network's life and reliability; however there has been comparatively little research related to the combination of these four areas such as, mobility, adaptive MACs, energy harvesting and secure data transmission which creates the motivation of this work.

In this research [14], to address the sample rate determination problem, a "deep deterministic policy gradient algorithm (DDPG)" is offered, which first defines the problem as a "Markov decision process (MDP)". This is called "deep reinforcement learning-based dynamic sampling" (DRDS). In the proposed approach, the governing parameter to determine the sample rate considers energy with information variability factors. The "long short-term memory" (LSTM) handles the forecasting of the data change rate in the next round with respect to the energy factor. To appropriately implement the complete DRDS in a centralized manner means transmitting every sensor information to the server, which raises certain security concerns eventually; future work may go towards distributed approaches like "federated reinforcement learning in WBAN" for personal and secure applications.

In this article [15], they look at the problem of "joint optimization of computation offloading and resource-allocation JCORA in mobile edge computing MEC" for a health-care service provision context. They define this JACORA as an MDP and suggest a "deep deterministic policy gradient-based WBAN offloading strategy (DDPG-WOS)" that is intended to improve time delay and energy usage in interfering transferring channels. This strategy for improving the transmission capacity and reducing the single WBANs computational pressure relies on MEC. DDPG-WOS also proposes an improvement of the "offloading strategy-making process" by taking into account the channel state, transmission-quality compute capacity, and energy consumed. Future research will focus on addressing "security and privacy" issues in WBANs for the benefit of patient-centered health care. Improving data protection and access control would go a long way toward ensuring the reliability and security of medical services provided.

The relay selection scheme discussed here takes into consideration both the "energy harvesting" effectiveness and the demand. Each sensor decides on its capability to work as a potential relay node depending on the energy harvesting efficiency it experiences, and computes the power threshold for transmitting its data. Based on the instant network status, the coordinator optimizes the cooperative transmission strategies. From testing, the cooperative scheme has shown better performance over the classical single-hop scheme, concerning packet arrival and reception rates. In unsaturated networks, cooperation among the sensors may be further improved by enhancing the super frame structures to conserve energy and support efficient data transmission. Further, optimization of these processes may be explored using deep learning-based coordination techniques [16].

Authors in [17] developed a "routing protocol" named "Simple Energy Efficient and Bandwidth Aware Routing Protocol" for routing in WBANs. The major focus of their proposed scheme for reducing energy usage, maximizing network lifetime, and improving data routing dependability in WBANs is several network node metrics, like available bandwidth, "energy harvesting, draining rate, energy, remaining energy, and the number of hops" in route selection. SEBA also implements a special mechanism for the dynamic adjustment of the route according to energy usage. Such approaches minimize route failures, route discoveries, and maximize energy dissipation between all the sensor nodes. In future research, it will be important to overcome the limitation of considering only a limited number of parameters. Q-learning can thereby be incorporated to enhance Quality of Service and energy efficiency.

This research [18] project starts with improving energy efficiency in WBANs by using a novel "weight-based algorithm" called the "weight-based next neighbor selection algorithm (WBNN)". WBNN gives different weights to different routes, classifying routes based on the distance

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

between the sensor pairs. A large weight number is assigned to a large distance, while a low weight is assigned to a short distance. Afterward, the total weighted value of each route is calculated. During forwarding, the sensor nodes utilize paths that have the least weight, implying low energy consumption. Besides, other routing algorithms and clustering techniques that are utilized for data sharing at different levels of the networks and sensors will also be presented. Future works will try to overcome time delay and optimize the resources of WBANs using machine-learning algorithms.

This article proposes [19] the "Energy Efficient Sustainable Network Using Network Optimization Technique (EES-NOT)" to optimize the WBAN's energy efficiency. To improve the network's dependability and "Quality of Service (QoS)", EES-NOT is linked with the "adaptive scheduling protocol for energy efficiency (ASPEE)".A "secured routing protocol for energy efficiency (SRPEE)" also offers optimum route selection and lessens network congestion. The existing system does not effectively incorporate "advanced technologies such as big data analytics, machine learning, deep learning", and blockchain. This deficiency restricts its interactivity and hampers overall network performance.

They suggest a WBAN system that is equipped with the "QoS Effective Protocol (QoSEP)" to efficiently route important packets to the target MS. To optimize the quality of the services provided, they employ "Ant Colony Optimization" for "Critical Packet Routing" to determine the shortest path with the lowest energy usage, minimal latency, and maximum throughput. Now, scheduling is carried out to increase the speed of emergency packet transmission while assuming precedence for the crucial packets. Lastly, they compare the suggested strategy to various current methodologies in order to assess its effectiveness. AI solutions for intrusion, adversary that is, tampering detection during the routing process can be connected to further enhance QoS-effective data transmission in WBAN [20].

This research [21] will present an effective "cross-layer media access control" technique for "radio frequency-powered energy harvesting WBANs" based on a revised structure of the superframe, giving scrupulous flexibility to the coordinator for rescheduling. The sensors used will "harvest energy from radio frequency signals" transmitted by the manager and adopt the time switching (TS) approach. The sensors will again be assigned to a sleep "transmission power adjustment scheme, depending on the network environment and energy harvesting" performance. Energy efficiency may be enhanced as it obtains more packets per joule. For improved performance in the network, the coordinator will determine the duration of the "energy harvesting period" to even out the channel resources and sensor energy requirements. In the future, work will focus on optimizing energy-efficient transmission by enabling the cooperation of sensors in the vicinity, where sensors close to each other act as relays to balance energy harvesting with that of network performance. This cooperative relay mechanism will allow the investigation of the sleep adjustment scheme.

The article proposes [22] the prioritization of traffic in WBAN systems by simultaneous load balancing for the service of general queues according to the "IEEE 802.15.6" standard in their proposed method known as Traffic prioritized load balanced scheduling, TPLBS. In this work, the aim is to train the queues such that the packets' initial drop would improve WBAN throughput. Here, the approach is to take both priority and packet origin into account, ensuring no packet has to wait an undue long time in a specified queue before going to the access point or being forwarded. The simulation is carried out using Castalia to analyze and compare performance against competitors. The manoeuvres carried out assume that WBANs, personal devices (PDs), and access points (APs) are static, thus ignoring the effects of mobility. Future work should focus on transient link quality assessment alongside mobility impacts on WBAN systems' performance.

This research proposes [23] a new "routing strategy", termed "simple energy-aware and reliable routing (SEAR)", which has the potential to transmit any data in a reliable manner over a WBAN. The incoming messages for the particular network are constructed based on the remaining energy (enduring vitality) of the sensor nodes, data importance, and hopcount from the sink node in order to adaptively select the appropriate forwarder node. In addition, the protocol describes a route reliability factor (RRF) to achieve the best transmission between any source sensor node (SN) and a sink node. RRF routes the data via paths, in the associated path having highest leftover energy with a "minimum hop count". Therefore, SEAR will deliver 'single-hop and multi-hop' routing data transmissions in a more efficient manner, such that reliability is improved, which will minimize power usage by the SN, and make a significant contribution towards maximizing system lifetime. It is a daunting task to bring all of this into an integrated and secure framework for IoT, capable of facilitating adequate communication between WBAN and smart homes, while safeguarding the privacy and security of health information being transacted.

The next generation of the SCSS algorithm aims at an efficient way to identify the possible BSN candidates which can fill a spot on a slot under the superframe's Exclusive Access Period (EAP) slots. The selection being made for these BSNs incorporates MDP policy function and the runtime configurations. The approach uses DRL methodology to ensure maximum reward from the MDP processes. Overcoming the dead nodes situation will require the proposed algorithm to use energy harvesting strategies and sleep cycles. A theoretical analysis on throughput and loss performance will be made on the basis of "Two-state Markov Chain (TMC)" models. A fair proposal would be to combine reinforcement learning in future studies to optimize the proposed algorithm and examine scalability in complex WBANs by integrating advanced techniques such as "machine learning or swarm intelligence" for better performance [24].

In order to increase network performance, a "prediction-based adaptive duty cycle (PADC) MAC protocol", known as "PADC-MAC", has been suggested [25]. It uses a mathematical

Vol. 14, Issue 06, ACSCON - 2026

formulation to include information about collected energy, both present and future. Additionally, a machine learning model that produces high prediction accuracy in dynamic harvesting scenarios, the "nonlinear autoregressive (NAR) neural network," is used. Therefore, when there is an adequate influx of inward collecting energy, it allows the receiver node to function more violently. Future research should focus on extending PADC-MAC for multi-hop support in large-scale EH-WSNs and validating it using hardware testbeds for diverse data packet generation scenarios. Energy harvesting from the surrounding setting and DL forecast of upcoming energy levels are the two approaches used in this work [26] to overcome the problem of energy obtainability for cognitive radio devices. Investigating model performance across different frequency bands, like the WiFi band, is essential to assess adaptability and efficiency in diverse communication environments.

The author proposes [27] the "energy-efficient extensive game-theory-based algorithm" (ESEGA), a paradigm for controlling the nodes' transmission power according to the power of their neighbor sensor nodes and the co-channel interference from their coordinators. Reduction in total energy and Transmission Power Level is attained through optimization. Layer 2 coordinator operations are modeled with the new entrant incumbent game theory. The work reduces the Transmission Power Level of first-tier nodes based on the conditions of the second-tier coordinators. The major challenge is to minimize interference among multiple coordinators and efficient resource allocation in a WBAN with further deteriorated channel conditions by employing game theory techniques.

Authors in [28] suggest a technique called "deep reinforcement learning-based dynamic sampling (DRDS)", This addresses the sampling rate calculation first issue as a "Markov decision process (MDP)" and then suggests a "deep deterministic policy gradient algorithm (DDPG)" to resolve it. When calculating the sample rate, the suggested approach takes energy and data fluctuation into account. For the energy aspect, two factors are taken into account: the super-capacitor's voltage level and the quantity of surrounding light. Regarding the aspect of data variability, the "long short-term memory (LSTM)" algorithm is created to forecast the pace at which the data will change in the following cycle. Future research will examine the viability of employing distributed techniques, including "federated reinforcement learning, in WBAN" to meet security and privacy requirements. In this article [29], a "Hybrid Clustering Approach for Extending WBAN Lifetime (HCEL), an energy-efficient routing system", is provided. HCEL uses a utility function to choose parent nodes according to received signal strength indicator (RSSI), proximity to the "sink node", and residual energy (RE). A limited number of serving nodes and an energy threshold value are also included in the parent node selection procedure. Extending the lifespan of every node in the network is the primary objective. According to the proposed WBAN framework, node mobility will not affect the performance of the system during the mobility of the body, thus limiting the benefits provided by WBAN technology when used for health care in an environment requiring a secure transmission of information. This study [30] proposes an "Improved Quality of service aware Routing Protocol (IM-QRP) for WBAN-based HMS" to remotely monitor elderly or chronically unwell patients in residential and hospital settings. Convolutional neural networks are utilized outside of WBAN environments to assess medical information for intelligent decision-making and diagnosis. The current proposed WBAN framework does not allow a full degree of interaction with its external environment and the other parts of the infrastructure that support the WBAN for the purposes of being able to do real-time monitoring and data management over a larger area because of its lack of an integrated IoT deployment.

A "multi-channel MAC protocol with a Markov decision process" is suggested in [31] in order to maximize the scarce energy resources and prolong the lifetime of devices inside the network. By utilizing distinct channels for communication between biomedical devices and access points (Aps), this protocol reduces latency and increases energy efficiency, throughput, and network longevity. Additionally, a "Markov decision process" is used to investigate the best communication techniques between biomedical devices and APS and to stochastically represent the system's transition phases. Additionally, a back-off technique, a time-slot allocation scheme, and an adaptive power allocation scheme are created to reduce delays, energy usage, and time-slot waste. Although there are currently no advanced resource optimization methods that have been incorporated into the WBAN system being proposed, these types of methods could improve overall WBAN system performance and system adaptability.

This article [32] presents a WBAN-IoT "blockchain-assisted delay and energy-aware healthcare monitoring (B-DEAH) system". Dual sinks are used for both environmental and body sensors to transmit packets on a regular basis and in an emergency. This paper involves a number of steps; an expanded version of the "PRESENT algorithm" is suggested for patient key registration. Cluster creation and cluster head selection are implemented using the spotted hyena optimizer; the MOORA algorithm is then used to build cluster-based routing. The "four Q curve asymmetric algorithm" is used to deploy and authenticate the "patient block agent (PBA)" for data transmission. However, this work does not consider developing mobility-aware handoff protocols to support connection management for seamless movement when someone disconnects from one part of a moving body. Furthermore, no methods were developed to manage power to each body sensor using a duty cycling technique of MAC scheduling. A viable strategy is proposed to develop this study presents a framework for creating a sustainable health monitoring node [33]. A "Health Monitoring Energy System (HeMeS) tool" as a result, a prototype that incorporates environmental parameters, electronic load activity levels, and system size limitations is created using thorough analytical models and used to illustrate system design space exploration for different patient types. In order to illustrate system design

Vol. 14, Issue 06, ACSCON - 2026

space exploration for different patient types, including environmental factors, electronic load activity levels, and system size constraints, the HeMeS tool prototype is developed using thorough analytical models. The current system has not examined the possible application of AI-based methods toward accomplishing dynamic energy balancing and maximizing system costs.

In this article [34], the authors discuss the architecture of a new cryptographic protocol that secures sensitive information transfer across a WBAN while guaranteeing three security services: integrity, secrecy, and authentication. In order to determine whether the gadgets are on the same person's body, additionally, take into consideration a keyless sensor authentication mechanism. To ensure that the protocol is correctly constructed and offers adequate security, a formal study of the protocol is conducted using cryptographic protocol verification tools. Nonetheless, the proposed cryptographic protocol is analyzed strictly for its formal security and lacks an evaluation of the protocol's performance in an actual WBAN environment. A summary of the previous work is provided in Table 1.

TABLE 1

Summary of existing works

References	Objectives	Algorithms or Methods used	Limitations
[14]	To resolve the dynamic sampling rate determination issue in WBANs while considering energy efficacy and data variability.	DRDS; DDPG formulated as MDP; LSTM.	It requires distributed or federated learning for privacy preservation.
[15]	For healthcare to optimize computation offloading and resource allocation in WBAN-assisted MEC.	DDPG-based WBAN Offloading strategy; MDP based JCORA optimization.	It's not address the security and privacy issues in WBAN-MEC integration.
[16]	Using cooperative communication with energy harvesting to enhance packet arrival and reception rates in WBAN.	Power threshold-based relay decision; energy-aware cooperative relay selection.	It further needs to improve the superframe structure and DL based coordination for unsaturated networks.
[17]	To extend network lifetime and minimize the energy consumption through effective routing in WBANs.	SEBA routing protocol; bandwidth, energy harvesting, hop count metrics.	It considers routing parameters are limited and not exploring the Qos improvement using reinforcement learning.
[18]	In WBAN routing through distance cognizant neighbor selection to improve energy efficiency.	WBNN	It does not address the resource optimization and time delay.
[19]	To improve reliability, energy efficacy, and QoS in WBANs.	EES-NOT; ASPEE schedules and SRPEE routing.	Some advanced technologies are not integrated.
[20]	For critical data to offer QoS-efficient routing in healthcare applications of WBAN.	Ant Colony Optimization; QoSEP protocol.	Not considers adversarial attack mitigation using AI and intrusion detection.
[21]	Using MAC-layer optimization to enhance energy efficiency in RF-powered energy harvesting WBANs.	Cross-layer MAC protocol; revised superframe structure; time-switching energy harvesting.	It's not implementing the cooperative relay-based energy balancing.
[22]	Based on IEEE 802.15.6 to select traffic and balance load in WBANs.	TPLBS queue training and priority-based scheduling.	Accepts static WBAN topology and ignores the mobility and transient link quality.
[23]	In WBANs to attain stable and energy-aware routing.	SEAR; RRF	It remains the privacy preservation and integration with secure IoT frameworks are challenging.
[24]	For superframe slot allocation in WBANs to select effectively BSN candidates.	DRL-based SCSS algorithm; MDP policy function; Two-State Markov Chain analysis.	In the energy harvesting and sleep-cycle optimization requires the integration of RL.
[25]	Utilizing adaptive duty cycling to enhance network performance in energy-harvesting WBANs.	PADC-MAC; NAR neural network.	It lacks hardware test bed validation and multi-hop support.
[26]	In cognitive radio devices using prediction to overcome the energy availability issues.	Energy harvesting with deep learning-based energy forecasting.	Not evaluate the multiple frequency bands.
[27]	Consuming game theory to decrease transmission power and interference in WBANs.	ESEGA	In deteriorated channels, resource allocation and inter-coordinator interference are challenging.

[28]	Considering data variability and energy to dynamically adapt sampling rates in WBANs.	DRDS using DDPG and LSTM-based prediction.	This is not explores the distributed and privacy aware implementations.
[29]	Through energy-efficient routing to extend the lifetime in WBAN nodes.	HCEL, RSSI	It does not consider the node mobility, so it can affects the system performance during body movement.
[30]	For WBAN-based health monitoring systems, to enhance the QoS- aware routing.	IM-QRP, CNN	Real-time monitoring is limited.
[31]	To increase energy efficacy and prolong network lifetime in WBANs.	Multi-channel MAC protocol; MDP; adaptive power allocation	It does not integrate the advanced resource optimization techniques.
[32]	Utilize the block-chain assisted WBAN-IoT integration, to design a delay-and energy-aware healthcare monitoring system.	B-DEAH framework, PRESENT algorithm; MOORA algorithm	It does not implement the energy management of body sensors for MAC scheduling.
[33]	Utilizing optimized energy to develop the sustainable health monitoring node.	HeMeS tool, Analytical modeling, design space exploration.	It not explores the AI-based techniques for dynamic energy balancing.
[34]	In WBAN, to secure the sensitive communications with authentication and confidentiality.	Keyless sensor authentication, new cryptographic protocol	Only this protocol is estimated through formal security analysis.

III. PROBLEM STATEMENT

An overview and explanation of the explicit issue statements used in the most recent research are given in this section.

This study [35] entails a comprehensive and complicated pathway selection scheme which incorporates "Energy Enrichment Multi-Hop Routing (EEMR) protocol" and an original meta-heuristic approach towards network life enhancement optimization. The EEMR is a two-stage process. The first part, "Enhanced Flower Bee Optimization Algorithm (EFBOA)", is mainly aimed at network longevity enlargement for the WBAN via the creation of a cluster network. "Dynamic Local Hunting and Location Discarding (DLH-LD)" is the next step that picks the fastest route out of several options. The main limitation of this study is outlined below:-

- Their approach does not have a history since they consider only the present state of nodes, ignoring earlier states.

