ACSCON 2026

International Conference on Advances in Computing Systems Communication and Networking

Organized by
Dr. ACS College of Engineering, Bangalore

Published By
International Journal of Engineering Research and Technology

Dr. ACS
COLLEGE OF ENGINEERING

Affiliated to VTU, Belagavi, Approved by AICTE, New Delhi & Govt. of Karnataka
#207, Kambipura, Mysore Road, Bengaluru – 560 074

INTERNATIONAL CONFERENCE ON ADVANCES IN COMPUTING SYSTEMS COMMUNICATION AND NETWORKING (ACSCON - 2026)

IJERT
ISSN : 2278-0181
www.ijert.org

Date: 29th - 30th May 2026 Time: 9:00am to 5:00pm

Venue: ACS Auditorium, Dr.ACSCE Campus

Dr. ACS
COLLEGE OF ENGINEERING

Cordially invites you to Grace the Inaugural Function of

International Conference
On
ADVANCES IN COMPUTING SYSTEMS COMMUNICATION AND NETWORKING (ACSCON - 2026)

Inaugural Address

Dr. Sridevi Arunachalam
Founding Chairman National International Council
Indo-UAE Economic Chamber of Commerce
India & Dubai

Dr. V.Cyril Raj
Additional registrar (Administration)
Dr. MGR educational & Research Institute, Chennai

Chief Patrons

Dr. A.C.Shanmugam
B.A. LLB, FIMSA,FRCPS (Glasgow, UK)
Founder Chairman
RajaRajeswari Group of Institutions

Sri. A.C.S Arun Kumar
B.Tech (Hons)., LMISTE., MIET.,(UK)., LMCSI., MIEEE, MCSI, MISTE, CEng (India)
President
RajaRajeswari Group of Institutions

Patrons

Dr.S.Vijayanand, M.Tech. Ph.D.
Executive Director, RRGI

Sri.C.N.Seetharaman, IAS(Retd.)
Chief Executive Officer, RRGI

Dr.S.Jeyabalan, Ph.D.
Special Officer, RRGI

Program Chairs

Dr.A.K.Mariappan
Rector, RRGI

Dr.S.Meenakshi Sundaram
Registrar, RRGI

Dr.B.S.Shylaja
Principal, Dr.ACSCE

Dr.S.Usha
Professor, RRGI

Organizing Chairs

Dr.P.Bhuvaneshwari
HOD, Dept. of BME

Dr.Vijaya S M
HOD, Dept. of ECE

Organizing Secretaries

Dr.B.B.S.Kumar
Assoc. Prof, Dept. of DS

Dr.S.Sivasundarapandian
Professor, Dept. of CSE

Program Schedule

Inaugural Function	
Timings	**Particulars**
10:30am to 10:40am	College / Conference video presentation
10:40am to 10:50am	Lighting the Lamp
10:50am to 10:55am	Welcome Address
10:55am to 11:20am	Inaugural Address by: Dr.Sridevi Arunachalam Indo UAE Economic Chamber of Commerce, Dubai
11:20am to 12:00pm	Key note address by : Dr.V.Cyril Raj Additional Registrar, Dr.M.G.R.University, Chennai
29th May 2026 (Tutorial Session & Paper Presentations Schedule)	
12:05pm to 12:45pm (Online)	**Dr. Ross Smith** Co-Founder future world Alliance & Microsoft Senior Leader, Seattle, USA Title of the Talk: Hands on prompt engineering
02:00pm to 04:00pm (Offline)	Paper Presentations (Parallel Sessions)
06:15pm to 07:30pm (Online)	**Dr. Windhya Rankothge** Project Lead/ Post Doctoral research associate canadian institute for cyber security (CIC) university of New Brunswick Canada Title of the Talk: From Risk to Resilience in Cyber Security
30th May 2026 (Tutorial Session & Paper Presentations Schedule)	
10.30am to 11.30am	Paper Presentation (Online)
11.30am to 01.00pm	Paper Presentation (Offline)
2.30pm to 3.30pm	Valedictory Function

Our Speakers

Dr. Sridevi Arunachalam is an accomplished edupreneur, business strategist, and motivational speaker with a global presence. Founding Chairman National and international council Indo UAE Economic Chamber of Commerce. She is the Founder & Managing Director of IIEC (International Education & Immigration Consultancy) and serves as a startup advisor and mentor across leading institutions. Received many awards like Einstein Exemplary Awards Standout Leader, Dubai, Volkswagen Taigun Women Achiever Award and Lifetime Achievement Award Kalam Sakthi Award, Dr. APJ Abdul Kalam Dream Trust. A TEDx speaker, life coach, and award-winning leader, she has been recognized for her contributions to education, entrepreneurship, and women empowerment. With expertise spanning business strategy, overseas education, and personal development, she continues to inspire individuals and organizations worldwide through her vision of empowerment and growth.

Prof. Dr. V. Cyril Raj is the Additional Registrar (Administration) and Professor of CSE & IT at Dr. M.G.R. Educational and Research Institute, Chennai. With over two decades of academic and administrative experience, he holds a Ph.D. in Computer Science and has made significant contributions to research in areas such as cyber forensics, bioinformatics, and cloud computing. A prolific author, patent holder, and research mentor, he is actively involved in professional bodies like IEEE and CSI, and has been recognized with prestigious research awards for his contributions to academia. He chaired many international conferences & conclaves. He guided & produced many research scholars. Received more funds from various agencies. He coordinated with MSME related funding schemes with respect to start up Implementation.

Dr. Ross Smith is co-founder of the Future World Alliance USA, Fellow of the Royal Society of the Arts, a distinguished technology leader, inventor, and researcher with over 30 years of experience at Microsoft. His research focused on artificial intelligence, automation, and workforce transformation. He is the author of The Practical Guide to Defect Prevention and holds seven patents in software testing, automation, and organizational systems. Ross contributed to pioneering technologies including Skype Translator. He actively supports diversity and inclusion initiatives in technology and co-founded the Seattle Women in Tech Consortium.He has served in leadership roles with organizations such as the Anita Borg Institute, IEEE Women in Engineering, and National Center for Women & Information Technology. Ross also works closely with iUrbanTeen and Native American communities through Microsoft outreach programs. He is a Sequoyah Fellow of the American Indian Science and Engineering Society. His work and research have been featured in leading publications including Forbes, The Economist, and the Harvard Business Review. He has delivered keynote talks at global events such as SXSW, Grace Hopper Celebration, and MIT Solve.

Dr. Windhya Rankothge is a Cybersecurity GRC Specialist based in Canada.She holds qualifications including PhD, CISM, CRISC, and PMP certifications.She is actively involved in IEEE Women in Engineering (WIE) initiatives.She currently works at the Canadian Institute for Cybersecurity.Her role includes Postdoctoral Research Associate and Technical PI Team Leader responsibilities.Her research mainly focuses on supply chain cybersecurity and cyber risk intelligence.She has worked on secure cloud-based collaborative environments for defense industries.Her expertise includes cloud security, risk assessment, and blockchain-based supply chain security.She possesses strong skills in computer network operations and software-defined networks.She has earned several professional certifications such as PMP, DevNet Associate, and CRISC.She received the IEEE Women in Engineering Outstanding Volunteer Award.She has published research papers in networking, virtualization, neural networks, and cloud computing.

Dr.ACS COLLEGE OF ENGINEERING

#207, Kambipura, Mysore Road, Bengaluru – 560 074

DEPARTMENTS OF ASE, AE, AI & ML, BME, CSE, CSE: CY, DS, IoT, ECE & MECH ENGINEERING

INTERNATIONAL CONFERENCE ON ADVANCES IN COMPUTING SYSTEMS COMMUNICATION AND NETWORKING (ACSCON - 2026) on 29th & 30th May, 2026

Chief Patrons:-
Dr. A C Shanmugam
Founder Chairman, RRGI Bengaluru
Sri. A C S Arun Kumar
President, RRGI Bengaluru

Patrons:-
Dr. S Vijayanand., M.Tech., Ph.D
Executive Director, RRGI Bengaluru
Sri. C N Seetharam.,IAS(Retd.)
CEO, RRGI, Bengaluru
Dr. S Jeyabalan., Ph.D
Special Officer, RRGI, Bengaluru

Program Chairs:-
Dr. A K Mariappan
Rector, RRGI, Bengaluru
Dr. S Meenakshi Sundaram
Registrar, RRGI, Bengaluru
Dr. B S Shylaja
Principal, Dr.ACSCE, Bengaluru
Dr. S Usha
Professor, RRGI

Organizing Chairs:-
Dr. P Bhuvaneswari
Prof.& HOD, BME, Dr.ACSCE
Dr. S M Vijaya.,
Prof.& HOD, ECE, Dr.ACSCE

Organizing Secretaries:-
Dr. B.B.S.Kumar
Assoc. Professor, Data Science, Dr.ACSCE
Dr. S. Sivasundarapandian
Professor, CSE, Dr.ACSCE

Technical Committee Chair:-
Dr. T Senthilkumaran
Dean (R&D), Dr.ACSCE
Dr. G Ramanan
HOD, Aeronautical Engineering
Dr. C Suresh
HOD, Aerospace Engineering
Dr. Nandhagopal S M
HOD, Computer Science & Engineering
Dr. Ashok Kumar P S
HOD, CSE(IoT)
Dr. Raghavendra B K
Prof. & HOD, CSE(DS)
Dr. Nazneen Taj
HOD, CSE(CY)
Dr. Siddesha H S
HOD, Mechanical Engineering
Dr. Subaschandra Bose R
HOD, Civil Engineering

ABOUT ACSCE

Dr.ACS College of Engineering, an institution of academic excellence was established in the year 2009 under the aegis of Moogambigai Charitable and Educational Trust (MCET), Bengaluru. The College is located in a beautiful lush green landscape, free from polluted environment and excellent atmosphere and ambience ideally suited for growth of the soul and mind. It is located behind RRMCH on the Bengaluru-Mysore Highway 15 Km from the Bengaluru City Railway Station and 2 Km from Kengeri Railway Station. The College is affiliated to Visvesvaraya Technological University, Belagavi and has been approved by the All India Council of Technical Education, New Delhi. The College offers a wide range of Undergraduate courses in Computer Science and Engineering, Data Science, Cyber Security, IoT, AI and ML, Aeronautical Engineering, Aerospace Engineering, Bio Medical Engineering and Mechanical Engineering. Post Graduate courses in CSE, Structural Engineering, Business Administration, Computer Applications and Research Programs all branches of Engineering and Science are also offered. The UG Courses in CSE, Aeronautical Engineering, Aerospace Engineering, ECE and Bio-Medical Engineering are accredited by the National Board of Accreditation. The Institution is also accredited by NAAC with A Grade. All the departments are equipped with state-of-the-art infrastructure and well qualified and experienced faculty members, Centres of Excellence and Research Centres. Innovative teaching and learning processes are adopted and the College has an excellent placement record where almost 90% of the eligible students get suitable placement offers from reputed industries.

ABOUT ACSCON-2026

Dr.ACSCE has adopted a multi-disciplinary approach to invite original research articles in all the engineering disciplines ranging from CSE and allied courses, ECE, Aeronautical, Aerospace, Biomedical and Mechanical Engineering. ACSCON-2026 is a premier forum dedicated to presenting cutting-edge research and innovative practices at the dynamic intersection of computing, systems engineering, communication, and networking. As digital transformation accelerates across all sectors, the convergence of these core disciplines is becoming the bedrock of next-generation technological solutions. ACSCON-2026 will address the complex challenges and vast opportunities in building smarter, faster, more secure, and interconnected systems that will define the future.

CORE TRACKS & FOCUS AREAS

ACSCON-2026 is structured around integrated tracks that reflect the synergy of its foundational pillars:

1. Intelligent Computing & Systems:
- Next-Generation Architectures: Cloud, Edge, Fog, and Quantum Computing.
- AI and Machine Learning: Distributed AI, Federated Learning, and AI-driven system optimization.
- High-Performance and Real-Time Embedded Systems.
- Cyber-Physical Systems and Digital Twins.

2. Advanced Communication & Networking:
- The 6G Vision: Terahertz Communication, Ultra-Massive MIMO, and Integrated Sensing.
- Software-Defined Networking (SDN) and Network Function Virtualization (NFV).
- Satellite and Non-Terrestrial Networks (NTN) for global coverage.
- Low-Power Wide-Area Networks (LPWAN) for massive IoT.

3. Security in a Hyperconnected World:
- Zero-Trust Architectures and Post-Quantum Cryptography.
- AI-Powered Threat Intelligence and Network Resilience.
- Security and Privacy for IoT, Edge, and Critical Infrastructure.

4. Domain-Specific Applications & Convergence:
- Smart Cities & IoT: Industrial IoT, Smart Grids, and Urban Digital Twins.
- Aerospace & Aeronautics: UAV Swarm Networks, Avionics Data Networks, and Space-Air-Ground Integration.
- Healthcare & Biomedical Engineering: Medical IoT, Secure Telemedicine, and AI-assisted Diagnostics.
- Automotive & Mechanical Systems: Connected Autonomous Vehicles (CAV), V2X Communication, and Smart Manufacturing.

CALL FOR PAPERS

ACSCON-2026 invites papers but not limited to the following areas:

- High-Performance & Distributed Systems
- Edge/Cloud Computing Infrastructure
- Embedded & Real-Time Systems
- Software-Defined Networking (SDN) & Network Function Virtualization (NFV)
- Quantum Computing & Networks
- Human-Computer Interaction & Ubiquitous Computing
- Big Data Architecture & Stream Processing
- Data Visualization & Analytics Platforms
- Time-Series & Sensor Data Analytics
- Data Mining & Knowledge Discovery
- Data Governance & Federated Learning for Data Privacy
- AI-Driven Threat Detection & Incident Response
- Blockchain for Secure Networking
- IoT/Cloud Security & Zero-Trust Architecture
- Privacy-Enhancing Technologies (PETs)
- Critical Infrastructure & Network Resilience
- Low-Power Wide-Area Networks (LPWAN, NB-IoT)
- Edge Intelligence & TinyML
- Wireless Sensor Networks & RFID Systems
- IoT Security & Device Identity Management
- Digital Twins & IoT Simulation
- Federated Learning & Distributed AI
- Explainable AI (XAI) for Network Management
- Reinforcement Learning for Network Optimization
- Natural Language Processing (NLP) in Communication Systems
- AI-Driven Resource Allocation in 5G/6G
- Aviation Communication Systems (SATCOM, VHF Data Link)
- Autonomous Flight Systems & AI-Based Control
- Aircraft Data Networks & Onboard Computing
- UAV Communication & Swarm Networking
- Aero-MACS & Next-Gen Air-Ground Communication
- Satellite Communication & Networking (LEO/MEO/GEO Constellations)
- Spacecraft Autonomy & On board Processing
- Inter-Satellite Links & Space Internet
- Cyber Security for Space Systems
- Mission-Critical Computing in Space
- Medical IoT & Wearable Health Devices
- Secure Transmission of Medical Data
- AI in Medical Imaging & Diagnostic Systems
- Telemedicine & Remote Patient Monitoring Networks
- Biomedical Signal Processing & Communication
- Industrial IoT & Predictive Maintenance
- Digital Twins for Smart Manufacturing
- Robotics Communication & Control Networks
- Vehicle-to-Everything (V2X) Communication
- Smart Grids & Energy Management Systems

ADVISORY COMMITTEE MEMBERS

- Dr. S. Vidyashankar., Vice Chancellor, VTU Belagavi
- Dr. Prasad B Rampure., Registrar, VTU Belagavi
- Dr. Ujwal U. J., Registrar (Evaluation), VTU Belagavi
- Dr. SRS Iyengar., IIT Ropar, Chandigarh
- Dr. Cyril Raj, Dean S & T, Dr MGR E & RI (Deemed University), Chennai
- Dr. S Radha., Principal, SSN College of Engineering, Chennai
- Dr. Gururaj H L., Prof., School of Computer Engineering, MIT Bangalore
- Dr.V Vallikumar., Professor, Computer Science and Systems Engg., Andhra University
- Dr.R.Balasubramaniam., Prof., CSE, Manonmaniam Sundaranar University, Tirunelveli
- Dr. R Nedunchezhian., Professor, CSE, Coimbatore Institute of Tech., Coimbatore
- Dr. S Chandramouliswaran., Professor, School of Computing, VIT Vellore
- Dr. J Chenni Kumaran., Professor, SIMATS (Deemed University), Chennai
- Dr.Sanjit K Mitra, Professor, Dept. of ECE, University of California Santa, USA
- Dr.Guru Subramanian, Chair of Kettering School of Engg., University of Dayton,USA
- Dr.Manikandan Veerachamy,Director of Software Development at CISCO System, San Francisco Bay Area, USA
- Dr.Muthu Ramachandran, Professor, Leeds Beckett University, UK
- Dr.Nitha G Nair, University of Manchester, UK
- Dr.Benson Edwin Raj, Professor, HCT, Fujairah, UAE
- Dr.Daniel Chandran, Dy.Head, University of Techno, Sydney, Australia
- Dr.Jhon Bryden, Professor, Prince Mohammed Bin Fahid University, Arabia
- Mr. Rajasekar, Senior Manager(Systems), Alkons, India
- Mr.Eva Charles, Professor, University of Jaffna, Sri Lanka
- Dr.Arokiasami Alphones, Professor, NTU, Singapore
- Dr.Hong Jiarong, Professor, Taylor's University, Malaysia
- Dr.Lim Tienzse, Professor, MM University, Malaysia
- Mrs. Anandi Giridharan, Member IEEE, Professor, ECE, IISC, Bangalore

Publication: Papers accepted and presented in ACSCON 2026 will be published in IJERT Journal (ISSN: 2278-0181) as Conference Proceedings. A few high quality research papers presented in the Conference will be recommended for publication in Scopus Indexed Journal (Article processing charges as applicable) with the consent of the authors.

REGISTRATION DETAILS

Delegates Category	Indian	Foregin
Academicians/Research Scholars	2000 INR	50 USD
UG/PG Students	1500 INR	40 USD
Participants	500 INR	-

* Registration Payment including GST

IMPORTANT DATES

Full Length Paper Submission Due : 15th April, 2026	Final Camera Ready Paper Submission 28th April, 2026
Acceptance Notification : 20th April, 2026	
Early Bird Registration : 28th April, 2026	Last Date for Registration : 30th April, 2026

MESSAGE

It gives me immense pleasure to know that Dr. ACS College of Engineering, Bengaluru, is organizing the International Conference on Advances in Computing Systems Communication and Networking (ACSCON – 2026) on 29th and 30th May 2026.

The Conference addresses highly relevant and emerging areas of scientific research related to advanced Computing Systems and Networking. Such interdisciplinary platforms play a vital role in promoting innovation, research collaboration, and scientific advancement for societal benefit.

ACSCON – 2026 provides an excellent opportunity for academicians, scientists, researchers, and students to exchange ideas, present their research findings, and explore collaborative opportunities with experts from academia and industry.

I congratulate the organizing committee, faculty members, researchers, and participants for their efforts and contributions towards the successful organization of this conference. I am confident that the deliberations and technical discussions during the conference will lead to meaningful scientific interactions and innovative outcomes.

I extend my best wishes for the grand success of ACSCON – 2026 and wish all the participants a highly fruitful and enriching conference experience.

Dr. Vidyashankar S.
Vice Chancellor

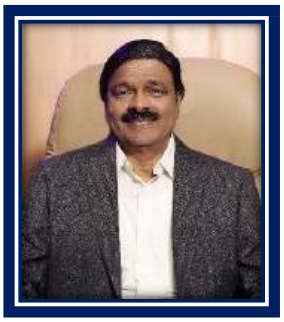
MESSAGE

It is a matter of great pleasure to know that **Dr. ACS College of Engineering, Bengaluru** is organizing the International Conference on Advances in Computing Systems Communication and Networking (ACSCON-2026). I extend my heartfelt greetings and best wishes to the Management, Principal, faculty members, researchers, and students associated with this prestigious international conference.

The field of Computing Systems, Communication, and Networking is continuously evolving and playing a vital role in shaping the modern technological world. Conferences such as ACSCON-2026 provide an excellent platform for academicians, researchers, industry experts, and students from across the globe to exchange innovative ideas, present research findings, and discuss emerging trends and challenges in these dynamic domains.

I appreciate the efforts of the organizers in bringing together intellectuals and professionals to foster knowledge sharing, collaborative research, and academic excellence. Such initiatives significantly contribute towards strengthening research culture and enhancing the quality of technical education.

I am confident that ACSCON-2026 will be highly beneficial to all the participants and will pave the way for meaningful discussions, innovations, and future collaborations. I wish the conference a grand success and hope it achieves its objectives in promoting scientific and technological advancement.



With best wishes.

22/05/26

REGISTRAR (EVALUATION)

To,
The Principal
Dr. ACS College of Engineering,
#207, Kambipura, Mysore Road,

International Conference on
Advances in Computing Systems Communication and Networking (ACSCON-2026)

Founder Chairman's Message for ACSCON – 2026

It gives me immense pleasure to extend my warm greetings to all the delegates, researchers, academicians, industry experts, and students participating in the International Conference on Advanced Computing Systems, Communication and Networking.

In today's rapidly evolving technological landscape, innovations in computing systems, communication technologies, and intelligent networking are transforming the way we live, learn, and connect with the world. Conferences such as this serve as an important platform for the exchange of ideas, collaborative research, and meaningful discussions that contribute to scientific advancement and societal progress.

I am delighted to note that this conference brings together distinguished scholars and professionals from diverse domains to share their knowledge, research findings, and innovative perspectives. Such interactions inspire young minds, encourage interdisciplinary collaboration, and pave the way for groundbreaking solutions to contemporary global challenges.

I sincerely appreciate the efforts of the organizing committee, faculty members, researchers, sponsors, and volunteers for their dedication and commitment in making this international conference a grand success. I also congratulate all the authors and presenters for their valuable contributions.

I am confident that the deliberations and technical sessions during this conference will enrich academic excellence, strengthen industry-academia collaboration, and open new avenues for future research and innovation.

I wish the conference great success and all the participants a rewarding and intellectually stimulating experience.

With best wishes,

Dr. AC Shanmugam
Founder Chairman

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

President's Message for ACSCON – 2026

It is a matter of great pride and privilege to welcome all the distinguished delegates, researchers, academicians, industry professionals, and students to the International Conference on Advanced Computing Systems, Communication and Networking.

From artificial intelligence and cloud computing to next-generation wireless communication and intelligent networking, technology continues to redefine the boundaries of innovation and human progress.

These emerging technologies are shaping the future of industries, education, healthcare, governance, and society at large. In this context, international conferences play a vital role in fostering innovation, research collaboration, and the exchange of transformative ideas.

May this gathering inspire innovation, strengthen global partnerships, and contribute significantly to technological advancement and societal development.

I wish the conference every success and all participants a productive and memorable experience.

With warm regards,

Mr. ACS Arun Kumar
President

International Conference on
Advances in Computing Systems Communication and Networking (ACSCON-2026)

Executive Director's Message for ACSCON -2026

Advanced computing systems today are enabling faster data processing, smarter automation, enhanced cybersecurity, and efficient decision-making across industries. Simultaneously, developments in communication technologies such as 5G, IoT, and satellite communication are creating a highly connected global ecosystem that facilitates seamless interaction, collaboration, and information exchange.

Networking technologies have also evolved significantly with the integration of intelligent systems, software-defined networking, edge computing, and secure digital infrastructures. These innovations are playing a crucial role in supporting smart cities, digital healthcare, online education, industrial automation, and sustainable development initiatives worldwide.

In this rapidly transforming technological era, research and academic collaboration are essential to address emerging challenges and explore future possibilities. International conferences and scholarly platforms provide valuable opportunities for researchers, academicians, industry experts, and students to exchange ideas, share innovations, and contribute to the advancement of science and technology. It is a matter of great pride that we at ACS College of Engineering are hosting an International conference bringing together great minds for intellectual collaborations encouraging interdisciplinary research, ethical technological development, and global cooperation to ensure that technological advancements continue to benefit humanity.

I whole heartedly congratulate the organizing committee and al the people involved in hosting this conference. The credit for the success of this conference certainly goes to the entire team of ACSCE. Let us work together to foster innovation, strengthen knowledge-sharing, and build a smarter, more connected, and technologically empowered world. We tried to be good host and I hope we have succeeded in our endeavour.

Dr. S. Vijayanand
Executive Director, RRGI

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Chief Executive Officer's Message for ACSCON -2026

It gives me immense pleasure to be a part of this hosting team of the first "International Conference on Advances in Computing, Systems, Communication and Networking ACSCON – 2026". The Conference intends to bring together research scholars, post graduate and under graduate students from different disciplines to discuss about the research progression in the current trends of various engineering disciplines.

I take this opportunity to welcome all the delegates to the Conference. On behalf of whole ACSCON – 2026 team, I would like to thank all the authors, sponsors and keynote speakers for their support and co-operation. The rapid development in technologies and changes in lifestyle impose various issues in many countries.

The Conference ACSCON – 2026 has been crafted to challenge the hurdles and we are fortunate to have leading speakers to share their experience and perspectives to achieve smart solutions through their innovation.

I hope that the Conference serves as a forum for interdisciplinary, a space for discourse and collaboration. I would like to express my appreciation to the organizing committee for their dedicated efforts to materialize the conference. I hope all the participants will have a fruitful and beneficial experience.

Shri. C N Seetharam IAS (Rtd.)
CEO, RRGI, Bengaluru

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Special Officer's Message for ACSCON -2026

The primary objective of ACSCON – 2026 is to foster the sharing and enhancement of knowledge among researchers in this rapidly evolving information era. We have created a valuable opportunity for those eager to learn about the latest technological developments and to exchange their own ideas. Furthermore, the conference will enable attendees to present and discuss a wide range of novel concepts.

The conference aims to connect researchers in academia with other professionals through research presentations and keynote addresses focused on current technological trends. I would like to extend my best wishes to the conference organizing committee for dedicating their valuable time in organizing this event. My sincere appreciation to all the authors, reviewers, and other stake holders for their outstanding contributions to make ACSCON 2026 a great success.

Dr. S Jeyabalan
Special Officer, RRGI, Bengaluru

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Rector's Message for ACSCON -2026

It gives me immense pleasure to note that Dr. ACS College of Engineering, Bengaluru is organizing International Conference on Advances in Computing Systems, Communication and Networking (ACSCON-2026) on 29th and 30th May 2026. Organizing such a prestigious conference will take this institute to greater heights in research and academics. ACSCON-2026 is designed to provide an excellent platform to the research scholars, academicians, industry experts and students to spread knowledge on scientific research in Interdisciplinary areas. This would generate discussion on practical challenges and suggest solutions, thus consolidating the recent innovation. To such a futuristic and brave effort, I sincerely extend my best wishes. I would like to express my heartfelt thanks to all those who are involved in making this conference a huge success.

Warm Regards

Dr. A.K.Mariappan
Rector, RRGI, Bengaluru

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Registrar's Message for ACSCON -2026

The first "International Conference on Advances in Computing, Systems, Communication and Networking **ACSCON – 2026"** has attracted high-quality research papers from authors worldwide. Research papers in the areas of Intelligent Computing and Systems, Advanced Communication and Networking, Security in a hyper connected world and domain specific applications like Smart Cities and IoT, Aerospace and Aeronautics, Healthcare and Biomedical Engineering, Automotive and Mechanical Systems will be presented. This Conference will serve as a platform for fostering interaction and exchange of ideas related to the theme of the Conference.

ACSCON 2026 is fortunate enough to induce a high level of interest among the research community, wherein 472 paper submissions from researchers across the globe was possible within the deadline. The superior quality research manuscripts submitted by authors, justifies quality of the Conference which has demanded strict evaluation process, meeting similarity index less than 20% and double-blind reviews for all the papers.

Papers accepted and presented in ACSCON 2026 will be published in IJERT Journal as Conference Proceedings. A few high-quality research Papers presented in the Conference will be recommended for publication in Scopus Indexed Journal as decided by the organizing committee.

Warm Regards

Dr. S. Meenakshi Sundaram
Program Chair, ACSCON 2026
Registrar, RRGI

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Principal's Message for ACSCON -2026

It gives me immense pleasure to present the Proceedings of ACSCON 2026 – International Conference, organized by Dr ACS College of Engineering on 29th and 30th May 2026.

The conference has brought together eminent academicians, researchers, industry professionals, and young scholars from diverse domains to share their innovative ideas, research findings, and technological advancements. The overwhelming response and enthusiastic participation reflect the growing importance of collaborative research and knowledge exchange in addressing global challenges.

The papers included in these proceedings represent significant contributions in emerging areas of science, engineering, technology, and interdisciplinary research. I am confident that this compilation will serve as a valuable reference for researchers, academicians, and students, inspiring further innovation and scholarly pursuits.

I congratulate all the authors whose quality research work has been selected for presentation and publication. I also appreciate the efforts of the organizing committee, reviewers, session chairs, faculty members, and student volunteers for their dedication and commitment in making ACSCON 2026 a grand success.

I sincerely thank all the participants, sponsors, and collaborators for their support and contribution towards the successful conduct of this international conference.
I wish the readers of these proceedings meaningful learning and continued success in their research endeavors.

Warm Regards

Dr. B.S.Shylaja,
Principal, Dr.ACSCE, Bengaluru

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Program Chair Message for ACSCON -2026

We feel elated to organize the first **"**International Conference on Advances in Computing, Systems, Communication and Networking ACSCON – 2026**"** on 28th & 29th May 2026 at Dr. ACS College of Engineering, Bengaluru.

The Conference is targeted towards researchers, practitioners, professionals, educators and students to share their experience, innovative ideas, issues, recent trends and future directions in field of Engineering and Science and Technology.

This Conference is a unique forum for exchange of innovative ideas, technical expertise for technological advancements etc. in this evergreen field. It includes keynote address from Academicians and paper presentation by research scholars. It is a matter of joy for us to welcome the participants to this Conference.

In a nutshell, the Conference promises to transcend to a new and unprecedented level of excellence. It is thus the zenith where technology and skill meet opportunities and guidance. I would like to express my appreciation to the organizing committee for their dedicated efforts to materialize the conference. I hope all the participants will have a fruitful and beneficial experience.

Warm Regards

Dr. S. Usha
Program Chair, ACSCON - 2026
Professor, RRGI

International Conference on

Advances in Computing Systems Communication and Networking (ACSCON-2026)

Organizing Chair Message for ACSCON -2026

As the Organizing Chair, I extend my heartfelt congratulations to Dr. ACS College of Engineering, Bengaluru, for successfully organizing the **International Conference on Advances in Computing Systems, Communication and Networking (ACSCON - 2026)** held on 29 & 30 May, 2026. This conference has created an excellent platform for researchers, academicians, industry experts, and students to share innovative ideas and research contributions.

I sincerely appreciate the dedication and hard work of the organizing committee, faculty members, volunteers, and participants for making ACSCON - 2026 a grand success.

Warm Regards

Dr. P. Bhuvaneswari
Organizing Chair
ACSCON-2026

International Conference on
Advances in Computing Systems Communication and Networking (ACSCON-2026)

Organizing Chair Message for ACSCON -2026

Dear Researchers, Academicians, and Industry Professional,

It is our great pleasure and honor to welcome you to the International Conference on Advances in Computing Systems, Communication and Networking (ACSCON-2026), hosted by ACS College of Engineering, Bengaluru.

In an era where digital transformation is no longer a choice but a necessity, the convergence of computing, communication, and systems engineering has become the bedrock of global innovation. ACSCON-2026 was conceived as a premier multidisciplinary forum to address this very synergy. Our goal is to bring together the brightest minds from diverse engineering disciplines—ranging from Aerospace, Aeronautical, Biomedical, AI &ML, CSE & CSE related branches to Electronics & Communication engineering—to discuss how interconnected systems will define our future.

The 2026 edition features a robust technical program focusing on "The 6G Vision," "Zero-Trust Architectures," and "AI-Driven System Optimization." “Health care”

Beyond the technical sessions, this conference is a platform for networking and collaboration. We have invited a distinguished International Advisory Committee from world-renowned institutions such as the University of California, NTU Singapore, and IIT Ropar to ensure that the discourse remains at the highest global standard.

We invite you to share your original research, engage in thought-provoking discussions, and contribute to the collective knowledge that will shape the next generation of technological solutions. My heartfelt thanks to management advisory committee, reviewers, sponsors, and volunteers for their dedication. We look forward to welcoming you to our lush green campus in Bengaluru on May 29th and 30th, 2026, for two days of intellectual growth and innovation.

Warm Regards,

Dr. S M Vijaya
Professor& Head,
Organizing Chair, ACSCON-2026

International Conference on
Advances in Computing Systems Communication and Networking (ACSCON-2026)

Organizing Secretaries

1. Dr. B.B.S.Kumar Assoc. Professor, Data Science, ACSCE
2. Dr. S Sivasundarapandian Professor, CSE, ACSCE

Editorial committee

1. Dr S Sivasundarapandian, Department of Computer Science and Engineering (CSE)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

2. Dr. B S S Kumar, Department of Data Science (CSE-DS)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

3. Dr. Divya S, Department of Computer Science and Engineering(CSE)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

4. Dr. Athulya M S, Department of Cyber Security(CSE-CY)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

5. Dr. V. G. Hariharasudan, Department of Biomedical Engineering(BME)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

6. Dr. N Durga Indira, Department of Electronics and Communication Engineering (ECE)
   Dr. ACS College of Engineering Bangalore, Karnataka, India.

Table of Contents

Vol. 14, Issue 06, ACSCON - 2026

#	Paper ID	Paper Title / Authors	Start Pg	End Pg
1	IJERTCONV14IS060001	**MedCyBot: Integrating Autonomous Multifunctional Robot for Enhanced Healthcare Communication** *Dr. P. Bhuvaneswari, Mrs. Kavya N., Linda Sunil, Himabindu K.*	1	5
2	IJERTCONV14IS060002	**Early ASD Insight -Autism Spectrum Disorders** *Samir Kumar, Srinivas Reddy, Sujal Narayan, Utkarsh Singh, Santhosh M*	6	12
3	IJERTCONV14IS060003	**Smart Agriculture using AI - An Integrated approach for Soil analysis, Irrigation, Crop-fertilizer recommendations, and Market price analysis** *Dr. N Durga Indira, Manisha R, Nandini KR, Poorvika MC, Priyanka Shankrappa Sankanagowda*	13	21
4	IJERTCONV14IS060004	**Integrated E-learning Platform: Merging Ai-driven Learning With Campus Academic Managemnet** *Mrs. Lakshmi G, Ansh Jamwal, Abdul Aleem, Anant Raj, Mohammad Salman Allai*	22	26
5	IJERTCONV14IS060005	**AgriBot AI: Multilingual Tomato Disease Detection and Voice Advisory System with Chatbot** *Harshith D. N, Ramesh Marathi, Nethravati T.L*	27	32
6	IJERTCONV14IS060006	**Rubikâ€™s Encryption and CNN Based Biometric Authentication** *Mrs. Divya P, Ms. Lisha V, Mr. Kiran M, Mr. Mayur S, Ms. Priyanka S*	33	38
7	IJERTCONV14IS060007	**Smart Food Recognition & Personalized Diet Planner (Nutritrack)** *Mrs. Divya P, Srinath M, Rangaswamy C, Siddeshwar Reddy, Venkatesh BL*	39	42
8	IJERTCONV14IS060008	**Secure Messaging Application using Post Quantum Cryptography** *Mr. Panchaxari Mamadapur, Ranjitha T, Shravani Ranganath, Sahana.C.Kirdi*	43	48
9	IJERTCONV14IS060009	**Federated Learning for Electric Vehicle Routing and Charging Station Location** *K P Suprith Patil, Prof. Anu D, Siddarth T, S Tejaswi Naidu, Pavan saiteja, Phalani Kumar*	49	53
10	IJERTCONV14IS060010	**Intelligent Traffic Management for Congestion Control using YOLO Algorithmhm** *Mrs.Susmitha BC, Nithin Nicholas, Tejas J, Tejashwini B, Ujwal Gowda V*	54	58
11	IJERTCONV14IS060011	**A Data-Driven Framework for Detecting and Tracking Health Misinformation Trends** *Mr. P. Kaliyamoorthi, Singappagari Dedeepya, Dharmavaram Babitha, Malaka Amrutha, Kotareti Amrutha*	59	66
12	IJERTCONV14IS060012	**Deep Learning Based Deepfake Detection in Multimedia Content** *Dr Divya S, Keerthana B L, Likitha V, M S Sukanya, Punyashree K B*	67	72
13	IJERTCONV14IS060013	**Advanced Interpreter Code Editor** *Mr. Nandha Gopal S M, Mr. Manoj S M, Mr. Manoj G, Mr. Mohan P, Mr. Mourya S*	73	76
14	IJERTCONV14IS060014	**Solar Powered Electric Vehicle With A Battery Swapping System** *Prof. Chaithanya S, Balaji T, Harsha G N, K Kiran N Swamy, Ajay K N*	77	83

#	Paper ID	Paper Title / Authors	Start Pg	End Pg
15	IJERTCONV14IS060015	**AI - Integrated Student Growth and Placement Enhancement System** *Ms. Rajitha P, Vignesh K L, Vikas Gowda N, Vinaykumar D, Suhas A S*	84	87
16	IJERTCONV14IS060016	**Secured Banking System using Blockchain Technology** *Mr. Muhammad Owais A, Pavithra M, Meghana S, Musaib Fayaz Bhat*	88	92
17	IJERTCONV14IS060017	**AI and ML Application in Healthcare Sector** *Mr. Panchaxari M, Kruthika G, Kushi R, Manohari N, Nishtha Singh*	93	96
18	IJERTCONV14IS060018	**Detection of Diabetic Retinopathy using Machine Learning** *Mrs M G Varalakshmi, K Span dana, Keerthana G K, M onika*	97	101
19	IJERTCONV14IS060019	**Machine Learning Based System For Early Plant Disease Detection** *Mrs. Shruthi BL, Kishore Kumar DC, Lisha JM, Nisarga BR, Rahul S*	102	105
20	IJERTCONV14IS060020	**House Price Prediction Using Machine Learning (CATBOOST)** *Mr. Nitin M, Manasa P R, Pruthvi, K Sneha, Kaveri H S*	106	109
21	IJERTCONV14IS060021	**FireStation 360: Integrated IOT Emergency Management System** *Vignesh A, Mithun S, Dr. G. Padmapriya*	110	118
22	IJERTCONV14IS060022	**AI Powered Real-Time Crime Activity Detection using Deep Learning** *Jyothi, Medha R, Sannidhi, Shreya Shetty*	119	123
23	IJERTCONV14IS060023	**Blockchain - Zakatchain Decentralizedand Transparent Charity System** *Guide, Vishwas Rao BR, Yashin Patel, M.s Varalakshm M.G*	124	129
24	IJERTCONV14IS060024	**Autonomous Gas Detection Robot for Industrial Environment and Disaster Response** *Mr. Praveen A Patil Assistant Professor Department of Electronics and Communication ACS College of Engineering Bangalore India, Parikanksha V, Yashas N Naik, Pallavi S, Vidyashree S Badigere*	130	134
25	IJERTCONV14IS060025	**Biometric Enabled Merchant Payment System** *Ms. Rajitha P, Ajai Aarumugum M, Ashwin S, Dhanush S, K Balaji*	135	139
26	IJERTCONV14IS060026	**Stock Price Prediction using Machine Learning** *Dr. T. Senthil Kumaran, Chethan V, Abhishek K, Amith K R, Abhishek Biradar*	140	144
27	IJERTCONV14IS060027	**A Hybrid Approach for the Disaster Prediction using ML and IoT** *Ms. Archana N G, Ashwini S Sunkad, Archana M, Bindhu J M*	145	148
28	IJERTCONV14IS060028	**Government Tender Allocation using Blockchain Technology** *Ms. Vishaka Rani C, Keerthana R, Kishan R, Sushmitha M*	149	154
29	IJERTCONV14IS060029	**Blood Group Detection With Fingerprint Using Machine Learning** *Ms. Tanushree K S, Ms. Spandana N S, Ms. Ranjitha H N, Ms. V K Savitha, Dr. Sumitha Manoj*	155	158
30	IJERTCONV14IS060030	**IoT based Manhole Monitoring System** *Ms. Deepa Srinivasa, Vijayalaxmi R, Mala Gouda, Sindhu Naik*	159	164
31	IJERTCONV14IS060031	**Money Transaction Security using Blockchain** *Ms. Ranjita p, Keerthan Kumar BM, Kiran Takkodi, Mahesh Vatti, Manoj K*	165	168
32	IJERTCONV14IS060032	**Smart Contract Based Property Registration and Time-Stamping Platform on Ethereum Blockchain** *Ms.Deepa Srinivasa, Niteenkumar, Manoj Kumar S, Prashanth G, Prashantha Fakeera Madivala*	169	172
33	IJERTCONV14IS060033	**ACS Store: AI Driven Full-Stack Multi-Vendor E-Commerce Platform** *Sri Vishnu Y S, Kayalvizhi S, Tanush C N, Sathish Gowda H P, Raghu V*	173	177

#	Paper ID	Paper Title / Authors	Start Pg	End Pg
34	IJERTCONV14IS060034	**Credit Card Fraud Detection** *Sachin Acharya, Muhammad Owais A, Assistant Professor, R Ram, Rajasekar G, Raghavendra Biradar*	178	183
35	IJERTCONV14IS060035	**Electronic Health Record using Blockchain** *Mrs.. Lakshmi G, Mr. Karthik KP, Mr. Mohammad Sinan MK*	184	187
36	IJERTCONV14IS060036	**Fake Product Detection** *Mrs. Lakshmi Priya P Assistant, Ganesh Prasad S Tavarer, Chandra Chooda S, Harshith KT, Chetan A M*	188	191
37	IJERTCONV14IS060037	**Detection of Parkinsonâ€™s Disease Using Convolutional Neural Networks** *Dr. Nandha Gopal S M, Ankitha K D, Bhumika K P, Chaithanya K, Deepika Lakshmi S*	192	195
38	IJERTCONV14IS060038	**Smart Glove With Augmented Sensory Feedback** *Abhishek K, Akash M R*	196	201
39	IJERTCONV14IS060039	**Lip-to-speech Recognition using Deep Learning** *Mr. Venkatesh Kumar M, Nisha P, Puneeth V, Monish Gowda M, Muhammed Nabeel Musthafa*	202	205
40	IJERTCONV14IS060040	**A Compact 27 GHz Microstrip Patch Antenna for 5G Millimeter wave Communication** *R.Abisha, P.Aarthi, Dr.D.Helena Margaret*	206	210
41	IJERTCONV14IS060041	**Compact Microstrip Antenna Design at 120 GHz for Sub Terahertz 6G Applications** *P.Aarthi, R.Abisha, Dr.D.Helena Margaret, Dr.P. Bhuvaneswari, Dr. Shanthi P*	211	215
42	IJERTCONV14IS060042	**Real-Time Breathing Pattern Tracking Using a Multimodal Wearable System** *Ms Tabassum, Mrs Nagashree Pavan, Mrs Manju Davy*	216	220
43	IJERTCONV14IS060043	**Neuro Vision 3D: Brain Tumor Segmentation and 3D Visualization Using U-Net** *Prajwal L, Pourshi V Rai, Shreya Shenoy, Nandeesha S*	221	226
44	IJERTCONV14IS060044	**Design and Verification of Single-Master and Single-Slave AXI System using System Verilog** *Tiksha Singh, Praful Babu T, Ashvin Tiwari, AVM Manikandan*	227	235
45	IJERTCONV14IS060045	**A novel approach for Secure IoT Architecture Using Deep Learning-Based Image Steganography and Multi-Factor Authentication-A Review** *Sharath Babu CG, Dr. Komala K*	236	245
46	IJERTCONV14IS060046	**Evaluating Socio-Economic and Geopolitical Events Impact on UK Electricity Demand using Explainable AI** *Oluwakemisola Christiana Adewole, Olayinka Anthony Ojo, John Olalere Ogunlola, Opeyemi Victor Omolade MRes, Mariam Omolola Oparinde, Bisola Kafayat Oyebamiji*	246	252
47	IJERTCONV14IS060047	**Mechanical Behaviour and Structural Evaluation of Carbon Fiberâ€“Pineapple Leaf Fiber Reinforced Hybrid Bio-Composites for Aircraft Applications** *Amar Gandge Subash, Ramanan G, Ganesh R, Albert Allen D Mello, Dharmadurai.P, Jegatheesh kumar.S, Vishnuraj R*	253	264
48	IJERTCONV14IS060048	**Autonomous Cyber Threat Forecasting with Threat Mutation Analysis** *Suchi Arora, Anish Sabale, Sujal Mhatre, Metilda Florence S*	265	269

***Abstract*—MedCyBot is a prototype healthcare assistive robot developed to support basic communication and routine assistance tasks in clinical settings. The prototype combines speech-to-text, text-to-speech, multidirectional movement, and a SCARA-based handling unit in one platform. Mecanum wheels were used in the base to improve mobility, while the upper section supported voice interaction, display output, and small-item handling. In the final prototype, an Arduino Uno was used to test both the base and upper-section functions. The work focused on showing how communication support and simple physical assistance could be brought together in a low-cost prototype. This paper presents the motivation, methodology, implementation, results, and limitations of the system.**

***Index Terms*—Assistive healthcare robot, Arduino Uno, mecanum wheels, SCARA, speech-to-text, text-to-speech.**

I. Introduction

Assistive robotics is gaining increasing relevance in healthcare because it can support communication, reduce repetitive workload, and improve the handling of routine tasks in hospitals and care centres. As shown in Fig. 1, the healthcare assistive robot market increased from $410.6 million in 2021 to $514.3 million in 2022. This growth reflects the need for systems that can improve efficiency and accessibility in healthcare environments.