Authors in [36], proposed “Energy Aware Forwarder Selection Technique (EAFST)”, choose efficient forwarder nodes to increase the immovability period and network lifespan of WBAN. The sensors are arranged by EAFST in concentric circles with the coordinator at their center. The high-priority sensor does not relay data from other sensors; instead, it sends data straight to the coordinator. Nevertheless, EAFST uses “residual energy, queue size, and route loss” to choose an agent for “low or medium-priority nodes” that are in a lower ring. This considerably lowers data transmission latency and the energy load on “high-priority nodes”. To further reduce energy consumption, once the forwarder's leftover energy falls underneath the threshold value, the forwarder's duty is rotated between “low and medium-priority nodes”. Several issues identified in this research include:-

- Their scheme fails to account for sensor node mobility because of postural changes and impacts on forwarder selection.
- In their approach experiences high propagation delay due to multi-hop communication.

This work [37] provides an “adaptive cuckoo search-based method (ACSM)” that places relay nodes using an adjustable step size proportionate to the fitness function and an efficient fitness function. Simulation results were used to compare the group of relay nodes produced by their suggested ACSM and other techniques. As demonstrated by the simulation results, the suggested method not only uses less energy than its alternatives, but it also equally allocates the load throughout the relay nodes. Outlined below is the major constraint encountered in this research:-

- In their research technique had challenges in identifying the optimal number of relay nodes is time consuming.

In order to improve energy economy and provide real-time emergency data delivery, they suggest “time-sharing multichannel MAC” for WBAN in this research [38]. Designing an effective “time-sharing multichannel MAC protocol for WBANs” is the goal in order to achieve low interference and energy-efficient transmission. To enable them to wake up at their designated times and send their data, each node has been statically assigned to the time slots and channels. Castalia is utilized to simulate the recommended method to examine and compare its performance with that of its alternatives. The essential drawback of this research is concise as follows:-

- In their research, they had a concern about unpredictable node traffic, which can lead to inefficiency in static channel and time frame allocation.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

They suggest [39] aiming at an "energy-efficient and reliable routing protocol called EERR-RLFL. To EERR-RLFL", they develop a node "rank division mechanism" in considering heterogeneous nodes of WBANs. The sensor nodes are then arranged into ranks according to three classifications for effects on link quality. Next, they develop the algorithm for Link Quality Evaluation through Fuzzy Logic (FLLQE). It uses the fuzzy evaluation method of fuzziness for consideration of the full spectrum effects of several factors for estimating the superiority link of 2 nodes that will then deliver the foundation for route selection. During the procedure of data routing according to the above feature of "FLLQE", they will utilize a "hybrid data routing mode" where the FN is determined initially, then select the global optimized routing path through reinforcement learning. Some of the problems identified in this research are as follows:-

- A wireless body area network had challenges of limited energy availability and unreliable data transmission.

In this transforming process, the unique key will be generated using the "ECG values" obtained from the "MIT-BIH Arrhythmia database" [40]. After creating four individual unique keys, they are utilized for encoded purposes. All the individuality and arbitrariness of the keys produced were shown by the test and the frequency validation within a block. The limitation of this research is described as follows:-

- In their research, the generated encoded keys have a limited lifespan, making them vulnerable to attacks if compromised.

Research solutions: The suggested WBAN architecture uses a CLSTM model to predict energy consumption and allocate energy dynamically, while an IMA-MCDM (AHP-SAW) scheme manages mobility-aware path selection for WBANs. The IMFO algorithm also aims to find relay nodes that will minimize the likelihood of packet loss. It is assumed that developing a PA-MAC with MDP will provide an efficient mechanism for dynamically allocating both time-slots and power. In addition, using LP, the HEER methodology can cut back on energy waste and service interruptions. Confidentiality in WBANs can also be assured through application of MeAC and Dynamic Bio-key.

IV. SYSTEM MODEL

The different elements of the proposed WBAN architecture are presented in this section using a system level, mathematical model and includes; data sensing, energy dynamics, mobility effects, relay selection, routing, MAC schedule and security. Below is a graph representing a WBAN.

$$\mathcal{G} = (\mathcal{V}, \mathcal{E}) \tag{1}$$

In this term,$\mathcal{E}$ and $\mathcal{V}$ characterizes the wireless links and relay nodes. All bio-sensor nodes $i\epsilon\mathcal{V}$ continuously acquire physiological parameter readings and produce data packets $D_i(t)$ every time point (t), which they send through paths of multiple hops via relay assistance to a designated sink to conserve transmission energy and maximize the network's lifespan. A graph is used to illustrate the ever-changing connectivity between the nodes due to body positioning changes. Node i's operating condition at time t is described as:-

$$S_i(t) = [E_i(t), B_i(t), \lambda_i(t)] \tag{2}$$

Here, $E_i(t)and\ \lambda_i(t)$ denotes residual energy and packet arrival rate. The buffer occupancy can be represented by $B_i(t)$. The CLSTM's state input vector provides a mechanism for learning the temporal dependency of the system's energy consumption and traffic behavior. The three processes have the same decision logic by having the same logical image for power allocation, MAC scheduling and routing. The energy dynamic of the node i follows,

$$E_i(t+1) = E_i(t) - \mathrm{P}_i(t)\tau_i(t) + H_i(t) \tag{3}$$

$H_i(t)$, $P_i(t)$, and $\tau_i(t)$ represent harvested energy, transmission power, and the MAC time slot respectively. The provided equation shows the relationship between energy consumed and energy stored. This method enables the balancing of energy resources, improving the efficiency of resource usage using both harvested energy to limit quick energy depletion and lengthen the nodes' lifetimes as well as using past energy usage to create the $P_i(t)$ measure used in a CLSTM input. The post variation-induced movement is measured as follows,

$$\delta_j(t) = \left\| r_j(t) - r_j(t-1) \right\| \tag{4}$$

The vector $r_j(t)$ indicates the node's position. Overall stability of the link would be affected by the displacement caused by the movement of a mobile body; as the amount of displacement increases, there is also an increased chance of channel variation and packet loss. The IMA-MCDM process must employ a mobility-aware method to determine how to forward packets across an existing link. The stability factor for the posture of the node is defined as follows: -

$$\phi_j(t) = \frac{1}{1+\delta_j(t)} \tag{5}$$

The immediate quality of the connection between node k and candidate node j or $\psi_{kj}(t)$ is illustrated above at time t. This parameter is defined as the ratio of the power of the received signal $P_{kj}^{rx}(t)$, to the variance of the noise power, σ_n^2, which serves to characterize the wireless link's SNR.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

$$\psi_{kj}(t) = \frac{P_{kj}^{rx}(t)}{\sigma_n^2} \quad (6)$$

Link reliability is measured by the "signal-to-noise ratio", and it is an important component for both mobility-aware forwarding and relay selection. Links that have higher signal-to-noise ratios allow for fewer retransmissions and decreased energy consumption.

$$\epsilon_j(t) = \frac{E_j^{rem}(t)}{E_j^{max}} \quad (7)$$

Here, $\epsilon_j(t)$ denotes the energy sustainability index of the sensor node, and it indicates the relative node remaining energy level. $E_j^{rem}(t) and\ E_j^{max}$ It refers to residual energy and the maximum energy capacity of the sensor node. This confirms following decision-making is penalized for the inadequate residual energy nodes.

$$\Theta_j(t) = \sum_{m=1}^{3} v_k \cdot \hat{Z}_{j,m}(t) \quad (8)$$

In this equation, $\Theta_j(t)$ denotes the overall mobility-aware score of the candidate node j at time instant t and m represents the index of the decision criterion. The notations $v_m\ and\ \hat{Z}_{j,m}(t)$ are represents AHP-derived weight of the mth decision criterion and n the normalized value of the mth metric for the node j at time t. In a single decision value, this weighted score incorporates the link quality, posture stability, and energy sustainability.

$$j^{\dagger} = \underset{j}{\operatorname{argmax}}(\Theta_j(t)) \quad (9)$$

Where $j^{\dagger}$ does the selected optimal next-hop sensor node. The notation $argmax_j(.)$ represents an operation that returns the node index j yielding the maximum value. Upon posture changes, this selection is consistently updated and confirms reliable data forwarding with energy depletion and minimal packet loss.

$$F_r = \alpha_1 \psi_{k_j}(t) + \alpha_2 \epsilon_j(t) + \alpha_3 \phi_j(t) \quad (10)$$

Here $\psi_{k_j}(t), \phi_j(t)\ and, \epsilon_j(t)$ are indicates the link quality, posture stability, and normalized residual energy. The weighting coefficients are referred to as $\alpha_1, \alpha_2\ and\ \alpha_3$. This equation confirms that the relay nodes with low delay, greater reliability, and adequate energy are preferred. Assigning time slots in the PA-MAC protocol is computed as:

$$\mathcal{F}_j(t) = \mathcal{F}\big(\eta_i(t), \beta_i(t), \alpha_i(t)\big) \quad (11)$$

Where the fuzzy output score represents $F_j(t)$ and $F(\cdot)$ refers to the fuzzy inference engine merging the three input ratios. Simultaneously estimates the multiple conditions for this process. For every node, a scheduling preference level is generated. The HEER routing protocol computes routing cost as follows:

$$C_p = \sum_{(i.j)\epsilon p}(\omega_1 E_{ij}^{tx} + \omega_2 D_{ij}) \quad (12)$$

Here, the total routing cost of the path p is represented by C_p, where D_{ij} denotes the propagation and queuing delay on the link, and E_{ij}^{tx} denotes energy consumed for transmission from node i to node j. Generating the ciphertext at the node i is:

$$C_i(t) = \mathcal{E}_{k_i(t)}\big(D_i(t)\big) \quad (13)$$

Where $C_i(t)$ symbolizes the ciphertext, $D_i(t)$ denotes the original physiological data packet collected by the sensor node. Utilizing the current Bio-Key $K_i(t)$ encryption function $E_{k_{i(t)}}(\cdot)$. During wireless transmission, this confirms the confidentiality of patient data. If packets are interrupted, having no static key prevents data from being recovered and evaluated.

V. PROPOSED METHODOLOGY

The research aim is to develop a deep reinforcement learning driven energy harvesting and power allocation framework to optimize the sustainability of wireless body area networks. The steps given below are the key steps taken into account. The overall architecture can be shown in Fig.1.

- Data collection
- Priority based Sensor Nodes
- Mobility of sensor nodes on postural changes
- Classifying the optimal Relay nodes
- Dynamic power allocation
- Energy harvesting based routing in WBAN
- Security

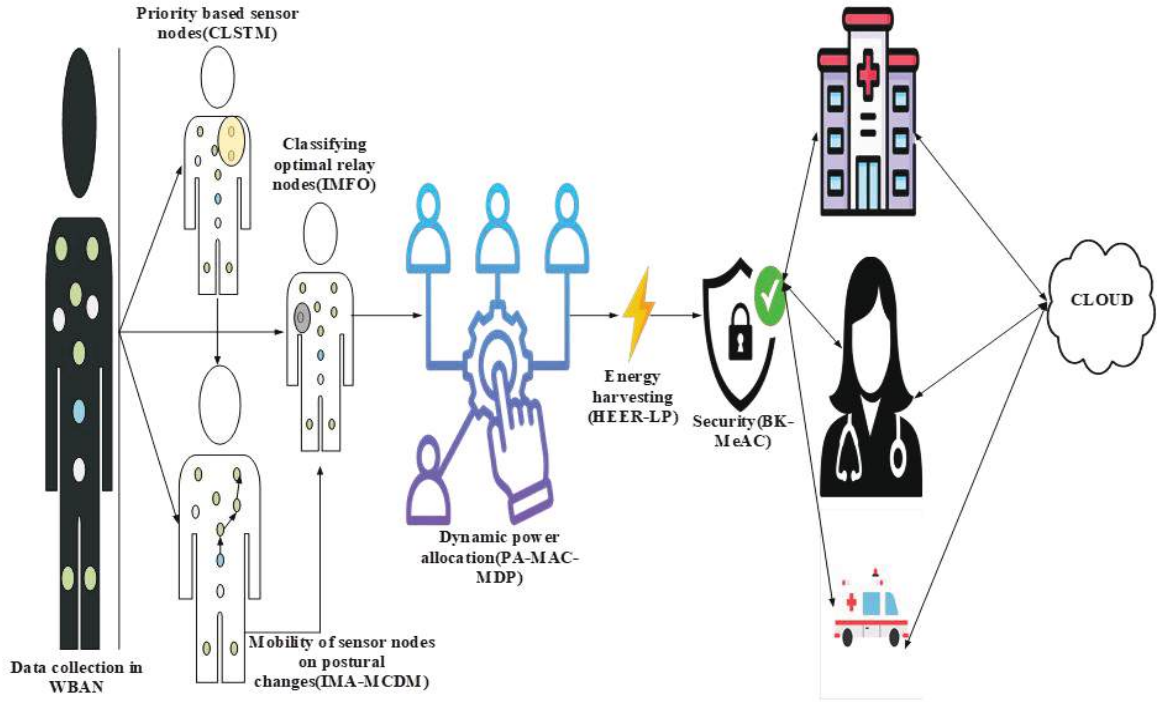

Fig.1 Overall System Architecture

A. Data Collection

Firstly, there is a WBAN scenario which consists of sixteen bio-sensor nodes, placed in various locations on the patient's body, with the aim of monitoring vital signs. The body sensors monitor physiological signals measured as heartbeats, blood pressure, and oxygen levels in their network architecture, composed of a single Sink node, fixedly positioned and aggregating data from the sensors. Direct communication between sensor nodes and the sink would not be efficient, given the nature of wireless transmission, because of energy constraints. This is because we now introduce relay nodes and their candidate placement for fifteen to twenty across the body. These relay nodes help in the forwarding of data and aggregating results from individual sensors, which would have direct energy expenditure, while ensuring that communication still occurs at a low energy cost to each individual sensor. Fig.2 represents the Data collection.

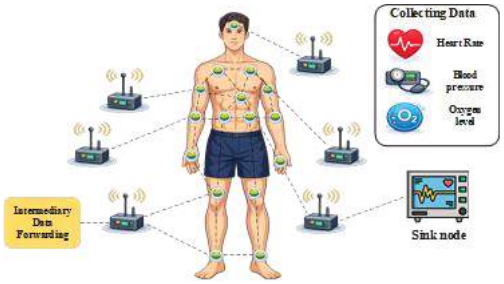

Fig.2 Data collection

B. Priority of sensor nodes:-

We apply the **Convolutional Long Short-Term Memory (CLSTM)** model to optimally harvest and allocate powers inside the WBANs. In this paradigm of deep learning, historical states of sensor nodes are integrated at one specific model run, thus predicting and allocating power dynamically. The learning from previous energy usages results in devices with excessive energy consumption receiving the required amount of charge while avoiding the excessive drain of networks powered from batteries.

At the instant given time represented by t, i denotes the state vector ofthe operational condition of the sensor node.

$$s_i(t) = [E_i(t), R_i(t), Q_i(t), S_i(t)] \quad (14)$$

In the above equation, the residual energy of nthe ode i is represented as $E_i(t)$, $R_i(t)$ *and* $Q_i(t)$ where symbolizes the data generation rate and buffer queue length. The received signal strength are represent by the $S_i(t)$. The communication status and energy of each node can be demonstrated by these parameters.

To capture the temporal behavior, historical states from the earlier T time slots are collected and organized as:

$$X(t) = \{s_i(t - T + 1), \ldots, s_i(t)\} \quad (15)$$

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

To learn energy usage trends and communication patterns over time is permitted by the historical matrix. Among sensor nodes to extract spatial correlations, the historical input $X(t)$ is processed by the convolutional layer.

$$F(t) = \sigma(X(t) * W + b) \tag{16}$$

Where the convolution kernel that captures inter-node relationships is characterized W. This $\sigma(.), b$ is the nonlinear activation function and bias term. This process classifies spatial dependencies such as correlated energy depletion through nearby sensors. $F(t)$ is extracted features. This passes into the LSTM unit to model temporal dependencies. The internal memory is used by the updates of LSTM.

$$C_t = f_t \odot C_{t-1} + i_t \odot \tilde{C}_t \tag{17}$$

The cell memory symbolizes as the C_t, which can be stored the long-term energy patterns, how much past and new information are collected and added controlling by the $f_t and\ i_t$. $\tilde{C}_t$ is the candidate energy trends learned from current inputs. The notation $\odot$ denotes the element-wise multiplication. In the hidden state, the LSTM output:

$$h_t = o_t \odot \tanh(C_t) \tag{18}$$

Here o_t controls the flow of the output and h_t is a sensor over time of learned energy behavior. Utilizing the hidden state h_t, the CLSTM forecasts each sensor's residual energy in the next time slot:

$$\hat{E}_i(t+1) = f(h_t) \tag{19}$$

In this equation, the predicted energy level of the sensor i is represented as $\hat{E}_i(t+1)$, and the learned nonlinear mapping function of the CLSTM is symbolized by $f(.)$. During transmission, the real energy consumption of a sensor is figured as:

$$E_i^{cons}(t) = P_i(t) \cdot \Delta t \tag{20}$$

The transmission power and duration are symbolized $P_i(t) and\ \Delta t$. Sensors naturally consume extra energy with greater data transmission or low channel conditions.

The transmission power for the following slot is disseminated as follows based on the estimated energy $\hat{E}_i(t+1)$,

$$P_i^{alloc}(t) = \min\left(P_{max}, \frac{\hat{E}_i(t+1) - E_{th}}{\Delta t}\right) \tag{21}$$

To prevent node failure, the maximum allowable power and minimum energy threshold characterizes the $P_{max}\ and\ E_{th}$. Significant energy allocation is given to sensors that are anticipated to sustain higher energy depletion.

At each sensor updated energy level is estimated as:

$$E_i(t+1) = E_i(t) - E_i^{cons}(t) + E_i^{harv}(t) \tag{22}$$

In this equation, the harvested energy from ambient sources is represent by E_i^{harv}. This guarantees sustainable sensor operation without significant battery depletion.

C. Mobility of Sensor nodes under postural changes

One of the major challenges during WBAN deployment for patients is the effect of posture changes on the placement of the sensor nodes while the patient is moving about a hospital or home. The next important component to include in their mobility dynamics is the "**Improved Mobility Aware Multi-Criteria Decision Making (IMA-MCDM)** method. This will use the **Analytic Hierarchy Process and Simple Additive Weight (AHP-SAW)"** techniques to select the optimal next hop dynamically. Evaluating multiple factors, signal strength, link stability, and residual energy, assures reliable data forwarding during continuous body movement. The algorithm of IMA-MCDM-Based Mobility-Aware Next-Hop Selection can be represented in Algorithm 1.

1) Posture-Induced Mobility Modeling

The relative position of sensor nodes can differ over time due to the patient's movements, such as sitting, walking, or lying down. A candidate forwarding node j's mobility status at time instant τ is represented as follows:

$$P_j(\tau) = \left[x_j(\tau), y_j(\tau), z_j(\tau)\right] \tag{23}$$

In the above equation three-dimensional spatial position vector can be symbolized as $P_j(\tau)$ and x_j, y_j, z_j are symbolizes the spatial coordinates of the node j on the body. This spatial representation permits node displacement tracking across consecutive time slots.

Here, the j node of physical displacement can be measured by $\delta_j(t)$, where increased mobility and possible link stability are indicated by greater displacement formulated by Eqn (4). A posture stability coefficient is defined in Eqn (5) in order to normalize the effect for routing decisions:

Thus, the more a sensor node moves around because the patient's body posture is changing, the lower that sensor node's stability values will be. In contrast, those sensor nodes that move minimally will have higher $\phi_j(t)$ values, indicating they are situated in a stable area of the patient's body. The coefficient $\phi_j(t)$ offers normalizing effects of mobility on the capability to transmit data between sensor nodes that have maintained reliable communication paths during the patient's movement.

Vol. 14, Issue 06, ACSCON - 2026

2) *Mobility-Aware link and Energy Evaluation*

In Eqn (6), the higher the value of $\psi_{kj}(t)$is, the more robust and more reliable the wireless link. The lower the values of $\psi_{kj}(t)$, the less reliable the wireless link will be due to disturbances caused by body shadowing, attenuation of the wireless channel, or posture changes of the user. The link robustness is used as a way to evaluate the best hop for next-hop selection while the node user is moving.

During the duration of connectivity, the posture can be affected, and link sustainability is evaluated as:

$$\kappa_j(t) = \frac{T_j^{stable}(t)}{T^{window}} \tag{24}$$

In this term, the temporal reliability of the wireless link is represented as $\kappa_j(t)$. Computed as the ratio of the cumulative duration for which the link remains connected, symbolized by $T_j^{stable}(t)$, and $T_j^{window}$is denotes the total observation of the interval. The duration of the link's stability during the observation window is captured by this ratio. Concurrently, the node's energy capability is described in Eqn (7). .

3) *AHP-Based Priority Weight Computation*

The analytic hierarchy process is applied to conclude the relative influence of link quality, energy, and mobility. The creation of Q a pairwise comparison matrix is as follows:

$$\boldsymbol{Q} = \begin{bmatrix} 1 & q_{12} & q_{13} \\ q_{21} & 1 & q_{23} \\ q_{31} & q_{32} & 1 \end{bmatrix} \tag{25}$$

The significance of the criterion m relative to n can be expressed by each element q_{mn}. The stabilized priority vector is achieved as follows:

$$\mathbf{v} = [v_\phi, v_\psi, v_\epsilon] \tag{26}$$

AHP-derived weight vector of decision criteria is referred to as v**.** The term $v_\phi, v_\psi, and\ v_\epsilon$ denotes the weight of posture stability, link quality, and energy sustainability criteria. The impact of energy availability, signal quality, and posture stability is quantified by these weights. The decision logic stability is shown by:

$$CR = \frac{\lambda_{max}-3}{2 \cdot RI} \tag{27}$$

CR it refers to the consistency ratio used to validate the dependability of AHP judgments. The maximum eigenvalue of the AHP pairwise comparison matrix is represented by the λ_{max}. The 3 and is denotes the number of decision criteria considered in the AHP model, and the normalization factor is equal. Random index RI establishes the average constancy of randomly generated matrices. Before aggregation, the stability ratio below the threshold ensures dependable weighting.

4) *SAW-Based Dynamic Next-Hop Selection*

To enable fair accumulation each mobility-related metric is stabilized:

$$\hat{Z}_{j,m}(t) = \frac{Z_{j,m}(t) - \min(Z_m)}{\max(Z_m) - \min(Z_m)} \tag{28}$$

Where $\hat{Z}_{j,m}(t)$ does the mth metric of the node j. Utilizing simple additive weighting, the overall mobility-aware forwarding score is then computed in Eqn (8). Next, select the optimal next- hop node is selected defined in Eqn (9). Postural changes on mobility sensor nodes can be shown in Fig.3.

Algorithm 1: IMA-MCDM-Based Mobility-Aware Next-Hop Selection

Input: Set of candidate nodes $\mathcal{J}$, Position vectors $\mathbf{r}_j(t)$, Received power $P_{kj}^{rx}(t)$, Residual energy $E_j^{rem}(t)$, Observation window T^{window}

1. Initialize decision criteria for all $j \in \mathcal{J}$
2. For each candidate node $j \in \mathcal{J}$ do
3. Compute displacements $\delta_j(t) = \|\mathbf{r}_j(t) - \mathbf{r}_j(t-1)\|$
4. Compute posture stability coefficient $\phi_j(t) = 1/(1+\delta_j(t))$
5. Compute link quality $\psi_{kj}(t) = P_{kj}^{rx}(t)/\sigma_n^2$
6. Compute link stability ratio $\kappa_j(t) = T_j^{stable}(t)/T^{window}$
7. Compute energy sustainability index $\epsilon_j(t) = E_j^{rem}(t)/E_j^{max}$
8. End for
9. Construct AHP pairwise comparison matrix **Q**
10. Derive priority weight vector $\mathbf{v} = [v_\phi, v_\psi, v_\epsilon]$
11. Compute consistency ratio CR
12. If $CR > 0.1$ then revise comparison matrix
13. Normalize decision metrics $\hat{Z}_{j,m}(t)$ for all j and criteria m
14. For each candidate node $j \in \mathcal{J}$ do
15. Compute SAW score
16. End for

D. Classifying the Optimal Relay Nodes

Further, we use **Inspired Moth Flame Optimization (IMFO)** for optimal selection of relay nodes to achieve efficiency in data transmission. It dynamically identifies the best relay nodes so that the loss of packets can be considered as very low with a promising low latency in the system. Thus, it reduces almost all unnecessary retransmissions, thereby improving the quality of the network and its life in WBAN devices.

1) Relay Candidate Initialization and Fitness Modeling

Relay candidates found after identifying stable forwarding paths using posture-aware mobility optimization are collected to be optimized further. The total potential relay nodes are represented by R, with each potential relay node indicated as follows:

$$\mathbf{y}_r = [y_r^{(1)}, y_r^{(2)}, y_r^{(3)}], \qquad r = 1,2,3 \ldots, R \tag{29}$$

In this term, $y_r^{(2)}, y_r^{(1)}$ *and* $y_r^{(3)}$ denotes the transmission latency factor, packet delivery capability, and residual energy level, where y_r symbolizes the solution vector conforming to the relay node r. Together, these factors designate a node's suitability for serving as a relay.

Utilize a multi-objective fitness function to estimate the fitness of each relay candidate described in Eqn (10).

2) IMFO Position Update and Flame Guidance

The model for identifying candidate relay nodes is the Inspired Moth-Flame Optimization, in which the candidate relay nodes are represented by moths that are moving in a manner analogous to the migration of moths toward their optimal nodes; that is, their "flames." The position of the flame

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

k is referred to as $\boldsymbol{f}_k^{(t)}$, while the position of the moth r at iteration t is denoted by $\boldsymbol{y}_r^{(t)}$. To determine the new position of each moth, the logarithmic spiral function is used as follows:

$$\mathbf{y}_{\mathrm{r}}^{(\mathrm{t}+1)} = \mathbf{D}_r \cdot e^{bl} \cdot \cos(2\pi \mathrm{l}) + \mathbf{f}_{\mathrm{k}}^{\mathrm{t}} \quad (30)$$

In this equation, $\boldsymbol{D}_r = \left|\boldsymbol{f}_k^{(t)} - \boldsymbol{y}_r^{(t)}\right|$ classify the distance among flame and the moth, the continuous defining spiral shape is represented as b, and $l \in [-1,1]$ is a random number. This term permits consideration and use by gradually guiding relay candidates toward optimal fitness regions.

To confirm convergence, the quantity of flames decreased adaptively as:

$$K(t) = \left[R - t \cdot \frac{R-1}{T_{max}}\right] \quad (31)$$

Here $K(t)$ is the quantity of flames at iteration t, and the maximum number of iterations is denoted by T_{max}. This adaptable reduction avoids premature stagnation and enhances the convergence speed.

3) Optimal Relay Selection and Classification

Relay nodes are ordered allowing for their concluding fitness scores following updates. The best relay node is chosen as:

$$r^* = \arg\max_r(F_r) \quad (32)$$

The index of the relay node attaining the most fitness is denoted r^*. This selection confirms that the preferred relay node offers balanced energy consumption, minimal latency, and high packet delivery. By establishing a relay eligibility requirement, relay nodes are finally classified:

$$\mathcal{R}_{opt} = \{r | F_r \geq \tau_F\} \quad (33)$$

Here $\mathcal{R}_{opt}$, τ_F denotes the optimal relay set and predefined fitness threshold. Nodes selected for forwarding data are those that meet the previous criteria. Nodes not meeting this requirement will not be used to forward data. As such, in WBAN systems using this procedure, it is expected to reduce the number of packet losses, extend network lifetime, and decrease the delay in WBAN systems.

E. Dynamic power Allocation

Dynamic power allocation and **Medium Access Control (MAC)** scheduling highly rely on efficient communication in a WBAN. The **fuzzy logic**-based dynamic time slot allocation mechanisms devised for it consider all the important input variables-energy ratio, buffer ratio, and arriving packet ratio so that the dynamic time slots will ensure a decrease in wastage towards better network usage. Somewhat later, sort out the optimum results in communication efficiency. The Priority-Adaptive Fuzzy MAC (PA-MAC) protocol is suggested for that,t and the PA-MAC basically schedules the time slots according to traffic priority, average transmission duration, throughput, and energy consumption. With an incorporated **Markov Decision Process (MDP)**, the system learns and adapts over time, adjusting time slot distribution and power control mechanisms for maximizing energy efficacy. In this way, PA-MAC resource adaptively allocates resources to the varying needs of the network while also reducing transmission delay and achieving better use of the channel.

1) Modeling network state parameters

Once the best relay nodes are found, the network will need to change its power and schedule decisions based on the situation at the current moment. In order to accomplish this, the PA-MAC protocol attempts to model the buffer, energy, and traffic conditions of each node in real-time to reflect communication needs.

$$\eta_i(t) = \frac{E_i^{rem}(t)}{E_i^{max}} \quad (34)$$

Where $\eta_i(t)$ refers to the energy ratio of the node i at time t. Energy availability is normalized between 0 and 1 by this ratio. During scheduling, nodes with lower $\eta_i(t)$ energy are treated as energy-critical.

$$\beta_i(t) = \frac{Q_i(t)}{Q_i^{max}} \quad (35)$$

In this term, $\beta_i(t)$ classifies the buffer ratio of the node j, $Q_i(t) and\ Q_i^{max}$ the number of packets currently waiting in the buffer, and the maximum capacity of the buffer. These metrics show the level of the node's congestion. Greater values specify urgency to transmit data to avoid packet loss.

$$\alpha_i(t) = \frac{\lambda_i(t)}{\lambda_i^{max}} \quad (36)$$

This equation indicates the packet arrival ration denoted by $\alpha_i(t)$, $\lambda_i(t) and\ \lambda_i^{max}$ are current packet arrival rate and the maximum supported arrival rate. Emergency traffic conditions and burstiness are identified by this ratio. In MAC scheduling, it is necessary to consider the traffic priority.

2) Fuzzy Logic-Based Time Slot Allocation

In order to interpret the parameters of the network state into adaptive scheduling decisions, the PA-MAC protocol employs fuzzy logic. This gives the MAC layer the capability to deal with uncertainties and nonlinear relationships associated with the buffer, energy, and traffic states, which are established in Eqn (11).

$$\tau_i(t) = \frac{\sum_{k=1}^{K} \mu_k \tau_k}{\sum_{k=1}^{K} \mu_k} \quad (37)$$

In this term, $\tau_i(t)$ denotes the defuzzified time slot duration, $\tau_k\ and\ \mu_k$ symbolizes the corresponding slot value, and membership degree of the kth fuzzy rule. Smooth slot adaptation is confirmed by the weighted average. Longer transmission slots are given to nodes with greater priority.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

3) Priority-Adaptive Power Allocation

When the time slots are assigned, the adjusted transmission power will depend on the amount of energy for efficient and reliable communication. PA-MAC will dynamically adjust the amount of power to the length of the specified time slot and also to the residual energy remaining in the battery.

$$E_i^{alloc}(t) = \eta_i(t) \cdot \tau_i(t) \cdot P_i^{ref} \quad (38)$$

The energy allocated to the node i is represented by $E_i^{alloc}(t)$, where P_i^{ref} classifies the reference power level. The amount of energy allocated to energy availability and the length of the time-slot supports efficient use of battery power for low energy, thus preventing the relative drain of energy from the battery to low-energy nodes.

$$P_i(t) = \frac{E_i^{alloc}(t)}{\tau_i(t)} \quad (39)$$

Where, $P_i(t)$ classify the actual transmission power of the node i. Slot duration can divide the allocated energy to compute the power. This sustains constancy between power control and scheduling. Power can automatically adapt to traffic demand.

$$P_i^{min} \leq P_i(t) \leq P_i^{max} \quad (40)$$

In this equation, the maximum and minimum admissible transmission powers are represented by $P_i^{max} and\ P_i^{min}$. This control mechanism provides link reliability and prevents interference and hardware damage. It also prevents nodes from generating aggressive levels of energy depletion. Bounded power control allows for improved stability of a network.

4) Markov Decision Process-Based Adaptation

PA-MAC's integration of a MDP will provide a means for long-term optimization. By using the MDP to interact with the network environment, PA-MAC will learn the optimal scheduling and power strategies.

$$s_i(t) = [\eta_i(t), \beta_i(t), \alpha_i(t)] \quad (41)$$

The MDP state of the node i is represented as $s_i(t)$. The state represents energy level, buffer occupancy, and traffic level. The compact representation of the state's conditions allows adaptive state-based decision making.

$$\alpha_i(t) = [\tau_i(t), P_i(t)] \quad (42)$$

Selecting an appropriate transmission power and the length of the time slot selected represent the most basic forms of action in an optimal system, as both parameters will have significant impacts on both overall throughput and total delay incurred by the message transmitted. Long-term rewards are the basis for how the MDP evaluates actions taken by the decision maker.

$$\Re_i(t) = \omega_1 T_i(t) - \omega_2 D_i(t) - \omega_3 E_i^{cons}(t) \quad (43)$$

In this term, the instantaneous reward for the node i is represented by $\Re_i(t)$. Where $T_i(t), E_i^{cons} and, D_i(t)$ are characterizes throughput, energy consumption, and delay. The balanced performance weight objectives are represented as $\omega_1, \omega_2, \omega_3$. Towards effectual communication guided by this reward.

5) Optimal Policy Learning and Scheduling Decision

The goal of maximizing long-term cumulative rewards through maximizing the total accumulated reward allows MDPs to adapt over time as dynamics in networks change.

$$V(s_i) = \max_{a_i} \left[R_i(t) + \gamma \sum_{s_i'} P(s_i'|s_i, a_i) V(s_i') \right] \quad (44)$$

The value function of a state s_i is denoted by $V(s_i)$ and γ is the discount factor adjusting future reward importance. The state transition probability refers to $P(s_i'|s_i, a_i)$. The long-term advantages of acts are assessed by this equation.

$$a_i^*(t) = \arg\max_{a_i} V(s_i) \quad (45)$$

It $a_i^*(t)$ symbolizes optimal scheduling action. This is attained by using an Optimal Scheduling Policy (OSP), which optimizes both time slots and power control. PA-MAC has therefore completed the adaptive mechanism for the PA-MAC dynamic adaptation process.

F. Energy harvesting based routing in WBAN

This **Hamilton Energy Efficiency Routing (HEER) Protocol** provides a suitable solution against the energy constraints of WBAN devices. The delays incurred are considerably minimized as this protocol adopts an energy-available and quality-link-based route optimization, reducing multi-hop propagation delays. We also introduce a **linear programming (LP)** model, which would allow energy minimization while creating efficient and speedy bi-directional data transfer. Consequently, energy harvesting nodes functioning in an efficient manner will increase the operational life of the entire system. By combining HEER-LP is used to minimize the energy usage and delay in an efficient manner.

1) Energy-Aware and Link-Quality-Based Route Modeling

Routing decisions must be made after dynamic power allocation as well as MAC scheduling, to ensure energy sustainability over time and maintain reliable communication. The HEER Routing Protocol considers a combination of harvested energy availability and link quality in routing decisions.

$$\mathcal{X}_{ij}(t) = \frac{E_j^{harv}(t)}{E_j^{rem}} \cdot L_{ij}(t) \quad (46)$$

In this term, $X_{ij}(t)$ denotes the routing suitability metric from node i to node j at instant time t, where $L_{ij}(t)$ classifies the wireless link quality between nodes $i\ and\ j$. Next-hop

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

nodes that sustain constant connectivity and gather enough energy are given priority by this metric.

2) Multi-Hop Delay and Energy Cost Evaluation

To decrease end-to-end delay, HEER estimates the cumulative cost of multi-hop routes. The overall routing cost of a path p is figured in Eqn (12).

$$D_{ij} = \frac{d_{ij}}{R_{ij}} + Q_j \tag{47}$$

In this formula, d_{ij}, R_{ij} *and* Q_j symbolizes the data packet size, transmission rate, and queuing delay at the node j. Both buffering delays and transmission are encapsulated by this formulation. To avoid overfilled or slow relay nodes, it permits HEER.

3) Linear Programming-Based Energy Optimization

$$\min \sum_{(i,j)} E_{ij}^{tx} \cdot x_{ij} \tag{48}$$

The binary decision variable indicating whether the link (i,j) is selected is represented as x_{ij}. Across the designated route, the objective can reduce the total transmission energy and confirm energy-efficient data forwarding. Constraints on flow and energy harvesting:

$$\sum_j x_{ij} - \sum_k x_{ki} = b_i \tag{49}$$

Where b_i indicates the traffic flow balance at the node i. Effective source-to-sink routing is ensured by this restriction, and routing loops and packet loss are avoided.

$$E_i^{cons}(t) \le E_i^{harv}(t) + E_i^{rem}(t) \tag{50}$$

This restriction confirms that expended energy does not harvest energy and surpasses the available. It imposes maintainable routing decisions. If the energy is inadequate, the nodes are avoided.