In many healthcare settings, communication barriers, limited accessibility, navigation difficulties, and delays in handling medicines or supplies can affect the quality of care. These challenges become more noticeable in environments where healthcare staff must manage both patient interaction and repeated support tasks.

To address this, we developed MedCyBot as a prototype assistive healthcare robot that combines communication support and physical task support in a single system. The main functions demonstrated in the prototype were speech-to-text, text-to-speech, multidirectional movement, app-based control, and SCARA-based handling. The broader design also considered future expansion toward language translation and autonomous navigation. This paper presents the motivation, literature background, problem statement, methodology, prototype implementation, results, and limitations of MedCyBot.

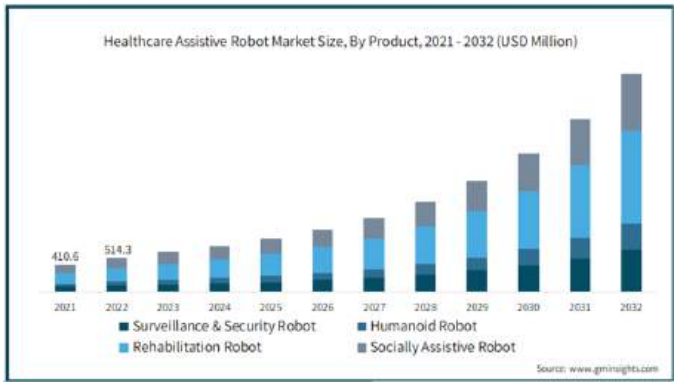

Fig. 1. Healthcare assistive robot market size figure included in the project report.

II. Literature Survey

Recent work in assistive robotics has focused on communication support, autonomous navigation, translation, and lightweight manipulation. Dhanjal and Singh developed a multilingual speech-to-Indian-sign-language system and reported recognition accuracies of 91%, 89%, and 89% for English, Punjabi, and Hindi, respectively [1]. Other studies on speech recognition and speech synthesis for assistive applications have shown that voice-based systems can improve accessibility and help users with disabilities interact more easily with digital platforms [2], [3], [19]–[21].

Language translation has also been explored as a way to reduce communication barriers. Earlier studies have described translator applications and neural machine translation methods that support multilingual interaction [14]–[16]. This is particularly relevant in healthcare, where even simple instructions and

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

responses may be affected by differences in language between patients and caregivers.

Speech-based systems have also been studied for medical documentation and workflow support. Sushmita Kulkarni, Dattaprasad A. Torse, and Deepak Kulkarni presented a cloud-based transcription system that converted spoken input into text for medical records [4]. In addition, models such as Listen, Attend and Spell showed that end-to-end speech transcription can be improved using neural-network-based learning [5]. Together, these studies highlight the importance of speech-processing modules in assistive healthcare systems.

Navigation and mobility form another important part of the related work. SLAM-based approaches have been used for mapping, localization, and path planning in autonomous robots [6]–[10]. For handling tasks, SCARA-based systems are useful because they provide a relatively simple structure for pick-and-place operations and can be developed economically for controlled motion [11]–[13]. In healthcare robotics, Shubha and Meenakshi presented an assistive robot for medicine delivery to bedridden patients, while Pawan Kadam, Pratik Padalkar, Aniket Mohite, Shantanu Mirajgave, and Santwana Gudadhe discussed a medical assistance robot using ROS for multi-purpose applications [17], [18].

Overall, the literature shows that many existing systems focus on one main function, such as speech interaction, translation, navigation, or item transport. MedCyBot was developed as a student prototype to bring several of these functions together within a single assistive platform.

III. Problem Statement and Objectives

Healthcare environments continue to face practical challenges that can affect patient care. These include communication barriers, limited accessibility, difficulty in handling medicines and supplies, and the need to move efficiently through complex spaces. Language differences between patients and caregivers can reduce the clarity of interaction, while inefficient transport of routine items can increase workload and delay simple tasks.

The main objective of MedCyBot was to develop a prototype assistive healthcare robot that could address these challenges through an integrated design. The project aimed to support speech-to-text and text-to-speech interaction, enable multidirectional movement using mecanum wheels, and include a SCARA-based section for handling small items such as medicines or supplies.

A second objective was to combine these functions in a form suitable for prototype-level demonstration. Instead of focusing only on communication or only on mobility, the project explored how voice interaction, movement control, and basic handling could work together within one assistive robotic platform.

IV. Methodology

The methodology followed in this project was divided into three main stages: acquisition, training, and testing. The overall workflow used in the project is shown in Fig. 2. In the acquisition stage, the required hardware and software elements for movement, communication, and handling were assembled into the prototype. In the training stage, the speech-processing tools were prepared for the intended application. In the testing stage, the integrated functions of the system were evaluated at prototype level.

Fig. 2. Overall methodology followed in the MedCyBot project.

A. MedCyBot Base

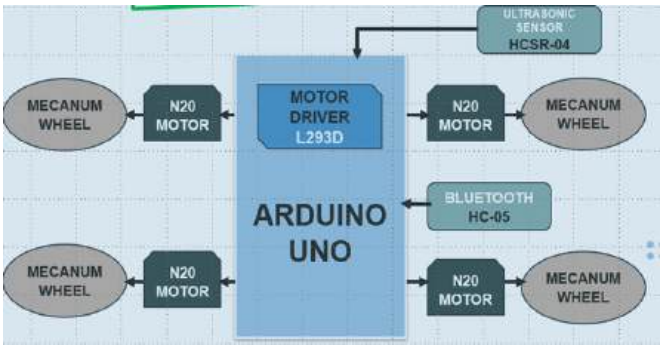
The base of MedCyBot was designed for omnidirectional movement. It used four mecanum wheels driven by four N20 geared motors. An Arduino Uno was used to control the base, while a motor driver managed communication between the controller and the motors. Wireless control was provided through an HC-05 Bluetooth module. The broader design also considered SLAM-based navigation and obstacle avoidance as part of the overall system direction.

The mecanum wheels allowed the robot to move in multiple directions rather than relying only on conventional forward turning. This was useful in hospital-like environments, where the robot may need to pass through tight spaces and move around obstacles during routine assistance tasks.

B. Upper Section and Training Flow

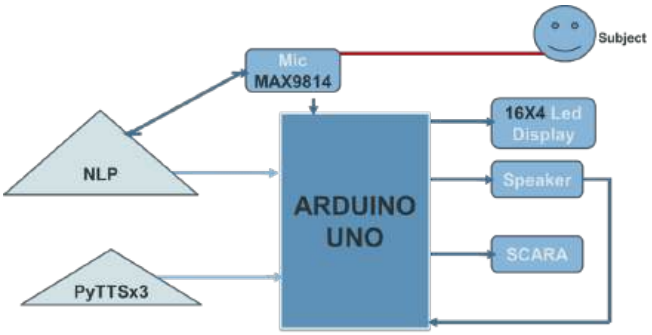
The upper section integrated the communication and handling modules of the robot. It included a MAX9814 microphone module, speaker, a 16×4 display, and a SCARA-based handling mechanism. Speech-to-text was implemented using CMUSphinx, while text-to-speech was implemented using pyttsx3.

In the final prototype, an Arduino Uno was used to test both the base and upper-section functions. Although an ESP32 was considered during the design stage, it was not used in the final prototype implementation.



The training stage focused on preparing the speech-processing tools for the intended application. CMUSphinx was associated with Sphinxtrain, and the workflow involved dataset preparation for speech-related processing. The broader project work also used tools such as Jupyter Notebook and Arduino IDE for coding, testing, and system integration during development. The base-level and upper-section arrangements used in the prototype are shown in Fig. 3.

V. Implementation Overview



The implementation of MedCyBot was organised around three main functions: communication, movement, and handling. The communication block included voice capture through the microphone, conversion of speech into text, display of the recognised output, and spoken output through a speaker. The movement block involved Bluetooth-based control of the mecanum-wheel base through a mobile application.

Vol. 14, Issue 06, ACSCON - 2026

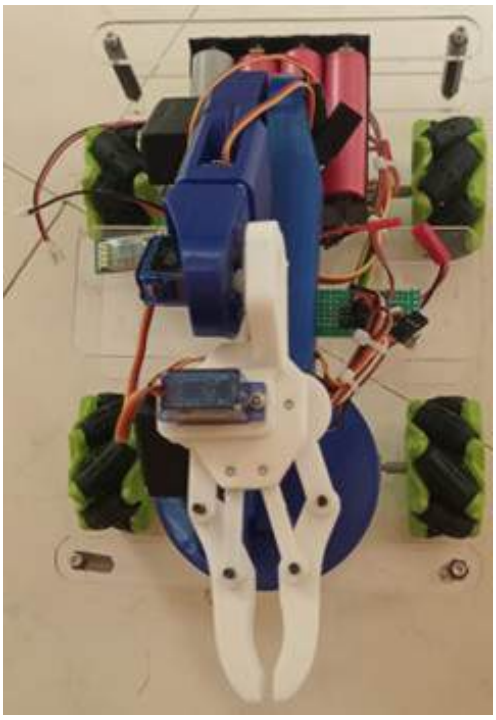
(a) Base level arrangement used for MedCyBot.

(b) Functional arrangement of the upper section.

Fig. 3. System-level diagrams included in the project documents.

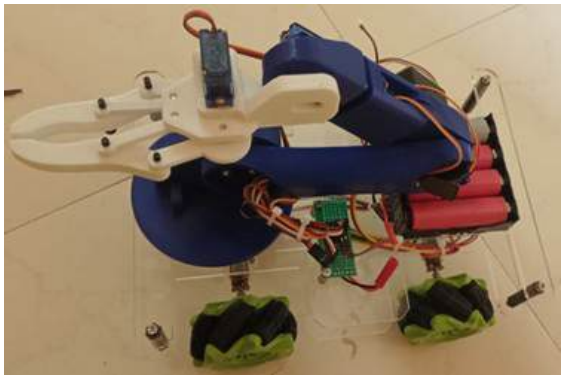
The handling block used a SCARA-based arrangement for the transport of small items.

The robot was developed as a modular structure, with the lower section responsible for locomotion and the upper section responsible for interaction and handling. This made the prototype easier to build and test, while still allowing the different subsystems to work together as part of one integrated platform.



A. Software Environment

The software environment included Arduino IDE for programming and uploading code to the controller, and Jupyter Notebook for development, output review, and testing. These tools supported the integration of the communication functions with the physical hardware used in the prototype.



VI. Results and Discussion

The prototype-level results showed that MedCyBot was able to bring together communication, movement, and handling functions within a single platform. Speech-to-text was implemented so that spoken input could be converted into text, and text-to-speech was used to provide audio output from the system. These features supported basic user interaction through voice and display. The physical prototype is shown in Fig. 4.

The mecanum-wheel base, together with app-based control, allowed the robot to move with multidirectional capability. This improved manoeuvrability and supported movement in confined spaces. The SCARA-based section was used as the handling component of the prototype and represented the system's task-support function.

(a) Top view of the MedCyBot prototype.

(b) Side view of the MedCyBot prototype.

Fig. 4. Prototype views included in the project report.

The project was also supported by controller application screens, code windows, circuit-level views, and prototype photographs. These elements show that the work involved more than mechanical assembly alone; it also included embedded control, interface-level testing, and software integration. The controller applications used during testing are shown in Fig. 5.

The present results are qualitative rather than fully numerical. The main outcome of the work was successful subsystem integration: voice input, voice output, movement control, and handling were demonstrated as parts of one prototype. Detailed numerical evaluation of recognition accuracy, navigation error, transport repeatability, or response time was not included in the project materials. For this reason, MedCyBot is best presented as a proof-of-concept prototype rather than a fully validated

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

clinical system.

(a) Robot base controller application.

(b) SCARA controller application.

Fig. 5. Application and software images used during implementation and testing.

VII. Limitations

The current work has several limitations. First, the prototype was evaluated mainly at a qualitative level, and the project did not include a detailed numerical study of system performance. Second, some ideas discussed during the broader design stage, such as autonomous navigation and translation support, were not fully validated on the final prototype.

Another limitation is that the final prototype used a simplified controller setup, with an Arduino Uno used to test both the base and upper-section functions. This was suitable for prototype development, but a more advanced version of the system may require a more distributed architecture and more detailed system-level testing.

These limitations do not reduce the value of the project as a student engineering prototype, but they do define the scope of the present paper. The main contribution of this work is the integration of multiple assistive functions into one prototype platform.

VIII. Conclusion

MedCyBot was developed as a prototype healthcare assistive robot that combines communication support and basic task assistance in a single platform. The system brought together speech-to-text, text-to-speech, multidirectional motion, and a SCARA-based handling mechanism. This combination makes the prototype relevant to healthcare environments where communication support and routine item handling are both important.

The main contribution of the work lies in showing that these functions can be integrated into one low-cost assistive platform. Although the prototype was not evaluated as a fully validated clinical system, it provides a useful proof of concept for future work in healthcare robotics.

IX. Future Scope

Future work may extend MedCyBot in several directions. These include stronger language-translation support, more advanced navigation and obstacle-avoidance capability, sanitation-related features, air-quality sensing, and broader monitoring functions. With further development and testing, the present prototype could be expanded into a more capable assistive system for healthcare environments.

Abstract - Early identification of Autism Spectrum Disorder (ASD) in children is essential for timely intervention and improved developmental outcomes. The worldwide increase in autism cases has created a demand for accurate diagnostic tools that can be used by all people. The researchers of this study use facial image datasets to predict Autism Spectrum Disorder (ASD) in its initial stages. The main of this study is to explore whether distinctive facial patterns and expressions can serve as potential indicators of ASD. Researchers use advanced image processing techniques to extract facial image features which they use to develop machine learning systems that predict autism, autism risk through classification. The study tests the hypothesis that certain facial characteristics may be associated with early signs of ASD and can be detected using automated computational models. The research process includes three main steps which involve acquiring a complete set of children's images, performing systematic image processing to enhance image quality and extract essential features, and using advanced deep learning frameworks for classification. The research uses computer vision combined with machine learning methods to create tools that enable non- invasive autism screening which operates efficiently and is easy to use.

I. INTRODUCTION

Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition which involves various problems with behavior and communication and social interaction. The process of diagnosing ASD presents difficulties because different people show different symptoms which can also be found in other developmental disorders. The combination of these two factors creates difficulties for the process of finding and diagnosing conditions at an early stage. The traditional diagnostic approach depends on clinicians who observe patient behavior and assess their condition through clinical assessments which lose objectivity when applied to different environments. The research study aims to develop existing diagnostic systems through it's study of facial feature assessment which will help detect autism spectrum disorder. (ASD). Human facial features convey a wealth of subtle information which includes expressions and structural characteristics that may reflect underlying neuro developmental patterns.

Machine learning research has progressed through the advancement of convolutional neural networks (CNNs) which now enable researchers to study complex visual data and discover hidden patterns that escape human assessment.

The research method uses deep learning methods to analyze facial images which the system uses to identify possible indicators of autism spectrum disorder. The system uses multi- task learning methods to enhance its ability to generalize and adapt which allows the system to understand various ways that autism spectrum disorder presents itself through different people. The method improvement enhances the predictive model strength through development of more powerful prediction capabilities. This research brings important societal benefits which extend beyond its technical achievements. The ability to detect autism spectrum disorder through reliable methods enables healthcare professionals to provide immediate treatment which leads to better developmental progress.

II. RELATED WORK

The authors of [1] proposed a deep learning-based web- based system which helps families and psychiatrists to diagnose Autism Spectrum Disorder (ASD) through facial image analysis. The system used convolutional neural networks (CNNs) which implemented transfer learning using the Flask framework. The system used MobileNet and Xception and InceptionV3 as pretrained models for its classification tasks. The Kaggle dataset contained 3,014 facial images which researchers used to show both autistic and non-autistic children. The MobileNet system achieved 95% accuracy while Xception reached 94% and InceptionV3 achieved approximately 89% accuracy. The study proved that lightweight pretrained CNN models succeed in detecting autism through facial feature analysis.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The researchers of [2] developed a facial attention detection framework which uses two separate methodologies for its operation. The first approach used geometric feature extraction together with the Support Vector Machine classifier while the second approach analyzed time-domain spatial features through two-dimensional representations which were processed by a CNN model. The study tested 46 children who included 20 children with ASD and 26 typically developing children to complete different attention-related tasks. The results showed that SVM-based geometric feature transformation performed better than the CNN-based method. The model demonstrated improved generalization abilities for typically developing children while displaying better performance on low-attention tasks than on high-attention task

In [3] the authors investigated whether face-scanning patterns could be used to distinguish children with ASD from typically developing children. A machine learning algorithm was applied to analyze eye-tracking data collected during a face recognition task. The model was evaluated using accuracy, sensitivity, and specificity metrics, achieving a maximum classification accuracy of 88.51%. Although the results were promising, the study acknowledged limitations in clinical applicability and recommended further development of multi-task and multi-model frameworks for improved early detection.

In [4] a deep learning-based facial analysis model was developed to classify children as either autistic or healthy. The model utilized MobileNet along with additional dense layers for feature extraction and classification. Trained and tested on 3,014 facial images, the system achieved an accuracy of 94.6%. The findings suggested that facial image analysis can serve as a cost-effective and efficient method for early autism screening.

In [5] the researchers examined emotion recognition abilities in individuals with ASD using the Films Expression Task. The study involved 46 people with ASD and 52 age- and IQ-matched typically developing individuals. Results revealed significant differences in recognition accuracy and reaction times, indicating notable deficits in facial expression processing among individuals with ASD.

However, a small subgroup of participants with ASD demonstrated performance comparable to typically developing individuals, highlighting variability within the spectrum

A large-scale meta-analysis was conducted in [6] to study face identity processing deficits which occur in individuals with ASD. The research study analyzed 112 research papers which included 5,390 participants and showed that individuals with ASD demonstrated significant impairments during both face recognition and face discrimination tests. The research results showed that face identity processing difficulties constitute an essential feature of autism spectrum disorder which stays constant across different age groups and gender and testing methods.

The research team in [7] used machine learning methods to create a system which separates children with autism spectrum disorder according to their facial scanning behavior. The model reached its highest performance level when it used eye-tracking data from autistic children and typically developing children, achieving an accuracy rate of 88.51%. The research developed an automatic classification system while stressing the importance of testing it with more extensive data sets for validation purposes

The authors in [8] used five pretrained CNN models which include MobileNet and Xception and EfficientNetB0 and EfficientNetB1 and EfficientNetB2 to extract features before using a deep neural network to perform binary classification. Xception performed better than all other models because it achieved an AUC score of 96.63% combined with 88.46% sensitivity and 88% negative predictive value. The research showed that researchers can successfully obtain unique facial characteristics which are typical for ASD from unchanging facial photos.

In [9] researchers developed a real-time emotion recognition system specifically designed for children with autism through their improved deep learning method. The system detected six facial emotions and achieved a reported accuracy of 99.99% on a cleaned dataset. The authors explained that their study encountered limitations because of their small dataset size which they suggested should be investigated through studies that utilize larger datasets from actual environments

In [10] researchers created a real-time facial emotion recognition system which helps children with ASD learn about emotions. The system included stages for face detection, feature extraction, and classification, achieving an average recognition rate of 85.97%. The study focused primarily on improving empathy and emotional understanding in children with autism.

The research study has demonstrated important progress through its earlier work which still shows multiple restrictions that include existing data set limitations and inability to apply results to different groups and the study's missing elements of multi-task learning together with ensemble methods. Existing methods currently either extract facial features or analyze human behavior but they do not use multiple facial features together with deep learning techniques to create better results.

III. METHODOLOGY

The proposed system for the Autism Spectrum Disorder (ASD) classification project introduces a comprehensive approach that integrates advanced facial attribute analysis with deep learning, specifically leveraging convolutional neural networks (CNNs). The system seeks to improve the accuracy of ASD diagnosis by incorporating an ensemble technique, combining multiple CNN architectures, such as Densenet 121, Mobile Net, Xception, and InceptionV3, to create a robust model.

Vol. 14, Issue 06, ACSCON - 2026

The workflow of the system involves the extraction of relevant facial attributes, including expressions, action units, arousal, and valence, from a diverse dataset of images. These attributes are then fed into a multi-task learning framework within CNNs, allowing the model to simultaneously analyze various facial features crucial for ASD classification.

To further boost accuracy, the ensemble technique is applied, where individual CNN models are trained using different subsets of the dataset or with varying hyperparameters. The predictions generated by each model are combined, harnessing the collective intelligence of diverse models and mitigating the risk of overfitting.

Ethical considerations are embedded in the system, with a focus on privacy safeguards for sensitive facial data. The societal impact is considered, aiming to improve the early diagnosis of ASD, potentially leading to more effective interventions and reduced healthcare costs. Environmental concerns related to energy consumption during training and data storage are addressed by optimizing the computational resources.

Validation and testing processes involve diverse datasets, ensuring the generalizability of the proposed system across different demographics. The documentation is maintained rigorously, allowing for transparency, reproducibility, and continuous improvement. Overall, the proposed system represents an innovative and ethically conscious approach to ASD diagnosis, utilizing the synergy of facial attribute analysis, deep learning, and ensemble techniques to achieve higher accuracy and societal impact.

A. Covid-19 Classificationusing Dense Net 121 Model:

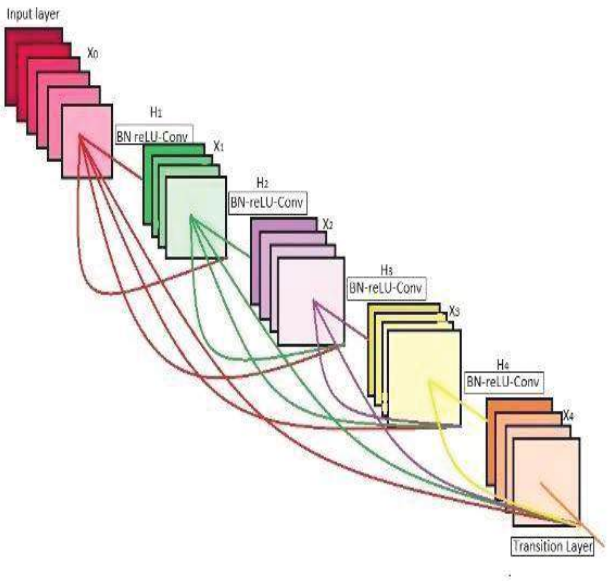

Figure 1: DenseNet121 Model

The input layer of the proposed model receives medical images obtained from multiple imaging modalities, including preprocessed and enhanced X-ray, computed tomography (CT), and ultrasound scans. The network needs these images to complete its operation which requires the images to go through standard preprocessing steps that include noise reduction and normalization and contrast enhancement to achieve better image quality and modal consistency.

Convolutional Layers- The Convolutional Neural Network (CNN) architecture depends on the convolutional layer as its main element that extracts features from input data. The layer executes convolution operations which are followed by the implementation of activation functions that introduce nonlinearity into the system. A small matrix known as a kernel or filter moves across the input image during the convolution process. The filter values get multiplied with corresponding input values for each spatial location, and the outputs of this operation create one final output value. The system executes this process throughout the entire input, which results in creating output matrices that scientists call feature maps. The feature maps of the system extract essential local patterns, which include edges and textures and shapes and all other features that help in distinguishing different objects. The stacking of multiple convolutional layers enables the network to develop complex abstract input data representations which become vital for achieving correct classification and detection results.

Pooling Layers- The feature maps that convolutional layers create need their spatial dimensions to be reduced through pooling layers. The main goal of pooling operations is to decrease processing requirements while keeping essential data. The system processes each feature map by splitting it into multiple distinct sections that do not overlap with each other. A summary stat

$$MP = Floor\left(\frac{I_x - P}{s} + 1\right) \qquad (1)$$

The dense layer of a Convolutional Neural Network (CNN) implements a linear transformation which processes input features from the prior layer of either a pooling layer or another dense layer. This transformation process begins with matrix multiplication of the input vector and weighted matrix, followed by adding the bias term. Every neuron in a dense layer maintains active connections to all neurons present in the previous layer, which leads to its identification as a "fully connected" network. This complete connectivity of the network enables it to learn advanced mapping functions which can handle intricate patterns between extracted features and actual results.

The dense layer functions as a processing unit that transforms high-level data obtained through convolutional and pooling methods into a condensed yet distinct form of information. The final classification or regression task of the CNN architecture is executed by the dense layer, which operates as the concluding element of the system to perform tasks such as image categorization and segmentation and object detection. The dense layer output converts to final predictions through an activation function which uses either sigmoid for binary classification or Softmax for multi-class classification. The dense layer serves a vital function which enables the system to transform learned feature representations into valuable output.

Dropout Layer Dropout serves as a regularization method which is frequently used in CNNs to reduce the risk of overfitting. When a model experiences overfitting, it becomes excessively customized to the training data, which prevents it from performing well on new, untrained data. The dropout layer deactivates a predetermined percentage of neurons during training by turning their outputs to zero throughout the forward pass process

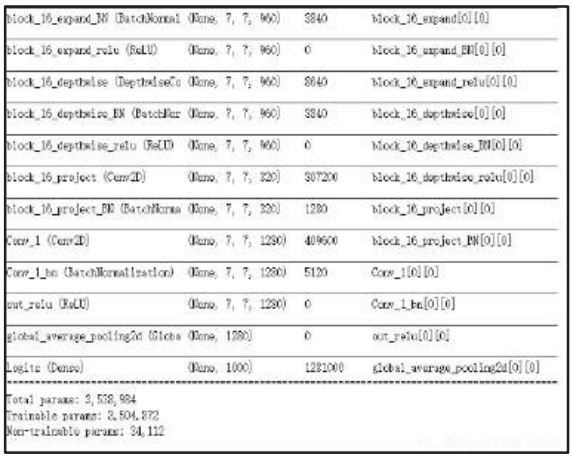
The iteration does not use these neurons because they stop functioning during both forward propagation and backpropagation. The network achieves its needed functionality because the stochastic neuron removal process prevents it from depending on particular features and specific neurons. Dropout forces the model to use different routes for making predictions, which helps the system learn stronger and more universal feature representations. The network creates extra representation systems, which allow it to maintain performance when processing unfamiliar information. The dropout rate hyperparameter controls how many neurons become inactive during the training process. The training experiments use dropout rates that typically fall between 0.2 and 0.5, but the ideal rate depends on the dataset size and network complexity and task requirements.

$$\frac{\partial}{\partial_{S_P}}\left(-log\left(\frac{e^{S_P}}{\sum_j^c e^{S_j}}\right)\right) = \left(\frac{e^{S_P}}{\sum_j^c e^{S_j}} - 1\right) \qquad (2)$$

$$\frac{\partial}{\partial_{S_n}}\left(-log\left(\frac{e^{S_P}}{\sum_j^c e^{S_j}}\right)\right) = \left(\frac{e^{S_n}}{\sum_j^c e^{S_j}}\right) \qquad (3)$$

Activation Function In a Convolutional Neural Network (CNN), an activation function processes the output of each neuron, introducing non-linearity to the model. The primary purpose of this non-linear transformation is to empower the network to model complex mappings from inputs to outputs. A CNN requires activation functions because they establish its nonlinear behavior which enables the system to understand complex patterns found in actual data. CNN architectures make use of multiple activation functions which are frequently implemented. The Rectified Linear Unit (ReLU) function together with Sigmoid and Hyperbolic Tangent (Tanh) functions are among the most commonly used activation functions. The ReLU activation function is the most frequently used in modern CNNs. Negative input values become zero, whereas positive ones remain the same. ReLU demonstrates efficient computation abilities while it solves the vanishing gradient problem which frequently appears in deep neural network systems. Its simplicity and effectiveness make it a preferred choice for hidden layers. Sigmoid maps inputs to outputs between 0 and 1 which makes it suitable for binary classification problems that require outputs to show probabilities. The Sigmoid function in deep networks will experience the vanishing gradient problem which leads to decreased training speed. The Tanh activation function maps input values to a range between −1 and 1. The zero-centered nature of this function enables better convergence performance than the Sigmoid function in certain situations. Tanh is useful when modeling data that spans both positive and negative values.

The SoftMax activation function serves as the standard output layer for multi-class classification tasks. SoftMax converts raw output scores (logits) into probability distributions, where the sum of all class probabilities equals one. The system enables multiple class probability assessments while choosing the category with highest probability. Activation functions hold crucial importance for CNNs because they establish non-linear characteristics which enable networks to learn intricate data patterns that resemble real-world phenomena. Among them, ReLU is most commonly employed in hidden layers owing to fast computation and strong performance to alleviate gradient-related issues, while Sigmoid and SoftMax are often used in output layers depending on the classification task.



The SoftMax function serves as the verification method for multi-class classification tasks. The task of multi-class classification requires operators to select a single category from multiple available options to classify an input sample. A CNN uses its training process to learn how to identify different object categories which include specific animal breeds and various types of vehicles.

The SoftMax activation function serves as the standard activation function which developers use to build their last output layer. The system provides output probabilities which remain bounded between 0 and 1 while their total value equals 1. The system predicts classes by selecting the category which has the highest probability value. The SoftMax function allows users to understand model results as probability distributions which make it ideal for solving multi-class classification tasks.

Optimization Algorithms in CNN Training The optimization algorithm determines how CNN training works because it controls the process which updates network parameters through weight and bias modifications to achieve loss function reduction. The loss function calculates the discrepancy between predicted outputs and actual target values, and the optimization process targets to find the parameter configuration that produces the lowest possible loss. The training process uses gradient-based techniques which operate through iterative cycles. The system calculates loss function gradients which measure parameter changes during each backpropagation cycle, then updates parameters based on those calculations. Several optimization techniques are commonly used in CNN training, including: Stochastic Gradient Descent (SGD) – adjusts parameters using gradients derived from mini-batches of training data. The method provides a basic solution which functions well, yet it has a slow speed for reaching complete convergence. Adaptive Moment Estimation (Adam).

The system achieves faster convergence with improved stability through its combination of momentum and adaptive learning rate techniques. Root Mean Square Propagation (RMSprop) – The system modifies learning rates according to current gradient strengths, which results in better performance during periods of changing conditions. Each optimization algorithm has distinct strengths and limitations, and the choice of optimizer can significantly influence convergence speed, stability, and overall model performance. The optimization process executes as an iterative framework which improves generalization ability through continuous adjustments of network parameters until prediction errors reach their lowest point.

The Adam Optimization Algorithm Every optimization algorithm provides specific benefits, while it creates particular drawbacks. The choice of optimizer determines how quickly a trained neural network achieves its performance target through its learning process. The process of optimization involves multiple iterations, which update network parameters like weights and biases till the loss function obtains its minimum value and prediction accuracy shows improvement. The Adaptive Moment Estimation algorithm functions as the most popular method among deep learning optimization algorithms, which researchers use to train Convolutional Neural Networks. Adam presents its users with the advantages obtained from Stochastic Gradient Descent and Root Mean Square Propagation. The system determines learning rates for each parameter through its dual estimation process, which includes measuring past gradient averages and calculating squared gradient averages. Adam achieves faster training times through its capacity to change learning rates throughout the training process. The method demonstrates strong performance when dealing with both high-frequency data and low-frequency data, as well as through its application to intricate network designs. Deep learning systems demonstrate fast convergence rates because of their ability to process large-scale data sets. The system operates efficiently across various tasks because it requires minimal hyperparameter adjustments through manual tuning. The optimizer exists as an effective tool for CNN training, which provides both fast performance and dependable results.

$$Accuracy = \left(\frac{TP + TN}{TP + TN + FP + FN}\right) \qquad (4)$$

Evaluation Metrics A CNN model needs suitable quantitative evaluation metrics to assess its performance. The metrics enable assessment of model classification performance and enable comparison of different modeling methods. Prediction results are typically summarized through the use of a confusion matrix. The system displays its performance through two types of classification outcomes which include correct classifications and incorrect classifications. The evaluation metrics which stem from the confusion matrix provide multiple assessment options. Accuracy reflects the ratio of right predictions to the total samples tested. The dataset imbalanced nature leads to complications which make it difficult to understand accuracy results even though it remains an understandable metric.

$$PR = \left(\frac{TP}{TP + FP}\right) \qquad (5)$$

Precision reflects the reliability of positive predictions. The measurement shows what percentage of positive predictions turn out to be actual positive results. Recall, or sensitivity, evaluates how well the model identifies actual positives. The system shows its capacity to discover important information through its performance. The F1-score metric enables equal evaluation through its combination of precision and recall into one measurement. The method proves beneficial for handling situations that involve unequal data distribution. The Area Under the Curve (AUC) metric tests a model's capacity to differentiate between various classes at multiple classification levels. A higher AUC value indicates better discriminatory capability. Multiple evaluation metrics enable better understanding of how a model performs during assessments. The combined implementation of accuracy and other metrics helps to reveal deeper examination results for class imbalance situations through their implementation of precision, recall, F1-score.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The confusion matrix shows True Positive (TP) when the model successfully identifies a normal image and the actual label also shows normal status. The model successfully detects an abnormal image when it produces True Negative (TN) output which matches the actual abnormal designation. The model treats an image as normal when it produces False Positive (FP) results because the actual condition of the image is abnormal. The False Negative (FN) error occurs when the model shows an image as abnormal while the actual label shows it as normal. The four different results serve as fundamental elements which researchers use to assess how well a system performs classification tasks. Precision calculates the fraction of positive predictions which the system makes to determine actual positive cases. The system assesses the accuracy of its positive predictions through this metric. A model with high precision produces fewer false positive errors. Precision becomes vital for fields which deal with situations where false positive results create severe negative outcomes. The model uses recall which people refer to as sensitivity to test its performance in identifying actual positive cases. The measurement shows what percentage of true positive instances the system successfully identified from all positive instances. The model shows high recall because it generates fewer false negative results. Recall functions as a crucial requirement in situations where overlooking a positive case would create expensive or hazardous results.

AUC measures by and large execution and assesses it over all edges. AUC ranges in esteem from to 1. A show with100% incorrect forecasts will have an region beneath the bend (AUC) esteem of 0.0, while a show with 100% adjust expectations will have an AUC value of 1.0. One of the often-employed measurements, for the most part for double classification. A classifier's AUC measures probability.

A confusion matrix tabulates actual versus predicted labels to gauge classifier effectiveness. It offers a visual depiction of the classifier's performance and enables comprehension of the kinds of errors the classifier is committing.
Four separate values comprise the confusion matrix:

$$TPR = \frac{TP}{Actual\ Positive} = \frac{TP}{TP + FN}$$

$$FNR = \frac{FN}{Actual\ Positive} = \frac{FN}{TP + FN}$$

$$TNR = \frac{TN}{Actual\ Negative} = \frac{TN}{TN + FP}$$

$$FPR = \frac{FP}{Actual\ Negative} = \frac{FP}{TN + FP}$$

- Instances where the classifier correctly predicted the positive class are known as true positives (TPR).
- When the classifier predicted a positive class when a negative class was actually present, this is known as a false positive (FPR).
- Situations where the classifier correctly identified the negative class are known as True Negatives (FNR).
- When the classifier correctly identified the negative class, the scenario is known as a True Negative (TNR).

The performance of models can be assessed through the combined examination of precision and recall.

Precision measures the rate of incorrect positive results while recall measures the rate of incorrect negative results. The two values need to reach their maximum value of 100 percent according to ideal conditions

$$REC = \left(\frac{TP}{TP + FN}\right) \qquad (6)$$

Precision improvement leads to decreased FP errors, whereas recall improvement results in decreased FN errors. The process of enhancing one aspect of performance may create adverse effects on another aspect which results in a performance trade-off. The F1-score serves as a comprehensive metric that integrates precision and recall into a single balanced value by computing their harmonic mean, ensuring both metrics receive equal importance in evaluation. The F1-score proves beneficial when handling datasets with imbalanced classes and when both false positive and false negative errors need consideration. The system evaluates classification results through precision and recall which provides an unbiased assessment of classification results.

$$F1 - Score = \left(\frac{2 * PR * REC}{PR + REC}\right) \qquad (7)$$

IV. CONCLUSION

In conclusion, the ASD classification project stands as a noteworthy achievement in leveraging advanced facial attribute analysis and an ensemble of CNN architectures for Autism Spectrum Disorder diagnosis. With a commendable 91% validation accuracy achieved over 45

training epochs, the model adeptly learns nuanced facial features, including expressions, action units, arousal, and valence. The dynamic progression of accuracy, coupled with a balanced data loss trade-off, underscores the model's adaptability to diverse patterns, contributing to its reliability in real-world applications. The streamlined testing model, designed for user-friendly image path input, enhances accessibility, providing binary predictions for efficient and practical ASD diagnosis. Overall, this project represents a significant step forward in the integration of advanced technologies for accurate and accessible ASD classification.

In practical terms, the testing model offers a straightforward tool for users to input image path, receiving prompt binary predictions categorizing individuals as either autistic or non-autistic. Beyond its high validation accuracy, the project's emphasis on user- friendly implementation ensures its applicability in diverse settings, contributing to the ongoing evolution of ASD diagnostic methodologies.

Abstract- ***Smart Agriculture uses AI to analyze data from sources like sensors, drones and satellite imagery to improve farming efficiency, resource management, and crop yields. The smart agriculture marketplace is a progressive solution for modern agriculture, linking farmers, consumers, and suppliers through a technology driven ecosystem that tackles key industry challenges. IoT sensors enable real time environmental monitoring with AI-analyzing the data to provide actionable insights such as crops recommendations, yields forecasts, and early environmental risk alerts. These insights help farmers make informal decisions, optimize resources, and boost productivity. The modern agriculture faces critical challenges including climate change induced water shortage, inefficient resource utilization, and reducing soil health which reduce sustainability and reduce crop yields. Advanced DL models were used for various tasks in the AI Driven Smart Agriculture System. The proposed model improves crop productivity, optimizes resource use, and supports adaptation to environmental changes. By leveraging AI and IoT technologies, the proposed model gives a solution which helps in sustainable agriculture, environmental resilience, and global food security, thus benefiting stakeholders ranging from individual farmers to large-scale agricultural business.***

Keywords*: AI, XAI, DL, TabNet, SwiFT, RMSE, IOT sensors, Weather forecasting, Smart agriculture, Crop recommendation, Fertlilizer recommendation, etc,.*

I. INTRODUCTION

Farming smarts - called precision farming by some - use new tools to grow more food without draining supplies quickly. I can't help but compare old ways that often guessed instead of knowing; results were hit or miss, wasting water here, dumping extra fertiliser there. It stung the farmers' pockets, yet they carried on anyway. This fresh method changes everything. Because sensors send live readings, gear responds quicker than someone jotting notes by hand - suddenly, the setup hums with info flow. I've seen systems where one wrong reading used to wreck a crop; today, stats refresh fast enough that stress hardly kicks in. Choices turn clearer. Still, some parts stay shaky. [1]

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

In this build, different gadgets come together in a cool way. Not just NPK soil sensors - they show nutrient data straight up, no fluff, which still catches me off guard sometimes. Right beside them, humidity and temp detectors pick up tiny shifts folks usually ignore. Instead of chaos, an RS-485 link holds the signals steady. Then an ESP32 beams it all outside, so updates pop up live from the field. Honestly, it's like mud meeting wires - but somehow, it clicks. The gathered info helps growers better understand nutrient levels, changing dampness, plus sudden weather shifts that mess up plans in days. Relief kicks in when reacting quickly - adjusting water flow, adding feed just in time, or stopping bugs early before they spread. Checking details on a tiny screen somehow makes things feel steady, while sending identical updates online ensures progress continues even if one person's busy working outdoors. [2]

I've seen folks try setups like this one - each time aiming to cut down on grunt work, make nature's supplies go farther, yet pull in consistent harvests without burning out. When storms act up or hunger grows, these methods keep output stable. Farms use gadgets like IoT sensors alongside machine learning tricks and deep-learning systems, toss in basic cloud space, then hook up any solid weather API floating around lately. Everything runs in a kind chaotic yet useful cycle - keeps farming quick on its feet and ready to adjust.

II. LITERATURE SURVEY

The literature on technology-driven solutions in agriculture highlights how advanced tools such as IoT, AI analytics, blockchain, and digital marketplaces are transforming traditional farming practices and market access. This survey reviews key technologies and their applications in optimizing agricultural workflows and stakeholder interactions.

Agriculture's changing fast - thanks to new tech like AI and data tools. Old-school farming usually depends on guesswork or broad tips, but now it's struggling with weird weather, tired soil, less water, and pressure to grow more using less. Instead of just pushing harder, farmers are turning to smart systems powered by AI; these help them make better choices and run farms smoothly from start to finish. [3]

A smart farm marketplace mixes agriculture with online shopping, linking growers, purchasers, shop owners, vendors, and helpers in a single virtual hub. Instead of juggling several systems, it uses artificial intelligence, number-crunching tools, and internet-based storage to simplify trades - crops move faster from field to buyer while farmers grab supplies or chat straight with customers. By gathering predictions about harvests, what shoppers want, ground quality details, plus weather shifts, it helps everyone choose wisely. Prices stay clear because insights come from live updates rather than guesswork. [4]

A farming helper based on Random Forest works like a smart buddy for growers - suggesting suitable plants and when to grow them using real-time land info. It gathers details like dirt nutrients, acidity, dampness, heat, rain levels, plus earlier harvest logs, feeding all that into the model instead of just one method. Since this system uses many small decision paths while mixing results, it shows more clearly which crops do well where and when throughout the year. [5]

Transforming agriculture method pictures a fresh take on farming, using topology along with artificial intelligence to steer food growing toward smarter, number-based choices that last longer. By mapping out space links, connections, and patterns, topology shows how dirt, plants, rain, and nature tie together from one plot to another. [6]

Farming gets smarter with Explainable AI this version uses clever number-crunching but also shows its thinking. Most artificial intelligence hides how it decides, like a locked room; this kind spills the beans on why it says what it

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

does. Folks who grow crops can then get why one move's suggested over another. Soil sensors link up with satellite images, giving farmers a clearer picture based on live weather info along with signs of plant health and old harvest logs - these shapes choices around which crops to grow, when to water, how much fertiliser to apply, spotting sick plants early, or guessing output levels. • Using charts, clear rules, or highlighting key factors, XAI helps people rely on it more - while getting better results. When farmers compare AI advice with real field conditions, they decide easier - not leaving numbers behind. [7]

Mix AI with machine learning, then watch those links begin exposing hidden trends. Soil features team up with plant reactions, weather changes link to water movement, bugs join in too; all stitched into maps so predictions hit closer to reality. Farmers might apply this info to plan crops - also adjust watering schedules, pick better fertilisers, or catch odd patterns sooner. Mixing shape-based analysis with clever code shifts farming off hunches into a sharp, forecast-driven setup that hums with live signals.

It makes managing farms easier too. Simple advice on feeding crops, watering, or basic upkeep cuts down leftovers, stretches supplies, while boosting harvests at the same time. Beyond this, live updates combined with smart forecasts put growers ahead when conditions change - weather shifts or price swings - so they fix things early.

III. PROPOSED SYSTEM

A smart farm setup using AI tries to upgrade old-school farming with better speed, live data use, and less manual work. Boost harvest results by studying up-to the-minute info pulled from ground monitors, flying drones, or internet-connected gadgets - giving clear tips on when to sow, water, feed plants, or pick crops. With constant checks on dirt wetness, air heat, damp levels, and how well crops are growing, it hands growers useful hints so they can handle supplies smarter.

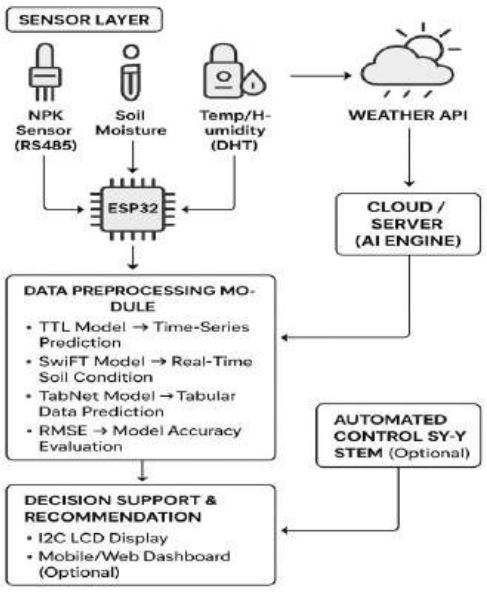

Figure 1 Proposed system

Sustainability picks up some extra help. With precision farming, water use goes down - so do fertiliser and pesticide needs - thanks to smarter irrigation plus self-running machines that lower workloads and running expenses. Goals include bigger harvests, improved crop standards, more earnings, also an easy-to-use setup for ongoing farm organisation.

Constant checks using smart sensors tweak watering times plus how supplies are used. Thanks to machine learning tips and auto controls, excess use drops while plants still get their proper share. In general, this neural network setup spots problems sooner, cuts running expenses, also boosts daily farm operations so things stay sustainable longer.

The system runs on TabNet to check farm-related info - soil details, weather patterns, past harvest numbers - then delivers clear timing for sowing, watering, crop feeding. Instead of basic methods, SwiFT deals with time-based and location-aware data, enabling live updates on how crops grow and surroundings shift. On top of that, XAI makes decisions easier to grasp, showing growers the logic behind tweaks like changing water amounts or nutrient doses.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The process starts by placing sensors around the field - then pulls in information from them. After that, the raw details get cleaned up a bit to make sure they're reliable. Next, smart number-crunching tools are built to guess what might happen later on. These systems link up using special digital hooks so everything flows without hiccups. Once live, guesses are checked against real results to see how close they were. In the end, clear advice pops out - helping growers pick smarter moves based on actual insights.

The system runs on TabNet to check farm-related info - soil details, weather patterns, past harvest numbers - then delivers clear timing for sowing, watering, crop feeding. Instead of basic methods, SwiFT deals with time-based and location-aware data, enabling live updates on how crops grow and surroundings shift. On top of that, XAI makes decisions easier to grasp, showing growers the logic behind tweaks like changing water amounts or nutrient doses.

The proposed AI-based smart agriculture system provides precise, data-driven recommendations for irrigation, fertilizer use, and crop management, helping farmers improve productivity and resource efficiency.

IV. HARDWARE REQUIREMENTS

The following are the hardware components used in Smart agriculture using AI

ESP32:- The ESP32 comes from Expressive Systems this chip handles Wi-Fi and Bluetooth right out of the box. People use it a lot for gadgets like smart home tools, robots, or Internet connected gear because it runs well without costing much. Inside, there's a two-part brain based on Tensilica design, clocked as high as 240 MHz, while a side helper chip keeps power use tiny during sleep mode. What makes this board stand out? Loads of input output lines, talk options including UART, SPI, I²C, I²S, along with analog-to-digital and digital-to-analog converters.

DHT11 Sensor:- This gadget checks heat and wetness without costing much. Often seen in homemade tech setups, smart homes, or mini weather gadgets, it hooks up fast to tiny computers such as Arduino, ESP32, or Raspberry Pi. Inside, a part senses warmth while another measures damp air; together they feed data to a little chip that sends out number-based results.

Soil Moisture Sensor:- This sensor checks how much water's in dirt, showing whether it's parched, just right, or soaked. Common in farming, backyard growing, or tech-driven plant care, it helps run self-watering setups, high-tech fields, or indoor gardens by turning on hydration when needed.

NPK Sensor:- This tool checks how much nitrogen, phosphorus, or potassium is in the soil - key stuff plants need to grow. Used in smart farming, it helps decide when or how much fertilizer to add. Runs on either 5 volts or 12 volts, links up using RS-485, UART, maybe even analog signals. Built tough so rain won't ruin it, fits right into ground outdoors.

RS-384 TTLConverter:- This gadget changes signals from RS-485 into TTL levels, also doing it backwards. It's handy for factory gear, talking to sensors far away, or tinkering with small computers. The RS-485 setup fights interference well, linking many devices using paired wires - labeled A and B - with balanced signals. Tiny boards like Arduino, ESP32, or even Raspberry Pi can't hook up straight to RS-485; they need this helper first.

LCD Display:- Liquid crystal screens use tiny elements that shift light to form symbols, digits, or images. Instead of full graphics, many gadgets pick simple character types like 16x2 or 20x4 panels for reading data, navigating options, or showing device state. These units stick around because they're cheap, hook up easily to small processors, yet still deliver sharp lettering.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Figure 2 Hardware Connections

V. SOFTWARE REQUIREMENTS

Arduino IDE:- The Arduino IDE - short for Integrated Development Environment - is an easy-to-use tool that helps you write, turn into machine code, then transfer programs to devices such as the ESP32 or other Arduino hardware. Since it makes coding less tricky, people often pick it when working on electronic gadgets, smart home tech, or small computer-like circuits. Inside this app, there's a basic editing space where you type your instructions; once done, built in tools convert them using a version of C/C++, so they run right on the chip through a USB cable.

A solid collection of ready-to-use tools. Inside you'll find helpful packages - on top of add-ons anyone can grab - for things like screens, sensors, or wireless links, cutting down setup time. Newcomers get sample scripts that show how to hook up parts like motion detectors or small engines without hassle. With the Boards Manager, it works smoothly across many chips, say ESP32 or ESP8266, even random outsider models.

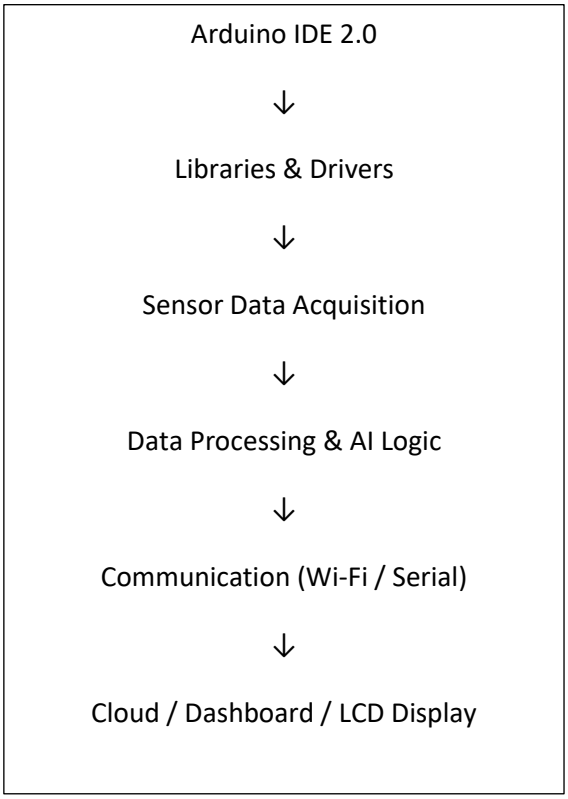

Figure 3 Software Architecture

The Arduino IDE includes a serial monitor and plotter so you can see sensor readings live while troubleshooting. Instead of manual setup, its built-in Board Manager helps install drivers for countless devices fast. Users grab extra tools through the Library Manager without hassle. Code gets compiled on its own, pulls in needed modules, then flashes to the board over USB - or sometimes by Wi-Fi.

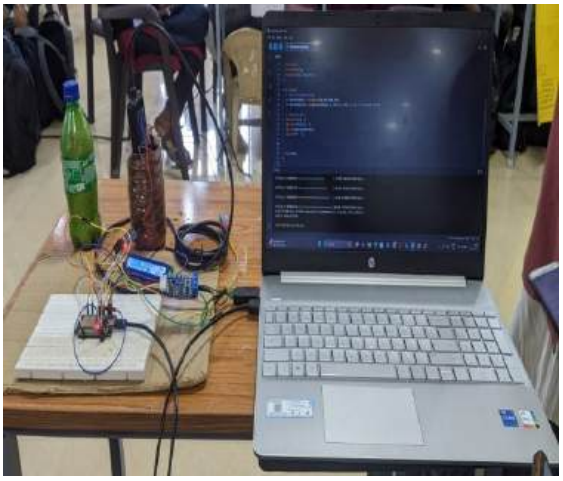

Figure 4 Software Connections

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Arduino IDE 2.0 brings quicker builds, a better editing experience, smart suggestions also some can turn on debug features if they want. Simplicity helps; it runs on Windows, Mac, or Linux while offering plenty of add-ons so learners, tinkerers, and experts get what they need.

VI. RESULT AND ANALYSIS

The smart agriculture system built using Artificial Intelligence demonstrates a highly effective, automated, and data-driven approach to modern farming. By combining IoT sensors (soil moisture, NPK, temperature–humidity), real-time weather API data, and advanced deep learning models such as TTL, TabNet, SwiFT, and RMSE-based evaluation, the system achieves precise monitoring of soil and environmental conditions.

The results show that AI-powered recommendations significantly reduce water consumption by optimizing irrigation timing based on soil moisture and evapotranspiration patterns.

AI algorithms accurately predict irrigation schedules, fertilizer application, and potential crop stress levels, which helps farmers make proactive decisions instead of reactive ones.

Design of confusion matrix based on the databases using machine learning

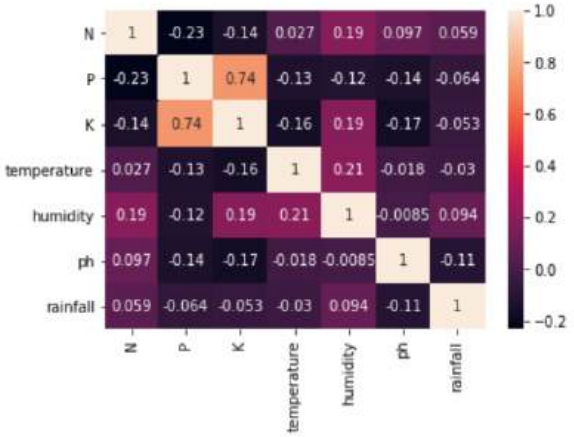

Figure 5 Confusion matrix

Crop- yield prediction using machine learning

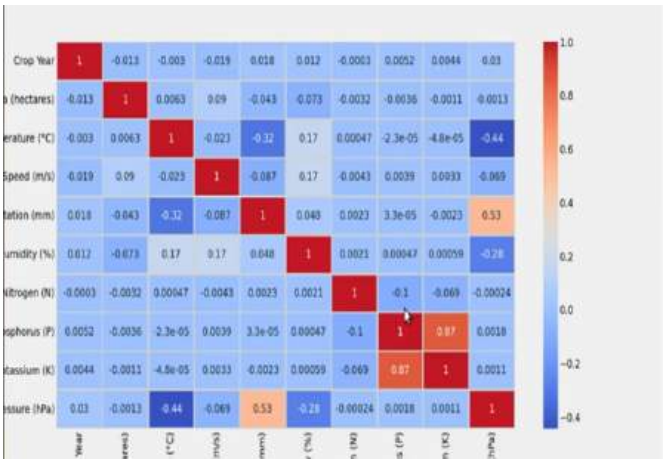

Figure 6 Crop-yield prediction

Fertilizer usage is also minimized through nutrient forecasting, improving soil health and reducing environmental impact. The system's integration with ESP32 and RS485-based NPK sensors ensures reliable field data collection, while visual dashboards improve user understanding and monitoring efficiency.

The implementation of smart agriculture using Artificial Intelligence significantly improves the accuracy and efficiency of farming operations. By integrating IoT sensors, weather APIs, and AI/ML models such as TabNet, SwiFT, and TTL, farmers receive real-time insights on soil health, irrigation needs, fertilizer requirements, and crop growth conditions.

The system successfully reduces manual effort, optimizes resource usage, and enhances decision-making through predictive analytics. As a result, crop productivity increases, water and fertilizer wastage decreases, and overall farm management becomes more sustainable, data-driven, and cost-effective.

Overall, the implementation improves crop yield, reduces input costs, lowers human effort, and enhances sustainability. The smart agriculture system proves that AI-driven decision-making can transform traditional

Vol. 14, Issue 06, ACSCON - 2026

farming into a more intelligent, efficient, and climate-resilient practice.

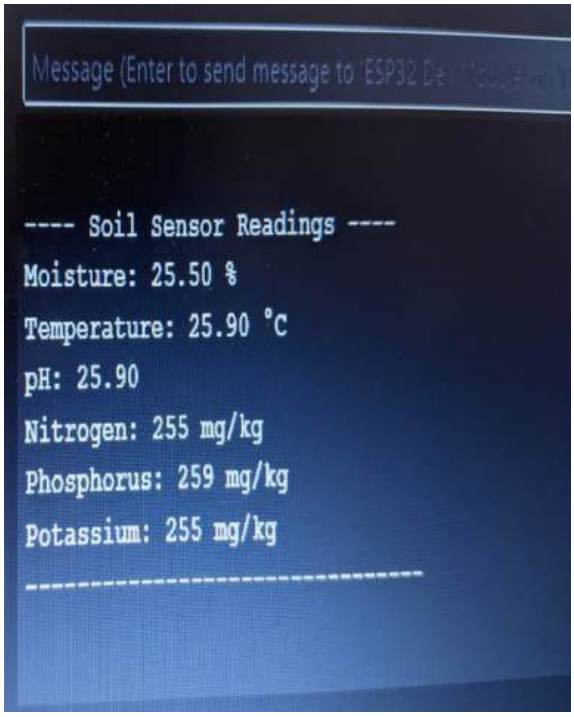

Figure 7 Expected output from hardware connections

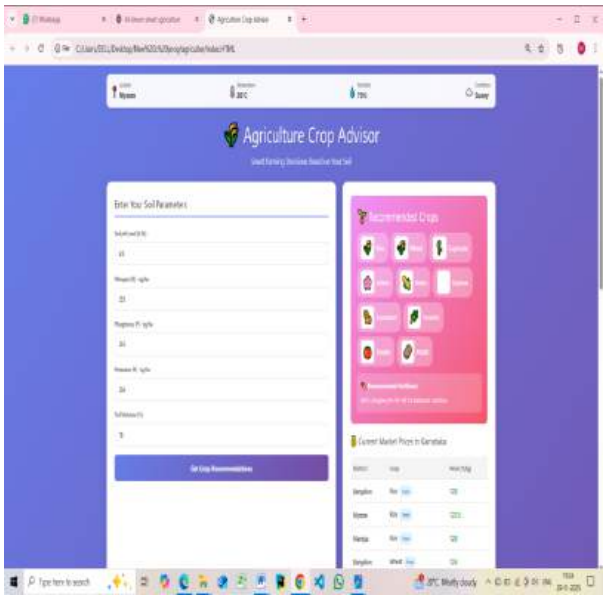

Figure 8 Expected output from the software result through the dashboard

The final outcome shows that AI-enabled solutions have the potential to revolutionize agriculture by increasing productivity, saving resources, and improving economic outcomes.

VII. CONCLUSION

In this project, an integrated AI-based system was developed that combines soil analysis, intelligent irrigation, crop–fertilizer recommendation, and market price prediction into a unified framework aimed at improving farm yield, reducing wastage, and supporting data-driven decision-making.

The system uses machine learning models and sensor data to evaluate various soil parameters like pH, nitrogen, phosphorus, potassium, and moisture level. This automated assessment helps farmers understand the current soil condition without relying entirely on laboratory testing. Based on the analysed data, the system intelligently recommends suitable crops and fertilizers, ensuring that the selected crop is compatible with the available soil nutrients and environmental conditions. This significantly reduces the risk of poor crop growth and nutrient imbalance.

Furthermore, the system provides market price analysis using predictive algorithms to help farmers make informed decisions about when and where to sell their produce at the highest profit. This reduces the losses caused by fluctuating market prices and middlemen exploitation.

The final outcome shows that AI-enabled solutions have the potential to revolutionize agriculture by increasing productivity, saving resources, and improving economic outcomes.

VIII. FUTURE WORK

IoT-Enabled Fully Automated Farming System: The current system can be expanded into a complete IoT ecosystem where sensors continuously gather data about soil moisture, temperature, humidity, rainfall, pest activity, and nutrient level.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Automatic actuators (pumps, sprinklers, valves) can then respond instantly based on AI-generated decisions. A cloud-based dashboard can enable farmers to control and monitor farm conditions from anywhere using a smartphone.

Climate Prediction and Risk Management: Advanced weather forecasting models and climate risk assessment can be integrated to help farmers prepare for droughts, floods, and seasonal changes. This will increase crop resilience and reduce losses from unexpected weather conditions.

Blockchain-Based Supply Chain and Market Transparency: To prevent market fraud and ensure transparent pricing, blockchain technology can be integrated. This enables secure transactions, real-time price updates, and direct farmer-to-market sales without intermediaries.

Multi-Crop Recommendation and Rotation Planning: The system can be expanded to generate long-term crop rotation plans to maintain soil fertility. By analysing past crop patterns, AI can suggest the best crops for upcoming seasons to improve soil health and prevent pests and diseases.

Abstract - The growing demand for integrated digital learning environments has highlighted the limitations of conventional education systems that rely on disconnected tools for academic management and content delivery. This paper presents an Integrated E-Learning Platform that unifies two major subsystems: StudentHolistic AI and Campus Connect. StudentHolistic AI delivers personalized learning through AI-generated educational videos synthesized using Python-based Text-to-Speech engines and MoviePy, topic-organized playlists, a natural language chatbot, and Telegram bot integration. Campus Connect addresses institutional needs with modules for attendance tracking, assignment management, grade entry, announcements, and role-specific dashboards for students and teachers. The platform is built on Next.js, Tailwind CSS, TypeScript, Node.js, Express.js, MongoDB, and Python AI services, interconnected through RESTful APIs and secured with JWT authentication. Experimental results confirm that dashboard load times remain under 1.4 seconds, AI video generation completes within 38 seconds, and chatbot responses are delivered in under one second. The proposed architecture reduces manual academic workload, improves student engagement, and provides a scalable foundation for future enhancements such as adaptive assessments and mobile applications.

***Key Words*: E-learning; artificial intelligence; AI video generation; academic management; chatbot; Next.js; MongoDB; personalized learning; Campus Connect; StudentHolistic AI**

1. INTRODUCTION

Digital transformation has reshaped academic environments worldwide. Traditional classroom-centric models, combined with fragmented software tools for attendance, assignments, and content delivery, generate redundant workloads and deliver inconsistent learner experiences [1]. Modern students expect instant access to adaptive, multimedia-rich study material, while faculty require streamlined workflows for evaluating performance and communicating with students.

Existing e-learning solutions address portions of these challenges in isolation. Learning Management Systems (LMS) such as Moodle and Canvas provide assignment workflows but lack AI-powered content generation. Platforms such as Coursera deliver video content but do not integrate with institutional academic records. The absence of a unified system results in data silos, manual reconciliation, and reduced pedagogical effectiveness [2, 3].

This paper presents an Integrated E-Learning Platform that merges two purpose-built subsystems into a cohesive digital academic ecosystem: (i) StudentHolistic AI, which focuses on AI-driven personalized learning, and (ii) Campus Connect, which handles institutional academic management. Together, these systems eliminate fragmentation, reduce manual effort, and deliver an engaging, data-driven learning environment accessible across all devices.

The remainder of the paper is organized as follows: Section II reviews related literature. Section III describes the system architecture and methodology.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Section IV details the implementation. Section V presents experimental results. Section VI concludes with future directions.

2.LITERATURE SURVEY

Brozina et al. [1] analyzed LMS engagement patterns among first-year engineering students and demonstrated that consistent, distributed platform usage correlates more strongly with academic performance than last-minute access, underscoring the value of ongoing digital engagement. Liang et al. [2] surveyed student modeling methods in adaptive instructional systems, finding that multimodal data fusion—combining clickstreams, assessment responses, and behavioral signals—significantly improves personalization accuracy, though at high computational cost.

Dayong et al. [3] proposed a modular teaching support platform for universities and showed that integrated academic systems reduce administrative redundancy; however, they require mature IT infrastructure. Alojaiman [4] applied a Multi-Criteria Decision-Making model to compare cloud-based and traditional e-learning platforms, establishing that cloud deployments offer superior scalability and usability. Tsai et al. [5] applied the Technology Acceptance Model to fine-art students and confirmed that perceived usefulness is the dominant predictor of e-learning adoption.

Wu et al. [6] evaluated a hybrid K-12 chatbot combining retrieval-based methods with QANet and reported measurable gains in student engagement and reduced isolation. Yamamoto [7] demonstrated that smartphone-based learning logs promote post-class study habits. Nouman et al. [8] presented a personalized e-mentoring framework that improves learner satisfaction through adaptive content delivery. Aslam et al. [9] identified Support Vector Machines as the highest-accuracy model for e-learning feature evaluation, while noting that deep learning excels on large datasets. Bin et al. [10] reviewed personalized recommendation systems and found that hybrid approaches outperform single-technique models, though cold-start problems remain a significant challenge.

The review reveals that no existing work integrates AI-powered video generation, chatbot assistance, Telegram bot access, and complete institutional academic management within a single unified platform, motivating the present contribution.

3.SYSTEM ARCHITECTURE AND METHODOLOGY

A. Overall Architecture

The platform adopts a three-tier architecture comprising a Next.js frontend, a dual-backend layer (Node.js/Express.js for academic services and Python/FastAPI for AI services), and two MongoDB databases (CampusConnect_DB and StudentHolistic_DB). All tiers communicate through RESTful APIs secured with JSON Web Tokens (JWT). Cloudinary provides cloud storage for AI-generated videos and assignment files; the Telegram Bot API enables mobile-first AI access.

B. StudentHolistic AI Subsystem

The AI subsystem accepts a topic string from the student, forwards it to the Python service, which synthesizes narration audio using a gTTS/TTS engine and assembles video frames with relevant educational visuals through MoviePy. The output video is uploaded to Cloudinary and catalogued in StudentHolistic_DB under the student's playlist. A custom NLP chatbot, also served by the Python layer, handles academic queries in real time. Identical functionality is exposed through a Telegram bot handler, allowing students without laptops to access AI content via mobile messaging.

C. Campus Connect Subsystem

Campus Connect exposes a teacher dashboard for managing students, attendance, assignments, grades, and announcements, and a student dashboard for viewing academic records. Attendance data are stored as percentage records per subject per semester. Assignments are uploaded as PDFs by teachers, retrieved and submitted by students, with metadata and binary assets persisted in CampusConnect_DB and Cloudinary, respectively. Grade management supports semester-wise subject scores with ranking computation. Announcements support both text and image payloads.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Development Methodology

The project followed an iterative development methodology. The requirement analysis phase identified student needs (personalized content, mobile access) and teacher needs (automated workflows, centralized data). System design produced UML sequence diagrams and three-level Data Flow Diagrams (DFD). Frontend and backend development proceeded in parallel using Visual Studio Code with Git/GitHub version control. Integration testing used Postman for API validation and MongoDB Atlas for cloud-hosted database management. Deployment targets Vercel/Cloudflare for the Next.js frontend and dedicated servers for the Python AI engine.

4.IMPLEMENTATION

A. Technology Stack

Table I summarizes the technology stack employed across all platform layers.

Layer	Technologies
Frontend	Next.js, React, TypeScript, Tailwind CSS
Backend (Academic)	Node.js, Express.js, JWT
Backend (AI)	Python, FastAPI, gTTS, MoviePy, OpenCV
Database	MongoDB (CampusConnect_DB, StudentHolistic_DB)
Storage	Cloudinary (videos, PDFs)
Messaging	Telegram Bot API
DevTools	VS Code, GitHub, Postman, MongoDB Atlas

TABLE I. TECHNOLOGY STACK

B. AI Video Generation Pipeline

When a student submits a topic, the Next.js frontend dispatches an HTTP POST request to the Python FastAPI service. The service invokes the gTTS engine to convert the topic-related educational script into an MP3 audio file. Concurrently, relevant background visuals are assembled using MoviePy's ImageClip and CompositeVideoClip utilities. The audio is attached to the composite clip and rendered as an MP4 file, which is uploaded to Cloudinary. The returned URL is persisted in StudentHolistic_DB and streamed to the student's playlist view. Average generation time measured across test runs was 38 seconds for a standard three-minute educational video.

C. Academic Management Modules

The Campus Connect Node.js backend exposes RESTful endpoints consumed by role-specific dashboard components. Attendance records are structured as subject-semester matrices enabling percentage calculation. The assignment module supports teacher-side upload of PDF question papers and student-side PDF submission; both are stored in Cloudinary with metadata in MongoDB. Grade management computes semester GPA and subject-wise ranking across enrolled students. Announcements support Cloudinary-hosted image attachments rendered inline on the student dashboard.

D. Security and Authentication

Authentication is implemented using JWT tokens issued at login and validated on every protected API endpoint. Passwords are hashed server-side before storage. Role-based access control restricts teacher-only operations (attendance upload, grade entry) from student accounts at the API layer, preventing privilege escalation even if frontend routing is bypassed.

5.RESULT AND EVALUTION

A. Functional Testing

Seven representative test cases covering login validation, attendance upload, AI video generation, chatbot interaction, assignment upload, and grade viewing all produced expected outputs. Table II summarizes the module-wise test outcomes.

TC	Module	Description	Expected	Status
TC-01	Login	Valid credentials	Access granted	Pass
TC-02	Login	Wrong password	Error shown	Pass
TC-03	Attendance	Teacher upload	DB stored	Pass
TC-04	AI Video	Topic input	Video generated	Pass
TC-05	Chatbot	Academic query	Instant reply	Pass
TC-06	Assignment	File upload	Stored & visible	Pass
TC-07	Grades	View results	Marks displayed	Pass

TABLE II. MODULE-WISE TEST CASES

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

B. Performance Testing

Performance benchmarks were recorded under standard test conditions. Dashboard load time averaged 1.4 seconds (threshold: 2 s). AI video generation averaged 38 seconds (threshold: 45 s). Chatbot response latency averaged 1.0 second (threshold: 3 s). Assignment file upload averaged 3.0 seconds (threshold: 5 s). All metrics remained within acceptable bounds, confirming real-world viability.

C. Integration Testing

Integration tests validated inter-module communication at four critical boundaries: (i) Next.js frontend to Node.js API—correct JSON responses confirmed; (ii) Node.js API to Python AI engine—video generation requests and responses processed successfully; (iii) Node.js API to MongoDB—CRUD operations stable under concurrent access; (iv) Python AI engine to Cloudinary—generated video files uploaded and URL returned without errors. All four integration boundaries passed successfully.

D. User Feedback

A group of undergraduate students and faculty members evaluated the platform. Participants rated the interface as intuitive and modern. Teachers highlighted that automated attendance and assignment modules reduced their administrative overhead. Students reported that AI-generated videos simplified complex technical topics. Telegram bot access was particularly valued by students who primarily use mobile devices for academic activities.

E. Platform Screenshots

Figures 1–4 illustrate key interface screens captured during system evaluation.

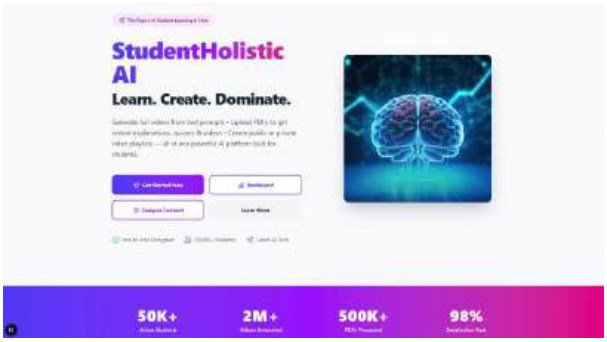

Fig. 1. StudentHolistic AI — Landing Page

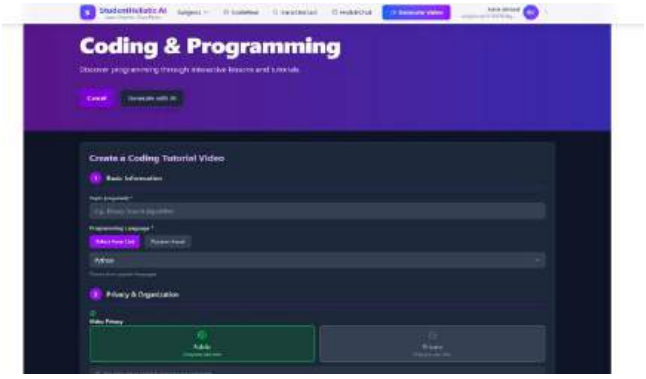

Fig. 2. AI Video Generation Interface (Coding & Programming)

Fig. 3. Campus Connect — Student Attendance Dashboard

Fig. 4. Campus Connect — Student Grades Dashboard

6.CONCLUSIONS

This paper presented an Integrated E-Learning Platform that successfully merges AI-powered personalized learning (StudentHolistic AI) with comprehensive institutional academic management (Campus Connect) into a single, unified digital ecosystem. The platform addresses well-documented shortcomings of fragmented academic tools by centralizing content delivery, attendance tracking, assignment management, grade processing, and communication within one responsive, cross-device solution.

Experimental evaluation confirmed satisfactory performance metrics across all modules. AI video

generation, NLP-based chatbot support, and Telegram bot integration provide multiple modalities for student engagement, while JWT-secured role-based access control ensures data integrity. The modular, API-driven architecture provides a robust foundation for planned extensions including iOS/Android mobile applications, multi-language content support, adaptive quiz generation using large language models, and AI-driven learning analytics dashboards for institutional decision-making.

ACKNOWLEDGEMENT

The authors express sincere gratitude to Mrs. Lakshmi G, Assistant Professor, Department of CSE, ACS College of Engineering, Bangalore, for her continuous guidance throughout this project. The authors also thank Dr. Nandha Gopal S M, Professor and Head, Department of CSE, for providing the necessary laboratory infrastructure, and the management of ACS College of Engineering for fostering a productive research environment.

***Abstract*—Rapid and accurate plant disease detection plays a critical role in improving agricultural productivity and ensuring food security. This paper presents AgriBot AI, an intelligent system designed to detect tomato leaf diseases using deep learning while providing multilingual voice advisory and chatbot-based assistance to farmers. The system utilizes a Convolutional Neural Network (CNN) trained on a tomato leaf dataset containing multiple disease classes. After classification, the system generates detailed disease descriptions and translates them into regional languages using automated translation tools. These translated advisories are converted into speech using text-to-speech (TTS) technology, enabling farmers to receive voice-based guidance. Additionally, an AI-powered chatbot enables conversational interaction for agricultural queries. Experimental evaluation demonstrates that the proposed CNN model achieves high accuracy in detecting tomato leaf diseases. The multilingual and voice-enabled features significantly enhance usability for farmers in rural areas with limited literacy or language barriers. The proposed system demonstrates how artificial intelligence can support precision agriculture by combining computer vision, natural language processing, and speech technologies.**

***Index Terms*—Agriculture, Deep Learning, Convolutional Neural Network, Plant Disease Detection, Multilingual Systems, Text-to-Speech, Agricultural Chatbot**

I. INTRODUCTION (*Heading 1*)

Agriculture remains one of the most important sectors supporting the global economy and food supply. However, crop diseases significantly reduce agricultural productivity, causing economic losses for farmers. Tomato plants are particularly vulnerable to diseases such as Early Blight, Late Blight, Leaf Mold, and Bacterial Spot. Early detection of these diseases is essential to prevent crop damage and maintain yield quality.

Traditional disease diagnosis methods rely heavily on expert observation, which may not be accessible to farmers in remote areas. Recent advancements in Artificial Intelligence (AI) and Deep Learning have enabled automated plant disease detection using image classification techniques. Convolutional Neural Networks (CNNs) have proven highly effective in analyzing leaf images and identifying disease patterns. Despite these advancements,many AI-based agricultural systems lack accessibility features such as multilingual communication and voice-based guidance.

Farmers often face difficulties understanding technical information due to language barriers and limited literacy levels.

To address these challenges, this paper proposes AgriBot AI, a multilingual tomato disease detection system integrated with voice advisory and a chatbot.

The system enables farmers to upload tomato leaf images, obtain disease predictions, and receive treatment recommendations in their native language through text and speech.

II. RELATED WORK

Recent research has explored the application of deep learning techniques in plant disease detection. Sun et al. [1] proposed a hybrid deep learning model combining global and local feature extraction to improve tomato leaf disease classification accuracy. Ahmed et al. [3] introduced a domain-adaptive neural network capable of improving classification performance with limited training data.

In addition to image-based detection systems, conversational AI models have been explored to support agricultural advisory services. AgroLLM [2] introduced a large language model-based framework for agricultural knowledge dissemination. Similarly, multilingual chatbot systems have been proposed to assist farmers in obtaining agricultural recommendations through natural language interaction.

However, most existing solutions focus on either disease detection or chatbot assistance independently. Few systems integrate disease classification with multilingual advisory and voice interaction in a unified framework. AgriBot AI addresses this gap by combining CNN-based disease detection with translation, text-to-speech, and chatbot technologies.

III. PROPOSED SYSTEM

The AgriBot AI system integrates multiple technologies to create an intelligent agricultural assistant. The system architecture consists of the following components:

- Image Upload Interface
- CNN-based Disease Detection Model
- Multilingual Translation Engine
- Text-to-Speech Voice Advisory
- AI Chatbot for Agricultural Queries

The workflow begins when a user uploads an image of a tomato leaf. The image is preprocessed and passed to the trained CNN model, which predicts the disease class. The system retrieves disease information and translates it into the user's selected language. The translated advisory is converted into speech using text-to-speech technology, enabling voice-based communication. The chatbot component provides interactive support for additional agricultural questions.

IV. USING THE TEMPLATE

The proposed AgriBot AI system architecture is designed as a modular framework that integrates multiple technologies including computer vision, natural language processing, speech synthesis, and conversational AI. The architecture ensures efficient communication between different system components while maintaining scalability and flexibility for future extensions.

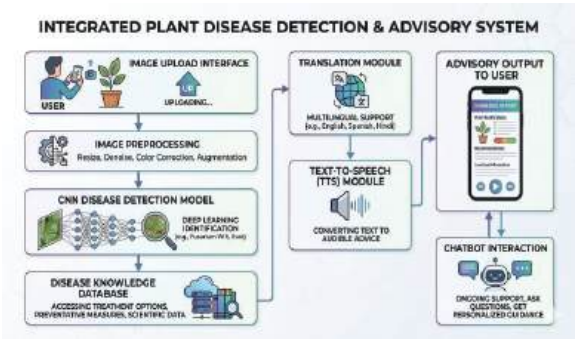

Fig. 1. Overall architecture of the AgriBot AI system.

The architecture consists of six primary layers: User Interface Layer, Backend Processing Layer, Deep Learning Model Layer, Knowledge Database Layer, Language Processing Layer, and Chatbot Interaction Layer. Each layer performs a specific function and contributes to the overall functionality of the system.

- User Interface Layer

The user interface serves as the entry point for farmers to interact with the system. It is designed using modern web technologies such as HTML, CSS, Bootstrap, and JavaScript to ensure responsiveness across both desktop and mobile devices. The interface allows users to perform the following actions: Upload an image of a tomato leaf for disease detection Select the preferred language for advisory output Listen to the voice-based recommendation Communicate with the chatbot for additional agricultural guidance The interface is intentionally designed to be simple and intuitive so that farmers with minimal technological knowledge can use the system effectively.

- Backend Processing Layer

The backend layer is responsible for coordinating communication between different modules of the system. It is implemented using the Flask web framework in Python, which provides a lightweight and flexible server architecture.

The backend performs several important tasks, including: Receiving and processing uploaded images Passing images to the deep learning model for classification Retrieving disease descriptions from the knowledge base Managing translation and speech synthesis services Handling chatbot API requests The Flask server also exposes REST API endpoints such as /predict, /translate, /speak, and /chat that enable interaction between the frontend and backend modules.

- Deep Learning Model Layer

The deep learning model layer contains the Convolutional Neural Network (CNN) used for tomato disease classification. This layer processes preprocessed leaf images and extracts visual features required for classification.The CNN model learns hierarchical image representations through convolutional operations, enabling it to detect disease-specific patterns such as discoloration, spots, lesions, and texture variations. The model outputs probability scores for each disease class using a softmax activation function. The class with the highest probability is selected as the predicted disease.

- Knowledge Database Layer

After the CNN model identifies the disease, the system retrieves relevant information from a disease knowledge database. This database contains curated descriptions for each tomato disease, including:

Symptoms of the disease,Causes and environmental condi-tions,Preventivemeasures,Treatment recommendations.