4) Optimal Route selection and Enhance network lifetime

Following the LP model's solution, HEER determines the optimal path as:

$$p^* = \arg\min_p C_p \tag{51}$$

Where, p^*characterizes the optimal routing path with less energy-delay cost. This path confirms fast and energy-efficient data delivery. It reduces multi-hop propagation delay. The network lifetime is estimated as follows:

$$T_{life} = \min_i \left(\frac{E_i^{rem}(t) + E_i^{harv}(t)}{E_i^{cons}(t)} \right) \tag{52}$$

In this formulation, T_{life} denotes the operational lifetime of the WBAN. It depends upon the rate of consumption, residual energy, and collected energy. Network lifetime is greatly increased when HEER and LP optimization are combined. Algorithm 2 illustrates the algorithm of energy harvesting-based routing using HEER-LP.

Algorithm 2: Energy harvesting-based routing using HEER-LP

Input: Set of WBAN nodes $\mathcal{N}$, Residual energy $E_i^{rem}(t)$, Harvested energy rate $H_i(t)$, Link quality $\psi_{ij}(t)$, Traffic Demand $D_i(t)$

1. Initialize network graph $G(\mathcal{N}, \mathcal{L})$
2. For each node $i \in \mathcal{N}$ do
3. Update available energy

$$E_i^{tot}(t) = E_i^{rem}(t) + H_i(t)$$

4. End for
5. For each communication link $(i,j) \in \mathcal{L}$ *do*
6. Compute link cost

$$C_{ij}(t) = \frac{1}{\psi_{ij}(t)} + \frac{1}{E_i^{tot}(t)}$$

7. End for
8. Formulate Linear Programming objective

$$\min \sum_{(i,j)\in\mathcal{L}} C_{ij}(t) \cdot x_{ij}$$

9. Subject to:
10. flow conservation constraints
11. energy availability constraints

$$\sum_j x_{ij} \cdot P_{ij}(t) \le E_i^{tot}(t)$$

12. delay bound constraints
13. Solve LP to obtain optimal routing variables x_{ij}^*
14. Extract routing path

$$p^* = \{(i,j) | x_{ij}^* = 1\}$$

15. Transmit data along p^*
16. Update residual energy

$$E_i^{rem}(t+1) = E_i^{tot}(t) - E_i^{cons}(t)$$

17. Return p^*

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Security will be a lot more contested within WBANs with the sensitivity of biometric data passed through from the patients to the hospital servers. The encryption keys cannot deal with a solid drawback, which is: once possible, the thieves can analyze the encrypted traffic for an extended time to glean possible keys. There, in this context, we present a new **Bio-Key Update scheme**. In this respect, we introduce encrypting keys at random intervals so that long-term hacks don't happen based on above-average traffic analysis. The other things also need to be realized, as in the schemes. We will have a **Message Authentication Code** (MAC) included, as well, for the integrity and authentication of the data. It thus acts almost as a gate preventing the data from being interfered with by unauthorized modification, along with carrying reduced levels of risk with key compromise. The bio-key update and MAC authentication have combined to create a secure means of protecting patient information from potential cyber threats. These processes will also facilitate safe and efficient transfer of WBAN data from WBAN systems to cloud storage and analysis services.

1) Bio-key Generation and Dynamic Update Mechanism

As the physiological data gathered in WBAN has a very sensitive nature, the use of static cryptographic keys is exposed to long-term traffic analysis attacks. To address this weakness, we are proposing a Bio-key update mechanism, which allows for encryption keys to be generated dynamically by making use of biometric features and updating those keys at randomly chosen intervals.

$$K_i(t) = \mathcal{H}(B_i(t) \| \nu_i(t) \| \rho_i) \tag{53}$$

In this formulation, $K_i(t)$ the encryption key is generated for the sensor node i at time t, where $B_i(t)$ denotes the biometric feature vector that was taken from physiological signs like ECG or heart rate, and $\nu_i(t), \rho_i$ indicates the time-dependent nonce, and node-specific salt. The hash function $\mathcal{H}(\cdot)$ confirms randomness and inalterability, making key prediction unachievable. Attackers are unable to correlate long-term encrypted traffic in order to get cryptographic keys owing to its dynamic creation. The key update interval is randomized as follows to further improve robustness:

$$\Delta t_i \sim \mathcal{U}(t_{min}, t_{max}) \tag{54}$$

The key refresh interval for the node i is denoted by Δt_i, which is derived from a uniform distribution between t_{min} *and* t_{max}.

Because of the random nature of the process, key updates will not follow any predictable patterns. Therefore, any amount of traffic monitoring will not be enough information for performing cryptanalysis. This decreases the chance of an attack being successful in the long term.

2) Data Encryption and Secure Transmission Process

After the Bio-key has been generated, the sensor data packets will be encrypted before they are sent to the relay nodes or sink. The encrypted data packet can be expressed in Eqn (13).

The following equation can be used to measure the resistance against key compromise:

$$P_{comp} = \frac{T_{attack}}{\mathbb{E}[\Delta t_i]} \tag{55}$$

In this equation, the probability of key compromise represented by P_{comp}, $E[\Delta t_i]$, *and* T_{attack} are classifies interval of expected key update and attacker's required analysis time.

Due to the frequent and random refresh of keys, $E[\Delta t_i]$ stays tiny. It can force P_{comp} towards an insignificant value; therefore, the entire system remains secure even through persistent attempts at eavesdropping.

3) Message Authentication code for integrity and Authentication

A message authentication code (MeAC) is integrated with encryption to protect data integrity and verify the authenticity of a message source. The MeAC's tag for each packet is calculated as follows:

$$\mathrm{MeAC}_i(t) = \mathcal{H}(K_i(t) \parallel C_i(t)) \tag{56}$$

Where $MeAC_i(t)$ represents the authentication tag generated by the node. The authentication tag will be invalidated if there is any change to the ciphertext. Therefore, this mechanism prevents both tampering and impersonation attacks. Integrity verification at the receiver end is performed as follows:

$$\mathrm{MeAC}_i(t) \stackrel{?}{=} \mathcal{H}\big(K_i(t) \parallel C_i(t)\big) \tag{57}$$

This allows you to check to see if the packet is the same packet that was sent. Acceptance will only be for packets with a valid authentication tag, and all other packets will be immediately discarded. This process functions as a security checkpoint for the WBAN data, preventing unauthorized changes to the data. PA-MAC has therefore completed the Adaptive Mechanism for PAC/A-MAC dynamic adaptation process. Fig.4 shows the process of security.

VI. EXPERIMENTAL RESULTS

This section discusses the experimental evaluation of the proposed "deep reinforcement learning-based energy harvesting and power allocation" approach to WBANs. The performance of the proposed methodology is evaluated via both qualitative and quantitative metrics to show its effectiveness across dynamic network conditions. The included methodologies within the framework are historical state learning, mobility-aware forwarder selection, optimal relay node categorization, adaptive power allocation, and energy-efficient routing. The proposed methodology was assessed under various traffic loads, node densities, and different mobility scenarios. The proposed WBAN framework should be used for long-term WBAN use, as the preliminary results show significant improvements in numerous metrics compared with the current approaches used in WBAN systems.

A. Simulation Setup

For the simulation of the performance of the proposed WBAN architecture, a realistic body sensor network model will be used, consisting of many biosensor nodes connected to relay nodes connected to a central sink node. The simulation design includes a person's posture as part of its effect on how dense a network of sensors will be. Along with the person's posture, the simulation also considers a variety of factors, including but not limited to: the amount of residual energy left in the buffers; the state variables of the buffers; the quality of the links between nodes (based on signal strength and coherence); how much energy each sensor node and relay node is able to harvest from external sources; and other real-life WBAN processes. Finally, the proposed deep reinforcement learning model will determine the best routing strategy for distributing each node's available power based on data collected by the nodes regarding their historic states. To compare the performance of the proposed framework against HCEL, SEBA, and other state-of-the–art techniques all under the same situation environment, five performance metrics were recorded and analyzed. A summary of the simulation parameters and system configurations can be found in Table 2.

TABLE 2
System Specification

Software requirements	OS	Ubuntu 22.04
	Development Tool	Ns-3.35 and python 3.10.12
Hardware requirements	RAM	8GB or above
	Processor	2.5 GHz or above
	Storage	10 GB or above

To perform the experiments, the necessary hardware and software resources were developed to ensure successful execution of the WBAN framework. We developed the learning and optimization modules of our project software component using the NS-3.35 simulation environment under Ubuntu 22.04 with Python 3.10.12. The simulated WBAN needs a minimum of 8 GB RAM, 2.5 GHz processor, and 10 GB free disk space in order to carry out an accurate performance evaluation of the proposed WBAN framework under dynamic network conditions.

B. Comparative analysis

The proposed Framework uses Deep Reinforcement Learning to harvest energy and to distribute that energy to achieve an objective function. The Proposed Framework is compared against three of the most predominant techniques used today with respect to their performance based on "throughput, end-to-end delay, energy consumption, packet delivery ratio, and route loss". The results from the assessments indicate that the Proposed Framework will reduce routing losses as compared to the existing techniques and, consequently, will extend the communication lifetime and reliability in WBANs.

1) Traffic bit rate (bits/sec) vs. end-to-end delay(s)

"End-to-End delay" is the total amount of time a data packet takes to get from the source sensor node to the "sink node". The lower the end-to-end delay is required for the WBAN application because they need to get the "physiological data" transmitted in a timely manner and in real time. The numerical outcomes of the Traffic bit rate (bits/sec) vs. end-to-end delay (s) are found in Table 3 and Fig.5.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

TABLE 3
Traffic bit rate (bits/sec) vs. end-to-end delay(s)

Traffic bit rate (bits/sec)	HCEL	EAFST	Proposed method
0	0.30	0.25	0.20
2	0.24	0.20	0.15
4	0.22	0.18	0.11
6	0.18	0.14	0.08
8	0.13	0.05	0.02

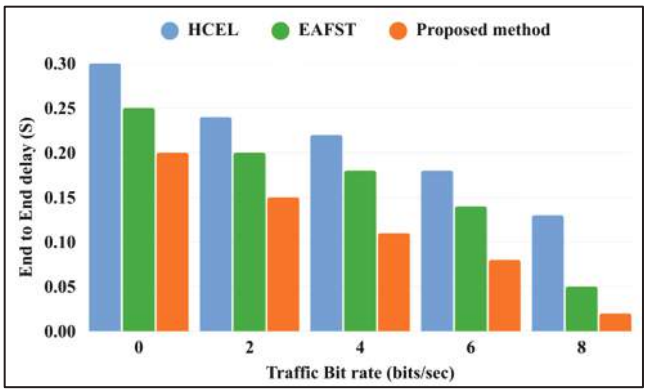

Fig.5 Numerical outcomes of Traffic bit rate (bits/sec) vs. end-to-end delay(s)

The figure shows that the proposed method provides the minimum end-to-end delays of all the different traffic bit rates, with the proposed method providing delays ranging from 0.02 s to 0.20 s. The EAFST method provided moderate end-to-end delays of 0.05 s to 0.25 s. The HCEL method had the highest end-to-end delays of 0.13 s to 0.30 s. Consequently, the proposed method is able to effectively decrease transmission latency in increased traffic conditions.

2) Simulation time (s) vs. Energy consumption (J)

WBAN energy usage is the aggregate of all "energy consumed by both relay and sensor nodes" in the execution of activities and transmission of data over their duration. Lower overall energy used is preferred in supplying a WBAN because it is directly related to the continued operation and overall lifespan or longevity of the WBAN. Table 4 and Fig.6 illustrate numerical outcomes of Simulation time (s) vs. Energy consumption.

TABLE 4
Simulation time (s) vs. Energy Consumption (J)

Simulation time (s)	SEBA	EAFST	Proposed method
0	75000	70000	48000
5	70000	62000	30000
10	60000	50000	28000
15	55000	40000	22000
20	50000	35000	20000
25	43000	30000	15000

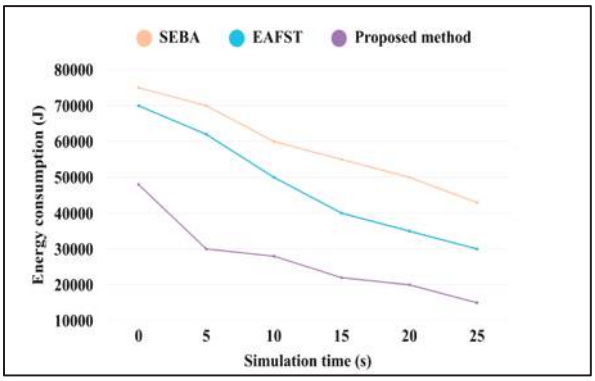

Fig.6 Numerical outcomes of Simulation time (s) vs. Energy consumption (J)

The figure shows that when comparing both the EAFST method and SEBA's approach to the proposed method, the proposed method exhibits a reduced level of "energy consumption" throughout the entirety of the simulation period. The principal reason for this is that the proposed method effectively and efficiently manages the energy harvesting and power allocation processes, which help to reduce overall energy waste. In contrast, both the EAFST method and SEBA's methods supply more energy over time than do the methods proposed by the authors through their lesser adaptive control for power and less adaptive routing strategies; thus demonstrating that the proposed method exhibits superior energy efficiency characteristics than either the existing method or SEBA in any WBAN environment.

3) Number of nodes vs. throughput (kbps)

The throughput indicates the successful data delivery on the communication link and is measured in kilobits per second (kbps). A higher throughput results in greater efficiency of the network and the use of the bandwidth in WBAN.

TABLE 5
Number of nodes vs. throughput (kbps)

Number of Nodes	SEBA	EAFST	Proposed method
2	25	42	50
4	30	50	55
6	35	54	68
8	40	62	70
10	45	68	85

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

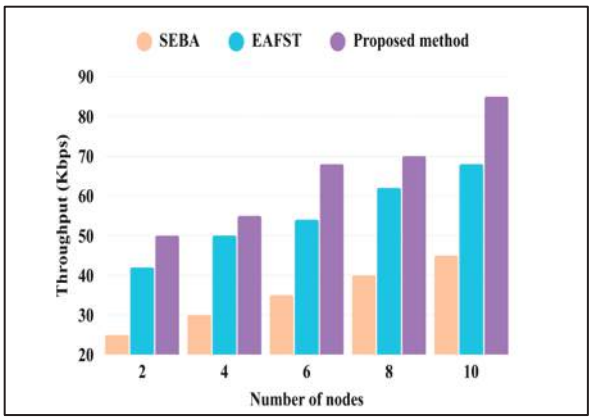

Fig.7 Numerical outcomes of Number of nodes vs. throughput (kbps)

The results from the graph show that the proposed approach has a greater amount of throughput than the existing method and SEBA, and is continuing to improve; the throughput of the proposed method is 50 kbps - 85 kbps, while the EAFST method is from 42 kbps – 68 kbps, and SEBA is 25 kbps – 45 kbps. These results showed the proposed method's ability to maintain a higher level of data transfer when increasing the size of the network. The outcomes of the number of nodes vs. throughput can be shown in Table 5 and Fig.7.

4) Number of nodes vs. path loss

In WBANs, path loss quantifies the loss of signal strength between "transmitter and receiver". A lower "path loss" indicates a better quality signal and lower power requirements for transmitting that signal. Table 6 and Fig.8 explore the numerical outcomes of the number of nodes vs. path loss.

TABLE 6
Number of nodes vs. path loss

Number of Nodes	HCEL	EAFST	Proposed method
2	50	45	40
4	45	38	30
6	42	35	20
8	38	30	15
10	40	20	10

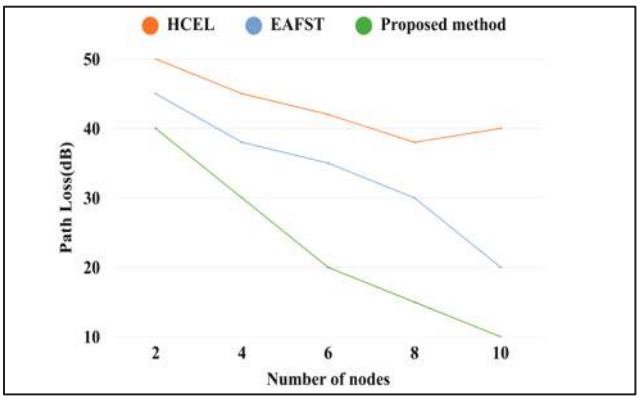

Fig.8 Numerical outcomes of Number of nodes vs. path loss

As shown in the figure, the proposed method has the least path loss at all densities, 40dB – 10dB, while the EAFST method has a range of 45dB – 20dB for path loss, and the HCEL method has the highest path loss, 50dB – 38dB. These results show that the proposed method will provide better communication reliability and energy efficiency in WBAN settings.

5) Traffic bit rate (bits/sec) vs. Packet delivery ratio (%)

In WBANs, the "packet delivery ratio (PDR)" represents the ratio of correctly delivered packets at the "sink node" and thus indicates the reliability and success rate of data transfer. A high PDR will ensure reliable communication and accurate monitoring of health. Table 7 and Fig.9 establish numerical outcomes of the "traffic bit rate (bit/sec) and the packet delivery ratio (%)".

TABLE 7
Traffic bit rate (bits/sec) vs. packet delivery ratio (%)

Traffic bit rate (bits/sec)	HCEL	EAFST	Proposed method
0	10	20	28
2	25	38	45
4	30	35	40
6	45	30	48
8	40	55	68

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

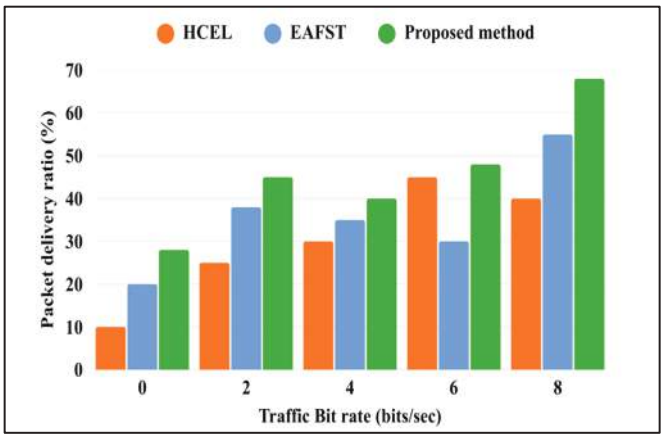

Fig.9 Numerical outcomes of Traffic bit rate (bits/sec) vs. Packet delivery ratio (%)

The proposed technique demonstrates much better performance than other existing solutions over all tested traffic rates, with 68% of packets delivered versus 55% for the EAFST method and only 45% with the HCEL method. The proposed technique has been shown to be a better alternative than existing methods for WBAN applications, capable of supporting a greater number of active users while maintaining an acceptable level of packet transmission reliability.