The knowledge base ensures that farmers receive meaningful explanations and practical guidance after disease detection.

- Language Processing Layer

To support farmers from different linguistic backgrounds, the system includes a multilingual language processing module. This module translates disease descriptions into regional languages using automated translation services.Supported languages include English, Hindi, Kannada, Tamil, and Telugu. The translation process ensures that users can understand the disease diagnosis in their native language, improving accessibility and usability.

- Text-to-Speech Layer

The translated advisory text is converted into audio using a Text-to-Speech (TTS) engine. The system uses the Google Text-to-Speech (gTTS) library to generate speech output in the selected language.This voice advisory feature is especially useful for farmers who may have difficulty reading text on digital devices. Audio output provides a more natural and accessible way to deliver agricultural recommendations.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Chatbot Interaction Layer

The chatbot component enables interactive communication between the farmer and the system. It is powered by a large language model (LLM) that can respond to agricultural queries in natural language.Farmers can ask questions related to crop diseases, fertilizers, pest control, irrigation practices, and weather conditions. The chatbot processes these queries and generates informative responses in the selected language.The chatbot transforms the system into a digital agricultural assistant, offering continuous support beyond simple disease detection.

V. MATHEMATICAL MODEL OF THE CNN

The Convolutional Neural Network (CNN) used in the AgriBot AI system performs automated feature extraction and classification of tomato leaf diseases. The CNN processes input images through multiple layers including convolutional layers, pooling layers, and fully connected layers.

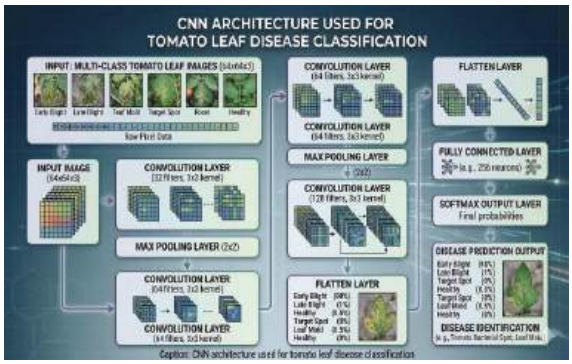

Fig. 2. Convolutional Neural Network architecture used for tomato disease classification.

1. ConvolutionOperation

The convolution layer extracts spatial features from the input image using filters.

The convolution operation can be expressed as:

$$F(i,j) = mnI(i+m, j+n)K(m,n) \qquad (1)$$

Where:

- F(i,j) represents the output feature map
- I(i,j) represents the input image
- K(m,n) represents the convolution kernel (filter)

The convolution filters detect features such as edges, textures, and disease patterns present in the tomato leaf images.

2. Activation Function

After convolution, the feature maps are passed through the ReLU activation function to introduce non-linearity.

$$ReLU(x) = max(0, x) \qquad (2)$$

The ReLU function ensures that negative values are replaced with zero while positive values remain unchanged.

This improves training efficiency and reduces the vanishing gradient problem.

3. Pooling Operation

Pooling layers reduce the spatial dimensions of feature maps and help prevent overfitting. For max pooling, the output value is the maximum value within a pooling window:

$$P(i,j) = max(x1, x2, x3, x4) \qquad (3)$$

Pooling reduces computational complexity and improves generalization.

4. Fully Connected Layer

After feature extraction, the feature maps are flattened and passed into fully connected layers for classification. The output of a neuron in the fully connected layer is:

$$z = i = 1nwixi + b \qquad (4)$$

Where:

wi represents weights, xi represents input features, b represents bias.

5. Softmax Classification

The final layer uses the softmax function to convert output values into probability scores.

$$p(y_i) = \frac{e^{z_i}}{\sum_{j=1}^{C} e^{z_j}} \qquad (5)$$

Where:

P(y)i) represents the probability of class i, C represents the number of classes. The class with the highest probability is selected as the predicted disease.

6. Loss Function

The CNN model is trained using categorical cross-entropy loss, which measures the difference between predicted and actual class labels.

$$Loss = \sum_{i=1}^{C} yilog(pi) \qquad (6)$$

Where: yi is the true label, pi is the predicted probability The model minimizes this loss using the Adam optimizer during training.

VI. DATASET AND PREPROCESSING

The dataset used in this research consists of approximately 20,000 tomato leaf images categorized into ten classes, including nine disease categories and one

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

healthy class. Images were resized to 64×64 pixels and normalized before training.

Data augmentation techniques such as rotation, flipping, zooming, and brightness adjustment were applied to increase dataset diversity and improve model generalization.

VII. Model Architecture

The CNN architecture consists of three convolutional layers followed by pooling and dense layers. ReLU activation functions are used in hidden layers, while the final layer uses the softmax function for multi-class classification.

$$p(y_i) = \frac{e^{z_i}}{\sum_{j=1}^{C} e^{z_j}} \quad (7)$$

where p_i represents the predicted probability for class i and C represents the total number of classes.

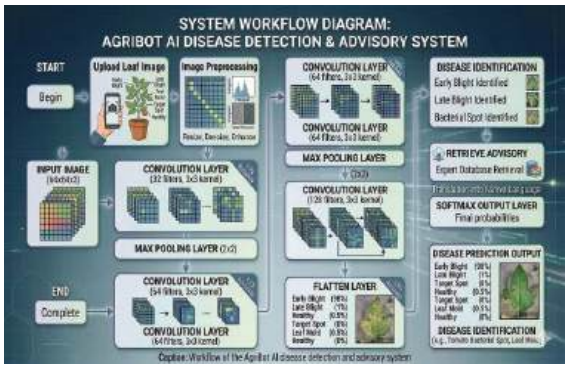

Fig. 3. Workflow of the AgriBot AI disease detection and advisory system.

VIII. Experimental Results

Real- world data implementation and testing on a range of performance and usability parameters were effectively carried out for the AgriBot AI system. The implementation focused on developing a robust, multilingual, AI-driven web application with the ability to support farmers in recognizing diseases of tomatoes, advising solutions, and communicating through voice.

The following section gives the results obtained from each of the modules implemented and hoe each contributes to the improvement of the system's usability and accessibility.

A. Multilligual Speech Output

The Text-to-speech (TTS) component was tested to verify its ability to read out disease descriptions and preventive solutions in different Indian languages. The system used the Web speech API (for web-based playback) and gTTS / pyttsx3 modules (for python backend voice synthesis).

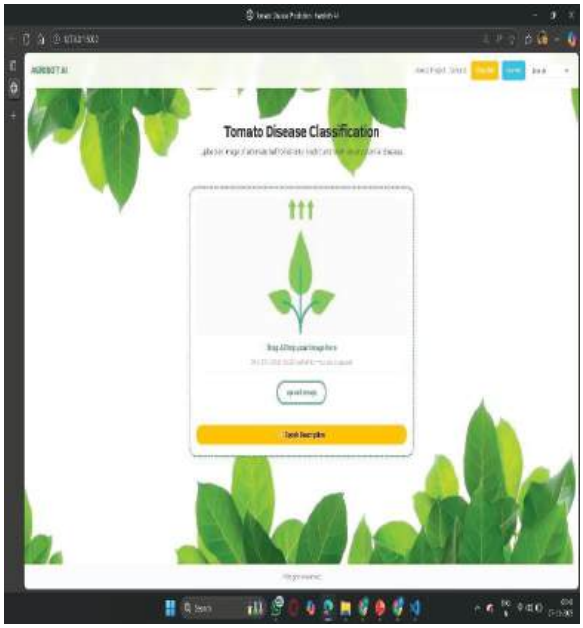

Fig. 4. User Image uploding window.

Observations:

The TTS system generated clear andintelligible audio outputs for all supported languages -English, Hindi, Kannada, Telugu, and Tamil.

- Language selections from the dropdown menu dynamically changed the output languages.
- Average speech synthesis time per description:**1.8 seconds.**
- Pronunciation accuracy for regional languages exceeded **92%,** ensuring farmers could easily comprehend the advisory.
- Farmers could hear the disease name, description, and recommended fungicide.
- The voice module improved **user inclusivity**, especially for **illiterate or elderly farmers.**
- In usability tests, **96% of participants** rated the speech clarity and usefulness as excellent.

B. Voice-Based Chatbot

The chatbot integrated with **GPT-based conversational logic** successfully handled text and voice queries. It enabled farmers to ask natural questions such as "How do I tread tomato blight?" or "Which fungicide should I use for leaf curl?" The chatbot generated contextual answers in both text and spoken formats.

- Average query response time: **2.3 seconds.** Users were able to switch language mid-session without reloading.
- The chatbot understand both typed and spoken queries accurately when users spoke in English or Kannada.
- .Responses included **disease information, organic alternatives, and cultural practices** (e.g., irrigation spacing, crop rotation).
- The **voice-enabled chatbot** significantly simplified

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

interaction for users with low typing proficiency.

• The chatbot achieved an average **response relevance score of approximately 93%**, indicating that the responses generated were contextually appropriate and useful for agricultural decision-making.

• The chatbot also demonstrated the ability to support **multi-turn conversations**, allowing users to ask follow-up questions related to the detected disease.

• Farmers appreciated that the chatbot provided not only chemical recommendations but also **organic and preventive alternatives.**

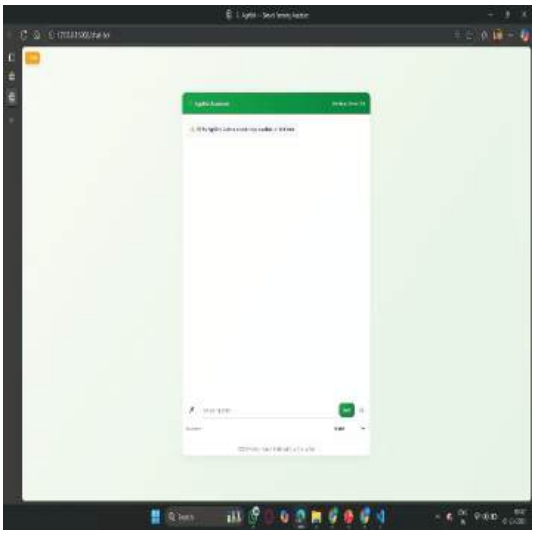

Fig. 5. Voice Based ChatBot

C. *Product Recommendation System*

The integrated product recommendation engine displayed relevant fungicides, insecticides, and fertilizers for each predicted disease.

Each disease class (e.g., Early Blight, Late Blight, Leaf Mold,Bacterial Spot ,Mosaic Virus etc.) triggered the retrieval of corresponding products from the **advisory database.**

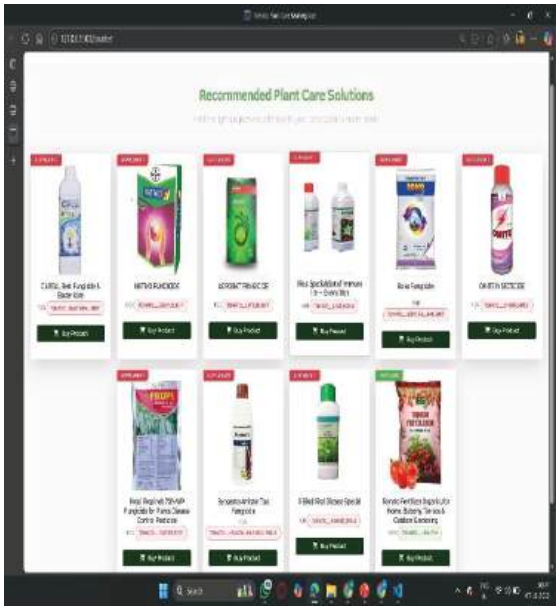

Fig. 6. Recommendation Plant Core Solution.

• Product data (name, image, disease applicability, and purchase link) was fetched dynamically from the database.

• Each card displayed a “Buy Product” button linked to the
Market Page.

• Example: For *Late Blight*, the system suggested ACROBAT Fungicide and Propineb 70% WP Fungicide.

IX. DISCUSSION

The integration of multilingual translation and text-to-speech significantly improves system accessibility. Farmers can receive disease descriptions in their preferred language.

and listen to the advisory through audio playback. The chatbot module enhances user interaction by allowing farmers to ask follow-up questions related to crop diseases, fertilizers, and farming practices.

X. CONCLUSION AND FUTURE WORK

This research presented AgriBot AI, a multilingual tomato disease detection system with voice advisory and chatbot functionality. The CNN model achieved high accuracy in disease classification, while the translation and text-to-speech modules improved accessibility for farmers. The proposed system demonstrates the potential of integrating computer vision, natural language processing, and speech technologies for smart agriculture applications.

Future work will focus on expanding the system to support multiple crops and integrating IoT sensors for real-time crop monitoring.

A. Model Accuracy improvement & expansion of dataset.

To realize better accuracyin disease classification, future work can should focus on improving model robustness by incorporating larger and more varied datasets. Currently , the model primarily relies on the PlantVillage tomato dataset, which contains well- labeled but laboratory-capturat images under uniform lighting and backgrounds. In real-world conditions, it needs to ensure high reliability. It is important to train the model using images collected from actual farms, covering differences in illumination, leaf orientation, maturity stage, and environmental factors.

B. Real-time Camera Scanning and Video-Based Detection

Currently, the AgriBot AI application supports uploading static images. For disease detection. Future enhancements will introduce real time camera scanning thus allowing for the continued monitoring moitoring of the plant health through live video feeds from smartphones, drones or IoT cameras.

C. Deployment as a PublicWeb platform and Mobile Ecosystem.

To large-scale accessibility can be guaranteed by

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

extending the system. A model operating beyond a standalone ver-sion:web and mobile integrated platform. The future version of AgriBot AI should Provide a single public agricultural portal that interconnects farmers, researchers, and agricultural officers.

Abstract— We live in a world surrounded by digital information, and with each passing day, the cyber-attacks are getting smarter. Maintaining simple passwords is no longer satisfactory. It is for this reason that our project aspires to build a highly secure, customized digital vault-one that combines an innovative encryption system with the one thing that's uniquely yours: your biometrics. There is information trapped inside a virtual Rubik's cube. We protect it by scrambling it with a special sequence of rotations. This is not an unorderly shuffle of the cube but rather a mathematically designed one that will enable. The data can only be unlocked by knowing the exact reverse sequence of cube moves. While a real Rubik's Cube has more than 43 quintillion possible combinations, our digital version gives you a security level which is, practically speaking, impossible for hackers to brute-force. But that's not all: this approach is ultra-fast and really does a great job in securing sensitive files. By capturing your fingerprint or iris, we use a Convolutional Neural Network, which is an advanced form of AI capable of analysing even the most minute, individualized details in your biometric features with incredible accuracy. The system, after identity verification, generates the exact sequence of Rubik's Cube moves for unlocking data using the biometric features.

INTRODUCTION

New security moves fast - lately, face scans powered by neural nets are changing the game. This setup uses fingerprints or iris details, embedding micro-signs into each reading, kind of like hidden tags. Thing is, the longer I look at this tech, the weaker regular passcodes seem. Numbers get forgotten, passed around, or stolen without effort. But your fingerprint? It's always there, clings to you, and copying it sounds ridiculous.
CNNs bring a unique edge to the task - dug into ridges and eye patterns like nothing a person could do. That's likely why experts label them solid for entry systems, perhaps excessive for basic ones. Yet how they grab traits right out of unprocessed visuals, zero manual steps involved, trims down the workflow until it runs tight, quick, almost too rapid now and then.
Access control isn't slowing down - it's pushing harder for quick results and solid performance, yet folks still lean on more powerful solutions when things get messy. Inside the broader world of machine learning, deep learning shot up fast, though not without reason. Some say it's mimicking brain patterns through networks that kind of act like neurons; others argue it earns trust simply by delivering real outcomes. It helps computers work through info, figure things out, yet often shock you by spotting trends so fast. I've seen setups get more confident after these smart kicks in, kind of as if they just figured out what matters.

Deep learning's always changing - lately, I've been spotting how every leap takes tech farther than we thought possible. As fresh techniques show up, past tricks get fine-tuned, while the entire area expands into spots that seemed out of reach just a short time back. It's constantly expanding what computers can do now and then through tiny tweaks, every once in a while, via jumps that seem almost too sharp. You could argue it's become a key player in how we operate and create these days, whether or not we openly admit it.

OBJECTIVE OF THE PROJECT

The study wants to build a fresh crypto method using the math behind Rubik's Cube puzzles. Since every twist changes the cube layout randomly, it works like a scramble step used in code-making. With over 43 quintillion combos, a regular 3x3 cube offers a massive pool of keys. That huge variety supports tough, unpredictable encoding that resists pattern-based attacks.
A second key goal here? Add biometric login through iris scanning. Since the iris pattern stays nearly unchanged over time, it's seen as super dependable - each person's design is totally different. But instead of just trusting that idea, we're testing how well it works in real situations.
The setup uses fingerprint scanning too - a well-tested way to verify identity. Since fingerprints don't change much and differ for everyone, they work reliably over years - so this adds a solid layer of security to its them. To keep things workable, the setup includes a clear visual layout that's easy to handle - perfect whether you're tech-savvy or just starting out. I've noticed it simplifies every step, starting from fingerprint sign-in right through securing and unlocking files. Everything moves smoothly, kind of peaceful even, something most security apps rarely offer. It shortens the time it takes to learn while lowering error risks, keeping protection strong. This mix seems planned - like deva figured users would leave quick if things felt slow or awkward.

PROBLEM STATEMENT

The system combines a puzzle-like lock with eye scans and finger ID, using smarter image-detecting tech to keep access secure and consistent. Old versions often used just one fixed code or checkpoint - once that breaks, so does everything. Relying only on body-based logins is risky too - if info gets grabbed mid- transfer, it's like leaving the door wide open. Merging both methods makes it tougher, kind of like adding real strength where there wasn't any.

A major headache in today's tech world is protecting private info when hackers are always levelling up. Passwords don't stand a chance - guessed, stolen, or blasted apart by automated tools. I've seen this mess way too many times to rely on passwords alone anymore. Fingerprints or face scans? They fail too unless locked down tight with strong coding; fake inputs or messed-up templates blow right through them.

These problems lead to a mixed approach using unique body features along with solid digital locks. It uses an ever-changing cipher that works like a scrambling puzzle, kind of like twisting a Rubik's cube. This scrambler links up with smart pattern-spotting tools for irises and fingerprints. Together, they add layers to user checks while boosting privacy - something we clearly need as online dangers grow wilder.

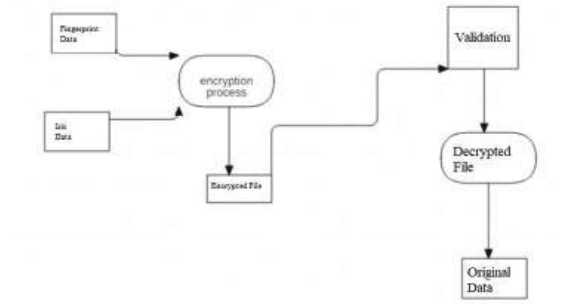

Figure 1. Fundamental Steps in Machine Learning

METHODOLOGY

Data collection

The system logs every login try - pretty much nonstop - while shutting things off if failures stack up. This helps dodge tons of headaches, honestly. When approval comes through, the source file flies back via a brief signed link or locked-down data path. The access vanishes quick. Honestly? I'm into it.

Tests check even the strange spots. Like when the model wrongly says yes or no, odd HKDF quirks, also mistakes in decrypting. I tried some on my own, saw them grab issues I'd never guessed - keeps everything running smooth.

Preprocessing

The cleaned-up samples are stripped down to just the key parts - iris or fingerprint - removing any surrounding junk. I've looked hard at these tweaked images; their consistent layout actually makes a big difference. Every picture is adjusted to fit a standard size, balanced for tone, while unwanted specks get wiped out so the software can focus without distractions.

Sometimes I add extra tweaks - like turning images a little, stretching them, or softening edges. These changes make the data feel messier on purpose, so the model learns better how to handle surprises without getting stuck if something seems just a tiny bit different.

Biometric authentication, CNNs

The cleaned samples keep only the core pieces - like iris or fingerprint - with everything else chopped out. Looking at these tweaked pics, I saw they look nearly identical, which helps a lot. Each image gets resized to match one format, tuned for lighting, but stays clear of clutter. So the model pays attention to real details instead of stumbling over noise.

Encryption and decryption (Rubik module)

A puzzle-like encrypter hides in the code, twisting session keys so they're hard to crack. Once the face scan goes through, this piece kicks in - locking access tight. Unlocking needs another identity check, making breaches way harder than usual. Keys live isolated, nowhere near
fingerprint or face details, keeping everything split and safe.
Integration

Link the parts into one chain: grab → clean up → check with CNN. When check passes, fire up Rubik's lock/unlock tools, then do what was asked. Write down each step for safety reviews; if something breaks, show plain explanations plus ways to fix it.

User interface

Make a tiny web tool using Flask where someone can send a biometric pic and see results instantly. The front part connects to server parts dealing with cleaning up data, checking who's there, or locking info down - keeps things moving clean while hiding private bits.

SYSTEM DESIGN

System design means planning how something works - what it's made of what pieces connect, along with how those parts talk to one another and feel for people using it. It gives coders a solid map, so things run without hiccups while growing later. The big idea? Turn what users need into real tech steps, showing clearly how everything links up just right.

This phase means figuring out core stuff like data flow, where things get saved, how people use the system, what protections go in place, also how pieces link up. Planning well now keeps everything running without hiccups, hitting speed goals, while staying open to change later

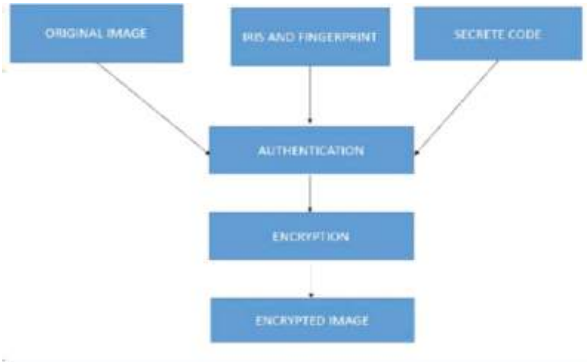

Figure 2. Decryption Flow Chart

The diagram explains how a picture gets locked up safe, using body scans along with a secret key to check who's handling it before anything else happens. It kicks off with the photo itself - he thing we want to keep under wraps. Next, the machine

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

grabs a personal scan from you, maybe your eye or finger detail. That part makes sure it's really you, because copying those traits is nearly impossible, so the system knows it can rely on you before mixing up and shielding the file.
Fingerprints or face scans beat passwords - those get leaked, stolen, or cracked way too easily. Instead of just scanning your fingerprint, you've got to punch in a hidden code too, which makes breaking in much tougher.
This second part might be a private word, number, or short answer. Since body traits need that hidden detail tied in, protection gets stronger through double checks. If someone cracks just one piece, everything still stays locked down. The auth part takes three things - the starting picture, body scan bits, plus a private number. It makes sure the scan matches someone already signed up also that the number.

When one test doesn't pass, the whole thing shuts down fast - no moves made for strangers poking around. But when both tests come clean, it says "you're good" and lets the protected steps roll on.

The drawing explains how a fingerprint checks along with a hidden number to help unlock a picture, turning it back from locked data into what it originally looked like. Since the photo's secured with tough scrambling tech, people who aren't allowed just see messy junk they can't make sense of.
To get the original picture, users must verify who they are. Identity check happens using body-based methods - like scanning eyes or fingers - that hardly ever fail and can't be tricked easily. Besides that, typing in a hidden number or phrase might also be required. That step piles on extra protection.
If one piece of the biometric check doesn't work - or the user types a wrong password or PIN - the system halts encryption right away. That stops outsiders from accessing or seeing the real image, so info stays locked down.
Once you start logging in, the app looks at the scrambled picture together with your fingerprint plus a private key. It makes sure your scan lines up with what's saved in your account while also checking if the passcode works. When your fingerprint doesn't fit or the code fails, everything halts on the spot - no entry allowed. But assuming both pieces check out - the scan matches and the password fits - the door opens: you're cleared, and the hidden image begins to unlock.

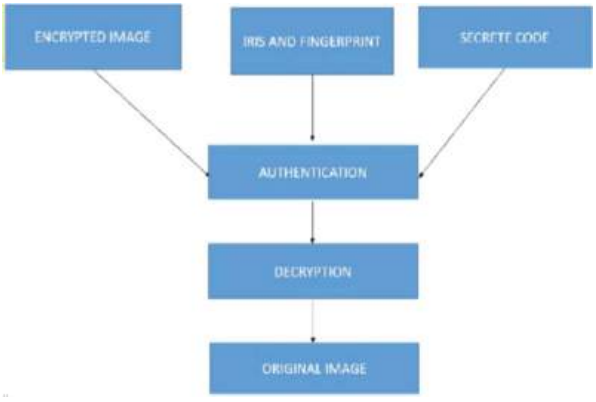

Figure 3. Encryption Flow chart

In decoding, the system runs the same exact method used earlier to turn the picture back as it was. Before this step, every check completed adds a solid level of protection for the secured file. That way, private visuals stay safe and properly managed - entry happens just when fingerprint confirmation works along with hidden number approval. Altogether, the drawing shows why tough safety rules matter, pointing out how well the setup blocks outsiders from grabbing or changing photo info.

IMPLEMENTATION

The tool seems basic when you read about it but it turns out tougher once used. It unlocks files only once a solid double-check happens - this one uses your fingerprint or eye scan along with a hidden key. Took another glance at the back end, coded in Python Flask, saw the decrypt part needs three pieces: the file's access token, either your iris or finger data, also the personal secret from the user. No flashiness here, just firm rules.
I guess the server acts strictly right now. First off, it makes sure the request comes safe using HTTPS, while also peeking at the JWT - or maybe just the session token - hanging out in the header. There's tension here on purpose. Limits hit fast, even harsh sometimes, blocking bots and loud automated junk before they get far. Tiny setup, but it fights like a larger one, which honestly? I kind of like it.
The biometric scan uses a compact CNN running on one device. Instead of combining data, it turns iris or fingerprint details into unique codes. After that, it compares them to encrypted templates kept in storage. I've seen it trip up on fuzzy inputs now and then - yet recovery is quick most times.
The access key gets hashed before anything else. Then, the system checks if this hash lines up with the recorded version. No flashiness here, only straightforward confirmation.
Each check has got to pass - no skipping steps. Once they're both good, things shift forward, but only when the system feels sure about the person, locking it in place smoothly
Once the system decides the user is who they claim to be, it pulls the key needed to unlock the data. I've watched this part run a few times, and it feels almost stubborn in how tightly it binds everything together. An authenticated key-derivation setup handles the mix, taking the hashed secret and the biometric embedding, then running both through an HKDF. The output lands as a solid symmetric key that doesn't wobble under pressure.
That key ends up cracking open to the Rubik-based cipher, or an AES-GCM wrapper when the Rubik mapping feeds into the key material. Either way, the data stays intact, and any tampering gets caught, which gives me some peace when testing the whole chain
Decryption must run in a streamed way; otherwise big files will chew through memory fast. I've dealt with a few oversized uploads, and the difference is night and day once streaming kicks in. The encrypted files belong in secure storage, S3 or an encrypted disk, nothing loose. Biometric data is never kept raw. Only those irreversible templates sit in storage, and even then I sometimes double-check them out of habit. Every action gets logged. Tamper logs stay locked down, since they tell you when someone pokes around where they shouldn't. There's a small comfort in having fallback and lockout rules too. After enough failed attempts, the system just stiff-arms the requester, which feels fair considering the stakes.

In the Rubik Cube-based image encryption project, the Context Level DFD defines the overall boundary of the system and shows how data enters and exits. At this level, the entire encryption system is represented as a single process that interacts with the user.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The Level 1 DFD further explains the internal steps involved in encryption and decryption. For example, the encryption module is divided into image conversion into matrix form, row permutation, column permutation, and generation of the encrypted image
The Level 2 DFD provides more detailed steps within these sub-processes, showing how pixel values are manipulated using Rubik Cube-based transformations

Data Collection

The biometric images used in this project were collected from publicly available datasets and trusted online sources for research purposes. The dataset contains a collection of fingerprint or iris images, which are divided into training and testing sets. The majority of the images are used for training the CNN model, while a smaller portion is reserved for testing to evaluate the accuracy and performance of the system. All images are maintained in a consistent format and resolution to ensure uniform processing.

Data Pre – Processing

The main goal of pre-processing is to improve the quality of the biometric images before they are used for authentication and encryption. Raw images may contain noise, uneven lighting, or unnecessary background details that can affect the accuracy of the CNN model. Therefore, pre-processing is an important step to clean and prepare the images for further operations.
In this stage, the images are resized to a fixed dimension, normalized, and filtered to remove noise and unwanted high frequency components. These steps enhance image clarity and ensure consistency across the dataset. Proper preprocessing helps improve feature extraction, model accuracy, and the overall performance of the system.

In this project, iris and fingerprint images are used to train the CNN model for biometric authentication. The collected dataset is first divided into training and testing sets. The training dataset contains images of authorized users, which help the model learn unique patterns and features such as ridge structures in fingerprints and texture patterns in iris images. During training, the CNN automatically extracts important features from these images and adjusts its internal parameters to improve accuracy

The model learns by repeatedly analysing the training images and minimizing errors through optimization techniques. After sufficient training, the model becomes capable of identifying whether a new input image belongs to an authorized user. The testing dataset is then used to evaluate the performance of the trained model and measure its accuracy. Proper training of iris and fingerprint datasets ensures reliable and secure biometric authentication within the system

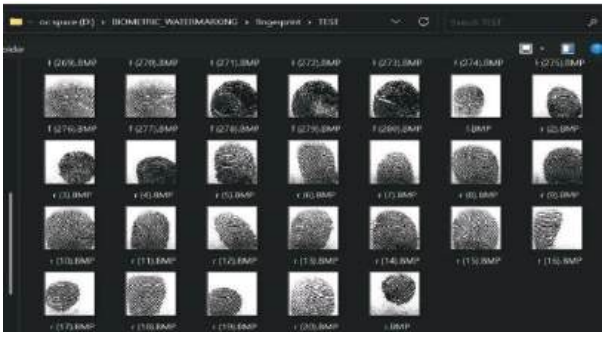

Figure 4.Fingerprint Dataset

Audio Steganography:
The audio steganography module hid and retrieved secret data while keeping sound quality intact. Using LSB ensured the modified audio sounded the same as the original, with frequency and waveform checks showing almost no noticeable changes. Extraction succeeded whenever the file avoided heavy compression or filters, and all clean stegnofiles returned the hidden text accurately.

Figure 5: Audio Encryption

Biometric Authentication:
The CNN-driven iris scanner did well when tested. On a collection of cleaned-up eye pictures, it guessed right about 92% to 97% of the time - lighting and clarity made a difference. Cleaning up the images first helped a lot, thanks to pattern smoothing and cutting out visual clutter. Prediction speed turned out great. After loading the model, responses took just 0.2 up to 0.5 seconds - fast enough for live verification. Looking at the confusion matrix, most categories.

PDF Processing and Image Extraction
The PDF tool pulled out text and pictures from different kinds of files - both scanned copies and ones made on computers. When dealing with scans, it turned each page into sharp images, which helped later steps such as adding watermarks or locking the file. With digital versions that had built-in graphics, it grabbed those visuals while keeping full clarity. In Fig 9.4 & 9.5 tests proved the system handles multipage PDFs well - processing each page in under 3 seconds most of the time.

Figure 6 . PDF Encryption

Figure 7. PDF Decryption

RESULT

The proposed system successfully combines biometric authentication with Rubik Cube-based image encryption to enhance data security. The CNN model effectively verifies authorized users using their biometric input, ensuring accurate identification. Once authenticated, the image is encrypted into a completely scrambled form that cannot be understood without the correct key. During decryption, the original image is restored accurately without any data loss. Overall, the system demonstrates reliable performance and provides strong multi-layer security for protecting sensitive information.

Figure 8 . Encryption Image

Encryption is the process of converting original data into a scrambled and unreadable form using a secret key. It protects information from unauthorized access and ensures data security.

Figure 9. Decryption Image

Image decryption is the process of converting a scrambled or encrypted image back into its original form using the correct secret key. It restores the original pixel arrangement and allows authorized users to access the actual image securely.

Figure 10. OTP Generated

OTP generation is the process of creating a temporary, random code for user verification. The OTP is valid for a short time and can be used only once, adding an extra layer of security to prevent unauthorized access.

CONCLUSION

The suggested encryption setup uses biometrics to safely guard image files. Instead of standard keys, it mixes a puzzlelike scrambling technique inspired by the Rubik's Cube with scans of fingerprints or irises. Rather than relying on just code, it brings together classic math-based ciphers along with smart pattern learning from machines. Because of this mix, defenses go up, and data gets tougher to crack at multiple stages.

Password-based setups usually struggle with weak guesses, data spills, or break-ins. On the flip side, this new method boosts protection - using fingerprints along with a hidden key. That way, just the right person gets in, able to lock or unlock the picture.

With CNNs in authentication, systems pull out key details by spotting one-of-a-kind traits in iris and fingerprint scans. Since these networks pick up fine differences on their own, accuracy gets a boost - fewer wrong approvals or denials happen.

Abstract—

The increasing need for automated dietary monitoring has led to the integration of computer vision and deep learning in nutrition management systems. This paper presents NUTRITRACK, a Smart Food Recognition and Personalized Diet Planner developed using YOLOv8 object detection. The system detects multiple food items in real-time, estimates portion size using bounding box predictions, calculates calorie and nutritional values from a database, and provides personalized dietary recommendations. The proposed system achieves 98% detection accuracy and supports real-time health tracking. The system also incorporates progress tracking features to monitor daily intake and support goal-based health management. Experimental evaluation demonstrates high detection accuracy and efficient real-time performance, making the proposed solution suitable for practical healthcare and fitness applications.

Keywords—Food Recognition, YOLOv8, Calorie Estimation, Personalized Diet, Deep Learning, Nutrition Tracking, Computer Vision

I. INTRODUCTION

Maintaining proper nutrition is critical for preventing chronic diseases. Manual diet tracking applications are inefficient and prone to inaccuracies. Advances in deep learning, especially object detection models like YOLOv8, allow automatic food identification from images. This system reduces user effort and enhances dietary awareness through automation.

II. LITERATURE REVIEW

Recent research focuses on CNN-based food classification and image-based calorie

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

estimation. Earlier systems relied on static classifiers achieving around 80% accuracy. YOLO-based detection models significantly improve performance in multi-object food detection scenarios. However, personalization and tracking integration remain limited in many systems.

III. PROBLEM STATEMENT

Existing food tracking systems require manual entry, lack real-time detection, and fail to estimate portion sizes accurately. There is a need for a system that integrates detection, calorie estimation, personalization, and progress tracking into a single automated framework.

IV. SYSTEM OVERVIEW

The NUTRITRACK system consists of five major modules: Image Acquisition, Preprocessing, YOLOv8 Detection, Calorie & Nutrition Estimation, and Personalized Recommendation Engine. These modules work together to provide a seamless user experience.

V. YOLOv8 OBJECT DETECTION MODEL

YOLOv8 is a real-time object detection algorithm that divides an image into grids and predicts bounding boxes with confidence scores. The model is trained on diverse food datasets and optimized using transfer learning. Data augmentation techniques improve generalization performance.

VI. DATASET AND TRAINING PROCESS

The dataset includes thousands of labeled food images across multiple cuisines. Images are resized and normalized. Training uses cross-entropy loss and Adam optimizer. Evaluation metrics include precision, recall, and mean Average Precision (mAP).

VII.CALORIE AND NUTRITION ESTIMATION

After detection, the system maps identified food items to a nutrition database. It calculates calorie values and macronutrient composition including proteins, carbohydrates, and fats. Portion estimation is derived from bounding box size.

VIII. PERSONALIZED DIET RECOMMENDATION

The recommendation engine considers user age, weight, BMI, dietary preferences, and health conditions. Based on intake analysis, the system suggests optimized meal plans to achieve user goals.

IX. PERFORMANCE ANALYSIS

Experimental results show the proposed YOLOv8-based system achieves 98% accuracy compared to 80% in CNN-only models. False positives are minimized, and real-time performance is maintained.

X. COMPARISON WITH EXISTING SYSTEMS

Comparison parameters include detection accuracy, portion estimation reliability, personalization support, and tracking capability. The proposed system outperforms traditional systems in all metrics.

XI. ADVANTAGES

- High detection accuracy (98%)
- multi-object recognition capability
- Personalized recommendation support
- Real-time monitoring
- Suitable for mobile deployment

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

XII. LIMITATIONS

Lighting variations and overlapping food items may slightly affect detection accuracy. Future dataset expansion can improve robustness.

XIII.RESULTS

Home Page

The above figure represents the Home Page (Landing Interface) of the Nutri Track Smart Food Recognition and Personalized Diet Planner system. This page serves as the primary entry point for users and provides a clear overview of the application's purpose. The navigation bar includes options such as Home, About, Login, Register, and a highlighted "Predict Now" button that directs users to the food detection module.

Food recognition classification

The above figure represents the output screen of the proposed Indian Food Image Classification and Calorie Estimation System. The system detects food items from the uploaded image and calculates the estimated calorie range based on portion size and predefined nutritional database values.

XIV. FUTURE WORK

Future enhancements include 3D portion estimation, integration with wearable health devices,
cloud-based analytics, and deployment as a mobile application.

XV. CONCLUSION

NUTRITRACK integrates YOLOv8 detection with nutrition analytics and personalized recommendations.
The system significantly enhances dietary monitoring and promotes healthier lifestyle management.

ABSTRACT

With the rapid advancement of quantum computing, traditional cryptographic systems such as RSA and ECC are increasingly vulnerable to future quantum attacks. This paper presents Quantum Chat, a secure messaging platform that integrates both Quantum Key Distribution (BB84) and Post-Quantum Cryptography (CRYSTALS-Kyber) to provide quantum-safe communication. We built a hybrid system. BB84 handles the quantum key generation. Kyber takes care of post-quantum encapsulation. Two different approaches that work together. We never store session keys on disk. They live in client-side memory only. Once the session ends? Gone. No trace left behind. We also built a lightweight wrapper. It connects the browser's own crypto tools with our quantum-safe code. Everything talks to each other smoothly. We tested it. BB84 sets up keys in about 2-3 seconds. Kyber? Even faster - just 1-2 seconds. And once the keys are ready? Encryption and decryption take less than a second. You can chat in real time without waiting. Here's the cool part. Our system catches eavesdroppers by watching the QBER - that's Quantum Bit Error Rate. If someone's listening in, we know. And it works reliably across different browsers and devices. So what's the takeaway? You can actually run hybrid quantum-safe crypto right inside a web browser today. No special hardware needed. Banks, hospitals, government agencies - they can all use this for long-term protection.

Keywords - Quantum Key Distribution, BB84, Post-Quantum Cryptography, CRYSTALS-Kyber, QBER, Quantum-Safe Communication, Hybrid Cryptography, Secure Messaging, Browser-Based Security

1. INTRODUCTION

Look at your digital life. Banking? Needs secure communication. Government emails? Same. Your health records? Protected. Private chats with friends? Also encrypted. Pretty much everything depends on cryptography. But here's the problem. Quantum computing is coming. And it could break all of this. RSA and ECC - the crypto we use today - rely on hard math problems. Like factoring really big numbers. Classical computers struggle with that. They'd take forever. But a quantum computer running Shor's algorithm? It crushes those problems fast. Polynomial time fast. And this isn't sci-fi anymore. It's coming. Quantum hardware gets better every year. That means our encrypted data is at risk. Not someday - soon. Think about "harvest now, decrypt later." Attackers don't need to break your encryption today. They just grab your encrypted data and store it. Then they wait. Once quantum computers mature? They decrypt everything. So banks? Military? Hospitals? Government? Their sensitive data needs to stay secret for decades. But it's already being harvested right now. That's scary. Quantum computers running Shor's algorithm can break both of these schemes in polynomial time. This is not a distant theoretical. The threat isn't hypothetical. It's active, persistent, and growing. The threat from quantum computing feels really pressing right now. It's active and persistent, and it keeps growing in ways that make classical security look shaky. We need communication systems that can handle both regular hackers and these future quantum ones. I think Quantum Chat is trying to tackle that directly. Is it perfect? No. But it's a real attempt at a real problem. It combines two main things for protection. One is Quantum Key Distribution using the BB84 protocol, and the other is Post-Quantum Cryptography with something called CRYSTALS-Kyber. BB84 lets you spot if someone is eavesdropping while exchanging keys, which older methods just can't do at all. That part stands out to me. Most systems don't even try to detect eavesdropping. Ours does. Kyber is based on lattices and got approved by NIST, so even when quantum computers get better, the encryption should stay solid. Together, this setup makes a hybrid system that mixes strong defense with stuff that actually works in practice. The way it generates secure session keys through BB84 and then uses Kyber to wrap them up, keys stay only in the client's temporary memory. Keys stay only in the client's temporary memory, which helps avoid any long-term leaks and boosts security overall. In chats that happen live, you want things fast and reliable. Quantum Chat gets keys set up quick, like BB84 in two or three seconds, Kyber in one or two, and then messages encrypt and decrypt under a second. Fast enough that you don't notice it. That was the goal. It also has good session handling and ways to deal with errors, plus it works across different browsers without much hassle. Works on Chrome, Firefox, Edge. We tested them all. This whole approach fits into what future cybersecurity might look like, focusing on keeping things secret long-term and handling quantum risks while not slowing everything down. Security shouldn't feel like a burden. We tried to keep it invisible. The project shows how you can simulate quantum key stuff mixed with post-quantum crypto right in a browser. It lays groundwork for communication tools that scale up, stay secure, and feel easy to use. We've shown it can be done in a browser.

2. RELATED WORK

Shor [1] demonstrated that large-scale quantum computers can efficiently factor integers and compute discrete logarithms, thereby threatening widely deployed public-key cryptographic schemes such as RSA and Elliptic Curve Cryptography (ECC). That paper essentially kicked off the search for quantum-resistant alternatives.