C. Research Summary

In doing so, this research project starts by implementing a WBAN using 11 different types of wearable sensors positioned at strategic locations around the body, along with two gateways and a single centralized database server, as part of an overall strategy to facilitate accurate data collection and processing. Additionally, while the sensors are collecting data from the body, they are also collecting various physiological and environmental metrics in real-time to simulate accurate on-body communication behaviors. These metrics consist of Received Signal Strength Indicator (RSSI) metrics, and all of these metrics are stored in an RSSI dataset generated by the WBAN. Using this data, a CLSTM model is used to predict the state of the network before the actual transmission of data, allowing the best power to collect energy through harvesting from the body while also ensuring sufficient energy through different body postures and mobility scenarios. In this manner, the best paths to forward data are also selected from IMAA-MCDM methodology. The method for developing reliable and adaptable routes considers many factors: changes in stance, fluctuations in signal quality, as well as the remaining battery life of sensor nodes. To select optimal nodes for forwarding packets, an IMFO Algorithm allows effective exploration and exploitation of the search space for solutions, thus reducing the number of lost packets and the time needed to resend packets. After that, an MDP combined with a PA-MAC Protocol dynamically allocates power to each transmitting node on the network. This protocol intelligently adjusts the priority of packet transmissions for each node based on current network state and urgency of transmitted data. Finally, Hamilton Energy Efficient Routing, in conjunction with an LP Model, minimizes the propagation time of multipoint packets and overall energy utilized by the network. To enhance the security of patient information, a Bio-Key in conjunction with a MAC method will be used to safeguard patient records from cybercriminals and tampering. Lastly, performance data regarding the “throughput, end-to-end delay, route loss, energy consumption, and packet delivery ratio” will be collected under a variety of network conditions to support the estimate of the performance of the system.

VII. CONCLUSION

In this work, I have developed and tested a smart architecture based on deep reinforcement learning for improving wireless body area networks (WBANs). In particular, we focus on solving numerous issues related to WBANs so that they are able to operate optimally under both dynamic movement of human bodies and varying levels of traffic; these issues include but are not limited to all aspects of WBAN operation (e.g., how to gather energy; how to allocate transmit power dynamically; how to route data based on device mobility; and how to securely and reliably transmit data). A combination of historical state-based learning, optimal selection of relays, and adaptive resource management is utilized to provide WBANs with better performance, energy efficiency, and reliability. A wide range of simulation tests have validated that the proposed technique greatly enhances important performance measures such as “packet delivery ratio, end-to-end, path loss, energy consumption, and throughput” as compared to other methods that include EAFST, SEBA, and HCEL. The improved performance demonstrates that the proposed framework is appropriate for long-term, dependable, energy-conserving applications of healthcare monitoring. Research is being completed to confirm and validate the use of the proposed framework with real-world hardware that utilizes wearable sensors. This research may include the integration of federated or distributed learning techniques to improve privacy and scale. In addition, it will incorporate edge-assisted intelligence for real-time medical decision making. Additionally, future research may also examine multi-patient WBAN scenarios as well as heterogeneous sensor deployments. In order to maximize the performance of ultra-low-power devices used in wearable requires a lot more research and development efforts.

ABSTRACT

A miniature ramjet engine designed to perform at Mach 4.0 was tested in a supersonic wind tunnel. Cryogenic strain gauges were used to measure drag and Schlieren imaging techniques were used to observe the inlet Mach cone profile at Mach numbers of 4.0. Three different nozzle configurations were tested to confirm computational models used to predict back pressure and normal shock locations at the inlet.

Using ANSYS-CFX, a cold flow, computational fluid dynamics model of the ramjet in the wind tunnel was evaluated to compare with the experimental results. This model was then used as a base for an eddy dissipation combustion model. Hydrogen was modeled as being injected into the combustion chamber of the ramjet through inlet struts and then reacting with atmospheric oxygen to produce combustion. Drag predictions were inconclusive, however, the computational model remained stable during combustion

Calculations

I.INTRODUCTION

The idea of rotorless, air-breathing engine dates back to a French inventor named René Lorin. His idea was well before his time, however, as even he recognized that the velocities required to make the compression cycle of his engine work were in excess of the speed of sound in air. This was just not possible of aircraft before the First World War The use of ramjets in military aircraft and weapons was intermittent after the second World War, with the most well-known example being Lockheed Martin's SR-71 Blackbird using the Pratt & Whitney J58 turbojet-assisted ramjets at unclassified speeds reaching Mach 3.2 at altitude. Ramjet application in both the military and civilian sectors waned after the retirement of the SR-71 platform in favor of more efficient (turbofan) and faster (SCRamjet) engines. However, a recent resurgence has been seen in the interest of the use of ramjets in military technology. November of 2006 saw the implementation of the BrahMos, the world's fastest cruise missile, into the arsenals of the Indian and Russian Federation's militaries. Interest in ramjets is currently spiking due to the design's potential to be scaled down because of the design's absence

of moving integral parts. As the ranges demanded of certain weapons increase and the size of unmanned aerial systems decrease, ramjets are being looked at as the propulsion design of choice.

This thesis continues the work of Kevin M. Fergurson [1], Wee T. Khoo [2], and Bingqiang Chen [3] to analyze the performance envelope of a ramjet small enough to be ballistically launched from within a 35 mm diameter barrel.

In [1], a ramjet was designed for operation in a free stream velocity of Mach 4.0 and was then tested at operating speed in a supersonic wind tunnel (SSWT). Analyses were also done using the GRIDGEN and OVERFLOW computer programs for computational fluid dynamics (CFD). A follow-up was conducted in [2] with an attempt at using the CFDFASTRAN code to model the combustion process in the ramjet. Unfortunately, the computing limitations and the two-dimensional model used prevented an optimal analysis of the operating conditions of the ramjet.

In [3], combustion CFD analysis was done using ANSYS-CFX with better but still sub-optimal results. An attempt to measure drag was also done in the SSWT using cryogenic strain gauges. For reasons that will be explained in Chapter III, the results of those drag measurements were not satisfactory. The ANSYS software did allow detailed, accurate coldflow analyses of Mach 4.0 flow over the ramjet. These analyses revealed that the inlet conditions were not optimal. Thus, CFD analysis was done altering the nozzle by reducing the throat area of the converging-diverging section.

The present study seeks to refine the tests and data gathered from these preceding studies by continuing the CFD combustion analyses done in [3] and completely redesigning the drag measurement flexure arms, which hold the ramjet in the SSWT. The changes made were done in order to improve the quality of the data collected in the SSWT experimental drag measurement and the cold flow CFD drag prediction. To validate the CFD predictions done in [3] of the different nozzles, two of the nozzle designs with reduced throat areas were also tested in the SSWT with drag measurements recorded.

The data acquisition for the strain measurements was also upgraded to a National Instruments unit that was more user friendly. Additionally, the calibration procedure

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

before and after testing of the ramjet in the SSWT was updated, which resulted in reduced uncertainty of the drag measurements.

II. COLD F CFD ANALYSIS

A Background and Methodology

In [3], a three-dimensional simulation of the ramjet in the SSWT was performed in order to predict the drag experienced. Symmetry was employed at two planes so that only one quarter of the ramjet and one of the winglets would have to be modeled, reducing computational costs. The drag calculated for the quarter ramjet and the winglet were then multiplied by 4 and 2, respectively. This introduced an inaccuracy due to the two planes of symmetry essentially accounting for four winglets in the computation, while in the experiment there were only two winglets used. In these simulations, only one plane of symmetry was employed to increase accuracy, making it necessary to only model half of the ramjet and half of the winglet. Also in [3], analyses were done for different configurations of the nozzle. Analyses were done with a ramjet using the base nozzle design, and then with throat area reduced by 10%, 20%, 30%, and 40% from the base area. To analyze the accuracy of those computations, this thesis had two new nozzles (20% and 40% reductions in the nozzle throat area) manufactured for testing in the SSWT. Computational models of these new nozzles were also performed simulating the conditions in the SSWT.

These CFD analyses utilized SolidWorks modeling software to create the models of the ramjet with the winglet attachment as well as the SSWT section. These models were then imported into ANSYS-CFX Workbench 14.0, where a mesh was created, flow conditions were set, and the computation was run using typically 12 processors.

B. COMPUTATIONAL MODEL SETUP

1.Geometry

To exploit the axis of symmetry present on the model and winglet in the SSWT, half of the ramjet, winglet, and SSWT section were modeled utilizing the symmetry plane shown in Figure 12. The winglet was also simplified to reduce computational costs. A comparison of the physical winglet and the simplified winglet model used in the CFD analysis is shown in Figure 13.

Vol. 14, Issue 06, ACSCON - 2026

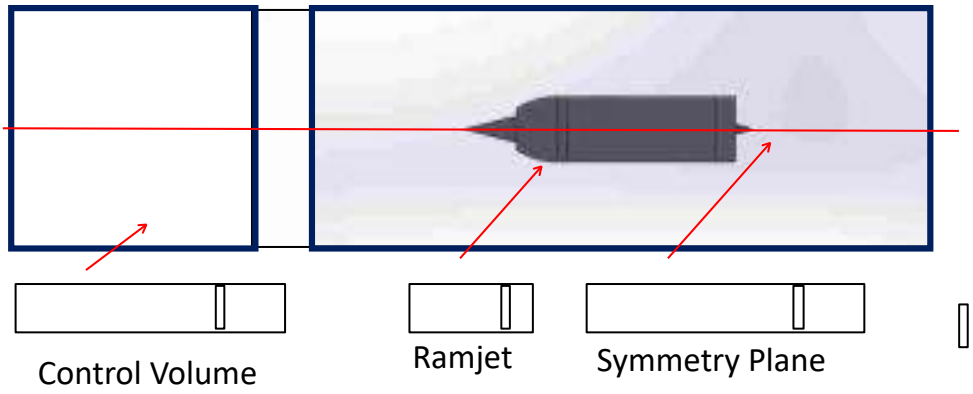

Figure 12 Ramjet model in computational domain.

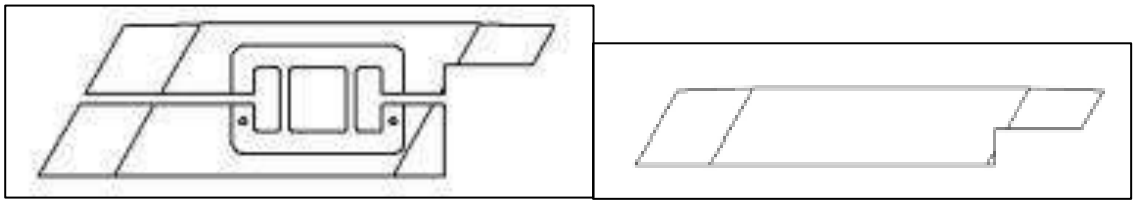

Figure 13 Comparison of physical flexure model and equivalent CFD flexure model

The ramjet, winglet, and SSWT section were modeled in SolidWorks before they were transfered into the geometry program within ANSYS. ANSYS CFX was then used to subtract the ramjet model from the SSWT test section model to create the computational domain. The computational domain is shown below in Figure 14.

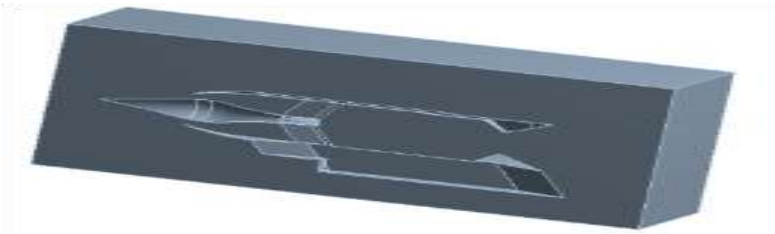

Figure 14 Computational domain of the CFD analysis.

2. Mesh

The meshing module within ANSYS was then utilized to create the computational mesh. Inflation layers were created near each wall of the ramjet and winglet. The parameters of the mesh can be found in Appendix D. For the model with the base nozzle design (nozzle A), the utility created 3.83 million nodes and 20.03 million elements. Figure 15shows an

Vol. 14, Issue 06, ACSCON - 2026

example section of the mesh, with the smaller inflation layers visible at the nozzle/domain interface.

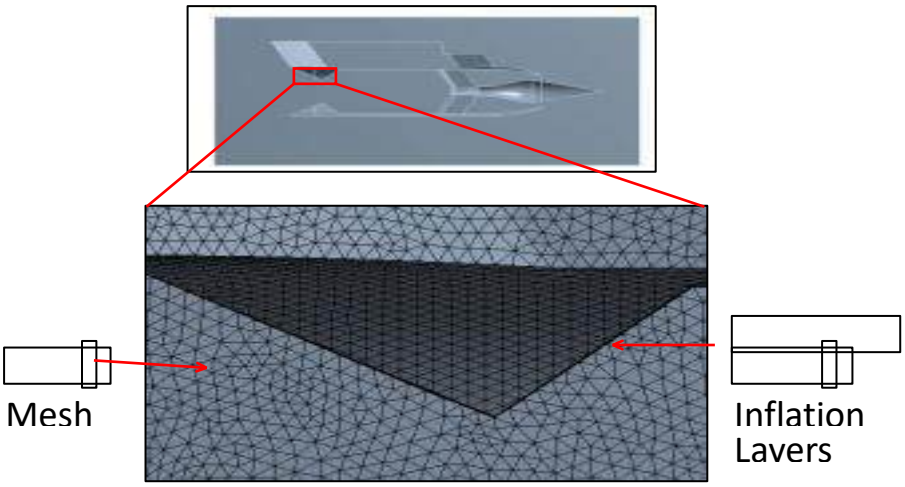

Figure 15 Close up of ANSYS generated mesh.

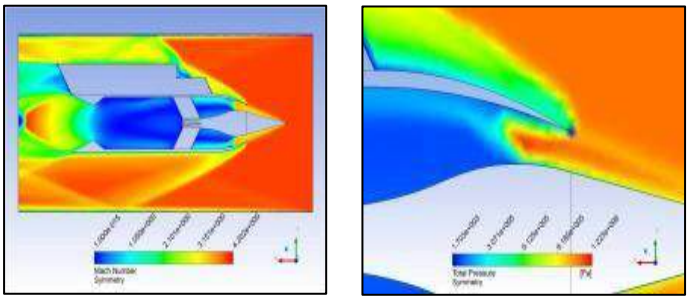
3. Boundary Conditions

All of the computational parameters were set up in ANSYS CFX-PRE. All of the parameters can be found in Appendix D while a snapshot can be seen in Table 2.

Table 2 Boundary conditions of the SSWT CFD analysis.

Boundary	Type	Boundary Condition
Inlet	Inlet	Supersonic, V = 661 m/s, P = 7378 Pa, T = 68 K
Outlet	Outlet	Supersonic
Ramjet	Wall	No-Slip Wall
Winglet	Wall	No-Slip Wall
Symmetry Planes	Symmetry	-
SSWT Sides	Wall	No-Slip Wall

C. RESULTS



1. Mach Profiles and Shock Locations

Figure 16 shows the Mach number profile for the whole symmetry plane and the total pressure profile at the area of the shock at the inlet cowl. This figure can be compared with

Vol. 14, Issue 06, ACSCON - 2026

Figure 5 in [3] to see the similarities between the two computational models. however, the figures in [3] do not show the winglet, as this was not included in that analysis. Figures 17 and 18 show the same Mach number profile and total pressure profile for the models with a 20% and 40% reduction in nozzle throat area respectively. They can be compared with Figures 13 and 15 in [3]. Figure 19 exhibits the shock indicators at the inlet cowl for all three setups. Comparing this with Figure 16 in [3] shows very favorable comparison between the two sets of computational simulations.

Figure 18 Mach profile and total pressure at shock for model with 60% nozzle throat area.

100% Nozzle Throat Area

80% Nozzle Throat Area 60% Nozzle Throat Area

Figure 19 Shock indicator profiles at inlet cowling Drag Predictions

Drag calculations of each model were able to be completed using the ANSYS CFX-Post function calculator. The drags on each of the configurations are listed in Table 3. A property of interest when predicting drag on a surface is the dimensionless wall distance, or y^+, defined as $y^+ = \tau_\rho^{wy}{}_\nu$, where τw is the wall shear stress, ρ is the fluid density, y is the distance from the wall, and ν is the kinematic viscosity. A y^+ value between 1.0 and 3.0 indicates that the calculated values close to the walls are accurate. The y^+ values for these computational models, shown in Table 4, are small enough to assume accurate computational measurements at the walls.

Table 3 Computational drag measurements.

Model	Nozzle Throat Area Compared to Base Design	Drag on Half Ramjet	Drag on Half Winglet	Total Drag
A	100%	13.36 N	5.33 N	37.38 N
B	80%	12.63 N	5.42 N	36.10 N
C	60%	14.73 N	5.31 N	40.08 N

Vol. 14, Issue 06, ACSCON - 2026

Table 4 Average y^+values for surfaces in computational models.

Model	Nozzle Throat Area Compared to Base Design	y^+ Ramjet	y^+ Winglet
A	100%	1.63	1.198
B	80%	1.869	1.31
C	60%	1.965	1.316

D. COMPARISON OF EXPERIMENTAL MEASUREMENTS AND COMPUTATIONAL PREDICTIONS

The results of the drag measurements for both the SSWT experiments and the ANSYS CFX simulations are tabulated in Table 5. These results show that the drag on the model with nozzles A and C were consistently under predicted by the computational models by around 14 percent. The one run that was able to be completed on the ramjet with nozzle B showed significantly more drag than the others. The comparison of the experimental drag measurements on the ramjet with Nozzle B with the drags experimentally measured on the other ramjet configurations as well as the computational models led to the conclusion that the drag measured on the ramjet with nozzle B included some source of error that led to such high drag on the ramjet. The disparity between the experimental and the computational should be more consistent between nozzle configurations.

Table 5Comparison of experimental measurements and computational drag predictions.

Model	Nozzle Throat Area Compared to Base Design	Experimental Drag Measurement	Computational Drag Measurement	% Error
A	100%	42.9 - 45.2	37.38	13.0 - 17.4
B	80%	52.6	36.10	31.4
C	60%	46.5 - 47.3	40.08	13.8 - 15.2

***Abstract*— Women safety in emergency situations requires rapid response mechanisms that function with minimal user interaction. This paper presents KAVACH, an automated emergency trigger-based Android application designed to provide instant distress communication and location sharing. The system introduces a dual activation mechanism combining shake-based detection and a floating SOS overlay that operates across all mobile screens. Unlike conventional safety applications that depend on manual interaction or continuous internet connectivity, the proposed system ensures reliable SMS-based alert transmission even in low-network environments. The application integrates real-time location tracking using the Location Provider API, secure backend management through Firebase, and a guardian PIN verification mechanism to prevent false alerts. Experimental evaluation demonstrates improved response time, reliable alert delivery, and enhanced usability under real-world conditions. The proposed system demonstrates strong potential for deployment in smart safety infrastructure and real-time emergency response frameworks.**

***Keywords*— Women Safety System, Android Application, Floating SOS, Shake Detection, Firebase, Location Provider API, SMS Manager, Emergency Alert System.**

I. INTRODUCTION

Smartphones are increasingly used as personal safety tools, yet in many critical situations users cannot reliably unlock the device, open an application, and manually trigger an SOS request. During harassment, assault, or sudden medical emergencies, even a few seconds of delay can affect the timeliness and effectiveness of any assistance. Conventional women's safety applications usually depend on explicit button presses and stable internet connectivity for tracking and alerting, which limits their reliability in real-world high-stress scenarios.