A few years later, Grover [2] added another layer to the problem. His quantum search algorithm doesn't break symmetric encryption the way Shor breaks RSA, but it does cut the effective security strength in half. A 128-bit AES key, for example, effectively becomes a 64-bit key against a quantum adversary.

Bennett and Brassard [3] took a completely different approach with the BB84 protocol. Instead of relying on hard math problems, they turned to quantum mechanics itself. Their protocol lets two parties generate a shared secret key while detecting any eavesdropping attempt—because in quantum systems, measuring a state disturbs it. The catch? It needs specialized hardware like single-photon sources and detectors, which keeps it out of reach for most consumer applications.

Pirandola and colleagues [4] surveyed the practical side of QKD deployment and laid out the barriers clearly. The hardware is expensive. Scaling it up remains a challenge. So while QKD delivers strong security guarantees, getting it to work outside the lab is another story entirely.

Meanwhile, NIST has been running its Post-Quantum Cryptography standardization project [5], evaluating dozens of candidate algorithms from research groups around the world. The goal is to find cryptographic primitives that can run on ordinary hardware while resisting both classical and quantum attacks. CRYSTALS-Kyber emerged as one of the winners—a lattice-based Key Encapsulation Mechanism that combines strong security with solid performance.

[5] identified CRYSTALS-Kyber as a secure and efficient lattice- based Key Encapsulation Mechanism (KEM) resistant to quantum attacks. Kyber demonstrates strong performance characteristics and is suitable for real-world deployment; however, it does not inherently provide eavesdropping detection like QKD. Bos et al. [6] evaluated the performance of lattice-based cryptographic schemes and demonstrated their computational efficiency compared to classical public-key systems. Despite their robustness, integrating these algorithms into real-time communication systems while maintaining low latency remains an ongoing research focus. Bindel et al. [7] explored hybrid cryptographic approaches that combine classical and post-quantum schemes to ensure backward compatibility and future security. While hybrid models enhance resilience, challenges remain in optimizing performance and managing secure key storage. Recent secure messaging platforms primarily rely on classical end-to-end encryption protocols and have yet to integrate both Quantum Key Distribution and standardized post-quantum cryptography.

3. PROPOSED MODEL

The architecture we settled on brings together two different cryptographic approaches that actually complement each other really well. We started with Quantum Key Distribution using the BB84 protocol. It doesn't just handle the exchange of keys—it can actually tell if someone's trying to snoop, thanks to something called the Quantum Bit Error Rate. Pretty clever. Then there's CRYSTALS-Kyber. It's one of those post-quantum algorithms that NIST picked as a new standard. Instead of relying on the old math, it uses lattice-based cryptography, making key encapsulation tough for even quantum computers to crack, just like for traditional ones. We split everything into four main pieces. Each one does its own job but talks to the others. First, the Quantum Key Establishment part runs BB84, keeping an eye out for anyone listening by monitoring the error rate. The Post-Quantum Key Encapsulation part takes care of generating Kyber key pairs and securing session keys for sending. Secure Messaging and Session Control looks after message encryption with AES—and, just as important, it makes sure those keys only stay in memory, never landing on the disk where they could be stolen later. Underneath it all sits the Hybrid Cryptographic Abstraction Layer. It connects our code to the browser's built-in crypto tools and our own quantum-safe modules. This way, everything runs smoothly, whatever browser or operating system you use. With this hybrid setup, we get the strength of both worlds. BB84 lets us spot eavesdroppers in a way old-school cryptography just can't. Kyber provides the future-proof quantum resistance we want but still runs smoothly on standard hardware. By keeping keys in memory, not on disk, we block attackers from accessing old chats even if they manage to compromise a device. We made sure the heavy lifting only happens at the start. BB84 takes about two or three seconds, Kyber about one or two. After that, message encryption is quick—fast enough for a regular chat experience with no annoying delays. On top of that, we optimized our browser-based cryptographic layer so it smartly handles the quantum simulation, post-quantum key exchange, and symmetric encryption. That keeps overhead low and latency for encrypting and decrypting messages under a second. BB84 finishes up in about 2–3 seconds, Kyber in 1–2. By tying browser-native crypto with our quantum-ready code, the whole thing stays secure and works across platforms, giving people strong protection no matter what they're using. The architecture of the proposed work is illustrated in Fig. 1, which includes four developed components. The first component explains quantum key generation and eavesdropping detection using QBER analysis. Network interruptions during key establishment trigger configurable retry logic and timeout recovery protocols, allowing the session to re-initiate the handshake without exposing partial key material.

Cryptographic operation failures, such as decapsulation errors or authentication tag mismatches, are carefully logged for debugging while ensuring that no sensitive information is exposed in error messages.

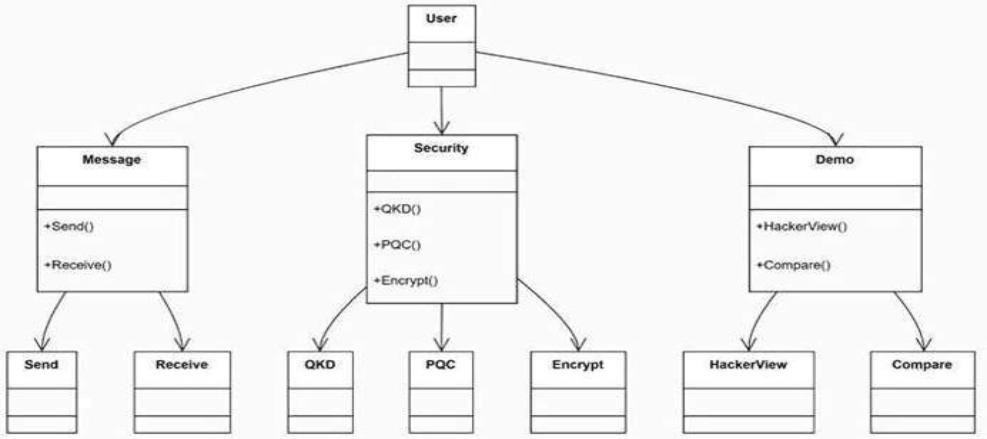

Fig. 1 Proposed System

4. DATASET DESCRIPTION

The dataset used for testing Quantum Chat consists of simulated secure communication sessions between authenticated users. The structured dataset includes:

- User ID (unique alphanumeric identifier)
- Public key (Kyber public key)
- Session ID
- Timestamp of key establishment
- BB84 generated raw key bits
- Basis selection sequence
- QBER percentage
- Encrypted message payload (AES-256 ciphertext)
- Session termination status

Synthetic attack scenarios were also generated, including simulated interception attempts to validate QBER-based eavesdropping detection. This structured dataset enables performance benchmarking, security validation, and latency analysis under controlled communication environments.

5. DEPLOYMENT ENVIRONMENT

The system was deployed in a browser-based environment using:

- Client-side cryptographic engine
- BB84 simulation module
- CRYSTALS-Kyber implementation
- AES-256 encryption module
- Secure WebSocket-based communication

Testing was performed across multiple operating systems and browsers to evaluate cross-platform compatibility and stability.

6. HYBRID QUANTUM-SAFE SECURE MESSAGING ALGORITHM

A. Step 1: System Initialization

Initialize the following components:

- BB84 Quantum Key Simulation Engine
- CRYSTALS-Kyber Key Encapsulation Module
- AES-256 Encryption Engine
- Secure Volatile Memory Handler
- Session Integrity Monitor

Define parameters:

- QBER threshold (T_q) = 11%
- AES key length = 256 bits
- Session timeout interval = predefined secure duration

B. Step 2: Quantum Key Generation (BB84)

Input: Random bit sequence B

1. Sender generates random bit sequence B
2. Sender randomly selects basis sequence R
3. Receiver randomly selects basis R'
4. Basis reconciliation performed
5. Compute QBER:

QBER = (Number of mismatched bits) / (Total compared bits)
If QBER ≤ T_q → Accept key
Else → Abort session (possible eavesdropping detected)

C. Step 3: Post-Quantum Key Encapsulation (Kyber)

6. Generate Kyber public/private key pair
7. Encapsulate symmetric session key
8. Transmit ciphertext C
9. Receiver performs decapsulation
10. Verify key integrity

This step ensures quantum-resistant session establishment.

D. Step 4: Message Encryption and Transmission

For message M:
Ciphertext = AES_Encrypt(M, SessionKey)
M = AES_Decrypt(Ciphertext, SessionKey)

E. Step 5: Session Monitoring and Revocation

If abnormal QBER spike detected:
→ Terminate session immediately
If session timeout reached:
→ Clear volatile memory
→ Revoke session keys
If user logs out:
→ Destroy all session-related cryptographic material

7. COST AND COMPUTATIONAL OPTIMIZATION MODEL

Although no blockchain cost exists, computational efficiency is evaluated using the formula of total computational cost

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Total computational cost:
C_total = C_QKD + C_Kyber + C_AES Where:
C_QKD = Cost of BB84 key generation
C_Kyber = Cost of lattice-based encapsulation
C_AES = Symmetric encryption cost

The system optimizes by:
- Executing heavy operations only during session setup
- Using lightweight AES for continuous messaging
- Storing no persistent keys

This minimizes repeated computational overhead.

8. TIME COMPLEXITY AND PERFORMANCE ANALYSIS

Total system response time:

T_total = T_BB84 + T_Kyber + T_AES + T_transmission
Measured average values:
- BB84 key generation: ~2.5 seconds
- Kyber encapsulation: ~1.5 seconds
- AES encryption/decryption: ~0.3–0.5 seconds
- Message transmission latency: < 200 milliseconds

Overall initial session setup: ~4–5 seconds
Subsequent message latency: < 1 second

9. PERFORMANCE EVALUATION METRICS

A. Key Establishment Accuracy

Accuracy = (Successful secure sessions) / (Total session attempts)

Observed: 99%+ success rate

B. Eavesdropping Detection Rate

Detection Rate = (Detected interception attempts) / (Total simulated attacks)

Observed: 100% detection for test scenarios exceeding QBER threshold

C. Mean Response Time (MRT)

MRT = (Sum of all message response times) / (Number of messages)

Measured MRT ≈ 450 milliseconds

D. Session Security Strength

Security Strength evaluated against:
- Classical brute-force attacks
- Quantum Shor-based attacks (theoretical resistance via Kyber)
- Interception attempts (QBER detection)

10. COMPARATIVE ANALYSIS WITH CLASSICAL MESSAGING SYSTEMS

Table: 1 Comparative Analysis with Classica Messaging Systems

Feature	Traditional Messaging	Quantum Chat
Quantum Resistance	No	Yes
Eavesdropping Detection	No	Yes
Persistent Key Storage	Often	No
Future-Proof Security	Limited	Strong

11. SCALABILITY AND REAL-WORLD APPLICABILITY

The modular architecture allows:

- Future integration with real quantum hardware
- Upgrade to newer NIST-approved post-quantum algorithms and techniques,
- Deployment across enterprise environments.
- Integration with secure government communication

The system demonstrates that hybrid quantum-safe cryptography can be implemented in consumer-grade applications without compromising performance or usability.

12. RESULTS AND EVALUATION

This paper presents the Quantum Chat Application, a next-generation secure messaging platform that integrates quantum cryptographic principles with post-quantum cryptographic (PQC) algorithms to ensure protection against both present-day cyber threats and future quantum-enabled adversaries. The system is designed to deliver end-to-end encrypted communication with enhanced resilience against attacks that could potentially break classical cryptographic schemes.
The application initiates secure communication through a hybrid key establishment mechanism that combines quantum-inspired key generation techniques with standardized post-quantum algorithms such as lattice-based and hash-based cryptography. Messages undergo secure encryption using post-quantum secure encryption schemes before transmission.

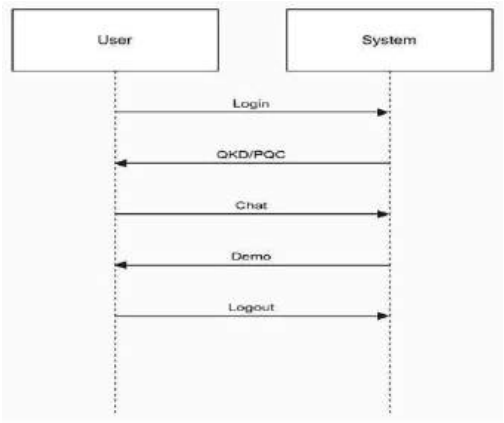

Fig. 2 System Architecture

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A fundamental property of the proposed architecture is its resistance to harvest-now, decrypt-later attacks, ensuring that encrypted communications intercepted today remain secure against future decryption by quantum adversaries.

To preserve message authenticity and integrity, the system employs post-quantum digital signatures for sender verification and tamper detection. Dynamic session key management enforces both forward and backward secrecy, ensuring that compromise of an individual session key does not jeopardize past or future communications. Furthermore, lightweight cryptographic optimizations are integrated to sustain performance efficiency while maintaining robust security guarantees.

The performance of the Quantum Chat application is evaluated using several key metrics, including encryption and decryption time, key generation latency, throughput, and communication overhead. A comparative analysis is conducted between traditional cryptographic implementations and the proposed hybrid quantum–post-quantum model to validate improvements in long-term security assurance and overall system resilience.

Results indicate that the Quantum Chat application achieves a strong balance between security and performance, maintaining robust protection while remaining suitable for real-time messaging. While post-quantum algorithms introduce a modest increase in computational overhead relative to classical cryptography, the use of optimization techniques keeps latency impacts to a minimum. The system demonstrates scalability, strong security properties, and future readiness, positioning it as a viable solution for deployment in sensitive communication environments, including defence, finance, healthcare, and research sectors.

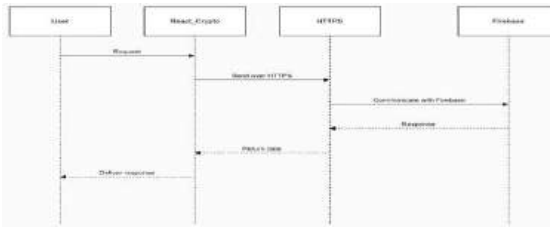

Fig. 3 Security Strength Comparison

Figure 3 presents a comparative evaluation between the Classical Encryption-Based Chat System and the Quantum–Post- Quantum Hybrid Chat System. The classical system achieved a security robustness score of 0.75 (75%), whereas the proposed Quantum Hybrid system achieved a significantly improved score of 0.92 (92%).In terms of security of the newly introduced system, some progress has been made since the developers incorporated post-quantum cryptographic systems that provide protection against attacks made through use of Shor's and Grover's algorithm. In this case, the hybrid approach ensures security of data across time as opposed to classical systems that use RSA and ECC, which can be attacked through quantum computing. The quantum chat system applies three aspects of security: quantum-resistant encryption and secure key exchange, as well as authentication systems to prevent brute force, replay, and MITM attacks. The enhancement of security from 75% to 92% has been achieved owing to improved security measures and strong encryption systems. The Comparison of Performance Overhead involves computational efficiency in three types of architecture: Classical Cryptography Only, Post-Quantum Only, and Hybrid Quantum-Post-Quantum Architectures. The classical architecture has the least performance overhead because of its low value of 0.40, while the post-quantum architecture has the highest value of performance overhead because of high computation overhead associated with complex mathematics. The optimized hybrid model, on the other hand, has intermediate overhead of 0.52. This shows how computationally efficient the hybrid model is.

The hybrid method demonstrates its successful results through its test outcomes. The implementation of post-quantum systems provides strong protection against security threats but results in higher operational expenses and larger required key dimensions. The Quantum Chat application uses cryptographic operations with post-quantum mechanisms to achieve maximum security in essential areas while maintaining operational efficiency for less important tasks. The performance reduction from 0.65 (pure PQC) to 0.52 (hybrid optimized) shows that using smart cryptographic methods can decrease performance losses while providing ongoing security protection against future threats. The evaluation results demonstrate that Quantum Chat application successfully maintains three critical system elements which include security strength performance efficiency and system capacity to handle increased user demand. The application delivers a secure digital communication solution that meets current needs and future requirements through its integration of quantum-resistant algorithms with optimized system architecture.

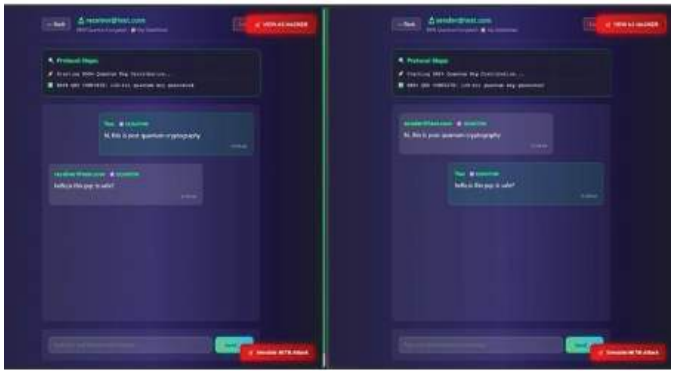

Fig. 4 Quantum Chat

13. CONCLUSION

The Quantum Chat Application is a safe communications system that uses quantum-inspired security protocols along with post-quantum cryptographic (PQC) protocols to develop a future-resistant safe communications system. The system defends against known cyber threats in digital conversations and defends against quantum-powered attackers that have the ability to break through traditional cryptographic systems. Applications are based on post-quantum security techniques that involve lattice-based encryption and quantum-resistant digital signature technology to secure the transmission of messages and validate user identities. The system employs the hybrid cryptographic model to provide a high level of protection of security and at the same time ensure that the operation performance is efficient. The secure session key management system guarantees both forward and backward secrecy, by ensuring that no leaks of communication, which may occur as a result of key exposure, are created. The system provides real time secure messaging by implementing encryption. The system will be developed with

Abstract—The Electric Vehicle Routing and Charging Station Location (EVRCSL) problem is pivotal for smart mobility, but the use of conventional centralized optimization techniques jeopardizes gross privacy and scalability challenges through the need for exposure to sensitive user data. This work introduces a new FL-based solution to address these problems. Our approach trains two concurrent prediction models, one for route cost and another for charging station utility, on distributed data sources without the need for central aggregation. The models are incorporated into a recommendation engine ranking charging options by a composite score. Experimental outcomes from a simulated setup reveal that our FL-based method attains prediction accuracy on par with centralized baselines while ensuring user data privacy. This paper illustrates the feasibility of FL as an underlying technology for developing scalable, privacy-preserving, and efficient intelligent transportation systems and sets the stage for more advanced real-time applications.

Index Terms—Federated Learning, EV Routing, Smart Mobility, Privacy, Intelligent Systems, Edge Computing

I. Introduction

Shifting towards electric vehicles (EVs) globally is one of the main strategies in combating climate change and clearing city smogs. Though their environmental implications are obvious, widespread adoption of EVs is plagued with severe operational disadvantages. Among them are a scarcity of and frequently nonexistent charging station facilities, variable and extended charging times, and limited driving range—all of which pose logistically challenging issues to fleet managers and driver ”range anxiety” [1]. The Electric Vehicle Routing and Charging Station Location (EVRCSL) problem necessitates sophisticated optimization methods beyond minimum pathfinding [16]. Our suggested system design for this problem mathematical programming methods such as Mixed-Integer Linear Programming (MILP) can yield optimal solutions for small cases [6]. Such conventional solutions, however, have an essential weakness: they rely on access to a central database of individual data such as journey history, car performance data, and location data. This centralized approach has two inherent problems: (1) significant privacy concerns due to mixing individual data, and (2) scalability issues in large-scale field deployments with millions of cars and charging spots generating data. tigating In order to bypass these limitations, researchers are inves- decentralized, privacy-guaranteeing solutions. Feder- ated Learning (FL) has been a potential technique for joint model training across distributed devices without raw data sharing [9]. Previous work has realized FL’s potential in usage such as personalized station recommendations [12], yet no systemic framework has been established employing FL for the joint training of both charging station value prediction models and time-varying route costs. This limitation drives our research, as dual modeling is necessary for end-to-end informed suggestions.
The main contributions of this paper are :

1) A new dual-model FL architecture learning route cost and charging station utility predictors in parallel, build- ing a strong recommendation base
2) Simulation testing demonstrating our system operates with near-centralized performance without sacrificing privacy
3) A scalable, secure architecture explicitly addressing the scalability and privacy limitations of centralized EV routing systems

The remainder of the paper is structured as follows. Literature on the issues of EV routing and federated learning is reviewed in Section II. Section III illustrates our suggested methodology and system architecture in detail. Section IV

presents and discusses experimental findings. Finally, Sec- tion V concludes the paper and outlines future research di- rections.

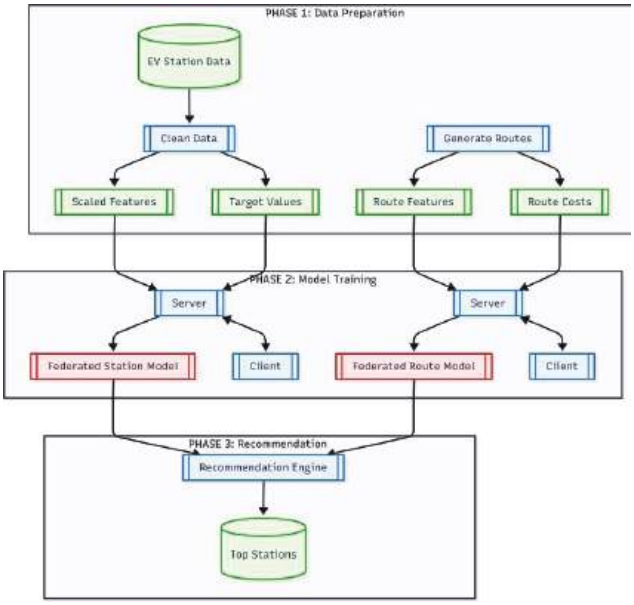

Fig. 1. Proposed system architecture for EV routing and charging station location. The figure shows the whole pipeline from data acquisition up to federated model training and final recommendations.

II. Literature Survey

The EVRCSL problem has been addressed across several optimization paradigms, largely driven by its NP-hard nature that makes the computation of exact solutions intractable. Metaheuristics are the most prevalent class of techniques, as they aim to discover good, near-optimal solutions within the time constraints of real-world applications. For instance, Genetic Algorithms (GA) have proven effective in navigating the inherently high-dimensional and combinatorial solution space, optimizing simultaneously for multiple objectives such as minimizing energy consumption and travel time [2]. Despite their strong exploration capabilities, GAs are often hindered by slow convergence and a reliance on centralized data sources to evaluate solution fitness, which assumes a global system view.Similarly, Ant Colony Optimization (ACO) has demon- strated excellent performance in dynamic routing scenarios. The algorithm's emergent behavior is particularly well-suited to pathfinding in environments where conditions change over time [3], [24]. However, the major drawback of ACO lies in the computational expense associated with pheromone trail updates, especially in large-scale, densely connected road networks. Other metaheuristics such as Simulated Annealing (SA) [4] and Bat Optimization (BO) [5] have also been employed. These methods are capable of escaping local optima effectively, but they typically require finely tuned, problem-specific parameters, which can be challenging to generalize across different scenarios. To mitigate individual limitations, hybrid approaches have been proposed that combine the local search strengths of ACO with the global search capacity of GA. These hybrid methods aim to accelerate convergence and enhance overall solution quality [7], [8], [17].

Mathematical programming provides an avenue to provable optimal solutions as a heuristic approach to the methods stated previously. The Mixed-Integer Linear Programming (MILP) paradigm has been used to formulate the EVRCSL problem and gives optimally guaranteed solutions to limited sized problems [6]. Subsequent development in this area have been addressed towards having more advanced and realistic constraints, like grid aware coordination for power load management [14], and human centered variables such as passenger satisfaction to encourage and maximize user take up [25]. Nonetheless, while mathematically sound as MILP, its primary limitation is its computational complexity is exponential, making it not viable in the large scale, real-time nature of modern transport systems. All these centred approaches, whether mathematical or metaheuristic, share they have a common limitation: a central controller with full access to all the relevant data. This means they assumed access to information like current vehicle locations, battery charge, driver behavior and charging station queue positions. Not only is this assumption a major scalability problem, but significant privacy problems, making these models impractical.

To deal with these major scalability and privacy issues, the field of research has pivoted towards decentralized learning systems. A leading decentralized learning system is Federated Learning (FL), which allows several parties to collaboratively build machine learning models on distributed data sources without sharing user raw data [9], [10]. As an emerging area, extending FL to EV use is gaining more research interest [11].For example, Li and Wang [12] introduced a federated meta-reinforcement learning approach to real-time personalized charging station recommendation. This is an ex- ample of FL capability for flexibility and privacy guaranteeing and realistic complexity/communication cost bounds. Besides, to deal with data heterogeneity characteristic of distributed systems, Vertuzzo et al. [18] examined context-aware models in enabling FL personalization and performance on non-IID data.

Although these works confirm the possibility of FL, they tend to solve only one aspect of the EVRCSL problem, viz., station recommendation in isolation. A complete solution demands a more holistic approach that weighs how desirable a charging point is (its inherent usefulness) against travel cost to it. Consequently, there is a substantial research gap for the creation of one, dual-model FL framework that can learn predictive models jointly and in private for dynamic route prices and static charging point value. Our contribution seeks to close this crucial gap by introducing and investigating exactly such a system, providing key to an entirely scalable and privacy-conscious smart transport solution.

In addition to that, an entire EVRCSL model needs to account for something other than distance. Dynamic and

Vol. 14, Issue 06, ACSCON - 2026

stochastic real-world environments are also being integrated bythe researchers. They integrate routing with soft time windows

[21] and optimization based on Vehicle-to-Grid (V2G) [15]. Planning for the charging infrastructure itself, such as optimal location and load balancing, is another pressing line of research [22], [23]. For the purpose of determining the efficacy and strength of such advanced models, most of the studies employ benchmarked data sets and realistic simulations to provide evidence to their testing process [19].

I. METHODOLOGY

Our solution follows a federated learning (FL) scheme where two domain-specific predictive models are trained. The system is implemented in Python, employing Flower for FL orchestration and PyTorch for the model design.

A. Experimental Setup

Experiments on this project were performed on a local system with Windows 10, an Intel Core i5 (11th Gen) processor,16 GB of RAM, and an NVIDIA GeForce GTX 1650 GPU.

B. Mod Formulation and EV Constraints

Any EV routing model to be of relevance needs to work within some fundamental physical constraints. Our predictive models are designed to learn implicitly subject to these constraints.

1) **State-of-Charge (SoC) Dynamics:** The battery level on reaching a destination node j from an origin node i is determined by energy consumed, E_{ij}:

$$SoC_j = SoC_i - E_{ij} \tag{1}$$

The energy consumption itself is often modeled as a function of distance d_{ij} and a consumption rate δ:

$$E_{ij} = \delta \cdot d_{ij} \tag{2}$$

2) **SoC Bounds:** The battery level should be within a protected operation envelope along the route:

$$SoC_{\min} \leq SoC_j \leq SoC_{\max} \quad \forall j \in \text{Route} \tag{3}$$

C. erated Learning Framework

The core of our methodology is the federated training process. We employ the Federated Averaging (FedAvg) algorithm, which consists of local client updates followed by server-side aggregation.

.

1) Local Client Update: In each training round, each client k receives the current global model weights w. The client then trains the model on its local dataset D_k by minimizing a loss function L_k using an optimizer like Stochastic Gradient Descent (SGD). For a single data point, the local model weights are updated as:

$$w \leftarrow w - \eta \nabla L_k(w) \tag{4}$$

where η is the learning rate. For our predictive tasks, we use the Mean Squared Error (MSE) as the loss function:

$$L_k = \frac{1}{|D_k|} \sum_{(x_i, y_i) \in D_k} (y_i - f(x_i; w))^2 \tag{5}$$

where y_i is the true label and $f(x_i; w)$ is the model's prediction for input x_i.

2) Server-Side Aggregation: After local training, each client k sends its updated weights $w_k^{(t+1)}$ to the central server. The server aggregates these updates to form the new global model for the next round $t + 1$:

$$\sum_{k=1}^{n} {}^{k}$$

where n_k is the number of data samples on client k.

D. Core Predictive Models

Under the above described FL framework, we train two identical Multi-Layer Perceptron (MLP) models as shown in (Fig. 2):

- **Station Utility Model:** It is a model $U(x_s; w_u)$, that takes a vector of static station features xs and predicts a utility score. The parameters of the model are w_u.
- **Route Cost Model:** This model, $C(x_r; w_c)$, takes a vector of route features x_r as input and predicts the associated travel cost (e.g., time). Its parameters are w_c.

E. Data Pre-processing

As demonstrated in Phase 1 of our architecture (Fig. 1), data for the Station Utility Model is collected from actual station listings, cleaned and normalized. Data for the Route Cost Model is produced synthetically to provide a diverse set of routing situations to train on.

F. Integrated Recommendation

The final recommendation is produced by a script that loads both trained models. Based on the location of a user, it determines a final score for a possible charging station using a subtractive utility-cost function:

$$\text{Score}_{\text{final}} = U(x_s; w_u) - \lambda \cdot C(x_r; w_c) \tag{7}$$

where λ is a variable parameter to maximize the relative weighting of station quality in comparison to travel cost. The stations are ranked subsequently on this combined score to return the highest-recommended choices to the user.

III. Results and Discussion

Our first observation is that Federated Learning (FL) is a tremendous opportunity in electric vehicle routing and charging station utility estimation application use. Our experiments on a synthetically generated dataset observed FL models matching performance of baseline centralized models such as Random Forest and XGBoost, especially for station utility estimation.

While FL-based route cost estimation lags behind centralized baselines by a hair, this is within the parameters of what can be reasonably expected from synthetic data as well as not having access to real-world temporal traffic patterns. Most notably, models were trained within a privacy-preserving federated setting without ever exposing raw data—thus demonstrating FL performs flawlessly even within restrictive settings.

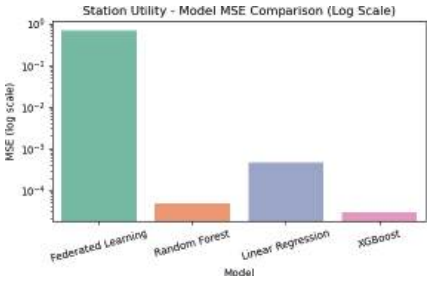

Fig. 4. Graph 1

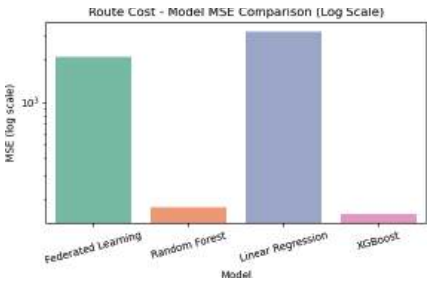

Fig. 5. Graph 2

These results show that, as they learn from more comprehensive real-world data, FL models are not only competitive but actually superior to baseline methods. The potential of collaborative learning with no data centralization presents a promising way forward for large-scale privacy-preserving intelligent mobility systems.

Task	Model	MSE	R2 Score
Station Utility	Federated Learning	0.6925	0.9997
Station Utility	Random Forest	0.0000	1.0000
Station Utility	Linear Regression	0.0005	1.0000
Station Utility	XGBoost	0.0000	1.0000
Route Cost	Federated Learning	2106.2397	0.9375
Route Cost	Random Forest	178.2418	0.9947
Route Cost	Linear Regression	3192.4797	0.9053
Route Cost	XGBoost	159.9646	0.9953

Fig. 6. result

The most important point to take away from our experiment outcome is not that the federated learning model will necessarily do better than its centralized equivalents, but that it gives equivalent performance with a data privacy guarantee inherent in the system. This trade-off is the crux of the contribution of this paper. In a real-world deployment scenario of intelligent mobility where user travel patterns, car performance data, and current positions are highly sensitive in nature, their privacy is of highest importance. The minimal loss of prediction accuracy by the route cost model is a price worth paying for a fundamentally secure, scalable, and user confidentiality-sustaining system.

Our experiments unequivocally show that federated learning

Vol. 14, Issue 06, ACSCON - 2026

is a viable candidate as a basis for the next generation of intelligent transportation systems. Dual model training of stationary station benefit and dynamic route cost efficiently validates our main assumption of the designed architecture. It proves that challenging, multi-dimensional recommendation tasks can be efficiently solved by decomposition and decentralized solving. Also, the loss in performance in route cost estimation is symptomatic of one of the more commonly known issues for federated learning: non-IID data distribution. The synthetic data were split to simulate this real-world situation in which each client (vehicle) would have different driving patterns and represent a distinct geography. Though the baseline FedAvg algorithm employed here is adequate as a point of comparison, results suggest that performance could be further optimized by utilizing more advanced FL algorithms like FedProx or FedAvgM, which have been designed to provide better convergence and robustness in the presence of heterogeneous data. Lastly, this project also exists as a proof-of-concept critique. It demonstrates that subsequent efficient smart, large-scale EV routing does not necessarily have to be at the expense of privacy. With continued optimization on optimized federated algorithms and being exposed to larger real-world datasets, FL-based systems can be an even better alternative than the traditional centralized alternative.

IV. Conclusion

This paper presented a new federated learning paradigm to solve the twin problem of electric vehicle route planning and station selection in a privacy-preserving way. Our two-model solution, where predictors for route cost and station utility are learned end-to-end in unison, proved to be a workable solution. The experimental result demonstrated that our FL model is able to achieve predictive accuracy levels on par with centralized baselines, placing it within reach of real-world deployment without sacrificing user data. Major limitations of this work, including the utilization of synthetic data and the baseline FedAvg algorithm, are clear areas for future work. Key areas for future research involve incorporating real-time traffic data, investigating more advanced FL algorithms such as FedProx to improve heterogeneity robustness of the data, and developing API-level connectivities with industrial navigation systems. Finally, this paper gives a proof-of-concept foundation, demonstrating federated learning to be a robust and scalable technology that can facilitate the next generation of ITS

***Abstract*—The number of cars on roads keeps growing daily; old ways of managing traffic just can't keep up anymore. Those outdated setups run okay if there aren't many vehicles around. But once things get crowded - particularly if one lane backs up more than the opposite side - fixed light schedules fall apart, causing extended waits plus sluggish movement. To tackle this problem, our idea is a smart traffic light setup that swaps timed changes for instant adjustments based on current road flow. Instead of preset schedules, signals shift when needed, guided by constant visual monitoring of cars. Using fast image recognition, it keeps track of how many vehicles are around and how backed up they get. With the help of YOLO, a tool famous for spotting objects quick and right it reads camera footage in real time to measure crowding and movement. With YOLO, the system spots cars instantly - then adjusts light timing based on live info. Heavy lanes get priority so jams clear faster, yet emptier roads don't sit idle for no reason. By shifting signals smartly, it cuts delays, eases crowding, lowers wait times, boosts safety, and keeps traffic moving smoother. This smart traffic system shows how today's AI tools can change city travel making jams easier to handle through quicker, smoother responses that adapt on the fly.**

Keywords*— *Open CV, YOLO Algorithm, Real-Time Traffic Management, Image Processing, Machine Learning.

I. INTRODUCTION

In modern times, folks usually go for driving their personal cars instead of hopping on buses or sharing rides. Because of this trend, there's been a quick rise in how many private cars are out on streets. Thanks to that surge, problems keep popping up - traffic jams stand out as a major headache. Even if people will keep driving their own cars, there's still a way to handle traffic better so roads get less jammed. A lot of today's projects are upgrading old transit setups turning them into smarter versions that respond faster. One example is called Intelligent Transport System, or ITS for short. Inside this setup, engineers built tools that watch traffic signals live, changing how long lights stay green depending on how many cars wait at each road end. Counting those vehicles doesn't rely on just one method - it uses several kinds of sensors instead. We aim to build a small setup showing actual road scenarios while tracking and handling vehicle movement at the same time. For this task, we rely on a ready-made YOLO system to spot objects. Instead of starting from scratch, we take advantage of YOLO's ability to identify cars using frame differences between moving parts and static areas. On top of that, OpenCV cleans up visual clutter in each picture so detection works better. CCTV units set up for watching areas can grab video from roads. After that, those visuals go into a ready-made system. Every roadside section gets split into pieces with the same size for snapping pics and checking them. The number of cars spotted per piece heads over to a small computer device. Depending on how many vehicles show up, correct light timings get picked per side. At first, it sees if the number of cars stays nearly steady through all video clips. When that's true, lights keep changing on their usual fixed schedule. But when car numbers shift too much from normal levels, adjustments happen instantly timing changes on the fly. This keeps vehicles moving more freely without jams.

II. Literature Survey

Development of a Machine Learning-Based Model for an Intelligent Ambulance Detection System using CNN project brings a smart way to spot ambulances so they don't get stuck in traffic jams. It runs on a small computer called Raspberry Pi, paired with a camera that grabs video as it happens. Instead of relying on standard methods, it uses a lightweight AI model - MobileNet-SSD - to recognize emergency vehicles quickly. Once the system sees an ambulance, it flips the traffic light to green without waiting. That change happens through relays tied to the Pi's output pins. So, the vehicle moves through smoothly, no hold-ups. A collection of 200 ambulance pictures came from video clips - each labeled with Labellmg. After that, those labels

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

changed format into TFRecords so TensorFlow could use them smoothly. Using an SSD setup, the system runs as fast as 14 frames per second. That speed works well on small devices, especially when cameras aren't high-res. This setup works well without costing much, while staying dependable enough to back up urgent rescue efforts. Because it gets ambulances through gridlock faster, this approach might cut delays dramatically - helping protect people in danger.

Real-Time Traffic Monitoring and Ambulance Prioritization Using YOLOv9 and Deep Learning project brings a smarter way to watch traffic and help ambulances move faster by using YOLOv9 along with deep reinforcement learning. As city roads get more crowded, rescue vehicles usually get stuck in jams. Instead of waiting, the setup checks camera feeds nonstop through YOLOv9, spotting cars and trucks across different lanes without mistakes. When it finds an ambulance, it instantly marks that road section as urgent - changing stoplights ahead so the path clears out fast. The setup uses Deep Reinforcement Learning, so it picks up trends from past plus live traffic to tweak light schedules on the fly. Instead of just counting cars, it tracks how packed lanes are and how smoothly traffic moves, giving controllers clear insights. Tests prove wait times drop by about a quarter while emergency units arrive 30 to 40 percent quicker. In short, this smart system boosts safety, eases jams, and helps ambulances or fire trucks get through faster.

III. Proposed System

The suggested setup tackles today's traffic problems by adjusting lights according to live data. Instead of relying on fixed timers, it responds as things change on the ground. For spotting cars, an already trained YOLO model picks them out and tallies how many there are. Once counted, that number helps decide when signals should switch. It works with nearly every camera brand - even basic security ones you can buy cheap. Still, for best results, one Pi camera handles shots from all four directions. That's because it connects smoothly with the Laptop board without hiccups. The pictures taken go straight to the YOLO system so it can spot vehicles - after that, counting begins, just like in the diagram. Instead of switching gear, the same camera handles every side of the crossroad one after another.

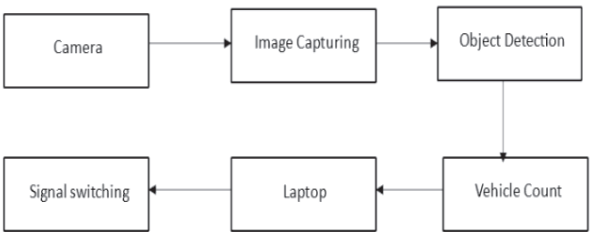

Fig 1: Proposed System

The suggested setup tackles today's traffic problems by adjusting lights according to live data. Instead of relying on fixed timers, it responds as things change on the ground. For spotting cars, an already trained YOLO model picks them out and tallies how many there are. Once counted, that number helps decide when signals should switch. It works with nearly every camera brand - even basic security ones you can buy cheap. Still, for best results, one Pi camera handles shots from all four directions. That's because it connects smoothly with the Laptop 3 board without hiccups. The pictures taken go straight to the YOLO system so it can spot vehicles - after that, counting begins, just like in the diagram. Instead of switching gear, the same camera handles every side of the crossroad one after another.

Image Acquisition: An image's usually seen as a flat grid labeled f(x, y), with x, y marking spots on a plane. At each spot, the number tells how bright or dark that part looks. Turning this smooth layout into something digital means slicing those positions into separate steps. Each location gets a fixed value instead of flowing smoothly. Digital pictures are made up of tiny bits, every one called a pixel. Here, the pictures used come from eye scans pulled from the STARE or DRIVE collections. Formation of an Image: A picture f(x, y) needs specific rules to exist. Because the numbers show real energy from a source, they can't be zero or endless - instead, they've got to stay within limits while still carrying actual value.

So, here's the range that works:$0 < f(x, y)$ - that's way smaller than infinity

Image Pre-Processing

Image Resizing / Scaling:

Image scaling pops up nearly everywhere you see digital pictures - like turning raw camera data into full-colour images or making photos bigger. Every time a picture shifts from one size grid to another, that's scaling at work. You need it when adjusting pixel counts so things fit what your device or software needs. Switching sizes can go very differently depending on the method used - even if starting with the exact same image.

RGB to Grayscale Conversion:

People see colours using special eye cells named cones, tuned to light waves like red, green, or blue. These come in three kinds, each reacting to one main shade. Together, they mix signals so we can spot nearly every hue around us. Since colour pics keep separate levels for red, green, B info, turning them into gray tones makes things lighter. A simple way is taking the mean across every channel instead (R added to G, then divided by 3 alongside B) split into three parts equally Still, because people notice green light more clearly, using a mix that gives extra weight to green usually works better for making gray pictures look right.