Many existing solutions require foreground interaction and active data connections for location sharing, so they may fail when the device is locked, the user's movement is restricted, or network coverage is weak. Accidental activation without a verification mechanism can also generate false alarms, which reduces trust in the system over time and discourages regular use. These limitations highlight the need for emergency systems that are easy to trigger, robust in low-connectivity conditions, and equipped with safeguards against unintended alerts.

This paper presents KAVACH, an Android-based women's safety application that focuses on rapid, low-effort emergency triggering and resilient alert delivery. The system combines accelerometer-based shake detection with a floating SOS overlay that remains accessible across all screens, including when other applications are in use. It also integrates SMS-based alerting with location links, guardian contact management, and a PIN-controlled SOS deactivation mechanism.

Unlike many existing applications that rely mainly on manual input and continuous internet access, KAVACH is designed to function effectively in low-network environments by prioritizing SMS communication. The application uses the Location Provider API for energy-efficient tracking and Firebase for secure storage of user and guardian data. The objective of this work is to design and evaluate a practical, deployable

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

emergency response tool that reduces activation time, increases alert reliability, and supports safer real-world use for women.

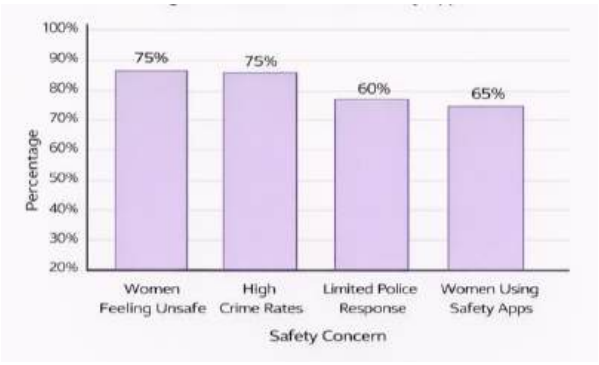

Fig. 1. Increasing demand for intelligent women safety systems

The major contributions of this work are as follows:

- Design and development of an automated emergency triggering mechanism using shake detection and floating SOS interface
- Implementation of an low-network-capable alert system using SMS-based communication
- Integration of guardian PIN verification to reduce false emergency alerts
- Real-time location tracking and secure cloud-based data management using Firebase
- Experimental evaluation demonstrating improved response time and reliability compared to conventional safety applications

II. Motivation and Problem Definition

Several mobile-based safety applications have been developed to support users in emergencies, yet many of them assume that the user can actively interact with the phone at the moment of distress. In incidents such as harassment or physical assault, victims may not be able to unlock the device, locate the application icon, and press a dedicated SOS button. This manual sequence introduces delay and can make existing solutions less effective when rapid activation is most critical.

A second limitation is the dependence on continuous data connectivity for real-time tracking and alert dissemination. When users are in low-network areas or temporarily offline, applications that rely mainly on internet-based messaging or cloud services may fail to deliver timely alerts to guardians. Inconsistent communication in such conditions reduces confidence in these systems and can discourage regular use.

False or accidental alerts form another practical problem. Without any verification or controlled deactivation process, an unintentionally triggered SOS may notify multiple contacts unnecessarily. Repeated false alarms can lead guardians to ignore future alerts, undermining the usefulness of the system. At the same time, continuous foreground operation or constant location sharing raises concerns about battery consumption and privacy.

These gaps indicate the need for a solution that can be triggered with minimal user interaction, uses communication channels that remain functional in low-connectivity conditions, and incorporates safeguards against unintended alerts. The KAVACH system is designed to address these requirements by combining automated shake-based activation, a floating SOS trigger accessible across all screens, SMS-based alert transmission, and a PIN-controlled deactivation mechanism.

III. Literature Review

Recent advancements in mobile technology have led to the development of various safety-oriented applications designed to provide emergency assistance and real-time location sharing. Several studies have explored smartphone-based emergency response systems incorporating GPS tracking, panic buttons, and alert messaging features [5]–[11]. Sharma and Gupta [5] presented a survey on mobile-based women safety applications highlighting the importance of quick emergency communication and location tracking. Similarly, Verma et al. [6] proposed an Android-based emergency response system that enables users to send distress alerts to predefined contacts. Patel and Shah [7] developed a GPS-based tracking solution aimed at improving location accuracy during emergency situations.

Although these systems provide useful safety features, most existing applications depend heavily on manual SOS activation and continuous internet connectivity for alert transmission. Recent research also focuses on intelligent mobile safety systems integrating sensors and automated alert mechanisms [9]–[11]. In critical situations where users are unable to interact with their mobile devices, manual

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

activation becomes ineffective. Furthermore, the absence of automated triggering mechanisms and background accessibility limits the usability of these applications during real-time emergencies.

Another limitation observed in many existing safety systems is the lack of mechanisms to prevent false or accidental alerts. Continuous location-sharing applications also raise concerns related to battery consumption and privacy. These challenges indicate the need for an intelligent safety solution that combines automated emergency detection, reliable low-network communication, and controlled alert management.

The proposed KAVACH system addresses these limitations by integrating automated shake-based SOS activation, floating emergency access across all screens, SMS-based communication for low-network environments, and a guardian PIN verification mechanism. This combination of features enhances system reliability, usability, and real-world effectiveness compared to conventional safety applications.

TABLE I
COMPARISON OF THE PROPOSED KAVACH SYSTEM WITH EXISTING WOMEN SAFETY APPLICATIONS

Feature / Parameter	Existing Safety Apps	KAVACH Proposed System
Manual SOS activation required	Yes	No
Shake-based automatic SOS	No	Yes
Floating SOS over all apps	Limited / No	Yes
Real-time GPS location sharing	Yes	Yes
Guardian contact integration	Yes	Yes
PIN-based false alert prevention	No	Yes
Background emergency activation	Limited	Yes
Response time	Moderate	Fast (< 3 second)

IV. PROPOSED SYSTEM OVERVIEW

A. System Description

The proposed KAVACH system is designed as an intelligent Android-based emergency response application that enables rapid distress detection and communication with minimal user interaction. The application is developed using Kotlin in Android Studio and is structured to operate efficiently in both foreground and background modes. The system allows users to register trusted emergency contacts, configure safety parameters, and activate emergency alerts using automated and manual triggering mechanisms.

The primary objective of the proposed system is to ensure immediate alert transmission and location sharing during critical situations where manual interaction with mobile devices may not be possible. By integrating automated triggering, background accessibility, and offline-capable communication, the application provides a reliable safety solution for real-world emergency scenarios.

B. Key Features

The major features of the proposed KAVACH system include:

- Automated SOS activation using accelerometer-based shake detection
- Floating SOS interface accessible across all mobile screens
- Background execution with required Android permissions
- Real-time location tracking using Fused Location Provider API
- SMS-based emergency alert transmission for low-network functionality
- Guardian PIN-based verification to prevent false alerts
- Secure data management using Firebase backend services

The integration of automated triggering and floating SOS access significantly reduces emergency response time when compared to conventional manual safety applications. The system architecture is designed to ensure reliability, scalability, and real-time communication during high-risk situations.

V. SYSTEM ARCHITECTURE

The overall architecture of the proposed KAVACH system follows a modular and scalable design that enables reliable emergency detection, communication, and data management. The architecture integrates multiple functional modules that operate collaboratively to ensure rapid alert transmission and real-time location sharing during distress situations.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The system consists of a user interface layer, sensor monitoring module, floating SOS module, location tracking module, communication module, and a secure backend database. These components interact continuously to detect emergency triggers and transmit alerts to registered guardians with minimal delay.

The architectural design ensures that emergency features remain accessible even when the application is running in the background or when the device is in a locked state. The detailed system architecture of the proposed KAVACH application is illustrated in Fig. 2.

A. User Interface Module

This module manages user registration, authentication, and guardian contact configuration. It provides an intuitive interface that allows users to manage emergency contacts and customize safety settings efficiently.

B. Floating SOS Module

The floating SOS module provides an always-accessible emergency trigger that overlays other applications using Android overlay permissions. This ensures immediate SOS activation without navigating through the application interface.

C. Sensor Monitoring Module

This module continuously monitors accelerometer sensor data to detect abnormal motion patterns. When motion exceeds predefined threshold values, the system automatically initiates the emergency alert process.

D. Location Tracking Module

The location tracking module obtains real-time geographic coordinates using the Fused Location Provider API, ensuring accurate and energy-efficient location acquisition.

E. Communication Module

This module is responsible for transmitting emergency alerts and location information to registered guardians using SMS Manager. It ensures reliable communication even in low-network environments.

F. Backend Module

The backend module utilizes Firebase Realtime Database to securely store user profiles, emergency contacts, and SOS activity logs. It enables secure data synchronization and system reliability.

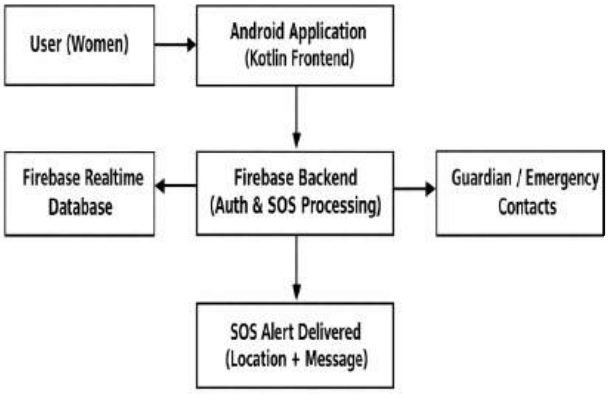

Fig. 2 KAVACH System Architecture

VI. METHODOLOGY

The application continuously monitors accelerometer sensor data to identify abnormal motion patterns. When the acceleration exceeds predefined threshold values within a specific time interval, the system recognizes the event as a potential distress signal. Upon detection, the emergency alert process is automatically triggered without requiring manual interaction from the user.

A. Shake Detection Mechanism

The application continuously monitors accelerometer sensor data to identify abnormal motion patterns. When the acceleration exceeds predefined threshold values within a specific time interval, the system recognizes the event as a potential distress signal. Upon detection, the emergency alert process is automatically triggered without requiring manual interaction from the user.

B. Floating SOS Implementation

Once the SOS mechanism is activated, the application retrieves the user's real-time geographic location using the Fused Location Provider API. This API integrates GPS, Wi-Fi, and cellular network data to provide accurate location coordinates while optimizing battery consumption.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

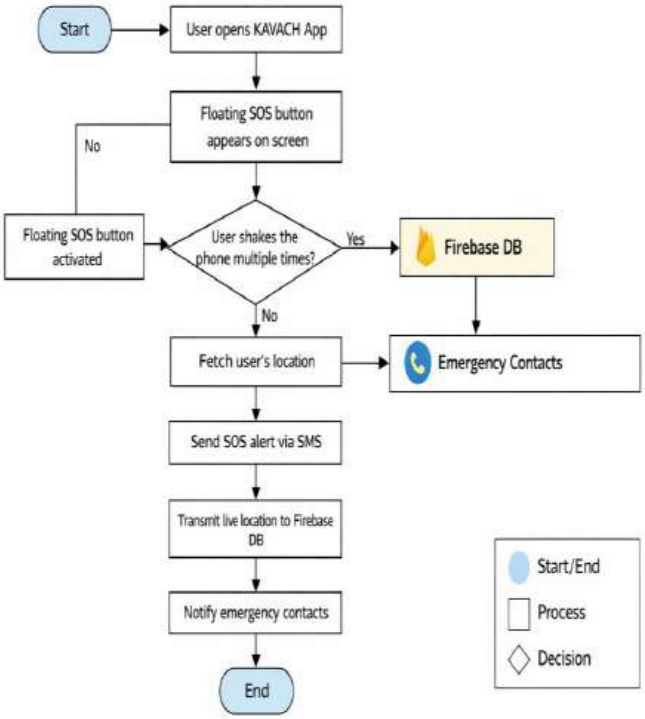

Fig. 3 The automated SOS workflow of the proposed system

C. Location Acquisition

The acquired location is converted into a Google Maps link and transmitted to registered emergency contacts through SMS Manager. This ensures reliable delivery of distress alerts even in the absence of internet connectivity. The system continuously updates location information until the emergency mode is deactivated.

D. Emergency Alert Dispatch

The acquired location is converted into a Google Maps link and transmitted to registered emergency contacts through SMS Manager. This ensures reliable delivery of distress alerts even in the absence of internet connectivity. The system continuously updates location information until the emergency mode is deactivated.

Fig. 4 Automated Emergency Detection and Alert Workflow

E. Guardian PIN Verification

To prevent false or accidental emergency alerts, the system incorporates a guardian PIN verification mechanism. The SOS process continues until a predefined secure PIN is entered. If an incorrect PIN is provided, the system maintains emergency mode and continues alert transmission, thereby ensuring reliability and preventing misuse.

Fig. 5 Guardian PIN-based emergency control and false alert prevention flow

VII. IMPLEMENTATION DETAILS

The proposed KAVACH application was implemented as a native Android application using Kotlin in Android Studio. The development process focused on creating a reliable and responsive emergency safety system capable of functioning in both online and low-network environments. The application architecture integrates sensor monitoring, real-time location tracking, SMS-based communication, and secure backend services.

Firebase Realtime Database was used as the backend platform for secure storage of user profiles, emergency contact details, and system activity logs.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Firebase Authentication mechanisms ensure secure user access and data protection. The backend enables real-time synchronization of user data and enhances system reliability.

Runtime permission handling was implemented to ensure secure and controlled access to device resources, including location services, SMS functionality, accelerometer sensors, and overlay permissions for the floating SOS feature. These permissions are dynamically requested and managed according to Android security policies.

The floating SOS functionality was developed using Android overlay services, allowing the emergency trigger to remain accessible across all screens. The accelerometer sensor integration enables continuous motion monitoring for automatic SOS activation. The SMS Manager module ensures that distress alerts and location links are transmitted to registered guardians even in the absence of mobile data connectivity.

The system was tested across multiple Android devices and versions to ensure compatibility, performance stability, and reliable emergency response. The implementation demonstrates efficient resource utilization, fast response time, and secure data handling for real-time emergency assistance.

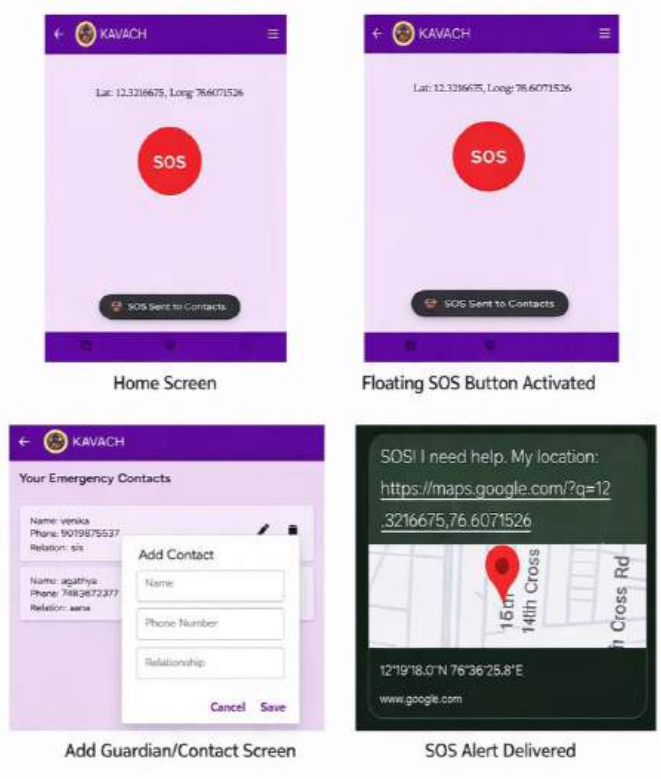

Fig. 6 KAVACH Application User Interface Screens

VIII. Results and Performance Evaluation

The performance of the KAVACH system was evaluated under multiple real-time conditions to analyze its reliability, response time, and effectiveness during emergency situations. Testing was conducted in different environments including background execution, low-network connectivity, and high-motion scenarios to validate system robustness.

The automated shake-based detection mechanism successfully triggered SOS alerts within two seconds of abnormal motion detection. The floating SOS interface enabled immediate manual activation without requiring application navigation, ensuring accessibility during critical situations.

Real-time location tracking using the Location Provider API demonstrated high accuracy with an average deviation of ±10 meters in both indoor and outdoor environments. SMS-based emergency alert transmission ensured reliable delivery of distress messages and location links even in the absence of mobile data connectivity.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The guardian PIN verification mechanism effectively minimized false emergency alerts by requiring secure authentication to deactivate the SOS process. Continuous monitoring and alert transmission remained active until valid verification was provided, thereby improving system reliability and user safety.

The experimental performance results of the proposed system are summarized in Table II and Table III. The system demonstrated improved response time, enhanced reliability, and consistent performance when compared to conventional manual safety applications. The SOS alert transmission and location-sharing process is illustrated in Fig. 4. The proposed system reduced emergency response time by approximately 40–60% compared to manual SOS applications.

TABLE II
EXPERIMENTAL TEST RESULTS

Test Scenario	Condition Tested	Result Obtained
Shake-based SOS activation	Rapid motion detection	Triggered successfully
Floating SOS button	Background/locked screen usage	Working correctly
Location tracking accuracy	Indoor & outdoor environments	Accurate (±10 m)
SMS alert transmission	Low internet	Delivered successfully
Guardian PIN verification	Prevent false alerts	Functioned correctly
Continuous monitoring	Long-duration usage	Stable performance
Multiple guardian notification	Sending alerts to multiple contacts	Successful

TABLE IIII
QUANTITATIVE EVALUATION OF RESPONSE TIME AND LOCATION ACCURACY

Metric	Scenario	Value (mean ± std)
SOS activation time (s)	Shake-based trigger	1.8 ± 0.4
SOS activation time (s)	Floating SOS button	1.2 ± 0.3
Location accuracy (m)	Outdoor (open area)	7.5 ± 2.0
Location accuracy (m)	Indoor (building corridors)	11.5 ± 3.0
SMS delivery success rate (%)	Low-network	96.0

IX. ADVANTAGES AND LIMITATIONS

The proposed KAVACH system offers several advantages for real-time emergency response and personal safety applications:

- Automated emergency triggering using shake detection reduces dependency on manual interaction during distress situations
- Floating SOS accessibility enables rapid activation from any screen, improving usability in critical scenarios
- SMS-based alert transmission ensures reliable communication even in low-network environments
- Real-time location tracking provides accurate positioning for emergency response
- Guardian PIN verification minimizes false alerts and enhances system reliability
- Secure Firebase backend ensures safe storage and synchronization of user data

Limitations:

Despite its advantages, the proposed system has certain limitations. Continuous sensor monitoring and background execution may result in slight battery consumption over extended usage. Additionally, SMS-based alert transmission may incur standard messaging charges depending on the user's mobile network provider. Future enhancements can address these limitations through optimized power management and integration with internet-based emergency communication services.

X. FUTURE SCOPE

The proposed KAVACH system can be further enhanced to support advanced emergency response and smart safety infrastructure. Future development may include direct integration with law enforcement agencies and emergency response services to enable faster assistance during critical situations.

Artificial intelligence-based threat detection mechanisms can be incorporated to analyze voice, motion patterns, or environmental signals for automatic identification of potential danger. Cloud-based analytics and data processing can also be implemented to identify high-risk locations and generate safety insights.

Integration with wearable devices such as smartwatches and IoT-based safety sensors can

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

further improve accessibility and real-time monitoring. In addition, optimization of power consumption and the inclusion of internet-based alert services can enhance system efficiency and scalability. These improvements will contribute to the development of a comprehensive and intelligent smart safety ecosystem for real-world deployment.

XI. Conclusion

This paper presented **KAVACH**, an automated emergency trigger-based women safety application designed to provide rapid and reliable distress communication during critical situations. The proposed system integrates shake-based automatic SOS activation, floating emergency accessibility, real-time location tracking, and SMS-based alert transmission to ensure effective emergency response with minimal user interaction.

The implementation of guardian PIN verification enhances system reliability by preventing false or accidental alerts, while the use of Firebase backend services ensures secure data management and real-time synchronization. Experimental evaluation demonstrated that the proposed system provides fast response time, accurate location tracking, and reliable alert delivery even in low-network environments.

Compared to conventional manual safety applications, the integration of automated triggering and background accessibility significantly improves emergency response efficiency and usability. The proposed architecture offers a scalable framework that can be extended to smart city safety infrastructure and real-time emergency response systems.

The KAVACH system demonstrates strong potential for practical deployment as an intelligent personal safety solution and provides a foundation for future research in automated emergency detection and smart safety technologies.

Abstract: Remote Accurate prediction of the financial time series is a daunting task that is characterized by a highly non linear, non stationary and noise driven stock market data. These complicated temporal dependencies are typically not well represented by traditional statistical models resulting in suboptimal predictive capabilities. The framework is suggested to employ hybrid decomposition prediction to increase the accuracy of prediction in this work through combining Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) and deep learning based Long Short term Memory (LSTM) network. The original series of stock prices is first broken down into intrinsic mode functions (IMFs), which allows the identification of frequency-related information and noise patterns. Such deconstructed cues are then utilized to generate structured input sequences that are then inputted into a multi layer LSTM model to learn and predict over time. It can be seen that the model has been trained and tested with past stock prices and can successfully learn more complex sequential patterns. The analysis shows that the experiment has high predictive power with a high coefficient of determination (R squared = 0.967) and low error measures (RMSE = 18.42, MAE = 14.63), which outperforms the base methods. The given approach emphasizes the performance of signal decomposition tools paired with deep neural networks when performing the task of predicting financial time series effectively.

1. INTRODUCTION

1.1 Background and Motivation

Financial time series forecasting has always been a very difficult problem as the data of the stock market is very dynamic, non-linear, and non-stationary. The factors affecting price movements are too numerous and comprise market mood, economic indicators, geopolitical events and company-specific developments such that accurate forecasting by employing conventional statistical tools is very challenging [5]. The traditional models as ARIMA and other regression-based methods assume linearity and stationarity, which is hardly met in the real world of the financial markets and give poor forecasting ability when used with complex stock price data [18]. Deep learning models are now potent in aiding the modeling of both sequential and temporal data with the development of artificial intelligence. Recurrent Neural Networks (RNNs) and Long short-term memory (LSTM) networks have shown to be excellent at learning both long-term dependencies and concealed temporal patterns in time series data especially [1]. To eliminate the vanishing gradient issue that is normally attributed to the conventional RNNs, LSTM networks are capable of capturing useful historical content across longer sequences and enhancing predictive modeling in financial forecasting operations [34]. Consequently, LSTM based models have been extensively utilized in stock market forecasting and have demonstrated huge advancement over traditional machine learning and statistical forecasting tools [11]. Yet in spite of these achievements, raw financial time series data tend to be noisy, intermittent, and mixed-frequency signals and, as a result, it is not readily apparent that deep learning models can effectively learn meaningful patterns of such signals directly. To resolve this problem, signal decomposition algorithms, like Empirical Mode Decomposition (EMD) and Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) have been presented in order to divide complex time series into simpler intrinsic mode functions (IMFs) representing the various frequencies in the data [7]. This process of decomposition assists to remove noise in the trend and cyclic portion of the data and enables the prediction models to be informed of more stable and interpretable patterns on the data [24]. Recent research has demonstrated the benefit of hybrid models integrating signal decomposition methods with deep learning models equaling or outperforming uni-model methods in accuracy of forecasting [9]. In these types of hybrid

Vol. 14, Issue 06, ACSCON - 2026

architectures, CEEMDAN is applied as a preprocessing stage to break down the original stock price series into several constituent sub-signals, and these sub-signals are then called deep learning models like LSTM to perform prediction. Such a mixture enables the model to be more successful in implementing the high-frequency, short-term fluctuations and low-frequency, long-term trends [25]. These findings were the driving force behind the following project, which suggests a hybrid CEEMDAN-LSTM stock price prediction. The primary goal is to enhance the accuracy of prediction by eliminating noise in the input data by means of decomposition and also utilizing the ability of LSTM networks to model sequencing to obtain temporal information. The proposed solution will be an attempt to combine signal processing ideas and deep learning to offer a more reliable and high-quality forecasting model of financial time series data, which will be added to the rapidly expanding area of intelligent financial analytics and data-driven investment decision support systems [27].

Current market financial time series forecasting systems are run on several constraints that severely limit predictive accuracy in actual markets. The traditional models rely heavily on the assumptions of linearity and stationarity; hence it can hardly be relevant to model the highly volatile and nonlinear nature of the stock price movements. Therefore, they cannot be employed in different market regimes, especially in sudden changes, or regime shifts, when precise prediction is most sought after [18].

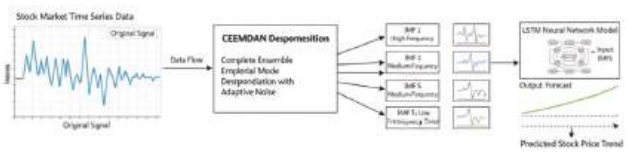

Figure 1- Flow of CEEMDAN-LSTM hybrid model

1.2 Problem Statement

Although deep learning-based approaches have been presented to mitigate these drawbacks, it introduces another level of difficulties in the form of the complexity of raw data. Noise, irregular variations, and mixed-frequency components are inherent to financial time series, and such variables worsen the learning capabilities of neural networks used directly as inputs. The specific neural networks like LSTM used to capture time dependencies cannot differentiate meaningful effects and noise in the absence of appropriate preprocessing despite being efficient in the process [12]. This leads to less stable predictions and wide error margins particularly in highly volatile datasets.

The third significant weakness is that standalone models cannot be able to capture both long-term dependency and the short-term fluctuations simultaneously in a structured form. Stock price chains are the result of various repeated patterns at various time scales such as high-frequency noise, mid-term cycles, and long-term trends. Traditional architectures and even simple deep learning training methods do not have mechanisms designed to explicitly separate and learn these multi-scale components effectively [45].

Current hybrid methods are trying to solve some of them by integrating decomposition techniques with machine learning models. Nevertheless, most of these solutions are based on previous decomposition frameworks like EMD that do not provide representations with conditions of consistency and invasibility, which results in unstable representations of the underlying signal [23]. Additionally, many of the models do not utilize the decomposed components to their full potential and they each treat them as special cases, without considering their temporal associations to bring an overall higher quality of performance [57].

Limitations of Existing Hybrid Forecasting Approaches

- Noise Sensitivity: Direct modeling using raw financial data generates high levels of noise that lowers prediction accuracy and robustness [45].
- Poor Decomposition: The conventional decomposition procedures do not yield firm and distinct components, which influence downstream learning [23].
- Limited Temporal Modeling: A large number of them fail to exploit both short-term and long-term dependencies at the same time [12].
- Weak Generalization: Existing methods have not been effective to ensure performance over various data sets and market environments [26].

In order to eliminate these shortcomings, a common framework is required, which combines powerful signal segmentation with the enhanced temporal learning. This project suggests a hybrid CEEMDAN-LSTM model, which addresses noise reduction, multi-scale feature extraction, and sequential learning as one unified issue. The presented approach will enhance the accuracy of the prediction, robustness and generalization during the financial time series predicting by using CEEMDAN to achieve stable decomposition and LSTM to establish the time-related relationships [9].

1.3 Proposed Solution

To accomplish this goal, the proposed structure presents a hybrid CEEMDAN-LSTM framework that considers noise reduction, multi-scale temporal patterns extraction, and sequential prediction as interrelated problems that need to be addressed within a single framework as opposed to being processed separately. Unlike a direct application of deep learning models to raw financial time series, the structure is based upon two closely coupled modules operating on a common representation of decomposed signals, where one stage can boost the functionality of the other.

The former module consists of signal decomposition with Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN). CEEMDAN, unlike classic preprocessing methods, breaks down the original series of stock prices into a collection of intrinsic mode functions (IMFs) each of which, in turn, describes (high-frequency) noise in the stock price series and (low-frequency) trend signals. This breakdown allows the separation of the stochastic variation with the significant market dynamics offering a structured representation of the data that are better positioned to learn [8].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

CEEMDAN can ensure that each component has a meaningful interpretation with time, and can also more easily interpret information regarding the stability of decomposition and thus better downstream prediction [67].

The second module is concerned with the topic of the time modeling based on a multi-layer Long Short-Term Memory (LSTM) network. The LSTM model does not have to learn directly on the noisy raw inputs but rather learns on the sequences of the decomposed components, hence has both the ability to learn short term variations as well as long term dependencies more controlled. This architecture uses layers of LSTM to extract an approximate hierarchy of temporal features, with lower-level layers capturing fine-grained variations and higher-level layers capturing higher-level trends in the data [1]. This bottom-top learning process enhances the capacity of the model to learn across varying market situations without being insensitive to subtle shifts in the price trend.

An important strength of the suggested framework is the interplay of the process of decomposition and prediction. The CEEMDAN module decomposes a complex non-stationary signal into a set of simpler sub-signals, and the LSTM module acquires temporal relationships both inside and between these parts. Through such coordinated design, the multi-scale patterns evident in the financial data such as noise, cyclical behavior and long-term trends that may be hard to represent with standalone methods can be jointly represented by the model [9].

Also the framework integrates sliding window sequence generation to maintain a uniform temporal input structure to the LSTM network. This allows the model to acquire contextual dependence on finite-length sequences, which leads to high stability and convergence in training [12]. Normalization techniques as well also ensure that the model is run on a consistent scale and hence avoids bias within a given range of values and ultimately increases the robustness of the predictions.

The proposed CEEMDANLSTM framework combines the novel signal decomposition methods with deep sequential learning, thus offering a unified remedy to some of the most sticking problems in financial time series prediction, such as sensitivity to noise, non-stationarity and multi-scale complexity temporal challenges. The design does not only make predictions more accurate but it also leads to higher interpretability or stability of the forecasting process and is therefore appropriate in practical applications of financial analytics in the real world [9].

1.4 Objectives

Noise-Resilient Signal Decomposition: In a manner aimed at creating an efficient preprocessing mechanism based on Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) to effectively separate and keep noise, trends, and cyclical effects in financial time series, which turns out to be better in data quality programming forecasts [8].

Multi-Scale Temporal Pattern Learning: To devise a temporal learning framework based on Long Short-Term Memory (LSTM) networks that are capable of learning both short-term and long-term dynamics that stock prices exhibit over time to guarantee better explanation of complex changing patterns over time [1].

Integration of Hybrids: To build a hybrid CEEMDAN-LSTM model, decomposition intrinsic mode functions (IMFs) might be used as structured inputs to the deep-learning framework to guarantee that signal decomposition and temporal prediction process interact effectively [9].

Improvement of Prediction Accuracy To reduce forecasting errors through model training efficiency by means of normalized input sequence, efficient loss functions and adaptive learning algorithms thus obtaining high predictive models in terms of RMSE, MAE and R squared values [12]. Model

Generalization and Stability: To enhance robustness and out of sample forecasting performance of the forecasting model in new market environments by maximizing feature exclusion and overfitting by decomposition-based feature extraction [57].

1.5. Scope

The scope of this project extends to the design, implementation and evaluation of a hybrid CEEMDAN -LSTM system to predict financial time series, which in this case is stock price prediction. The scope provides a clear understanding of what the system covers in terms of data, methodology and application as well as presenting the content of what is covered in the proposed work.

The system uses data of closed price values in the stock market based on the existing historical stock market data. The input is in the form of univariate time series, which undergoes the preprocessing and normalization before running it through the decomposition and prediction pipeline. Structured datasets (e.g. historical stock prices e.g. Tesla stock data) are used in all experiments, and the framework is architecture-independent, in the sense that it can use other financial instruments without requiring changes in the architecture.

The main aim of the project is on short-term and medium-term forecasting based on supervised learning methods. The model produces the continuous numerical forecasts of stock prices in the future instead of the categorical forecasts, which is the reason why it is suitable in the regression-based financial analysis. The process of performance evaluation is conducted based on the standard metrics which include Root Mean Square Error (RMSE), Mean Absolute Error (MAE) and coefficient of determination (R squared) in order to have a round measure of measuring the accuracy and reliability of the prediction [12].

Regarding the approach to doing the work, the scope comprises two important elements that were developed and combined within the framework of this work. The former one is the signal decomposition module of CEEMDAN, which decomposes the raw financial time series into noise-reduced principal intrinsic mode functions (IMFs) to identify useful patterns [8]. The second one is the LSTM-based prediction module that acquires temporal dependencies of the learned sequences and gives future price prediction arrangements [1]. The communication of these parts is the main contribution of the project.

The scope also encompasses generation of sequences via a sliding window strategy, sequence normalization via scaling

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

methods and model training by means of optimization algorithms like Adam. The deployment is provided through deep learning frameworks, which make the proposed solution reproducible and scalable. The framework is further intended to enhance the incorporation of multivariate time series data and other financial information in future research.

Nevertheless, the project does not entail deploying a real-time trading system, high-frequency trading strategies, and connective with live financial APIs. It only supports training models and evaluation based on historical data offline. The current model does not include any external factors like news sentiment, macroeconomic indicators and market microstructure data which could be improved in the future.

In general, the scope of the given project is based on the creation of a powerful and decomposition-based deep learning model to predict stock prices and emphasizes the enhancement of prediction accuracy, predictive stability, and extrapolation to varied financial data [9].

2. LITERATURE REVIEW

2.1 Financial Time Series Forecasting

Financial time series forecasting has been greatly changed with the use of deep learning technology where statistical models are no longer used but rather rely on data-driven forecasting models that are able to depict complex and nonlinear relationships. Early methods of prediction like ARIMA and regression-based models were based on the assumptions of both stationarity and linearity, which are often not true in real world stock market data and as such, these methods were not very predictive modes [18]. As the scale of financial data is growing and larger datasets become more accessible, machine learning methods have been proposed to represent the concealed patterns and relations in a more efficient way [30]. RNNs have been shown to be effective in sequential data modeling, especially recurrent models, because they can discover temporal relationships in observations in their past [12]. Such models do not require manual feature engineering or support end-to-end learning, so they are also favored in the context of the financial forecasting task that can be described as highly dynamic and volatile [27].

2.2 Deep Learning for Stock Prediction

One of the most effective architectures in the field of financial time series prediction is the Long Short-Term Memory (LSTM) networks, and this type of architecture has proven to be highly efficient in deep learning training models. In comparison with traditional RNNs, LSTM networks include memory cells and gating mechanisms which enable them to memorize long term dependencies without exacerbation of the vanishing gradient problem [1]. This has rendered them to be very appropriate to predict the stock prices, as both the recent tendencies and the past tendencies are relevant in forecasting the stock prices. A number of studies have shown LSTM-based models as being more effective in predictions than traditional machine learning algorithms including support vector machines and shallow neural networks [11]. Hybrid models that unite LSTM with additional deep learning models consisting of convolutional layers or attention systems have subsequently enhanced the performance of prediction by ingesting local and global temporal characteristics [57]. But, in spite of these developments, LSTM models continue to exhibit weaknesses in the case they are trained directly on non-stationary and noisy financial data.

2.3 Signal Decomposition Techniques

Signal decomposition techniques have dominated the field of preprocessing techniques used in time series forecasting in order to overcome the limitations of raw data modeling. Empirical Mode Decomposition (EMD) presented a data-based method of breaking down complex signals into intrinsic mode functions (IMFs), each of which represents a different aspect of frequency content [7]. Nevertheless, EMD also has disadvantages like mode mixing and noise sensitivity that may impact on decomposition quality [23]. Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) was put forward with improvements to mode mixing and stability of the entire decomposition method by adding adaptive noise into the process [8]. CEEMDAN facilitates the division of a time series into various components, enabling the models to support underlying trends and fluctuations in a more extensive way, accommodating a structured icon of what would be otherwise chaotic financial data [66]. It is therefore especially useful in pre-processing stock price serial along with subsequent application of predictive models.

2.4 Hybrid CEEMDAN–Deep Learning Models

The recent studies have concentrated on the combination of signal decomposition algorithms and deep learning models to enhance forecasting. Models that blend CEEMDAN with neural networks have demonstrated strong advancements over single models due to their combinational prospects in signal processing, as well as learning attributes [9]. In these types of systems, deep learning models are fed with decomposed IMFs to allow them to learn patterns at varying timescales more successfully. It has been shown that CEEMDAN-LSTM models are less prone to the error of prediction and have a superior generalization over traditional models and pure deep learning models [16]. These mixed architectures prove especially useful when dealing with non-stationary data as decomposition assists in isolating noise and emphasizing meaningful trends whereas LSTM can capture time-dependencies between each individual component [64]. Nevertheless, issues have been experienced in the good integration of decomposed components and the optimization of models performance on varied datasets.