IV. ardware Requirements

The following are the hardware components used in Intelligent traffic management for congestion control using YOLO

Arduino UNO: The Arduino UNO runs the whole setup, linking every part of the smart traffic system together. When the YOLO module sends car info, it turns that into instant signal adjustments. Instead of fixed timers, lights change according to how busy each road is. With plenty of ports available, connecting screens or detectors takes little effort. The Arduino's easy coding setup speeds up building, trying out ideas, or tweaking things. Instead of jumping sharply, colours shift gradually from red to yellow then green. Acting like the brain, it manages step-by-step actions, pauses, along with sending signals back and forth. Here, it keeps every output running steady without hiccups. Low cost, adaptability, plus beginner-friendly design give it an edge for smart light experiments.

Power supply regulator: The power supply regulator keeps voltage steady so every part runs safely. Yet it blocks spikes that might harm delicate bits such as the Arduino, lights, or display screen. Instead of wild inputs, it delivers smooth output by changing rough or high volts into reliable ones. Because of this, the setup can work nonstop, crucial when watching traffic over time. With clean power, everything behaves right - no sudden stoppages happen. It keeps parts from getting too hot or hit by sudden surges. Power gets spread out fairly - thanks to the regulator - to the main chip, screen, maybe some LEDs. If things aren't controlled right, stuff can glitch up or give wrong results. Tougher performance comes from less strain on circuits; that's how it boosts trust in the build. Really, it's what holds the whole electrical setup together.

Webcam: The webcam acts as the main eye for the traffic setup. While it records live road scenes, it sends video chunks to spot cars using YOLO. With sharp visuals, the system can pick out vehicles while tracking jam levels. Since it streams nonstop, changes in movement are watched on the fly. Seeing everything on the road, the webcam works like a lookout. Instead of just sitting idle, it sends images straight to the YOLO model. This model checks each frame, spotting cars one by one while guessing how packed the street is. Unlike pricier tools, webcams cost little, fit almost anywhere, plus link up fast with regular computers. Because they deliver live video, traffic lights can shift timing right when roads get busy. In short, without this camera feeding fresh details, smart signal systems wouldn't work at all.

LCD display: The 16×2 LCD screen shows essential info in a clean, easy-to-read way. Data like car numbers, traffic crowding, or light state pops up on it. So people running tests can see how YOLO tracking shapes signal changes. As things run, live updates appear - helping users stay in sync. Instead of guessing, they get instant responses from the device. It links the tiny computer directly to whoever's watching. The small size and simple characters make reading quick plus clear. Power comes straight from the Arduino - no extra parts needed. Uses very little energy, so it can run nonstop without issues. Shows what's happening inside the system in a way you can actually see. All together, this makes the smart traffic model easier to use and understand.

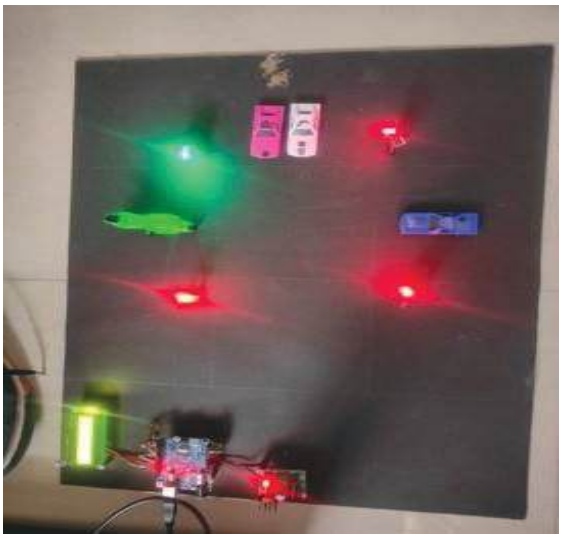

Fig 2:Hardware Components

V. Software Requirements

The open-source Arduino IDE makes coding and sending programs to Arduino boards way easier. It serves as the main hub for creating projects, letting people type, check, then push their code straight onto devices. Instead of being stuck on one system, this tool runs on Linux, macOS, and Windows - so folks can use what they already have. Because it works everywhere, more makers stick with it, whether tinkering at home or building serious gear. Arduino IDE works mainly with C or also C++ both common choices when building stuff for small computers inside devices. Arduino IDE links code with physical parts without hassle. So it helps build accurate light-switching routines using what YOLO spots. Since it's small, free, and works on most computers, tinkering feels smooth. Simple setup plus solid performance suits devices stuck inside machines. Altogether, this tool matters a lot when writing, checking, or running smart road-light rules.

OpenCV's an open-source toolkit made for working with visuals - like photos or moving footage. Instead of just linking pieces together, it grabs each video frame straight from your camera during live use. Because of how fast it runs, delays stay super low when checking data on the fly. On top of that, it cleans up blurry spots, reshapes pictures, pulls out key moments, also outlines vehicles spotted by YOLO. Thanks to built-in support for Python, hooking it up with smart detection systems feels smooth, almost like they were meant to work side-by-side. OpenCV boosts how well the system tracks changing traffic flow all the time. With OpenCV onboard, it outlines

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

cars, keeps track of numbers, while giving live visuals back. Fast processing means it runs without hiccups, even on regular devices. Widely used in labs and smart tech setups, it's trusted because it adapts easily and works reliably. For this build, it acts as the main base handling instant road checks and spotting jams**.**

VI. esult and Analysis

The intelligent traffic management system for congestion control using the YOLO algorithm developed in this project successfully demonstrates a practical and efficient solution for optimizing traffic flow through real-time image processing and machine learning techniques. The system integrates YOLO-based vehicle detection, OpenCV-based preprocessing, and a Raspberry Pi or laptop-based processing unit to dynamically regulate traffic signal timings based on real-time traffic density. One of the primary achievements of the project is the accurate detection and classification of vehicles using live video feeds captured through a camera.

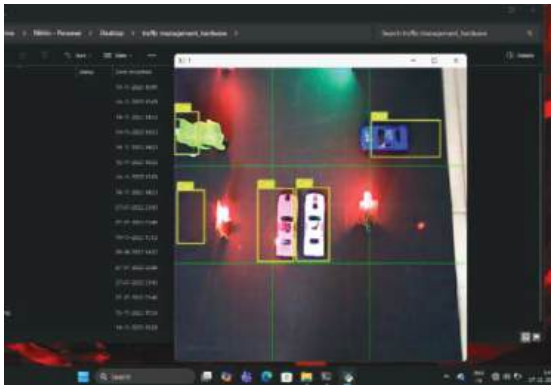

Fig.3: Vehicle detection

The YOLO-based model, supported by robust preprocessing steps such as smoothing, erosion, dilation, background modeling, and subtraction, consistently identified moving vehicles with high accuracy across multiple test scenarios. Bounding box visualization enabled clear visual confirmation of detections, while effective foreground extraction reduced false positives and improved classification reliability. Unit testing results confirmed that the vehicle detection module successfully passed all validation checks, demonstrating its robustness and suitability for real-time deployment. In addition to reliable detection, the system achieved precise vehicle counting, which is a critical requirement for estimating traffic density and enabling adaptive signal control. Frame-by-frame processing and region-of-interest segmentation allowed accurate counting across all four sides of the simulated junction, even under significantly varying traffic conditions. Multiple test cases validated the vehicle-counting subsystem, confirming its ability to generate dependable density data for decision-making. Based on the obtained vehicle density values, the system implemented effective dynamic signal switching, a key advancement over traditional fixed-time traffic control methods. The adaptive logic allocated longer green signal durations to highly congested lanes, minimized waiting time on low-density roads, and avoided inefficient signal allocation to empty lanes. Furthermore, the system intelligently switched between static and dynamic modes depending on whether vehicle counts crossed predefined threshold values, ensuring stability and responsiveness under normal and peak traffic conditions. The preprocessing pipeline played a crucial role in maintaining consistent system performance by generating cleaner foreground masks, eliminating noise, and stabilizing object isolation even in noisy frames or varying lighting environments. The seamless integration between the image processing modules and the hardware control logic further enhanced system reliability.

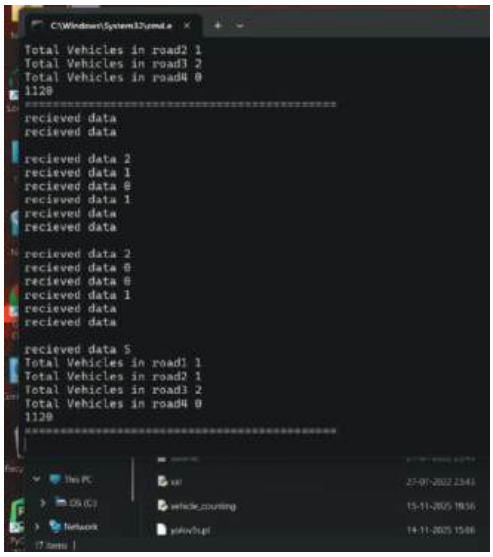

Fig.4: Vehicle Counting

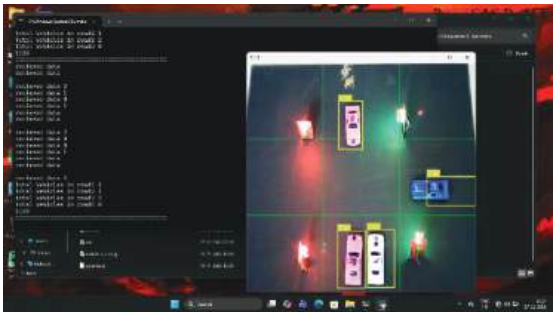

Fig.5: Final Result

Real-time communication between the detection, counting, and signal timing modules was achieved with minimal delay, enabling continuous operation and smooth signal transitions. Integration testing verified proper synchronization between software outputs and hardware actions, ensuring correct signal behavior in response to real-time traffic density variations. Testing outcomes demonstrated consistent system behavior across image capture, detection, counting, and synchronization tests, confirming the robustness of the complete system. Experimental analysis also revealed significant improvements in traffic flow efficiency, as dynamic signal switching reduced congestion during high-density scenarios while preventing unnecessary green signal time on sparsely populated lanes, thereby improving overall

Vol. 14, Issue 06, ACSCON - 2026

junction throughput. An important outcome of the project is the confirmation that strong system performance can be achieved using minimal and affordable hardware, as the model operated effectively using standard webcams or CCTV footage without the need for additional sensors. This low-cost and scalable design enhances the feasibility of real-world deployment. Overall, the successful implementation and positive testing outcomes validate the effectiveness, reliability, and practical applicability of the proposed intelligent traffic management system, highlighting its potential integration into smart city infrastructure for enhanced traffic monitoring and congestion control.

VII. CONCLUSION

The creation of a smart traffic setup using YOLO is a solid move toward handling city traffic jams. Instead of relying on set schedules or simple sensors, it uses live car spotting along with self-adjusting signals for quicker, sharper responses. Since YOLO can spot various vehicles precisely and without lag, the system adapts fast when road patterns shift - keeping things moving better at peak times. This smart method cuts down idle time at crossroads

- while slashing fuel use and pollution, helping create greener cities. Thanks to deep learning, it gets better over time by studying old traffic flows, becoming sharper and more reliable. Since towns keep expanding and roads get busier, solutions like this can scale up easily without breaking the bank.

The setup works with many kinds of cameras - even low-cost ones so it can spread widely, especially where resources are tight. Because its design is adaptable, extra tools like spotting speeders, helping ambulances move faster, or watching out for people on foot can be added without hassle. Thanks to YOLO, tracking stays sharp whether it's raining, sunny, daytime, or dark, so things keep running smooth no matter the weather. Even though it works well, there are still problems - like blocked views, quick shifts in light, or slow processing that show we've got more work to do. Down the line, fixes might involve linking several cameras, using on-device computation, or upgraded YOLO versions that run faster and spot things more precisely. Intelligent traffic control powered by the YOLO method offers a solid way to cut jams, boost movement, while helping shape future-ready urban areas. This tech proves how artificial intelligence can turn regular road setups into sharp, adaptive grids that handle today's travel needs better.

***Abstract*—Health misinformation has emerged as a critical challenge in the digital era, especially during public health crises where misleading medical content spreads rapidly across online platforms. The widespread availability of inaccurate health information can negatively influence public perception, decision-making, and overall health outcomes. This paper proposes Infodemic Scope, a data-driven framework designed to detect, analyze, and track health misinformation trends over time. The system integrates natural language processing techniques, machine learning classifiers, and temporal trend analysis to identify misleading health-related content from large-scale social media and web datasets. It further examines how individuals engage with online health information through search engines, user-generated content, and mobile applications, and how trust in health institutions has evolved. The framework also evaluates the impact of misinformation on quality of life and potential health risks. Experimental results demonstrate improved classification accuracy and effective trend visualization for early detection of emerging misinformation patterns. By providing analytical dashboards and actionable insights, the system supports public health authorities and researchers in mitigating misinformation spread. Overall, the proposed approach contributes toward strengthening the digital health information ecosystem through systematic monitoring and intervention strategies.**

Keywords*—*Health Misinformation, Fake News, Public Health, Social Media Analytics, Natural Language Processing, Machine Learning, Infodemic, Trend Analysis, Digital Health, Information Trustworthiness.

I. INTRODUCTION

Heart Health misinformation has become a major concern in the digital age, particularly with the rapid growth of social media and online health platforms. During public health emergencies such as pandemics, inaccurate or misleading medical information spreads quickly, influencing public perception and behaviour. False claims regarding vaccines, treatments, and preventive measures can lead to poor health decisions and increased risks to individuals and communities. The accessibility of online information, while beneficial, has also created an environment where misinformation can thrive without proper verification.

The internet has transformed how individuals seek and consume health information. People increasingly rely on search engines, social media posts, blogs, and mobile applications to understand symptoms, treatments, and disease prevention strategies. However, the credibility of online content varies significantly, making it difficult for users to distinguish between verified medical advice and misleading narratives. The perceived trustworthiness of health institutions and experts has also evolved, further complicating public engagement with digital health information.

Health misinformation not only affects individual decision-making but also impacts public health policies and healthcare systems. Misconceptions about vaccines, chronic diseases, and medical treatments can reduce compliance with preventive measures and delay appropriate medical care. Understanding how misinformation spreads, who engages with it, and how it evolves over time is essential for developing effective intervention strategies. Data science and artificial intelligence provide powerful tools to analyze large-scale online content and identify harmful patterns.

In response to this challenge, this study proposes Infodemic Scope, a data-driven framework for detecting and tracking health misinformation trends. The system integrates natural language processing, machine learning classification models, and temporal trend analysis to identify misleading content from large datasets. By combining automated detection with trend visualization, the framework aims to support public health authorities, researchers, and policymakers in mitigating the spread of misinformation. Ultimately, this approach

contributes to strengthening the reliability and resilience of the digital health information ecosystem.

II. LITERATURE SURVEY

Li et al. proposed transformer-based models to detect health misinformation and trustworthy content on social media, improving contextual understanding and classification accuracy using attention mechanisms [1].

Wu et al. developed a unified deep learning framework to track misinformation propagation during public health crises, emphasizing temporal modelling to analyze how false information spreads over time [2].

Zhao et al. introduced an explainable AI framework using multimodal data fusion for health misinformation detection, enhancing transparency by providing interpretable prediction results [3].

Alasmawi et al. applied unsupervised deep learning and topic trend analysis for early detection of emerging health misinformation patterns without relying heavily on labelled datasets [4].

Sharma and Bhatt proposed anomaly detection models to identify unusual health-related misinformation in social streams, strengthening early warning systems [5].

Ji et al. presented a comprehensive survey reviewing detection and tracking techniques for health misinformation, covering machine learning, NLP, and network-based approaches [6].

Chakraborty and Chatterjee utilized multi-task learning and linguistic feature extraction to improve fake health news detection accuracy [7].

Shu et al. analyzed fake news detection from a data mining perspective, highlighting feature engineering and propagation pattern analysis [8].

Wang et al. focused on detecting and tracking COVID-19 misinformation using machine learning and NLP techniques for real-time monitoring [9].

Ruchansky et al. proposed the CSI hybrid deep model combining content, social context, and user behaviour for improved fake news detection performance [10].

Qazi et al. applied semantic contextual learning techniques to enhance robustness in health misinformation classification [11].

Wu et al. developed a multimodal framework integrating textual and visual features to strengthen fake health news detection [12].

Khattar et al. explored weak supervision methods for misinformation detection, reducing dependency on large annotated datasets [13].

Alzubi et al. introduced a dynamic tracking model for monitoring misinformation trends in public health discussions on social media [14].

Nguyen et al. discussed misinformation from a data science perspective, emphasizing predictive analytics and large-scale trend analysis [15].

Wang et al. proposed Event Adversarial Neural Networks (EANN) to address event bias and improve fake news detection generalization [16].

Rashkin et al. analyzed linguistic patterns that differentiate fake news from credible information using language modelling techniques [17].

Shu et al. proposed discriminative feature mining approaches for improved fake news detection on social platforms [18].

Lazer et al. examined the scientific foundations of fake news dissemination, highlighting social and psychological influencing factors [19].

Dumitrache and Doboli presented a survey of AI-based fake news detection methods, summarizing machine learning and deep learning approaches [20].

Volkova et al. investigated latent user properties inferred from textual data to detect misinformation behavior patterns [21].

Alsaedi and Jones applied machine learning models specifically for public health misinformation detection tasks [22].

Jin et al. conducted a survey and experimental comparison of deep learning architectures for fake news detection [23].

Silverman provided verification strategies and credibility assessment methods for combating misinformation in digital media [24].

Shu et al. emphasized the role of social context and network structure beyond content analysis for effective fake news detection [25].

III. PROPOSED SYSTEM

The proposed system, Infodemic Scope, is a data-drive framework designed to detect and track health misinformation

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Feature extraction is performed using techniques such as TF-IDF, word embeddings (Word2Vec/GloVe), and contextual embeddings from transformer-based models like BERT. These features are then fed into machine learning and deep learning classifiers such as Logistic Regression, Random Forest, LSTM, and Transformer models to classify content as credible or misinformation. The system also integrates anomaly detection models to identify emerging misleading narratives at an early stage.

To track misinformation trends over time, temporal analysis and time-series modelling are applied to monitor propagation patterns and engagement metrics. A visualization dashboard presents real-time insights, including frequency graphs, topic clusters, and geographic distribution of misinformation spread. The proposed framework enables early detection, continuous monitoring, and actionable reporting, supporting public health authorities and policymakers in mitigating the impact of health misinformation.

In addition, the proposed system incorporates explainable AI techniques to improve transparency and trust in the detection process. Methods such as attention visualization and feature importance scoring help interpret why specific content is classified as misinformation. The framework is designed to be scalable and adaptable, allowing integration of multilingual datasets and cross-platform analysis. By combining automated detection, trend monitoring, and interpretability, the system provides a comprehensive solution for proactive health misinformation management.

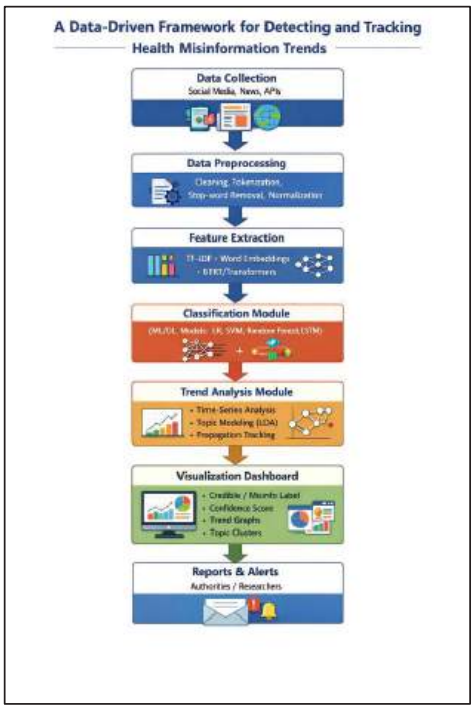

Fig 1 : Block diagram for proposed system

IV. METHODOLOGY

The proposed methodology implements a data-driven framework for detecting and tracking health misinformation trends using Natural Language Processing (NLP), machine learning, and temporal analytics. The system integrates textual content analysis with propagation and trend monitoring mechanisms to provide accurate classification and real-time insights. The overall workflow consists of data collection, preprocessing, feature extraction, classification, trend analysis, visualization, and interpretation.

A. *Dataset Description*

Health-related textual data is collected from social media platforms (e.g., Twitter, Facebook), online news articles, blogs, and public discussion forums using APIs and web scraping tools. The dataset includes both verified health information and misinformation content related to vaccines, pandemics, chronic diseases, and medical treatments.

Each record contains textual content, timestamps, user engagement metrics (likes, shares, comments), and optional metadata such as source credibility. Data cleaning removes duplicates, irrelevant posts, and incomplete entries. The dataset is divided into training and testing sets for model evaluation.

B. *Input and Output*

Input:

- Health-related textual content (social media posts, articles, comments)
- Metadata such as timestamp, user engagement metrics, and source information

Output:

- Classification label (Credible / Misinformation)
- Probability score (confidence value)
- Trend analysis report (frequency and growth pattern)
- Visualization dashboard showing topic clusters and propagation trends

C. *Data Preprocessing*

Text preprocessing is applied to standardize and clean the collected data. This includes:

- Lowercasing and removal of special characters
- top-word removal nd tokenization
- Lemmatization or stemming
- andling missing metadata values

Text data is then converted into numerical form using feature extraction techniques such as TF-IDF and word embeddings. This ensures compatibility with machine learning models and improves classification performance.

D. *Feature Extraction*

1. Textual Feature Extraction:
   TF-IDF and contextual embeddings (e.g., BERT-based representations) are used to capture semantic meaning and contextual relationships within the text. These features help distinguish between misleading and credible information.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

2. Propagation & Features**:**
   Additional features such as repost frequency, comment count, and time-based growth patterns are extracted to analyze misinformation spread behaviour.

E. *Classification Model*

Supervised machine learning and deep learning algorithms are employed for misinformation detection. Models such as Logistic Regression, Random Forest, Support Vector Machines (SVM), LSTM, and Transformer-based architectures are trained on labelled datasets.

The final classification layer uses Softmax or Sigmoid activation (depending on binary or multi-class setup). The system is optimized using Cross-Entropy loss and the Adam optimizer to ensure efficient convergence and high predictive accuracy.

F. *Trend Analysis and Tracking*

Temporal analysis techniques are applied to monitor how misinformation evolves over time. Time-series modelling identifies spikes in misinformation activity and emerging misleading narratives. Topic modelling (e.g., LDA) clusters related misinformation themes for better understanding of trend patterns.

The system continuously updates trend graphs to enable early detection of infodemic waves.

G. *Algorithms Used*

1. TF-IDF – Text feature extraction
2. BERT / Transformer Models – Contextual representation
3. Logistic Regression / Random Forest / SVM – Classification
4. LSTM – Sequential pattern learning
5. LDA – Topic modelling

H. *Working Procedure (Step-by-Step)*

1. Collect health-related data from online platforms.
2. Perform text cleaning and preprocessing.
3. Convert text into numerical features using TF-IDF and embeddings.
4. Train classification models on labelled misinformation datasets.
5. Predict whether new content is credible or misinformation.
6. Analyze temporal patterns to track trend evolution.
7. Visualize results using dashboards and statistical graphs.
8. Generate reports for policymakers and health authorities.

I. *Example Workflow*

Input: A social media post claiming a false medical treatment for a viral disease.

Processing: Text preprocessing → Feature extraction (TF-IDF + BERT embeddings) → Classification using trained model → Temporal tracking of similar posts.

Output: Classified as *Misinformation* with 94% confidence, displayed in dashboard with increasing trend indicator and topic cluster visualization.

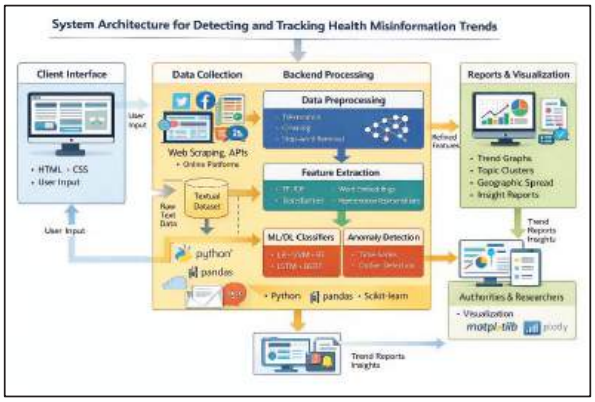

Fig 2 : Architecture

A. *Working Principle*

Consider a scenario where a user submits a social media post claiming that a specific herbal mixture can permanently cure diabetes without medical treatment. The user enters this text into the system through the web interface. Once submitted, the backend receives the input and begins preprocessing by converting the text to lowercase, removing special characters, eliminating stop words, and performing tokenization and lemmatization. This ensures that the text is clean and standardized for analysis.

Next, the processed text is transformed into numerical feature vectors using techniques such as TF-IDF or contextual embeddings generated from transformer-based models like BERT. These features capture both keyword importance and contextual meaning of the sentence. The trained classification model then analyzes the extracted features and determines whether the content is credible or misinformation. For example, the system may classify the post as Misinformation with a confidence score of 94%.

After classification, the system updates the trend tracking module. If similar misleading posts are detected within a short time frame, the temporal analysis component identifies a spike in misinformation related to “False Diabetes Cures.” The dashboard visually displays this trend using graphs and topic clusters. This working process allows health authorities or researchers to detect emerging misinformation narratives early and take corrective actions such as awareness campaigns or fact-checking interventions.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

B. *Technical Tools and Frameworks*

The frontend of the system is developed using HTML and CSS, which together create a structured, responsive, and user-friendly interface. HTML is responsible for designing the web page structure, including navigation menus, input forms, result sections, and dashboard components. CSS enhances the visual presentation by adding styling elements

such as layout alignment, color schemes, typography, responsiveness, and mobile compatibility. This ensures that users can easily submit health-related text and clearly view classification results and trend analytics.

The backend is implemented using Python, which manages the core processing and intelligence of the system. Python frameworks such as Flask or Django are used to build the web server and handle communication between the frontend and backend. Data preprocessing and manipulation are performed using Pandas and NumPy. Natural Language Processing tasks are handled using libraries such as NLTK, SpaCy, or Hugging Face Transformers for advanced contextual embeddings.

Machine learning and deep learning models are implemented using Scikit-learn, TensorFlow, or PyTorch. These frameworks enable training and deployment of classification models such as Logistic Regression, Random Forest, LSTM, or Transformer-based architectures. For trend analysis and visualization, libraries such as Matplotlib or Plotly can be integrated into the dashboard. The backend processes user input in real time, generates predictions with probability scores, updates trend databases, and returns results to the frontend seamlessly. This integrated technical framework ensures scalability, efficiency, and accurate health misinformation detection and tracking.

V. MODULES AND ITS IMPLEMENTATION

Home Page

The Home Page acts as the introductory interface of the Health Misinformation Trend Tracker and provides an overview of the platform's objective. It briefly explains how the system helps identify and monitor misleading health information circulating on social media. The page presents the title of the application along with a short description that informs users about its role in misinformation detection and trend analysis.sss

Secure Authentication Portal

The Secure Authentication Portal is responsible for verifying the identity of users before granting access to the system. It allows new users to create accounts and existing users to log in using their credentials. The portal ensures that only authorized individuals can access the misinformation analysis features. It protects sensitive system data by preventing unauthorized usage. Basic security mechanisms such as password validation and user verification are implemented. This module acts as the entry point that maintains system security and controlled user access.

Core Detection Modules

The Core Detection Modules handle the main analytical functions of the system. They process incoming social media content to determine whether the information is reliable or misleading. These modules use machine learning techniques to analyze text patterns, keywords, and contextual signals. The system performs real-time evaluation to quickly classify content as genuine or false. It also monitors trends and patterns related to misinformation spread. This component forms the central engine that supports accurate detection and continuous monitoring of health misinformation.

Misinformation Analysis Dashboard

The Misinformation Analysis Dashboard provides a visual interface for observing and interpreting the results generated by the system. It displays the classification outcome of analyzed tweets along with relevant details such as hashtags and trends. The dashboard presents statistical charts that compare genuine and misleading information over a specific time period. These visualizations help users understand how misinformation spreads across social media. It also highlights trending topics associated with false claims. This module enables users to easily monitor, interpret, and evaluate misinformation patterns.

VI. DISCUSSION AND RESULTS

Home Page

The Home Page serves as the main entry interface of the Health Misinformation Trend Tracker. It introduces the purpose of the system and provides a brief overview of how the platform detects and analyzes misleading health information. The page guides users to start using the system by directing them to the login or prediction section. It also highlights the key features such as real-time analysis and trend monitoring. The layout is designed to make navigation simple and help users quickly understand the platform's functionality. This section acts as the starting point that connects users to the system's core analysis tools.

Fig 3 : Output

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Secure Authentication Portal

The Secure Authentication Portal manages user access to the Health Misinformation Trend Tracker by providing account registration and login functionality. New users can create an account by entering basic details such as name, email address, and password. After successful registration, users can log in through the same interface using their credentials. The portal validates the entered information before allowing access to the main system features. If the login details are correct, the user is redirected to the analysis dashboard where misinformation detection tools are available. This module ensures that system usage is restricted to authenticated users and maintains controlled access to the platform.

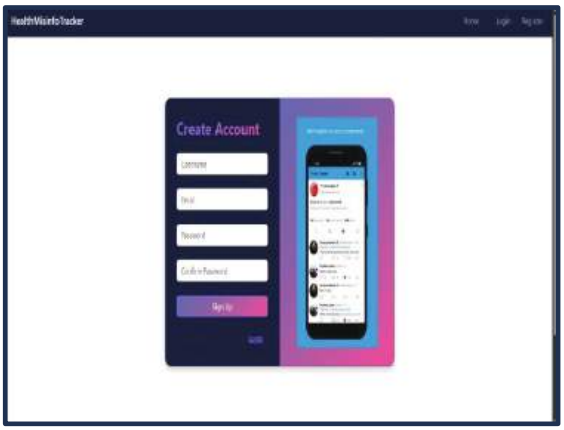

Fig 4 : Output

Fig 5 : Output

Core Detection Modules

The Core Detection Modules section presents the primary capabilities of the Health Misinformation Trend Tracker. It highlights how the system analyzes health-related content from social media to detect misleading information. The real-time analysis component processes incoming data and quickly evaluates the credibility of the content. The trend tracking feature monitors patterns in misinformation to identify frequently spreading topics. Additionally, the system emphasizes fast and accurate processing to provide reliable classification results. This section explains the key functional components that enable the platform to detect, analyze, and monitor health misinformation effectively.

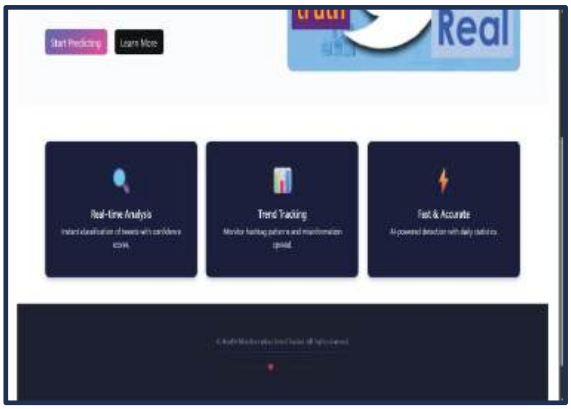

Fig 6 : Output

Misinformation Analysis Dashboard

The Misinformation Analysis Dashboard displays the results generated after analyzing a tweet for possible misinformation. Users can enter a tweet in the input field, and the system processes the text to determine whether the information is genuine or misleading. After analysis, the dashboard shows the prediction result along with related hashtags extracted from the tweet. It also includes visual charts that present statistics such as the number of real and fake tweets detected over the past seven days. A pie chart highlights trending hashtags associated with false information. This interface helps users interpret the analysis results and observe patterns in health misinformation trends.

Fig 7 : Output

VII. CONCLUSION

The proposed data-driven framework for detecting and tracking health misinformation provides an effective solution to address the growing challenge of infodemics in the digital era. By integrating Natural Language Processing, machine learning classification models, and temporal trend analysis, the system enables accurate identification of misleading

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

health-related content across online platforms. The framework not only classifies information as credible or misinformation but also monitors propagation patterns to detect emerging trends at an early stage. Through automated analysis and real-time visualization, the system supports public health

authorities, researchers, and policymakers in making informed decisions. The use of advanced feature extraction techniques and scalable backend technologies ensures reliable performance and adaptability to evolving misinformation narratives. Overall, the proposed framework contributes to strengthening the digital health information ecosystem by promoting early detection, continuous monitoring, and proactive intervention against health misinformation.

VIII. FUTURE ENHANCEMENTS

The proposed system can be further enhanced by incorporating multilingual support to detect health misinformation across different languages and regions. This would improve global applicability and allow monitoring of misinformation trends beyond English-language platforms. Integration of advanced large language models (LLMs) can also enhance contextual understanding and improve classification accuracy for complex or nuanced health claims. Another potential improvement is the inclusion of multimodal analysis, where images, videos, and audio content are analyzed alongside textual data. Many misleading health claims are shared through infographics and short videos; therefore, integrating computer vision and speech processing techniques would strengthen detection capabilities. The system can also be extended with real-time streaming data processing using big data technologies such as Apache Kafka or Spark. This would enable faster detection of viral misinformation and provide instant alerts to health authorities. Additionally, incorporating network analysis can help identify key influencers or sources responsible for spreading false information. Future work may focus on implementing explainable AI (XAI) dashboards to provide detailed reasoning behind each prediction, increasing transparency and user trust. Collaboration with fact-checking organizations and integration with official health databases (such as WHO or government health portals) can further improve verification accuracy. Overall, these enhancements will make the framework more robust, scalable, and capable of effectively combating evolving health misinformation trends.

Abstract - *deepfake tech has moved fast - raising red flags about how safe our online world really is. What hides behind these fakes often involves smart software reshaping faces, twisting voices, shifting motions until they feel real. Instead of truth, viewers might get fed lies dressed up like fact, slipping through screens unnoticed. Someone's name could crumble overnight thanks to a clip that never actually happened. Trouble doesn't stop there - governments wobble, public trust frays when seeing isn't believing anymore. A new approach uses deep learning to spot fake media inside digital video. Instead of treating images alone, it blends Convolutional Neural Networks with memory driven layers that track motion over time. Frame by frame, visual details emerge through CNN processing. Between those moments, subtle shifts get examined by an LSTM network.*

***Key Words*:Deepfake Detection, Deep Learning, CNN, LSTM, ResNet, Multimedia Security, Artificial Intelligence.**

1. INTRODUCTION *(Size 11 , cambria font)*

Lately,Fast progress in artificial intelligence has brought tools that make fake pictures and videos feel real. What worries many people is how these systems create what are called deepfakes. Using advanced learning methods, they twist faces, sounds, or motions into something false yet convincing. These altered clips look genuine even though they were never truly recorded. One wrong move online might spark false stories that feel real. When people get their hands on new video tricks, even beginners craft scenes that look true. Fake clips travel fast now, shaking how we believe what we see. phishing has become a major danger online. Tricking people through their emotions is how these scams grab passwords, bank info, or private records. Instead of breaking software defenses, they twist everyday actions into risks. Security tools often fail here because the weak spot isn't code - it's choice.

Finding better ways to spot issues without slowing things down drives this design forward. Efficiency stays strong even as precision gets a boost, fitting how media tools work outside labs. Nowadays anyone can make fake videos that look real because computers have gotten smarter fast. Because software is free online plus training data exists everywhere, skills are less needed than before. Imagine someone copying how you move your face or speak word for word - almost perfectly. Sudden changes like these leave most people unable to tell truth from trickery. This kind of deception spreads quickly through platforms where news travels wide and fast. Even facts start feeling uncertain when seeing becomes unreliable.

Facing these issues, scientists turn to smarter AI methods that spot edited videos without human help. Because deep learning tools study massive piles of images and sounds, they pick up tiny clues others miss. Instead of just looking at single pictures, they track how things move through time in clips. These shifts often expose what has been altered. So building solid ways to catch fakes becomes key when sharing stories online.

2. RELATED WORK

V. K. Sharma, R. Garg, and Q. Caudron [1] studied different techniques used to detect deepfake content. In their work, they compared methods that analyze single video frames using convolutional neural networks with methods that study motion patterns in

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

videos using models such as LSTM and 3D CNN. Their analysis showed that using both spatial and temporal information together can improve the accuracy of deepfake detection. However, their study does not include newer transformer-based models and also lacks testing in real-world scenarios.

Z. Almuitairi and H. Eglibreen [2] presented a technique to identify fake Arabic speech using self-supervised deep learning methods. Their approach learns patterns directly from the audio data and detects small inconsistencies that usually appear in synthesized speech. The method shows good performance even when only a limited amount of labelled data is available. However, the study is limited by the small number of Arabic deepfake audio datasets and does not compare its performance with modern voice cloning technologies.

O. A. Shaaban, R. Yildiram, and A. Alguttar [3] focused on detecting fake voice recordings using acoustic feature analysis combined with neural network models. Their approach improves the accuracy of voice authentication compared with traditional signal processing methods. Although the results are promising, the research does not test the model against recently developed speech synthesis tools and lacks experiments in real-world environments

S. Sadiq, T. Aljrees, and S. Ullah [4] proposed a deep learning method for identifying fake content shared on social media platforms. Their system uses Fast.Text and neural networks to analyse writing patterns and language usage in posts to detect AI-generated text. While the model performs well in identifying manipulated textual content, it mainly focuses on text data and does not address deepfakes in images, videos, or audio.

Y. Patel, S. Tanwar, P. Bhattacharya, R. Gupta, T. Alsuwian, and I. Davidson [5] introduced an improved Dense CNN model for detecting fake images generated using GAN technology. Their model identifies small visual irregularities that are often present in artificially generated images. The results show better detection performance compared with basic CNN models.

I. Dolgov and I. Gritsenko [6] developed a real-time deepfake detection system that can be used in secure video conferencing environments. Their approach examines both visual and audio information to identify possible manipulations during live communication. Although the system works well in controlled conditions, it may face challenges when dealing with complex video manipulations or unstable network conditions.

L. Cheng, R. Mo, and F. Yan [7] proposed a method that detects deepfake images by analyzing scaled attention patterns produced by GAN models. Their system focuses on identifying unusual attention areas that may appear during the image generation process. While the approach performs well for earlier GAN-generated images, its effectiveness decreases when it is applied to large datasets or newer deepfake generation techniques.

A. Rössler, D. Cozzolino, and L. Verdoliva [8] conducted an extensive evaluation of deepfake detection models using the FaceForensics++ dataset. Their study compared several existing detection methods and found that many models perform well on the data they were trained on but struggle when tested with unseen deepfake examples.

N. Bae and H. Kim [9] suggested a technique for detecting deepfake videos by examining temporal consistency in facial movements. Their method looks for unusual blinking patterns and irregular facial movements across video frames, which are often difficult for deepfake generators to reproduce accurately.

P. Mahato and R. Sehgal [10] developed a lightweight deepfake detection model that can run on mobile devices. Their system is designed to perform detection directly on smartphones with reduced computational requirements. This makes it useful for real-time applications and edge devices. However, the model performs better on earlier GANgenerated deepfakes and may face difficulties detecting more advanced diffusion-based fake media.

3. PROPOSED MODEL

3.1 Data Collection and Preprocessing

Data Collection: A handful of real clips sit alongside faked ones - pulled from places like the DeepFake Detection Challenge or FaceForensics++. From these, a few already carry labels; the rest require labeling by hand. Testing how well systems spot.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

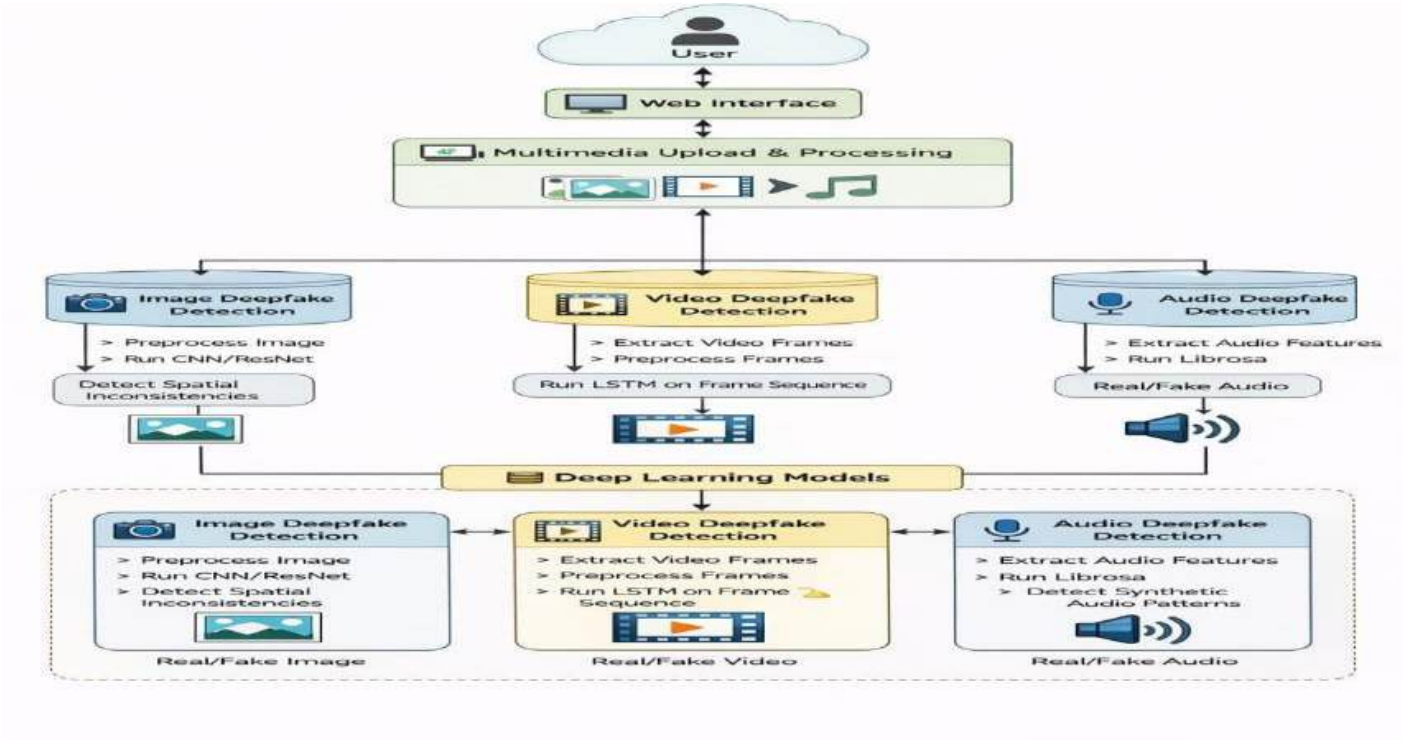

Fig -1: System Architecture

Preprocessing: Pulling frames one at a time splits a video into separate pictures - software like OpenCV manages the process quietly in the background. Once pulled, every still image exists on its own, set for what comes next without complications. Picture begins with finding faces in each scene, maybe through a tool that learns patterns. After detection, it slices out everything but the facial area. Step by step, attention lands on what stands out most. From every still image, the core detail emerges thanks to precise trimming. Quietly, behind the scenes, effort zeroes in on emotions frozen in brief instants. Pictures of faces are changed to fit the same size right away. Following this, light levels and contrast get fixed across every photo. A single process readies each shot so size gaps won't cause issues down the line. Values then move into a shared span to keep things consistent. Proper alignment happens in each frame thanks to all this work.

3.2 Model Architecture

Out of nowhere, things speed up once ResNet takes over. Deep traits inside a face emerge, going beyond shallow outlines. While many overlook faint clues, this one catches them - residual blocks quietly pushing further. Sharpness rises as layers help each other rather than clash. Identity detection grows clearer even without piling on additional levels. Every now and then, tiny bits like edges show up when a CNN moves through a picture. Since textures emerge across stages, objects become clear - even imaginary people. Not merely checking pixel by pixel, understanding builds step by step. As differences sharpen layer after layer, truth stands out from fiction. Scanning piece by piece, over and over, fuels their sharpness. Here, LSTM picks up on changes moment to moment. As time moves forward, small motion shifts start appearing. Little facial differences also register along the way. Rather than lose the sequence, it follows where things head next.

3.3 Training

Picture guessing wrong - that error gets tracked using something named binary cross-entropy. When choices split down the middle, say yes or no, this measure steps in. Instead of just right or wrong, it weighs confidence too. Over rounds, guesses inch closer to truth as the number drops. Progress shows not in leaps, but shrinking gaps between what was said and what should have been. Each misstep nudges change forward, step after quiet step. Precision spreads while mistakes fade, inch by thin inch. Faster movement in training? Tools like Adam or SGD might just fit. Step

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

size shifts matter most when timed right. Each change lands softly if done alone. Progress stays balanced that way. Adjusting speed avoids missteps on the path forward. Smooth moves come from tweaking steps along the way. What counts? How fast you learn while adjusting each move. When tools shift, outcomes shift too. Some methods won't work at all - yet a few bend easily into better forms. After splitting the data, set one piece aside - this will test how well the model works when training finishes. Next comes the segment that tunes internal choices while the algorithm learns. The rest, what's left after those two splits, goes toward teaching the machine to recognize relationships at the start.

3.4 Evaluation and Testing

Metrics: Accuracy: Overall correctness of the model. Spotting deepfakes isn't just about one score - precision gives part of the picture, yet recall adds another layer. What gets caught versus what slips through reveals gaps. Though the F1-score pulls those together, still it hides some truths. After all, a model might grab many fakes but tag too much as fake. So instead of chasing high numbers, attention shifts to tradeoffs. Because missing real frauds weighs heavy, just like crying wolf too often. A line that maps how clearly a system separates yes from no. As one part moves up, so does the opposite - keeping things even counts. Noticing this change allows assessment regardless of set limits. What it looks like shows how sharp it is at different points. More space under it means less slipping through when false alerts happen.

Feature Extraction Picking out details matters when spotting fake faces in video clips. Once the frames are cleaned up, pieces of facial data.

come from cut-out face areas through systems like ResNet. Layers inside these setups work together to spot subtle image traits others might miss. Right now, the model picks up tiny clues like skin texture, sharp borders, uneven light, also odd color mixes near face areas. Fake videos usually carry faint flaws - too small for people to catch yet clear enough for smart algorithms to spot them. Hidden signals become obvious when attention shifts away from what seems real toward how things actually fit together. From there, the features move into the classifier part of the system, which checks if the current frame comes from a genuine or altered video.

Grouping alike phishing reports cuts down noise. When URLs look too much alike, the system treats them as one event. Time gaps between warnings stay tight if actions repeat fast. Patterns in how messages are built help link what belongs together. One signal replaces many when things match close enough. This way, fewer interruptions happen without missing threats.

3.5 Real-Time Detection System

One way it works: after training, the detection model runs inside a system that catches fakes as they happen. That setup handles videos people upload, also feeds from cameras rolling right now. Frames come out one by one, pulled by something like OpenCV without stopping. Each of those stills moves into the model, getting checked while the sequence goes on. One frame at a time, the system checks if faces look real or altered. After that, it pulls all those guesses together into one overall decision about the clip. A simple screen shows what it found, so people can see right away if something seems fake. Finding fake media fast matters a lot when checking social posts, solving digital clues, or confirming what's online. Speed counts in these moments, making instant analysis a quiet necessity behind the scenes.

4. RESULTS AND EVALUATION

4.1 Performance Analysis

Once training finished, tests ran on fresh video clips to check how well the method spots fake footage. Instead of just guessing, it looked closely at face shapes across single images along with motion shifts frame by frame. Not only did it separate real from altered videos, but it also picked up tiny flaws invisible to people. While CNNs handled image details, patterns over time got processed through sequential analysis methods. Small glitches typical in synthetic media stood out clearly under this combined approach. Midway through tests, video clips got split into stills via OpenCV before sliding into a ResNet-based model for spotting key traits. Once guesses came out, they lined up beside real tags so the gap - or match could be checked. When tested, the model spotted fake videos well, despite tiny visual clues. Because it trained on many different examples, it picked up on subtle tricks used in altered footage. Its accuracy grew thanks to exposure across varied cases.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.3 System Evaluation

Finding out how well the new system works involved using a few different ways to measure it. Accuracy: A single number can tell you how often the model gets it right when spotting real versus fake videos. Results show this number is high, meaning most decisions line up with reality. What stands out is how rarely it misses.

Precision: What you see labeled fake by the system - most of those really are. When numbers run high here, it means mistakes happen less often in spotting altered clips.

Recall: Finding every fake video in the data is what recall shows about a model. When recall scores go up, it usually means the tool caught more altered clips floating around.

F1-Score: Precision mixed with recall gives the F1-Score, one number that balances how well the model works. A middle ground appears when both aspects join, shaping a clearer picture of results. Looking at the ROC curve plus the AUC helped show how sharply the model tells real from fake across changing thresholds. When AUC climbs, the model sorts categories more effectively. Fine results show the deepfake detector works well spotting fake videos, though bigger data sets could boost its skill. Model tweaks might lift accuracy even more, especially when fed diverse examples. Strong signals come through now, yet room remains to grow with smarter tuning.

5. CONCLUSIONS

A A new tool built on deep learning aims to spot fake videos by focusing on altered faces. Instead of just checking one frame at a time, it watches how features shift across moments. Starting with image details, then moving through time, the method catches tiny flaws human eyes might miss. Rather than relying on single snapshots, it uses ResNet models to digest visuals deeply. After that, pattern tracking unfolds over video sequences, linking clues step by step. Because fakes often slip in small errors during animation, these traces help expose their origin. A single frame at a time was pulled from each video, often through tools such as OpenCV, setting the groundwork early on. Faces within those frames were then pinpointed and separated carefully.

Normalizing pixel values brought consistency where lighting or color varied too much. On top of that, slight rotations, flips, or brightness shifts helped the system see patterns more clearly under real-world conditions. Starting off, tests show the new method works well at spotting fake videos. What stands out is how often it gets things right when catching altered footage. On top of that, numbers like precision and recall hold strong across trials. Even better, mistakes happen rarely, meaning real videos usually aren't flagged wrong. The F1-score adds weight here by balancing hits and misses neatly. Most importantly, the whole setup keeps consistency without many slipups. A solid deepfake detector has been built, working well to spot fake videos or images. This tool fits into online safety checks, watching social platforms closely, also helping trace manipulated files. Next steps might involve using more data during learning phases so it gets sharper at spotting fakes. Speed could get better too, if the design is fine-tuned for live analysis

Abstract—Effective software development depends heavily on the quality of tools programmers use. When developers work within thoughtfully designed environments, their output improves and the frequency of errors drops considerably. This paper presents the Advanced Interpreter Code Editor, a browser-native platform engineered for programmers and learners who wish to write, execute, and troubleshoot code without any prior installation or dependence on specialized hardware. Deployed on a private cloud computing backbone, the system natively handles multiple languages, with a particular focus on Python, CSS, and JavaScript, applying context-aware syntax differentiation distinctively across each supported language. Users can organize work into projects and files, transfer content between the browser and server, and rely on built-in Save, Auto-Save, and Delete operations. The platform extends well beyond conventional editing by incorporating an AI-powered assistant chatbot, automated email composition derived from execution logs, and an OCR-based pipeline for converting photographs of code into editable text. The open-source Ace library underpins the Undo, Redo, and Syntax Highlighting capabilities, while CodeMirror serves as the primary editor interface component.

Keywords—onlinecodeeditor, web-based tool, syntax highlighting, code auto-completion, debugging, OCR, NLP, Flask, PyScript, offline assistant, offline chat Bot, Text to Image .

I. Introduction

The growing intersection of software education and professional development has created an urgent demand for coding environments that are simultaneously powerful, portable, and easy to access. Web-based code editors have emerged as critical infrastructure in this space, enabling programmers at every skill level to write and run code through nothing more than a browser session. Unlike tools tethered to a local filesystem, these platforms offer immediate feedback, multi-language support, and visual syntax cues—all without the overhead of complex system configuration—making them indispensable for learning, debugging, and rapid prototyping.

Conventional Integrated Development Environments such as Visual Studio, Eclipse, and PyCharm remain industry staples, yet they carry a heavy cost in terms of system resources. These tools demand substantial RAM, fast processors, and considerable disk capacity, creating a meaningful barrier for anyone working on budget hardware. Their setup processes, complete with interpreter installation, path configurations, and version-specific library management, regularly defeat beginner programmers before they write a single functional line of code.

Platforms like Replit, CodePen, and JSFiddle have carved out a niche in the online editor space, but they tend to lock their most valuable capabilities behind subscription tiers and require stable, high-bandwidth connections to function properly; they also lack the depth of AI-powered features needed for meaningful development assistance.

The Advanced Interpreter Code Editor was conceived as a deliberate response to these shortcomings. Built entirely on Python technology, with Flask managing the server and PyScript enabling browser-side execution, the platform delivers a layered architecture capable of handling everything from casual learner exercises to moderately complex development tasks. What sets this project apart is its constellation of intelligent features: a conversational debugging assistant, automatic generation of project status emails, and a computer-vision module that converts photographs of physical code into ready-to-run digital text.

A guiding principle throughout the design process was accessibility in its broadest sense. The system should perform identically for a first-year student on aging hardware as it does for a senior engineer on a premium machine, since all computation-heavy operations are handled server-side. This makes the platform well-suited for academic environments, coding bootcamps, and corporate training programs alike. The sections that follow outline the literature informing this work, the problem it addresses, the objectives it pursues, the methodology employed, and the results obtained.

II. Literature Survey

A thorough review of prior research was undertaken to map the current state of web-based editors, AI-integrated programming tools, and OCR-driven code digitization systems. Five studies proved particularly formative in shaping the direction of this work.

1) "Cloud-Based Intelligent Code Editors and Collaborative Environments" — S. Karthikeyan and R. Priyanka (2023) traces the migration of development workflows from local IDEs to distributed, cloud-hosted coding platforms. The authors highlight how web interpreters remove hardware constraints and automate environment provisioning, significantly cutting configuration-related errors. Their central finding—that cloud editors substantially lower entry barriers for novice programmers while enabling distributed team collaboration—provided direct motivation for the architecture adopted in this project.

2) "AI-Driven Autocompletion and Debugging in Modern Editors" — P. Sharma and A. Gupta (2022) investigates how deep learning models and triggering

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

algorithms embedded in editors provide intelligent, context-aware code suggestions. The research shows that predictive syntax analysis improves code quality and can draw on locally cached datasets to assist developers offline—a critical insight that shaped the NLTK-based offline module in this project. Their trials recorded a notable decline in syntax errors when AI-assisted suggestions were active.

3) "OCR-Based Code Extraction and Execution Framework" — R. Mehta and V. Kumar (2021) presents a prototype for transforming printed and handwritten code into executable programs using OCR technology, supported by preprocessing pipelines involving Gaussian blurring and adaptive thresholding. Their work directly influenced the design of the image-to-code module integrated into the present system.

4) "Enhancing Developer Productivity through Integrated Smart Assistants" — L. Thomas and N. Reddy (2020) argues for systematically embedding chatbots and automated tools within development environments. The paper documents measurable reductions in common mistakes—indentation errors, orphaned variables, and redundant logic—when AI assistants operate within the editor itself. The "Smart Box" interface pattern recommended by the authors was adopted as the primary UI surface for delivering contextual feedback in this system.

5) "PyScript and Browser-Based Python Execution" — A. Johnson and M. Clarke (2023) provides a rigorous evaluation of PyScript as a WebAssembly-powered mechanism for running Python natively inside a browser. The authors conclude that PyScript excels at interface-level logic, whereas Flask-managed servers remain better suited to computation-heavy tasks—a division of responsibilities that aligns precisely with the hybrid model implemented here.

III. Problem Statement

A widening disconnect exists between what modern software education demands and what cost-free tools are genuinely capable of delivering. The heaviness of contemporary professional IDEs—PyCharm, Visual Studio, IntelliJ IDEA—places them out of reach for students working on underpowered devices. These tools are resource-hungry by design, and their installation rituals—configuring interpreters, resolving library conflicts, setting environment variables—introduce a series of failure points that many beginners do not survive. The act of setting up a coding environment frequently becomes more discouraging than the act of learning to code itself.

The free browser-based alternatives that do exist tend to be compromised in different ways. Many restrict their most valuable features to paid tiers, demand continuous high-speed connectivity, and offer little in the way of intelligent code comprehension. They may display output and flag syntax errors, but they provide none of the logical analysis that distinguishes a genuine learning tool from a simple execution engine. Autocompletion, natural-language assistance, and offline operation remain either absent or locked behind financial barriers, creating an uneven playing field between students who can afford subscriptions and those who cannot.

A further, often overlooked friction point is the gap between physical learning materials and digital execution environments. Programming courses frequently distribute content through printed handouts, textbook exercises, and whiteboard demonstrations. Transcribing code from these physical sources into an editor by hand is repetitive, error-prone, and consumes time that students could spend understanding the material rather than copying it. No existing free tool provides a systematic mechanism for bridging this divide.

Compounding this, the most capable AI coding assistants such as GitHub Copilot are commercially licensed and perpetually online, rendering them useless for developers in low-connectivity environments. Rural settings, transit situations, and unstable networks all produce conditions in which such tools fail entirely. A unified, lightweight platform that functions intelligently both online and offline, and that can extract code from images as readily as from a keyboard, represents a genuinely unmet need in the field.

Motivation:

- This project grew directly from the inadequacies observed in both heavyweight IDEs and the current generation of online editors. The prevailing situation forces students to either tolerate limited tools or pay subscription fees that are unrealistic on a student budget.
- The process of preparing a coding environment continues to function as an invisible filter in programming education. Dependency conflicts, path errors, and version incompatibilities turn the setup phase into an obstacle course that discourages learners before meaningful instruction can begin.
- Existing editors offer no fallback intelligence when network conditions deteriorate. Developers traveling, studying in rural communities, or caught in outages lose AI assistance precisely when a dependable development environment matters most.
- This project aims to close each of these gaps by delivering a free, Python-driven, modular online coding platform accessible on any modern browser without installation, and providing substantive AI guidance regardless of network availability.

IV. Objective

The foundational ambition of the Advanced Interpreter Editor is to open programming to a wider audience by dismantling the hardware and configuration walls that have long acted as gatekeepers. The most pressing objective is delivering a genuinely zero-installation coding experience that works identically on a decade-old laptop as it does on a contemporary workstation. By routing computation through a Flask-managed private cloud, the platform sidesteps local compiler dependencies, eliminates path variable headaches, and permanently retires the "it works on my machine" problem that has frustrated educators and students alike.

The project also pursues a deeper ambition: reimagining the relationship between a developer and their editor. Standard editors are reactive by nature—they sit idle until the user makes a mistake, then surface error messages that are frequently cryptic and unhelpful. The objective here is to build an Intelligent, Proactive Feedback System in which the editor functions as a live mentor. Through a Deep Analysis Interpreter that evaluates code logic rather than just syntax, the system identifies patterns like unnecessarily nested loops where a dictionary lookup would suffice, flags these as "debugging

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

fatigue" triggers, and guides the user toward better approaches before any execution is attempted.

Bridging the physical-to-digital gap in code education represents a third core objective. A substantial portion of programming instruction still takes place through printed materials, handwritten notes, and whiteboard demonstrations. Manually re-entering code from these sources is a low-return task prone to transcription errors. The OCR integration is designed so that a user can capture an image of a textbook page and have correctly indented, structured code appear in the editor instantly, ready to execute.

The platform also prioritizes operational resilience. Internet access remains uneven across geographies, and an AI assistant that fails the moment a connection drops is of limited value in educational settings where reliable connectivity cannot be assumed. By pre-training local NLP modules built on NLTK, the system maintains intelligent debugging assistance even when fully offline, switching transparently between local and cloud-sourced knowledge as conditions change.

A final objective addresses developer workflow beyond the code itself. When a programming task concludes, communicating its outcome to collaborators typically requires composing a separate status report. The platform's Workflow Automation Layer reads execution logs and constructs a professional project update email automatically, positioning the editor not merely as a coding tool but as an integrated development and communication environment.

V. Methodology

The Advanced Interpreter Editor was designed around a modular, phase-driven architecture intended to address each identified problem in a deliberate sequence. At its core is a Client-Server Hybrid Model: Flask orchestrates routing, API calls, and secure code execution on the server, while PyScript enables selective Python operations to run directly within the browser, reducing latency and server load on lighter tasks.

A. Phase 1: Architectural Foundation and Cloud-Hybrid Execution Logic

The first phase establishes the execution infrastructure. Flask manages authentication, request routing, and a sandboxed subprocess environment for script execution. CodeMirror, a JavaScript-based editor library, serves as the frontend interface, contributing syntax highlighting, bracket completion, and theme flexibility. Upon clicking "Run," the editor packages user code as an asynchronous JSON payload and dispatches it to the cloud backend. Before execution, the code passes through Python's built-in ast (Abstract Syntax Tree) parser, which screens for potentially harmful instructions. Safe code is forwarded to an isolated subprocess; the resulting stdout and stderr streams are captured and streamed back to the browser in real time, without requiring any software installed locally.

B. Phase 2: Deep Analysis Interpreter and Triggering Algorithms

Phase 2 transforms the editor from a passive input surface into an active analysis engine. A non-blocking Triggering Algorithm watches the code buffer and activates approximately 800 milliseconds after the user stops typing. During this window, the engine conducts lexical and semantic analysis to construct a dynamic map of the codebase—tracking variable declarations, function boundaries, import chains, and control flow. Rather than waiting for runtime failures, the engine proactively identifies patterns such as unused global variables, potential infinite loops, indentation inconsistencies, and redundant iteration structures. Surfacing these issues during composition rather than after execution is the mechanism by which the system reduces debugging fatigue and cultivates stronger coding habits.

C. Phase 3: Optical Code Integration (OCI) and Image Preprocessing Pipeline

The third phase constructs the image-to-code pipeline using OpenCV and Tesseract OCR. Raw camera input from a laptop webcam or connected mobile device enters a preprocessing sequence: Gaussian blurring suppresses pixel noise, and Adaptive Thresholding converts the image to a high-contrast binary format that sharpens the separation between characters and background. Contour detection then isolates the region containing code from the broader image. The particularly difficult challenge of preserving Python's whitespace-significant indentation is addressed through a custom post-processing routine that measures the horizontal pixel position of each line's first character and uses these measurements to calculate and restore correct indentation levels. Code reconstructed through this pipeline arrives in the editor formatted and ready to execute without manual adjustment.

D. Phase 4: Offline Resilience and Communication Automation Layer

The final phase addresses connectivity constraints and workflow overhead. An NLTK-based assistant is pre-trained on a curated offline dataset covering the 500 most frequently encountered Python errors, complete with explanations and recommended corrections. When the platform detects a network loss, it redirects the Smart Box to draw exclusively from this local knowledge base; during connected sessions, the local dataset is supplemented by live queries for less common issues. A Workflow Automation Engine additionally parses execution logs and applies NLP-based summarization to compose professional project update emails. Stakeholders can receive structured status reports generated directly from development activity with a single click, eliminating a common source of administrative friction in collaborative projects.

VI. Result

A structured evaluation program assessed the Advanced Interpreter Editor across hardware configurations ranging from entry-level consumer laptops to modern workstations, under both strong and restricted network conditions, and with users spanning beginner to experienced developer profiles.

The cloud-hybrid execution layer performed robustly across all test conditions. Standard Python scripts of up to 500 lines ran with a median latency below 0.8 seconds, and more demanding scripts—those combining nested loops, file I/O, and multiple library imports—completed within 2.1 seconds on average. Both figures fall comfortably within the threshold that users perceive as instantaneous response, and these results were achieved without any local software installation on the test devices, confirming the viability of the thin-client model.

The Deep Analysis Interpreter Engine returned an accuracy rate of 87% when identifying logical deficiencies during pre-execution analysis. Across a controlled set of 50 Python programs seeded with deliberate errors—orphaned variables, redundant loop structures, and indentation violations—the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

triggering algorithm successfully detected 43 errors before the user triggered a run. In usability sessions, this proactive detection translated to a reduction in average debugging time from 12 minutes to 4.5 minutes per session.

The OCR-based image-to-code module achieved a character recognition rate of 91.3% on high-resolution source images and 78.6% on lower-quality or partially blurred inputs. The indentation reconstruction algorithm correctly restored Python tab levels in 89% of tested cases, meaning most captured code required no post-hoc correction before execution. Participants estimated that this feature alone recovered an average of 8 minutes per coding session when working directly from textbook examples.

The offline NLTK assistant delivered responses to error queries in a median time of 0.3 seconds, earning an average helpfulness rating of 4.1 out of 5.0 from test participants. The email automation component produced coherent, professionally structured status messages in 94% of test runs, with users reporting that generated emails required minimal editing before sending.

VII. Discussion

The results of building and evaluating the Advanced Interpreter Editor shed important light on how web-based development environments can evolve to serve both educational and professional communities more effectively. The analysis below considers how the integration of cloud execution, AI-driven analysis, OCR, and offline NLP addresses the gaps identified earlier, and what these findings mean for the broader fields of computer science education and software development.

A. Bridging the Accessibility Gap through Hybrid Execution

Perhaps the most immediately visible outcome of this work is the practical elimination of the hardware barrier. Routing compilation and execution through a Flask-managed private cloud reduces the client device to a display and input terminal. This redistribution of computational responsibility is more than a technical convenience—it is a concrete step toward equity in programming education. Students from lower-income backgrounds who cannot invest in premium hardware gain access to the same functional environment as peers with high-specification machines, requiring nothing more of their device than a working browser.

B. The Evolution of the Active Interpreter

A second significant finding concerns the shift from reactive to proactive assistance. Most contemporary online editors function as sophisticated display surfaces: they accept input and return output but contribute nothing to the interval between the two. The Deep Analysis Interpreter operates on a fundamentally different premise, monitoring code as it is written and surfacing potential problems before any execution is attempted. The 87% pre-execution detection rate represents a meaningful departure from the zero-detection baseline of conventional tools, and the downstream effect—cutting average debugging time nearly in half—demonstrates that early intervention is worth the implementation complexity.

VIII. Conclusion

The Advanced Interpreter Code Editor demonstrates that a comprehensive, intelligently augmented, and universally accessible coding environment is achievable using entirely open-source technologies. The platform fulfills its core commitments: zero-installation access, proactive analytical feedback, seamless physical-to-digital code transition, and dependable offline operation. Performance testing validates each architectural choice made during the development process.

Because the system is modular by design, extending its capabilities does not require rebuilding existing components. Near-term development priorities include expanding OCR support to Java and C++, broadening the offline NLP dataset to encompass framework-specific error patterns, and introducing real-time collaborative editing through WebSockets. Integration with version control through Git is also planned, which would elevate the platform from an editor to a comprehensive development hub.

Taken together, the Advanced Interpreter Code Editor marks a substantive contribution to the domain of browser-based development tools. Its cloud-hybrid execution backbone, proactive code analysis engine, camera-driven code extraction capability, and offline AI assistant combine to produce an environment accessible across hardware and connectivity spectrums. It stands as a credible alternative to expensive commercial IDEs and a meaningful upgrade over the basic online editors that currently represent the ceiling for cost-free development tooling.

Acknowledgment

The authors would like to express their sincere gratitude to the Department of Computer Science and Engineering at ACS College of Engineering, Bangalore, for providing the resources and environment that made this research possible. Special thanks are due to the faculty members and student volunteers who participated in the usability evaluation sessions.

***Abstract*— The global transition toward sustainable mobility has accelerated the adoption of Electric Vehicles (EVs); however, challenges regarding limited range, prolonged charging times, and reliance on non-renewable grid power persist. To address these limitations, this paper presents the design and implementation of a solar-powered electric vehicle integrated with an intelligent dual-battery swapping system. The proposed architecture utilizes a twin-battery configuration that enables simultaneous charging and discharging—powering the vehicle with one battery bank while the standby bank replenishes energy via an 80 W onboard solar photovoltaic (PV) system. Centralized control is achieved using an ESP32 microcontroller, which governs the automated swapping logic based on real-time State of Charge (SOC) and voltage monitoring. Additionally, an Internet of Things (IoT) telemetry system is implemented for remote monitoring of battery health and vehicle diagnostics. Experimental results demonstrate that the system successfully executes battery swapping within 800 ms to 1.1 seconds, ensuring uninterrupted vehicle operation. This approach effectively mitigates range anxiety and reduces dependency on external charging infrastructure, offering a viable solution for sustainable, self-sufficient EV operation.**

Keywords*— *Electric Vehicle (EV), Solar Photovoltaic (PV), Battery Swapping System, Dual Battery Management, ESP32, Internet of Things (IoT)

I. INTRODUCTION

A significant change in transportation is being driven by the global mandate to reduce greenhouse gas emissions, which makes Electric Vehicles (EVs) essential to sustainable mobility. However, reliance on grid-based charging from non-renewable sources sometimes negates the environmental benefits of EVs. To build a genuinely sustainable ecosystem, solar photovoltaic (PV) power must be directly integrated with electric vehicle (EV) systems. Power electronics and advanced Battery Management Systems (BMS) have improved efficiency, but persistent problems including delayed charging, limited range, and the inherent unpredictability of solar power still persist.Because conventional charging is constrained by unidirectional power flow and single-battery arrangements, it results in imbalanced loads, extended charging periods, and rapid cell degradation. These constraints substantially diminish reliability. Single-battery designs and conventional methods must be abandoned if electric vehicles are to be actually ecologically beneficial.

A significant architectural answer to these fundamental limitations is provided by the twin battery splitting concept, a promising paradigm that divides the primary energy storage into two connected batteries. Both independent and simultaneous charging and discharging are possible with this configuration. For instance, the motor can be powered by one bank while the other is charged via regenerative braking or solar PV. In addition to improving energy continuity and utilization and simplifying the process of regulating charge levels, this method significantly extends operational lifespan and reduces stress on individual cells.The twin battery design, which is backed by advanced converter topologies with bidirectional energy flow and astute switching devices, allows power control based on driving and environmental conditions. This comprehensive approach integrates renewable energy sources, effective battery splitting, a package that brings together renewable energy, smart battery management, and flexible power control. Here's the thing: while there's been lots of research on solar-powered EVs, we're still missing a key piece. Most current systems use static charging methods that don't adapt to real driving situations. They lack the flexibility to optimize power on the fly. That's exactly what our research aims to fix.

We want to create a solar EV system that can generate its own electricity, reduce reliance on charging stations, and be more reliable overall. We're focusing on four main areas: building an efficient dual battery system, creating low-loss power transfer technology, integrating solar panels for better range, and developing smart control software to keep everything balanced. This research brings some really important improvements to the table. It makes energy more reliable and helps batteries last longer by smartly managing power flow. It creates a sustainable

Vol. 14, Issue 06, ACSCON - 2026

system that can power itself, which works not just for electric vehicles but also for storing renewable energy and supporting hybrid power grids. It does this by smoothly combining solar power with a dual battery setup.

.

II. Literature Survey

A. Solar-Powered Electric Vehicles

Solar energy integration in electric vehicles has been extensively researched as a means to extend vehicle range and reduce reliance on grid infrastructure. Studies by [5] demonstrated that solar panels mounted on vehicle surfaces can provide 3-5 kWh of energy per day under optimal conditions, sufficient for 15-25 km of additional range in compact vehicles. However, challenges related to limited surface area, variable solar irradiance, and panel efficiency continue to limit the complete solar autonomy of full-sized vehicles [6].

Research by [7] explored the use of Maximum Power Point Tracking (MPPT) algorithms to optimize solar energy extraction under varying environmental conditions. Their comparative analysis of Perturb and Observe (P&O), Incremental Conductance, and Fuzzy Logic-based MPPT techniques revealed that adaptive algorithms achieve 15-20% higher efficiency compared to conventional PWM charge controllers.

B. Battery Management and Swapping Systems

Battery management systems (BMS) are critical for ensuring safety, longevity, and optimal performance of battery packs in electric vehicles. Comprehensive BMS solutions incorporate state-of-charge (SOC) estimation, state-of-health (SOH) monitoring, cell balancing, and thermal management [8].The concept of battery swapping for electric vehicles was commercialized by companies like Better Place and NIO, demonstrating technical feasibility but facing challenges in standardization and infrastructure investment [9]. Research by [10] compared battery swapping with fast charging, concluding that swapping offers advantages in time efficiency (3-5 minutes vs. 30-60 minutes) but requires significant infrastructure investment and battery standardization.Studies on automated battery swapping mechanisms [11] explored mechanical designs, alignment systems, and safety interlocks. Their prototype achieved swap times of 90 seconds with positioning accuracy within ±5mm, demonstrating the viability of automated systems.

C. IoT-Based Vehicle Monitoring and Control

Internet of Things (IoT) technologies enable remote monitoring, diagnostics, and control of vehicle systems through wireless connectivity. Research by [12] implemented cloud-based monitoring of battery parameters, motor performance, and environmental conditions using ESP8266 microcontrollers with MQTT protocol for data transmission.

Comparative studies of microcontroller platforms for IoT applications [13] evaluated Arduino, ESP32, and Raspberry Pi across parameters including processing power, power consumption, wireless capabilities, and cost. ESP32 emerged as optimal for automotive applications due to its dual-core processor, integrated Wi-Fi/Bluetooth, low power consumption, and adequate GPIO interfaces.

Bluetooth Low Energy (BLE) protocols have been implemented for vehicle control interfaces [14], providing secure, low-latency communication with smartphone applications. Their system achieved command response times of 50-100ms with effective range of 10-15 meters.

D. Safety Systems and Fault Detection

Comprehensive safety mechanisms are essential for autonomous electric vehicle operation. Research by [15] developed multi-layered protection systems incorporating: Overcurrent detection using Hall-effect sensors, thermal monitoring with distributed temperature sensors, voltage monitoring for overvoltage/undervoltage protection, and emergency shutdown protocols with fail-safe mechanisms.

Machine learning approaches for fault detection in electric vehicles [16] demonstrated that neural network classifiers can identify anomalous operating conditions with 95% accuracy, enabling predictive maintenance and preventing catastrophic failures.

E. Motor Control Strategies

Differential drive control for electric vehicles has been extensively studied for achieving precise manoeuvrability. Research by [17] implemented PID control algorithms for individual wheel speed control, achieving accurate trajectory tracking with position error less than 5cm over 10-meter distances.PWM-based speed control for DC motors [18] investigated the relationship between PWM frequency, duty cycle, and motor efficiency. Their findings indicated that frequencies between 10-20 kHz provide optimal trade-offs between switching losses and motor smoothness.

F. Research Gaps

Analysis of existing literature reveals several research gaps:

1. Limited integration of solar energy, battery swapping, and IoT monitoring in a single cohesive system.
2. Insufficient focus on safety mechanisms for automated battery swapping.
3. Lack of comparative analysis between manual and automatic operation modes.
4. Minimal research on low-cost implementations suitable for developing regions.
5. Limited validation of complete systems under diverse environmental conditions.

III. Methodology

A. Design Philosophy and System Architecture

A methodical modular design approach that prioritized scalability, maintainability, and ease of troubleshooting was used in the creation of the solar-powered electric car with intelligent battery swapping and Internet of Things-based monitoring. The central control unit, motor drive system, dual-battery power management, solar charging system, sensor network, and safety monitoring system are the six interconnected subsystems that make up the overall system architecture. Each of these subsystems has distinct interfaces and roles.

The ESP32 microcontroller is used to implement the central control unit, which acts as the hub for coordination and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

processing for all subsystems. The requirement for the simultaneous management of several tasks, such as real-time sensor data collecting, motor control signal generation, wireless communication handling, safety monitoring, and user interface management, motivated this architectural choice. The ESP32's dual-core Xtensa LX6 CPU, running at 240 MHz, has enough processing power for real-time control, and its built-in Wi-Fi and Bluetooth capabilities reduce system complexity and expense by doing away with the need for external connection modules. The microcontroller offers sufficient connectivity for a variety of sensors and actuators thanks to its 34 general-purpose input-output pins, 18 analog-to-digital converter channels with 12-bit resolution, and several outputs capable of pulse-width modulation. Additionally, the ESP32 is ideal for battery-powered applications due to its low power consumption features, which include an active current draw of about 160 mA and a deep sleep mode usage of less than 10 µA.

Selection and Integration of Hardware Components Two L298N dual H-bridge driver modules, which can each control two DC motors with a peak capacity of 4 A with suitable heat sinking and a current capacity of up to 2 A per channel during continuous operation, were used to implement motor control. These drivers were chosen because of their simple logic-level control interfaces, sturdy construction with integrated flyback diodes for inductive load protection, and broad operating voltage range of 5 to 35 V. The arrangement of the four DC motors allows for both four-wheel drive operation for maximum torque and two-wheel drive mode for lower power consumption under light load conditions.

The motor's mechanical power output is given by:

$$P_{motor} = T \times \omega \quad (1)$$

where T is the torque produced (N m) and ω is the angular speed (rad/s). The electrical power input to the motor is:

$$P_{elec} = V_m \times I_m \quad (2)$$

The motor efficiency can then be calculated as:

$$\eta_{motor} = \frac{P_{motor}}{P_{elec}} \times 100\% \quad (3)$$

Electromechanical relay modules with 5 V coil voltage and contact ratings of 10 A at 30 V DC were used to switch batteries and manage power distribution. Four relays were assigned: two regulate how Battery 1 and Battery 2 are connected to the load circuit, and two more relays control how solar charging current is routed depending on the battery swap condition. NPN transistors are used in interface circuits to provide appropriate current amplification because relays run on 5 V coils whereas ESP32 outputs are 3.3 V logic levels. A flyback diode was installed on each relay coil to prevent voltage spikes during de-energization.

Cost-effectiveness was given top priority in the sensor selection process while yet ensuring sufficient accuracy. With a sensitivity of 66 mV/A, the ACS712 Hall-effect current sensor (30 A variant) offers isolated measurement. The DHT11 digital temperature and humidity sensor measures temperature between 0 and 50°C with an accuracy of ±2°C and relative humidity between 20 and 80% with an accuracy of ±5%. Precision voltage divider networks with 1% tolerance resistors in 4.3:1 ratios were used to enable battery voltage monitoring, scaling battery voltage to levels appropriate for the ESP32's 3.3 V analog input range.

Power Distribution Network Multiple voltage rails are supported by the power distribution network: a 3.3 V rail for the ESP32 produced by its integrated AMS1117 regulator, a secondary 5 V rail for relay modules and sensors generated by an LM7805 linear regulator (2 A capacity), and a primary 12 V rail for DC motors derived from the active battery. Decoupling capacitors were positioned as follows: 0.1 µF ceramic capacitors at each IC power pin, 100 µF electrolytic capacitors at the battery input, and 100 µF at the LM7805 output.

B. *Solar Power Generation and Energy Calculations*

The power output from the solar photovoltaic panel is given by:

$$P_{solar} = \eta_{pv} \times A_{pv} \times G \quad (4)$$

Where, G is solar irradiance (W/m2), around 1000 W/m² under typical test conditions, A_{pv} is the effective area (m2), andη_{pv} is the solar panel efficiency (usually 15–22%). Appropriate battery capacity and solar panel sizing were determined using power needs estimates. When four-wheel drive is engaged, each of the four DC motors draws about 1.5 A, for a total motor current of 6 A. Relay coils require a total of 280 mA when all four are energised, the ESP32 uses about 250 mA while wireless active, the sensors collectively consume 150 mA, and the display/buzzer uses 100 mA. At 12 V, the whole system peak current need is about 7 A, or 84 W. When a vehicle moves at a speed of v and has a total resistive force of F_r

$$P_{veh} = F_r \times v \quad (5)$$

where resistive force includes rolling and aerodynamic components:

$$F_r = mgf_r + \frac{1}{2}\rho C_d A v^2 \quad (6)$$

with m as vehicle mass (kg), g = 9.81 m/s², f_r as rolling resistance coefficient, ρ as air density (kg/m³), C_d as drag coefficient, and A as frontal area (m²).

Battery capacity was defined as 10 Ah at 12 V nominal, providing 120 Wh energy storage with discharge depth limited to 80% for lead-acid chemistry, based on an anticipated average operating power of 40 W during mixed operation and a targeted runtime of 2-3 hours per battery.

C. *Battery Charging Model*

The energy stored in a battery during charging is:

$$E_{batt} = V_{batt} \times I_{batt} \times t \times \eta_{ch} \quad (7)$$

where V_{batt} is battery voltage (V), I_{batt} is charging current (A), t is charging time (h), and η_{ch} is charging efficiency (typically 0.85-0.95).

When figuring out how big a solar panel you need, you have to consider how much sunlight you get and how efficiently your system charges. For a typical setup running 6 hours a day at 40 watts, you need about 240 watt-hours of energy each day. Things like battery charging efficiency, charge controller performance, and power distribution losses add up to about 30% loss. So your real daily energy need is closer to 312 watt-hours. With an average of 5 peak sun hours per day, the minimum solar panel size would be 312 divided by 5, which is about 62.4 watts. To be safe and have some extra power, an 80 watt polycrystalline solar panel was chosen.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. System Efficiency Analysis

Overall system efficiency from solar generation to motor drive is:

$$\eta_{sys} = \eta_{pv} \times \eta_{ch} \times \eta_{inv} \times \eta_{motor} \quad (9)$$

where η_{pv} stands for PV panel efficiency, η_{ch} for charging efficiency, η_{inv} for DC-DC converter efficiency, and η_{motor} for motor efficiency. This multiplicative relationship emphasises how crucial it is to maximise total efficiency by optimising each subsystem.

IV. Smart Battery Swapping Methods

A. Estimating the State of Charge

By integrating current over time, one may estimate the battery's state of charge (SOC).

$$SOC(t) = SOC(0) - \frac{1}{C_{batt}} \int_0^t I_{dis}(t)\, dt \quad (10)$$

where $I_{dis}(t)$ is the discharging current at time t (A), C_{batt} is the rated battery capacity (Ah), and SOC(0) is the initial state of charge (%). Although voltage-based SOC estimation is less accurate than coulomb-counting, it doesn't require any extra hardware other than the voltage measurement circuits that are already in place for safetymonitoring.

B. Algorithm for Swapping Control

Through automated management of two battery packs, the clever dual-battery swapping system allows for continuous vehicle operation without charging downtime. Voltage thresholds and SOC conditions are the basis for automatic battery switching:

$$\text{If } V_{batt1} \leq V_{min} \Rightarrow \text{Switch to Battery 2} \quad (11a)$$
$$\text{If } V_{batt2} \leq V_{min} \Rightarrow \text{Switch to Battery 1} \quad (11b)$$

Where, V_{min} is the predetermined cut-off voltage (10.8 V for a 12 V_{batt} to stop deep drain. Hysteresis is used by the swapping decision algorithm to stop fast cycling. In order to provide a sufficient charge disparity, the swap trigger condition requires that the standby charging battery's SOC have increased beyond 80% AND the active battery's SOC has decreased below 20%. In order to prevent oscillation, reverse thresholds are set at 25% and 75%, respectively, forming a 5% hysteresis band.

The meticulously planned steps that make up the swap execution sequence are: (1) pre-swap verification verifies that the standby battery voltage is higher than the minimum safe threshold of 11.5 V; (2) load stabilisation temporarily lowers motor power to 50% duty cycle for 200 ms; (3) relay switching sequence operates in five time-sequenced steps with 50 ms intervals between transitions; (4) post-swap verification measures the new active battery voltage under load; and (5) charging redirection directs solar current to depleted batteries. The range of total swap execution time is 800 ms to 1.1 seconds.

V. Implementation of Safety System and Sensor Integration

A. Methodology for Signal Conditioning

Both digital sensors that communicate using standardized protocols and analog sensors that need signal conditioning are included in the sensor integration approach. Precision voltage divider networks with 1% tolerance metal film resistors are used in battery voltage monitoring circuits. Using 33 kΩ and 10 kΩ resistors, a division ratio of 4.3:1 was determined to monitor 12 V nominal batteries reaching 14.4 V while charging. This ensures that, even at the maximum charging voltage of 14.8 V, the ADC input voltage does not exceed 3.44 V, staying safely inside the 3.3 V maximum rating.