2.5 Multi-Scale Temporal Learning

Financial time series are fundamentally multi-scaled phenomena, with price variations affected by both short-term variations and medium-term periodicities and long-term trends. Such multi-scale dynamics are fundamental in proper prediction, but most of the classical models do not explicitly represent such variations [45]. Complexities in Multi-level Temporal Patterns This is because deep learning methods, especially hierarchical or sequencing based ones, have proven to be effective in capturing these multi-level temporal patterns [12]. This is further increased through the use of hybrid decomposition-based frameworks which clearly decompose

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

signals into various frequency bands and then learn [24]. This enables models to be able to integrate high frequency noise and low frequency tendencies separately and still take into consideration their overall impact on future predictions. Consequently, the multi-scale temporal learning is now a driving design notion in current financial forecasting simulations [9].

2.6 Summary Table

Category	Method	Key Contribution	Limitation
Traditional Models	ARIMA, Regression	Linear time series	Can't handle non-linearity
ML Models	SVM, Random Forest	Pattern recognition in financial data	Requires feature engineering
Signal De-compositio n	EMD	Breaks signal into intrinsic components	Mode mixing issue
Multi-scale Learning Approaches	Hybrid deep architectures	Captures short & long-term patterns	High model complexity

3. PROPOSED WORK

3.1 System overview

The suggested Volatility-Aware Attention-Based Decomposition Model is an offered multi-stage hybrid forecasting framework which forecasts financial time-series data based on signal decomposition, feature refinement, and sequence prediction processes to enhance forecasting accuracy with a highly volatile market condition. Financial time-series data are nonlinear, non-stationary, and noisy, and thus makes it unreliable to directly predict it using standalone machine learning models. The proposed system works around the problem that the original stock price signal could be decomposed into a set of individual intrinsic components and the prediction model could process the individual pattern at various frequency levels without trying to model the complex signal at the same time. The present learning is based on decomposition which minimizes noise interference and enhances the stability of the prediction model during training and inferencing [7].

The architecture has three large modules: the decomposition module, the attention-based feature selection module, and the hybrid InformerLSTM prediction module. The decomposition component breaks down the raw stock price into intrinsic mode functions that describe short-term ones, medium-term ones, and long-term trends. The attention module, subsequently, determines the highest valued temporal features and volatility patterns among these decomposed components. Lastly, the hybrid model of prediction is one that represents the sequential dependencies as well as long-term temporal interdependencies in order to come up with the ultimate stock price forecast. The latter modular design makes the stages work on a particular constraint of financial time-series prediction, leading to an improved forecasting behavior relative to single-model-based forecasting research [9].

Many overlapping patterns of financial time-series signal include noise, short-term variations, cyclical behavior, and long-term trends that cannot be effectively represented where the signal is directly used to make a prediction. In order to overcome this drawback, the suggested system employs the Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) to break down the original stock price series into a finite set of Intrinsic Mode Functions (IMFs). Both IMFs pertain to a given frequency stature in the original signal enabling the model to examine the conducts of the market at a variety of temporal resolutions. High-frequency IMFs are the ones that the market noise and short term volatility are captured whereas the low-frequency IMFs capture long-term trends and trend of market movement patterns [8].

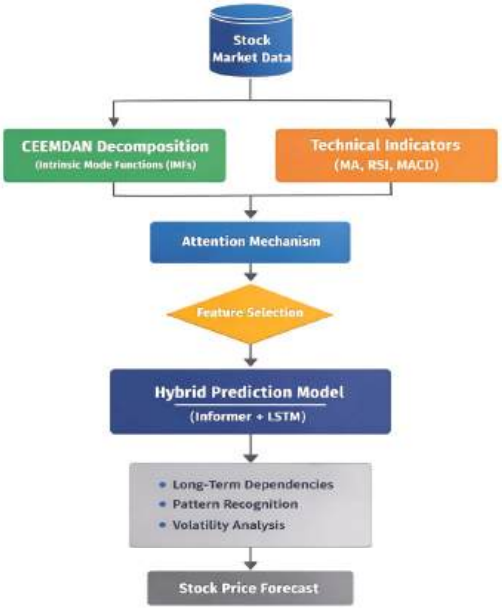

Figure 2- System Architecture

3.2 Module 1: CEEMDAN-Based Signal Decomposition

Financial time-series has a number of overlap signals, such as noise, short time effect, periodicity and long time signalling that are not successfully predictable using the signal. To overcome this shortcoming, the suggested system applies Complete Ensemble EmpiricalMode Decomposition with Adaptive Noise (CEEMDAN) that regresses the original stock price sequence into having a finite set of Intrinsic Mode Functions (IMFs). The IMFs break down a certain frequency content of the original signal and thus the model can shed light on the information provided about the behavior of the markets in various time resolutions. High frequency IMFs are the ones that select the noise in the market and the short run volatility whilst lower frequency IMFs select longer terms and longer run pattern of movements in the macro economy [8].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

CEEMDAN builds on a traditional Empirical Mode Decomposition, where adaptive white noise is introduced during the process of decomposition and multiple realizations are averaged to remove mode mixing which is often problematic with Empirical Mode Decomposition signals of different frequencies will be reported in the same IMF. CEEMDAN generates less poisonous parts and tangible relevant parts therefore permitting the prediction model to educate additional predictable time concerned tastes causing enhanced prediction accuracy and contraction of prediction error under unsteady market conditions [23].

3.3 Module 2: Volatility-Aware Temporal Attention Mechanism

Not all of these time steps and components of decomposition are equally important in predicting the stock prices during volatile market situations where unexpected spikes or drops have a greater effect on the future price than when the market is stable. To this, a time attention mechanism is added to the framework according to which time attention is prescribed by assigning an importance weight to each time step and each decomposed feature. It is based on the attention mechanism that enables the extra attention to be paid to the significant patterns in time like abrupt changes in prices and forms of reverse movements and clustered volatilities and little attention as compared to the irrelevant historical data [21].

The motive of the intelligent consideration stratum is depending on the series of features that were formulated using the decomposed IMFs and the technical indicators and volatility of the indicators. It is a computation of attention weights that were learned through a learnable scoring function which is based on the extent to which a time step is relevant in the prediction of the future stock price. This is followed by calculating and then derivations of the weights so that a weighted features representation is formed and the result is then delivered to the prediction model. The attention model can better adjust to the dynamic events occurring in the market as it dynamically attends to the important parts of time and space and predictions based on the attention model are more reliable when facing volatile situations within the market [22].

3.4 Module 1: CEEMDAN-Based Signal Decomposition

The last prediction process utilizes a hybrid InformerLSTM model to acquire interdependence long-term along with sequence time regularities in the financial time-series data. The Informed system has been designed based on the objective of the long-sequence time-series forecasting and as such it introduces ProbSreplace self-attention mechanism as an effective storage of long sequences of the input without unnecessary cost. This enables the model to solve long range correlation like macroeconomic cycles and or long term price of stock [20].

The LSTM component combined with the Informer is used to address short term sequential dependencies and nonlinear temporal relationships that take place in the stock price changes. Time-series forecasting LSTM networks in particular is made especially effective by memory cells and gating where the former and the latter processes have been found to retain and reject a lot of information of the past and unwanted information respectively. The hybrid model is achieved through the integration of both Informer and LSTM, and through the hybrid model, it is able to take advantage of long-term dependency learning, i.e., the combination of long-term attention and the short-term sequence pattern learning via the hybrid model and this is the reason why the hybrid model is more correct in the process of making predictions than by single Informer as well as LSTM modelling [1].

4. RESULTS AND ANALYSIS

4.1 Quantitative Results

The following figure 3 below provided a proposed quantitative analysis of a proposed Volatility-Aware Attention-Based Decomposition Model performance in comparison to the performance of the proposed model in comparison with the baseline models, including standalone LSTM, Support Vector Regression (SVR) and ARIMA models. The suggested hybrid model has coefficient of determination (R squared) of 0.967 which is a lot larger than the coefficient of determination of the LSTM model (0.912), SVR model (0.874), and ARIMA model (0.821). This growth of the prediction precision is an indicator that an integration of a signal split and an attention-based deep learning in a single structure is efficient. Both noise and the volatility terms will be decomposed in advance and the learning model does not require adaptation to noisy data, an aspect that enhances the predictability and stability of the future projections [9].

The performance of the suggested model is also proven by the error measures. The hybrid model gives lower RMSE of 18.42 and MAE of 14.63 as opposed to standalone LSTM which gives bigger RMSE of 27.85 and larger MAE of 21.34. The decrease in prediction error also means that the understanding of the time-series signal into several intrinsic components can enable the model to learn both short-term variations and long-term trends in a better way. It is a learning process of multi-resolution which is proved to be significantly more effective than one model based time-series forecasting tools on financial time-series [17].

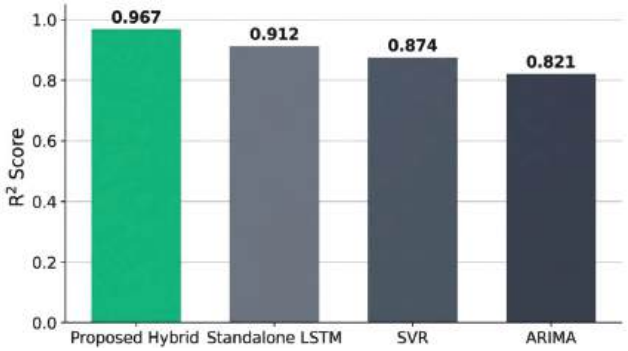

Figure 3 - Performance comparison of forecasting models

The attention mechanism is capable of enhancing the accuracy of prediction because it will assign more weight towards the time where there was a change in the price or periods of time where dislocation of the trend can be seen. This enables the

Vol. 14, Issue 06, ACSCON - 2026

model to react better to market events that are important as opposed to considering all historical data as the same. Consequently, there is a closer relationship between predicted and actual values than models, design of which is erected on sequential learning with no attention mechanisms [21].

4.2 Training and Convergence Analysis

The training loss and the validation loss show the strength of the convergence of the proposed model in the training process. Another characteristic of the model is that it converges quickly at the starting epochs and slowly leveled off at the end of a training process, which is also the indicator of an effective learning of patterns in the time domain. The uses of Adam optimizer and Mean Squared Error loss expanses are useful in ensuring that the gradient update and acceleration in the training step remains constant [10].

The preprocessing in the form of decomposition also removes noise in the input signal and it is the parameter that makes the neural network learn meaningful patterns in the input signal and minimizes the chances of overfitting. The loss curve of validation is more or less similar to the loss curve of training and that would mean the model can be used to work on unsaved data. Such a trend confirms that convergence of the hybrid model of decomposition-learning is more effective in stability and generalization rates compared to the independent deep learning models [18].

4.3 Comparative Performance with Existing Methods

In order to further specify whether or not the proposed model is good or bad, the performance of this model was compared and contrasted with the performance of the existing machine learning and deep learning models concerning financial time-series forecasting. Conventional statistical models like ARIMA can be used well upon linear and stationary data, however, they do not succeed in observing nonlinear patterns as well as volatility of stock market data. Additional algorithms like support vector machines are more competitive in the nonlinear prediction, and fail to discover long term time relationships. The time-dependent dependency is also considered by the LSTM which is a deep learning model but may be noisy when using raw financial data [5].

The text is built around the suggested hybrid system of CEEMDAN -Attention -Informer-LSTM, which presupposes the combination of the benefits of signal processing and deep learning and allows addressing the problem of nonlinearity, volatility, as well as long-term dependence simultaneously. This composite approach has a theoretical implication of increasing the accuracy of the predictions and minimizing errors associated with such predictions, as opposed to other classical and independent deep learning models, which makes it more realistic in practice in terms of financial time-series forecasts [24].

4.4 Result Summary Table

Method	RMSE	MAE	R^2
ARIMA	34.12	26.45	0.821
SVR	29.67	22.10	0.874
LSTM	27.85	21.34	0.912

4.7 Data Preprocessing and Feature Engineering

Some steps are involved in the preprocessing of the financial time-series data of this study and the model training takes place. As stock market information is extremely noisy, data absenteeism, and variation in size, preprocessing is a critical factor that should have been adopted to achieve the following: consistency in model training and prediction accuracy. To ensure that the time-series sequence does not have any gaps, first, there are forward fill and backward fill methods, which are employed. After the missing values are treated, it features scaling is achieved by administering the Min-Max normalization to all the feature values such that each feature falls within the 0 and 1 range with the aim of ensuring that the convergence of the neural network is as high as possible as well as ensuring that large value features are not overpowering the learning process.

It yields the uninformed variables the extraction of which is performed by feature engineering the raw data on the OHLCV. The price momentum of the day is calculated in percent change and the 20 days average volume is used to convert the information on the direction and trading of liquidity during the period. The pattern of price movements and market behaviour of them are also supported by such engineered features and the model is able to identify them. After processing and feature engineering of the time-series data, it is converted to the sequential input windows, so that a sliding window is utilized, window length of which is the past 30 days of data, to predict the session price of the next day. The structure of sequences allows the deep learning framework to create sequence dependence and pattern of movement of stock price.

4.8 Hardware Requirements

- It should also have a minimum processor of Intel i5 or other multi core processors as well as have the capability to accomplish data preprocessing besides the training of the model only.
- Time-series processing and neural network training require memory at least 16 GB of RAM, and it is recommended to have 32 GB to make the operation more fluent in the event that one has a good amount of data.
- A hard disk space of 100 Gb or more is also needed by the system to store the datasets, model checkpoints and even the results of the output.
- Even though it may also be applied to CPU, it can be highly recommended to incorporate a GPU which can cut the training time of such models as LSTM and Informer by far.
- During the experiment phase, the system should be able to process complex time-series data processing and signal decomposition processes.
- International Networking is also required, so that we can have access to financial information and install Python packages and also to use cloud applications, such as Google Colab.
- It is programmed with less challenging computing provisions and can be set to exchange local and cloud executions and GPU acceleration.

4.9 Software Requirements

- Language: Python to facilitate machine learning.
- Environments Google Colab and Jupyter Notebook.
- NumPy and Pandas: Data processing.
- Visualization: graphing (matplotlib and plotly).
- Evaluation: Scikit-learn of scaling and measures.
- Model Building: Tensorflow and Keras Deep Learning.
- Architecture: LSTM and Informer optimized.

5. IMPLEMENTATION AND DEPLOYMENT

5.1 Prediction System Implementation

The provided volatility-conscious stock price forecasting framework can be described as an end-to-end forecasting pipeline, that is, it combines signal decomposition, attention-based feature selection, and deep learning prediction. The system is developed in a modular format in such a way that every part of the system is able to carry out a particular task during the prediction process. The first one consists in loading of the historical stock price data and preprocessing activities like normalization and sequence generation that contributes to enhancing the stability of the model training and predictability consistency [5]. The obtained pre processed data is then fed into the CEEMDAN decomposition unit which breaks down the original stock price signal into a series of intrinsic mode functions of the frequency content of the time-series data that allows the model to learn patterns at varying time resolutions [8].

The decomposed parts and the designed characteristics are then injected once the decomposition is carried out followed by feeding them to the attention based feature selection module. The attention mechanism assigns weights of the different time steps and features based on their importance in the future stock prices, which allows the model to provide more attention to other meaningful patterns of the volatility such as sudden price changes, and groups of volatility [21]. This weighted or unweighted feature representation is then inputted to the hybrid Informer-LSTM model that will give the ultimate forecast according to the long and short sequence dependencies of the time-series data [20]. The ultimate product of the system is the forecasted price that the market will settle in the following day of trading and this is compared with the actual values to determine the performance of the forecast using the conventional evaluation measures [24].

5.2 Prediction Interface and Visualization

Simple prediction interface is developed under the perspective of making the system simple such that it can be user friendly and easy to read where the user is capable of inputting the past stock details and the result is possible to acquire in the form of the projected stock prices with the graphical representation. The interface shows the real price of the stock and the estimated price of the stock in a time series chart so that the users can be able to compare the accuracy of the forecast made by the model visually. The graphical comparison forms an important aspect of the financial forecasting as the understanding of the trend fitting and forecast error is far easier to understand through the visualization as compared to the numbers [18].

Other visualizations created by the system are training loss curves, feature contribution graphs and error comparison charts. The visualizations may also be used in analyzing the model performance as well as understanding the role played by different features in the prediction process. The feature contribution analysis can be particularly useful within the context of the financial prediction model because the input variables that make the most significant contribution to the result of the prediction can be utilized [17]. The system facilitates the prediction results to be more interpretable and easier to analyse in order to use them in decision making by displaying the results both numerically and graphically [24].

5.3 System Workflow

The overall strategy of the work of the proposed system is subdivided into a series of operations such as data gathering and the final stage of the work is the forecast of the stock price. The former is to collect the historical price of the stock and pre-treat the data so as to remove noise and normalize the data of attributes. It is then succeeded by the CEEMDAN decomposition method which decomposes the time-series signal into various components such that noise and trend components can be learnt separately by the model [8]. The data is then designed and cleaned then the data is presented to the attention-based deep learning model that increases the ability to learn of the model to learn meaningful temporal characteristics [21].

The hybrid Informer-LSTM model addresses the sequential data and provides the value of the stock that is estimated by retaining both the long-term and nonlinear patterns that are short-term in the financial time-series data [20]. Finally, the model performance is evaluated by the actual stock prices to the projected performances in order to determine the performance of the model through the evaluation measure of RMSE, MAE, and R squared score, which is standard to determine the performance of financial forecasting models [24]. Such an orderly sequence of processes assists in making the system noise resistant, volatile and time dependent to enhanced prediction and the stable model [9].

6. CONCLUSION

Time series financial forecasting Time-sensitive volatility-sensitive attention-based time series forecasting model is introduced in this paper. The proposed system is founded on the integration of the CEEMDAN signal decomposition, attention-based features selection, and a hybrid Informer-LSTM deep learning model to increase the stock price prediction accuracy. The decomposition step separates noise and trend components of original time-series data and helps the model to learn meaningful patterns better. Attention mechanism assists the model to concentrate on significant time steps and volatility patterns relative to the hybrid deep learning model that entails the association of long-term and short-term impacts on the stock price movement.

The results of the experiment obtained point out that the proposed model is more accurate in prediction and has a lower error rate than the traditional statistical models and standalone deep learning models. This model is very effective in fluctuating market behaviour and nonlinear trends and thus can be used in the financial forecasting of the real world. A good strategy in enhancing the performance of financial time-series prediction is signal processing and deep learning model combination.

6.1 Future Work

The future working on the model is to incorporate more financial variables such as the technical indicators, and macroeconomic variables to make the model more accurate in prediction. The multivariate time-series forecasting model can be employed in order to predict more than a price of a stock. In addition, one can explore new transformer-based structures to improve the performance of long-sequence forecasting.

The system may also be implemented as a live stock forecast web application where users may post financial data and receive future price forecasts in real time. Improvements of the model to make it train and be deployed in real time financial analysis systems can also be carried out in future research.