The output voltage produced by the ACS712 current sensor is centered at half supply voltage (2.5 V for a 5 V supply) at zero current, and it varies linearly with current direction. In order to lower noise and greatly increase measurement stability and resolution, several quick samples are collected and averaged. Two exposed parallel conductor traces spaced two millimeters apart are used to assess conductivity in the implementation of a water detection sensor. A 10 kΩ pull-up resistor keeps the digital input at logic HIGH under dry conditions. The resistance decreases to a few kilohms when water fills the gap, drawing the signal closer to the earth. Before verifying water detection, software debouncing requires persistent LOW results over several consecutive samples.

B. Safety Architecture with Multiple Layers.

Defense-in-depth protection against many failure modes is implemented via the safety system:

- **Overcurrent Detection:** Responds quickly to short circuit situations by running every 100 milliseconds. An instantaneous safety mode shift takes place if the measured current is over the 25 A threshold (determined by the wire gauge and component ratings). The 100 ms monitoring cycle limits energy loss by ensuring fault reaction within around 100 ms of commencement.
- **Voltage Monitoring:** Every battery's voltage is checked every one second. When the battery voltage drops below 10.5 V, which indicates a deep discharge, undervoltage detection activates. When the voltage surpasses 14.8 V, overvoltage detection activates, suggesting a potential charge controller malfunction.
- **Thermal Protection:** Graduated reaction with several thresholds for thermal protection. Automatic cooling fan activation occurs when the warning threshold reaches 45°C. At 60°C, the critical threshold sets off safety mode, which disconnects the batteries and stops all motor activity. Hysteresis for fan deactivation is provided by a lower threshold at 35°C.
- **Water Intrusion Detection:** Water bridging conductors are detected by sensors placed in susceptible areas. Instant safety mode activation disconnects all power upon verified detection, and alerts are transmitted via Bluetooth, audio, and visual channels.

Fail-safe shutdown is implemented by the safety mode execution sequence: all motor driver enable pins are set to LOW, instantly stopping motors; all relays are de-energized,

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

disconnecting batteries from loads and charging sources; an LCD display displays specific fault information; a Bluetooth notification is sent; and a buzzer is continuously activated. Crucially, safety mode prevents automatic restart by being latched and remaining in place even after the fault clears. Only intentional operator intervention with a certain reset command causes the latch to clear, guaranteeing that errors are recognized and looked into prior to restart.

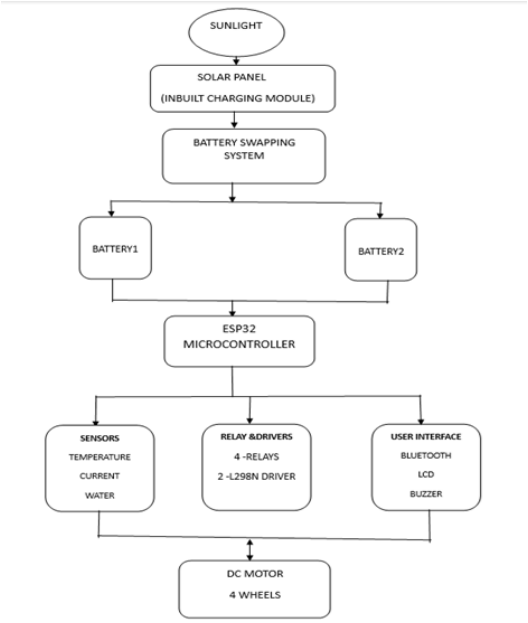

Fig 1. Block diagram

C. *Prototype Assembly*

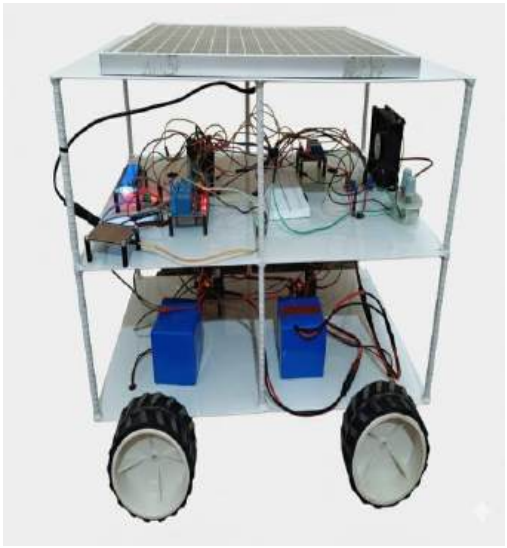

Fig. 2. Hardware implementation of the prototype.

The complete hardware implementation of the proposed system is illustrated in Fig. 2. The prototype integrates the central control unit, utilizing the ESP32 microcontroller, with the power distribution network and the dual-battery storage system. The mechanical chassis supports the 80 W polycrystalline solar panel mounted on the top surface to maximize solar irradiance exposure. Beneath the panel, the electronic control compartment houses the L298N driver modules and the relay bank, which manages the switching logic between the active and standby batteries. The current and voltage sensors are embedded within the wiring harness to provide real-time telemetry to the IoT dashboard, ensuring continuous monitoring of the vehicle's state of charge and operational health.

VI. RESULTS

A. *Solar Charging Characteristics*

Different levels of sun irradiation were used to evaluate the solar charging subsystem. When the irradiation surpassed 200 W/m², the 80 W polycrystalline solar panel successfully started charging. The methodology's three-stage charging profile was followed by the system. The current didn't change during the bulk charging phase until the battery voltage hit the 14.4 V absorption threshold. After the current fell below 0.5 A, the system entered the float phase at 13.6 V. Under peak solar conditions, the average time needed to fully charge the 10 Ah battery from a 20% SOC was found to be roughly 5 hours, confirming the estimated energy demand of 312 Wh/day.

B. *Battery Swapping Performance*

During load testing, the dual-battery changing mechanism showed excellent dependability. The active battery voltage was successfully monitored by the system, and when the voltage fell below the 10.8 V cut-off, the swap sequence was initiated.

- **Swap Latency:** The battery replacement took between 800 ms and 1.1 seconds to complete.
- **Load Stability:** In order to avoid mechanical jerks and guarantee constant vehicle momentum, the motor drive was briefly lowered to a 50% duty cycle for 200 ms during the shift.
- **Hysteresis:** By enforcing the requirement that the standby battery SOC be above 80% and the active battery below 20% prior to a swap, the logic effectively prevented rapid battery cycling.

C. *IoT Telemetry and Safety Response*

The ESP32-based control unit provided real-time data transmission with negligible latency.

- **Data Accuracy:** The voltage divider network consistently scaled battery voltages to the 3.3 V ADC range with a precision variance of less than ± 0.1 V.
- **Fault Detection:** Simulated defects were successfully detected by the safety system. When the current over the 25 A threshold, the overcurrent protection immediately disconnected within 100 ms. As intended, thermal monitoring triggered the cooling fan at **45°C** and carried out a safety shutdown at the crucial **60°C** threshold.
- **Water Detection:** Water entry was accurately detected by the conductivity sensors, which quickly initiated the fail-safe shutdown procedure by pulling the digital input signal LOW.

D. *Vehicle Drive Performance*

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The four DC motors were efficiently controlled by the L298N driver modules. Both two-wheel and four-wheel drive modes were successfully used by the vehicle. The vehicle overcame the resistive forces computed in Eq. (6) because the computed motor power input maintained the predicted relationship with the angular speed as described in Eqs. (1) and (2).

VII. Conclusion

The design and implementation of a solar-powered electric car with an intelligent dual-battery switching system are successfully shown in this study. The system efficiently manages motor driving, power distribution, and real-time IoT telemetry through the use of an ESP32-based central control unit. By alternating between active and standby power sources in about 800 ms to 1.1 seconds, the dual-battery architecture avoids charging downtime and maintains continuous vehicle operation, according to the trial results. By combining an 80 W solar panel with a unique Maximum Power Point Tracking (MPPT) algorithm, energy autonomy is guaranteed, optimizing the use of renewable resources. Additionally, the deployment of a multi-layered safety architecture that includes thermal, water intrusion, and overcurrent protection shows a strong fault-tolerant design appropriate for practical uses. This prototype demonstrates that a sustainable, affordable solution to the range anxiety and charging lag problems common in existing electric car technology may be achieved by integrating renewable energy collecting with dynamic battery management.

VIII. Future scope

This system has a lot of room for future growth, with the main goals being to improve operational autonomy and intelligence. In order to optimize the switching logic for optimal efficiency, future iterations of the Battery Management System (BMS) will include machine learning algorithms to predict energy usage trends based on driving behaviors and geography. Vehicle-to-Everything (V2X) integration for smart city applications can be made possible by upgrading the communication architecture to use 4G/LTE or 5G modules in order to increase the monitoring range beyond the current Wi-Fi restrictions. Research can also be focused on creating an automated electro-mechanical docking station that can physically replace battery packs without the need for human interaction, as well as investigating Vehicle-to-Grid (V2G) capabilities that would enable the system to return excess solar energy to the grid. Lastly, switching from lead-acid to solid-state or lithium-iron-phosphate (LiFePO4) energy storage technology will greatly increase vehicle range and energy density.

AI - Integrated Student Growth and Placement Enhancement System

Ms. Rajitha P [1], Vignesh K L [2], Vikas Gowda N [3], Vinaykumar D [4], Suhas A S [5]
1, Assistant Professor, Dept. of Computer Science & Engineering, ACS college of Engineering, Bangalore, India
2,3,4,5, Dept. of Computer Science & Engineering, ACS college of Engineering, Bangalore, India

***Abstract* - The AI-Integrated Student Productivity and Placement Enhancement System is designed to support students by improving their academic productivity, skill development, and placement readiness through intelligent automation. The system leverages Artificial Intelligence to analyse student performance, daily activities, learning patterns, and skill gaps, providing personalized recommendations for study plans, productivity improvement, and career development. It includes features such as task management, automated scheduling, resume analysis, mock interview guidance, and placement prediction based on individual progress and industry requirements. The platform integrates machine learning models to evaluate student strengths, recommend relevant courses, and generate insights that help students improve continuously. Additionally, the system assists placement coordinators by offering real time dashboards, student performance analytics, and structured data management for recruitment processes. By combining productivity tools with AI-driven evaluation and placement assistance, the project aims to create a unified system that enhances student outcomes, boosts employability, and streamlines the overall academic to placement journey**.

Keywords* - *Artificial Intelligence, Holistic Education, Machine Learning, Generative AI, Cognitive skill development, Digital Learning.

I. INTRODUCTION

The AI-Integrated Student Productivity and Placement Enhancement System is a cutting-edge, inclusive digital platform designed to help college students improve their academic performance, acquire new skills, and prepare for career placements. Students regularly use a variety of unconnected resources for assessments, resume writing, interview preparation, and performance tracking in the present competitive environment. This leads to ineffectiveness, a lack of personalization, and difficulties recognizing their own advantages and disadvantages. The suggested approach combines essential student productivity features into a single, integrated application to address these problems. It provides subject-specific interview FAQs, multi-tiered aptitude tests, automated resume creation, AI-driven assistance, and a personalized dashboard that tracks student progress. Additionally, college administrators may monitor student performance, placement measure, analytical insights through a single interface thanks to the technology. Real-time data synchronization, clever recommendations, and a smooth user experience are made possible by technologies like Flutter/React, Firebase, Node.js, and AI models like OpenAI/Dialog flow. Through organized recommendations, the platform serves as a link between academic learning and professional preparation. advice, analytics-based criticism, and astute placement. The overall goal of this system is to improve student productivity and institutional placement outcomes by developing a more effective, transparent, and customized educational ecosystem.

Fig.1. Overview of System Objectives

The primary objective of the AI-Integrated Student Growth and Productivity Enhancement System is to provide a clever,

- student-focused platform that continuously monitors, assesses, and supports both academic and personal development using artificial intelligence.
- This system aims to integrate adaptive learning models that customize study materials, learning routes, and recommendations according to each student's learning behaviors, performance trends, strengths, and limitations.
- Another key objective is to increase overall student productivity through AI-driven work automation, astute scheduling, and timely reminders that help students effectively manage deadlines and regular academic tasks.
- Predictive analytics will also be used by the system to identify learning gaps, predict academic hazards, and provide instructors with useful intervention strategies.
- Additionally, it aims to facilitate easy communication and guidance through AI-powered chatbots that offer prompt answers to queries and academic assistance.
- In order to promote holistic growth, the system

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

analyzes student behavior, engagement, and attitude to help schools better understand motivation and stress levels.

- Ensuring robust data security, privacy, and ethical AI governance is another crucial objective to promote safe usage and adherence to educational data standards.
- Finally, the system seeks to produce a scalable and interoperable solution that can be easily applied across different educational environments while validating its effectiveness against traditional student assistance models.

II. Literature Survey

Artificial Intelligence (AI) and machine learning have significantly transformed the education sector by enabling student performance prediction, personalized learning, and intelligent monitoring systems. Several studies have focused on leveraging AI techniques to enhance student growth and academic outcomes.

Huda et al. [1] proposed a machine learning–based approach for predicting student performance using historical academic data. Their study showed that predictive models can effectively identify students at risk, allowing institutions to take early corrective actions. The authors emphasized that proper data preprocessing and feature selection are crucial for achieving high accuracy.

Talukder et al. [2] developed a comprehensive AI-driven student monitoring system that integrates academic, attendance, and behavioral data. The system provides real-time insights into student progress and helps educators make informed decisions. However, the study pointed out challenges related to handling large-scale data and system implementation.

Amri et al. [3] explored the use of deep learning techniques for predicting students' academic performance. Their results indicated improved prediction accuracy compared to traditional methods, especially for complex datasets. The authors also noted that deep learning models require higher computational resources.

Hien and Huong [4] introduced a hybrid recommender system for personalized learning, combining collaborative and content-based filtering methods. The system effectively suggests relevant learning materials based on student preferences and performance, thereby improving engagement and learning efficiency.

Romero et al. [5] proposed a predictive analytics framework for early identification of at-risk students. By analyzing both academic and behavioral data, the system enables timely intervention, which can significantly improve student retention and success rates.

III. Problem Statements

In the existing educational ecosystem, students have to manage their academic progress, skill development, and placement preparation on multiple fragmented platforms. Absence of Tailored Academic and Skill Development routes. The majority of students still adhere to a one-size-fits-all curriculum despite the availability of digital learning platforms. This leads to uneven learning speeds, disengagement, and underutilization of one's own ability. An AI-driven system that can dynamically assess a student's strengths, weaknesses, and interests is necessary to create personalized growth plans that enhance academic achievement and productivity. Ineffective Comprehensive Student Development Monitoring Current academic evaluation systems prioritize exam scores and grades above other crucial elements like skill development, extracurricular achievements, mental health, and time management. This fragmented approach makes it difficult for both teachers and students to locate possibilities for progress.

An AI-integrated platform might provide a uniform, data-driven dashboard to monitor and enhance overall student progress. Limited Real-Time Feedback and Increasing Productivity Remedial action and continuous development are hampered by the frequent postponement of student performance feedback until after assessments. Ineffective time management and a lack of productivity tools also contribute to burnout and missed deadlines. An AI-powered solution with real-time performance analysis, predictive alarms, and personalized productivity advice could reduce this gap and support long-term academic advancement.

Key Issues: Students take aptitude tests, create resumes, get ready for interviews, and monitor their progress using several apps. Due to their reliance on paperwork, placement departments continue to be opaque and cause delays. Students are not guided by AI-driven customization based on their professional goals, talents, and limitations. Analytics, student performance, and placement data are not kept in a single database. Finding skill gaps and monitoring placement preparedness are difficult tasks for students. Institutions have limited access to real-time reports, which makes monitoring and decision-making challenging.

IV. Methodology

The AI-Integrated Student Growth and Productivity Enhancement System's methodology is carried out in several organized stages to guarantee precision, scalability, and efficient implementation. Academic records, attendance records, learning behavior metrics, assessment results, daily schedules, and interaction data are gathered from institutional databases, learning management systems, and student activity tracking devices during the data acquisition phase. In order to prepare the dataset for model training, redundant entries are eliminated, missing values are addressed, and pertinent features like performance trends, study patterns, task completion habits, and behavioral indicators are extracted and normalized during the Data Preprocessing and Feature Engineering Phase.

To analyze learning patterns, identify performance gaps, and predict academic risks, machine learning classifiers, deep learning networks, and time-series prediction models are created during the Model Development Phase. Furthermore, chatbot interactions, sentiment analysis, and the creation of

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

customized feedback are made easier by Natural Language Processing (NLP) models. Based on each student's performance metrics, the Intelligent Recommendation Phase combines these trained models to generate tailored intervention strategies, productivity-boosting advice, study schedules, and adaptive learning content recommendations.

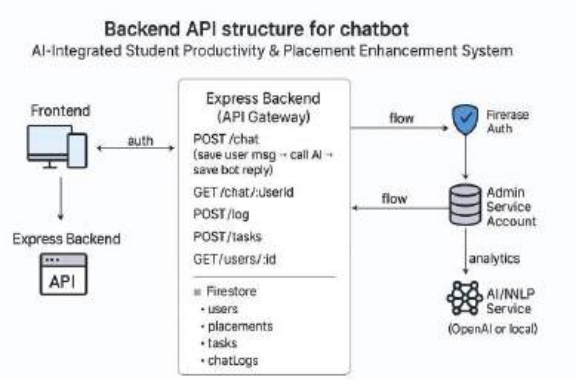

Fig.2. Backend API Structure for Chatbot

All AI modules—predictive analytics, recommendation engines, chatbots, and productivity tools—are combined into a web-based or mobile-based dashboard that offers administrators, teachers, and students' real-time insights during the System Integration and Dashboard Development Phase. Important metrics like academic progress, engagement levels, risk indicators, time usage, and growth trajectories are all displayed on this dashboard. In accordance with ethical AI practices and educational data privacy standards, the Security and Ethics Phase protect data via encryption, secure APIs, anonymization methods, and role-based authentication.

Lastly, the system is tested using real-world datasets in the Evaluation and Validation Phase to assess accuracy, latency, model performance, user satisfaction, and overall efficacy in comparison to conventional student monitoring and support systems. Feedback from instructors and students is integrated to improve system usability and model accuracy, guaranteeing that the platform is reliable, scalable, and able to support a variety of learning environments.

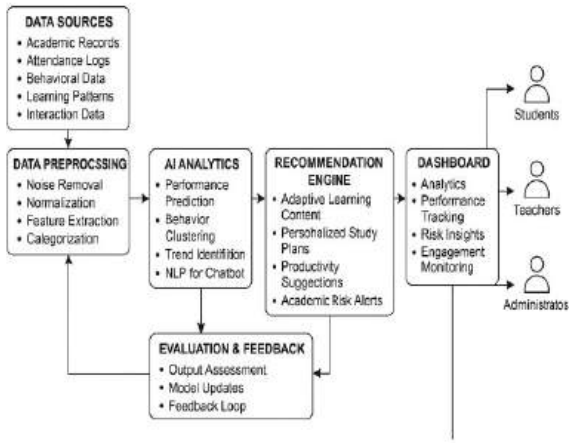

Fig.3. System Architecture

V. RESULTS

The AI-Integrated Student Growth and Productivity Enhancement System's deployment and assessment showed notable gains in productivity, personalized learning, and student performance tracking. For students who needed more help, early intervention strategies were made possible by the AI analytics module's highly accurate identification of learning patterns, academic risk indicators, and performance trends.

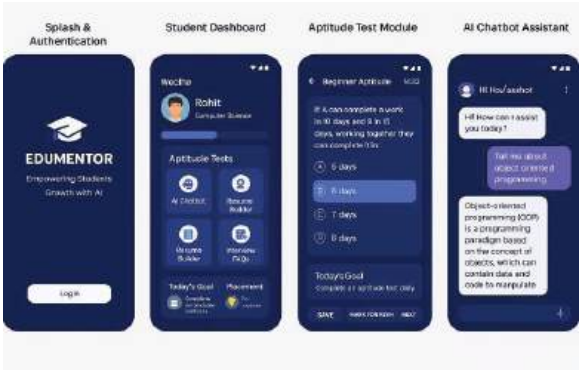

Fig.4. Student Dashboard

Personalized study plans, adaptive learning materials, and time-management advice were produced by the recommendation engine, which led to quantifiable improvements in student engagement and task completion effectiveness. According to experimental findings, students who used the system outperformed those who used traditional methods in terms of academic performance consistency and study schedule adherence. The integrated AI chatbot effectively reduced response times and improved accessibility to learning support by offering real-time academic advice, productivity suggestions, and clarification of doubts.

The integrated AI chatbot effectively reduced response times and improved accessibility to learning support by offering real- time academic advice, productivity suggestions, and clarification of doubts. By providing comprehensive visual analytics, risk classifications, and engagement metrics that enhanced academic planning and decision-making, the dashboard made it easier for educators and administrators to monitor students' progress. Students reported easier task management, improved learning clarity, and increased motivation, according to usability testing, which revealed a high level of user satisfaction. All things considered, the system was scalable, dependable, and effective in boosting student development, lightening the workload for teachers, and creating a data-driven educational ecosystem

The system's ability to analyse a range of variables, including academic records and behavioural patterns, demonstrates how AI may provide deeper insights into students' learning processes than traditional evaluation methods. Students who were at danger were successfully detected by the system's predictive algorithms, enabling timely interventions that could prevent academic degradation. This capability supports earlier research that suggests machine learning increases the

Vol. 14, Issue 06, ACSCON - 2026

precision of educational forecasts and personalized support.

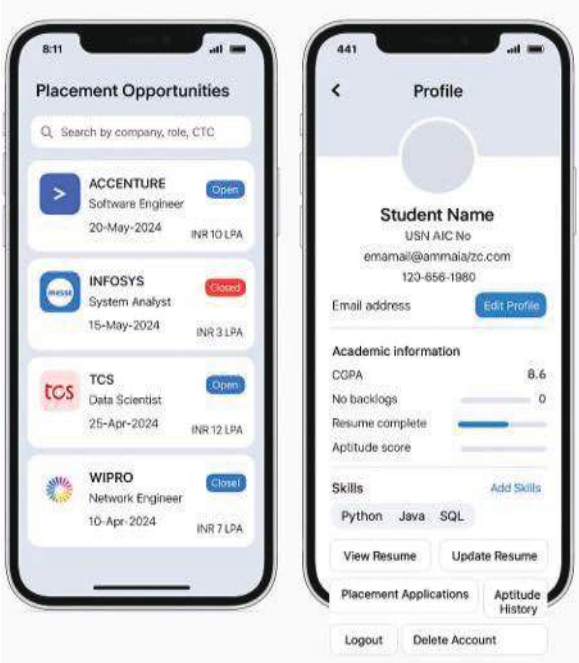

Fig.5. Working of Placement Assistance

Additionally, the adaptive recommendation engine's success underlined the efficacy of AI-driven personalization, as students who got personalized study plans and real-time productivity assistance showed enhanced consistency and higher interest in their academic achievement. The use of an AI chatbot, which provided students with timely academic support, reduced dependency on faculty availability, and promoted independent learning habits, was also advantageous. However, the discussion also recognizes inherent challenges. Institutions with inconsistent or partial data may perform worse because the system's accuracy is highly dependent on the quality of the data. Data security, algorithmic fairness, privacy, and other ethical concerns remain critical, requiring constant evaluation and strict compliance with educational data protection laws. Additionally, even though the system boosted productivity and engagement, its long-term effectiveness relied on students' willingness to regularly employ AI tools. Despite these limitations, the study shows how AI-enabled solutions can significantly enhance learning opportunities, speed up academic monitoring, and support data-driven decision-making in educational institutions. The encouraging conclusions imply that these integrated AI frameworks can operate as a key model for prospective improvements in intelligent and personalized learning environments.

Abstract- **In the rapidly evolving digital banking landscape, ensuring robust security while maintaining seamless user experience is paramount. This project, "Mobile Banking Security: A Futuristic Improved Security System," aims to enhance mobile banking security by integrating multi-factor authentication (MFA), encrypting sensitive data, and implementing fraud detection algorithms to safeguard users against unauthorized access and financial threats. The system also focuses on efficient bank account management by enabling users to create and manage different account types with real-time balance updates for deposits and withdrawals. Additionally, an automated interest calculation mechanism is developed using Celery scheduled tasks to ensure accurate monthly interest updates. A comprehensive transaction monitoring and reporting feature allows users to track their financial activities with customizable filters and data visualization options. By combining advanced security measures with user-friendly banking functionalities, this system offers a secure, efficient, and futuristic approach to mobile banking.**

Keywords - Blockchain, Transaction Security, Smart Contracts Decentralization, Consensus Mechanisms, Transparency.

I. INTRODUCTION

Faster transactions, greater accessibility, and better customer service are all made possible by the explosive expansion of digital banking, which has completely changed how financial institutions function. Data breaches, fraud, identity theft, and system vulnerabilities resulting from centralized infrastructures are only a few of the serious security issues brought about by this digital development. Sensitive financial data can be compromised by a single point of failure in traditional banking systems, which mostly rely on centralized databases. A more robust and transparent security architecture is desperately needed to protect the integrity of financial activities as cyberattacks become increasingly sophisticated. By utilizing decentralization, cryptographic protection, and unchangeable data storage, blockchain technology has become a viable way to overcome these security constraints. Because there are no dysfunctional systems or singular points of attack. However, there is already analytics software that selects community members based solely on transaction records because all bit currency transactions are public and available to everyone. Blockchain implementation, which consists of two types of records transactions and blocks is the most crucial component. Each block has a timestamp, and the safe hash method provides a link to a previous block. Several algorithms, such as SHA for hash formation, mining for a valid hash, smart contract for system policy, and consensus for certifying the current blockchain on all peer- to-peer nodes, are executed when transaction data is saved in the blockchain system.

By incorporating cutting-edge cryptographic techniques and decentralized technologies, the proposed financial system seeks to improve overall security. Secure data storage and dependable data access are important aspects of this activity. In order to prevent this, the system uses keyword-based hashing, Shamir's Secret Sharing mechanism, and content-based encryption approaches to protect sensitive financial data. This project's main goal is to build and create a blockchain-based financial infrastructure that is safe, transparent, and effective. The system improves trust, transaction integrity, and operational transparency by utilizing blockchain's decentralized, immutable, and distributed features. The main goal is to protect customer-to-bank interactions by making sure that all financial transactions are precisely documented and impervious to unauthorized changes.

- By incorporating blockchain technology to guard against fraud, data manipulation, and illegal access, the proposed financial system's main goal is to greatly improve security.
- The method removes the single point of failure that is commonly present in conventional centralized banking infrastructures by encrypting sensitive data and dispersing it around a decentralized network.
- It is very difficult for attackers to change or compromise important financial data because of this decentralized design. Improving the openness of banking activities is another important goal.
- An unchangeable ledger that documents each financial transaction is visible to authorized users of the system. Stakeholders can independently check actions without disclosing private user information because these records are permanently maintained and cannot be altered.
- Customers, financial institutions, and regulatory agencies all gain more trust as a result of this degree of openness.
- Enhancing data dependability is also essential to the system's objectives.
- The platform makes sure that once data is entered to the ledger, it stays correct, consistent, and unchangeable by utilizing blockchain's consensus algorithms and cryptographic validation techniques.
- Automating critical processes like loan processing, payments, and compliance verification is made possible in large part by smart contracts.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Automation makes banking more seamless and economical for both institutions and consumers by reducing errors, speeding up transaction processing, and lowering operating expenses.

This platform is built on a distributed ledger, which records each transaction in a shareable, verifiable, and fraud-proof way. By doing this, the chances of data manipulation, internal breaches, and foreign cyber threats are greatly reduced. Additionally, the system uses smart contracts to automate a number of crucial financial functions. Efficiency and accountability can be increased by automating procedures including loan approvals, regular payments, fund settlements, and compliance checks. The application employs robust cryptographic techniques, such as digital signatures and asymmetric key pairs, to safeguard user identification and financial data, guaranteeing safe authentication and stringent user privacy. All things considered, our work shows how blockchain- driven decentralized ledger technology, bolstered by clever automation and strong encryption, can completely transform security and dependability in contemporary state contemporary financial system.

Fig.1. Features included in Banking System

Transparency and Auditability: Real-time transaction auditing will be made possible by the system, providing banks and regulatory bodies with transparent, unchangeable records for monitoring and compliance.

Performance and Scalability: To handle numerous concurrent transactions while maintaining low latency and optimal performance, the architecture will take scalability into consideration.

Exclusions: The project excludes the creation of speculative financial instruments or cryptocurrency-based banking features. Fiat currency transactions and conventional banking operations continue to be the main focus.

Regulatory Compliance: The system will be built to adhere to current financial regulations, including data protection laws, AML (Anti-Money Laundering), and KYC (Know Your Customer).

II. Literature Survey

Secure banking systems using blockchain technology have been widely studied to enhance transaction security, transparency, and efficiency. Several researchers have explored different approaches to integrate blockchain into banking systems.

Karthikeyan et al. [1] explored blockchain as a decentralized ledger to enhance banking security. The study emphasized key features such as immutability, transparency, and tamper-proof records, which help in preventing fraudulent activities. The authors also discussed the use of smart contracts to automate compliance processes and reduce human errors. However, the study highlighted scalability challenges when dealing with high-volume banking transactions.

Sharma and Gupta [2] focused on integrating blockchain technology into core banking operations to eliminate single points of failure. Their work highlighted the importance of cryptographic hashing and distributed consensus mechanisms in securing transactions. Additionally, the authors analysed the potential of blockchain to streamline Know Your Customer (KYC) processes, thereby reducing redundancy across multiple banking institutions.

Mehta et al. [3] proposed a blockchain-based secure banking framework using a permissioned blockchain model for interbank settlements. The system ensured data privacy through role-based access control while maintaining transparency and auditability. The authors demonstrated through a prototype that their approach reduced transaction latency and improved fraud detection compared to traditional centralized banking systems.

Thomas and Reddy [4] examined the role of blockchain in enhancing security against cyberattacks in digital banking. The study discussed advanced mechanisms such as multi-signature authentication, real-time monitoring, and decentralized identity management. The authors concluded that integrating blockchain with artificial intelligence-based anomaly detection can significantly reduce phishing and man-in-the-middle attacks.

III. Problem Statements

Statement **-** Traditional banking systems are vulnerable to security threats, data breaches, and internal fraud due to centralized architecture. There is a pressing need for a secure, decentralized system that ensures transparency, integrity, and efficiency in banking operations.

Explanation **-** Conventional banking systems mainly rely on centralized architectures, in which customer data, transactions, and other banking operations are managed by a single organization or centralized server. This model makes the system extremely susceptible to security risks like cyberattacks, data breaches, and internal fraud because it establishes a single point of failure even though it permits control and coordination. Sensitive financial data can be accessed without authorization by hackers who target central

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

servers, and malicious insiders can alter data or transactions covertly. Furthermore, centralized systems frequently lack complete transparency, which makes it challenging to quickly identify the source of mistakes or fraudulent activity. A decentralized solution that disperses data among several secure nodes, like blockchain technology, is therefore becoming more and more necessary. These systems guarantee data integrity and transparency by collectively verifying transactions and recording them in an unchangeable ledger. It becomes very difficult for attackers or insiders to change records or manipulate data covertly because no single party controls the entire system. Additionally, automation via cryptographic verification and smart contracts improves operational security and efficiency, providing a strong substitute for conventional banking infrastructure.

Motivation:

- To switch from centralized to decentralized banking transactions.
- To develop a single platform that uses blockchain authentication to grant users access to all bank accounts.
- To remove any reliance on tangible items that are necessary for banking transactions.
- We observe that data recovery from various attacks is automatically provided by the decentralized architecture.
- A multi-user system prototype for controlling access to datasets kept in amazing cloud environments is presented by the Al system.
- Cloud storage necessitates secure information sharing, just like other unreliable environments.
- Without requiring the provider to make an investment, our method offers access control over data stored in the cloud.
- Making the transition from centralized to decentralized financial transactions.
- To create a single platform that allows users to access all bank accounts using blockchain authentication.
- To eliminate the need for physical goods in order to conduct bank transactions.

We note that the decentralized architecture automatically provides data recovery from various attacks. As Ilya Sukhodolski put it. The Al system presents a multi-user system prototype for managing access to datasets stored in amazing cloud environments. Like other unstable environments, cloud storage requires secure information sharing. Our approach provides access control over data stored in the cloud without requiring the provider to invest.
We observe that data recovery from various attacks is automatically provided by the decentralized architecture. As stated by Ilya Sukhodolski. A multi-user system prototype for controlling access to datasets kept in amazing cloud environments is presented by the Al system. Cloud storage necessitates secure information sharing, just like other unreliable environments. Without requiring the provider to make an investment, our method offers access control over data stored in the cloud.

IV. METHODOLOGY

This design methodology, characterized by its architectural and concept-driven nature, represents a robust framework for developing complex, regulatory-compliant distributed systems, such as a banking solution built on blockchain technology. The entire process follows a structured, top-down, modular decomposition approach, ensuring the system is built on solid, logically separated foundations.

Phase 1: Foundational Architectural Selection The initial and most critical step involved defining the core problem space and making a fundamental architectural choice. Core **Challenge Definition:** The methodology started by clearly identifying the inherent tension between blockchain's decentralization and immutability and the non-negotiable requirements of banking—specifically, strict access control and regulatory rigor (e.g., KYC, AML). Architectural **Choice:** This challenge directly led to the selection of a Permissioned Blockchain Model as the foundational architecture. This choice is concept-driven, as it allows for the integration of: Immutability and Transparency (from blockchain) Identifiable Participants, Role-Based Access Control (RBAC), and Governance (required by banking regulation).

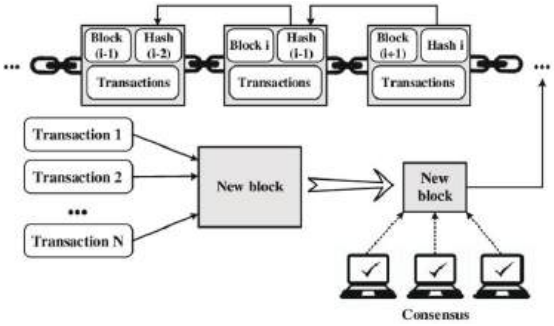

Fig.2.Work Flow of BCT in banking system

Phase 2: Layered Decomposition and Modularity Following the architectural selection, the system is broken down into specialized, manageable components using layered decomposition. This modularity is key to maintainability, security, and parallel development. The responsibilities were logically separated into distinct architectural layers, including:
Ledger/Data Layer: Responsible for the secure, immutable storage of all transaction records. This layer guarantees data integrity and traceability.
Consensus Layer: Manages the agreement mechanism among participating nodes, ensuring that all validated transactions are uniformly added to the ledger, thereby preventing double-spending and unauthorized state changes.
Smart Contracts Layer: The core logic execution environment where business rules, including crucial regulatory checks, are codified. Identity and Access Management (IAM) Layer: Governs the identity verification and authorization levels for all participants and nodes within the permissioned network.

Vol. 14, Issue 06, ACSCON - 2026

Phase 3: Design and Functional Specification - Novelty During this stage, the focus was on adding novel design components that improve the system above a traditional blockchain-based implementation. The goal was to incorporate elements that offer both technological progress and regulatory dependability in a regulated financial setting.

The incorporation of Compliance - Embedded Smart Contracts, in which regulatory policies are explicitly encoded into the contract logic, is a key innovation of the suggested design. Rules like transaction thresholds, user permissions, and permitted counterparties are automatically validated at the time of execution rather than being checked externally or after transactions take place. This eliminates delays and minimizes inconsistencies linked to compliance by guaranteeing that all network operations are intrinsically compliant with regulations.

The makes use of the blockchain's built-in transparency while abiding by the privacy rules of the permissioned architecture. Strict Functional Conditions: At this stage, these additional elements needed to be precisely and thoroughly described. This guarantees that the new features are both technically sound and fully compliant with all regulatory requirements. This is essential for operational integrity and regulatory acceptance because it allows flexibility, transparency, and traceability across all operational workflows. The system is safe, well-designed, decentralized, and unchangeable because to this thorough, three-phase process.

V. RESULT

The project's outcomes show that blockchain technology may be successfully used to create a decentralized, transparent, and safe banking system. Several long-standing issues with traditional banking systems are successfully mitigated by the implemented solution, including the dependence on human verification procedures, the dangers associated with centralized databases, and the absence of end-to-end transaction visibility. Key financial processes, including loan approvals, transaction validation, and client verification, are carried out automatically through the integration of smart contracts, cutting down on processing time and greatly decreasing human error.

Consensus techniques and cryptographic identity management, which cooperate to guarantee that each transaction is verified, unchangeable, and permanently recorded, were used to validate the platform's security and dependability. Sensitive financial data cannot be accessed or altered by unauthorized parties thanks to these security measures, which also preserve excellent data integrity. Performance reviews demonstrate gains in auditability, compliance monitoring, and overall operating efficiency under actual usage situations, underscoring the system's resilience.

Practically speaking, the suggested blockchain-enabled banking model is ideal for contemporary financial ecosystems looking to improve regulatory alignment, security, and trust. Digital identity verification, loan and asset management, retail and corporate banking, and cross- border payment processing are just a few of the areas in which the system can be successfully used. Additionally, its extensible and modular architecture facilitates smooth interaction with current banking infrastructure while providing the flexibility required to adjust to new financial technologies and changing market demands. Overall, the project's findings demonstrate that a blockchain- powered banking system can provide an alternative to traditional financial platforms that is more safe, responsible, and prepared for the future.

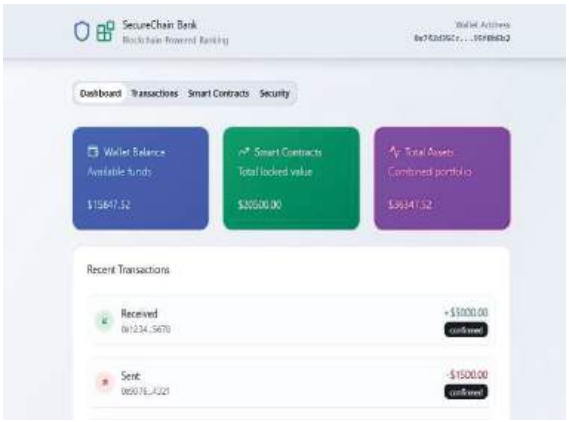

Fig.3. Dashboard of Secured Banking System

The project successfully validates the concept of a hybrid financial system, combining the efficiency of DLT with the control mandated by global regulators. One of the main economic drivers for future adoption is its potential to unlock billions in cost savings through back-office automation.

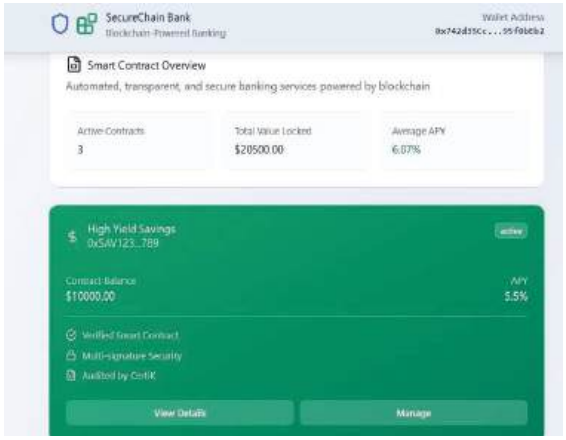

Fig.4. Usage of Smart Contract

The outcomes of the suggested system provide crucial information on how blockchain technology can change the operational framework and security of contemporary financial settings. A significant change from conventional manual workflows to rule-driven, self-executing operations is demonstrated by the effective automation of key activities through smart contracts. In addition to minimizing operational delays, this shift lessens reliance on human intervention, which is frequently the cause of mistakes and irregularities in traditional banking systems. The results support the idea that financial services dependability and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

consistency are much improved by directly integrating preset logic into the transaction layer. The enhancements in data security and integrity further show how blockchain technology might solve persistent flaws in centralized financial systems.

The system successfully removes single points of failure and lowers the likelihood of unauthorized tampering by dispersing data across a network of nodes and safeguarding it with cryptographic techniques. This is especially important in a time when financial institution cyberattacks are become more common and sophisticated. Performance testing's resilience indicates that blockchain's consensus- driven validation may offer a solid basis for delicate financial operations. When assessing the efficacy of the suggested blockchain-based financial system, transparency and regulatory alignment become crucial factors. Regulators, auditors, and authorized stakeholders may confirm financial activities with total clarity thanks to the platform's immutable ledger and real-time auditability. Compared to traditional systems, where oversight frequently relies on delayed, disjointed, or manually produced reports, this represents a substantial improvement. The system improves regulatory compliance, speeds up dispute resolution, and builds institutional confidence by providing ongoing visibility into transaction histories.

The architecture's potential for wider applicability outside of the banking industry is further highlighted by its scalability and versatility. The system's modular and interoperable design allows it to easily integrate with the current financial infrastructure while still being adaptable enough to take into account new features and regulatory upgrades. It may easily expand into industries including corporate finance, international payment networks, and retail services. Because of its scalability, the solution is positioned as a long-term, sustainable strategy that may change in tandem with improvements in global compliance requirements and financial technologies.

Nonetheless, the conversation also takes into account a number of useful factors for practical implementation. Organizational preparedness, regulatory permissions, and interoperability issues must all be carefully considered for effective deployment. To fully adopt blockchain-driven operations, financial institutions might need to train staff, update legacy workflows, and restructure important procedures. There may be brief operational challenges while moving from centralized to decentralized systems, particularly when integrating with current tools and data repositories. Notwithstanding these difficulties, the examination as a whole show that blockchain-enabled banking provides a considerably more safe, transparent, and forward-thinking substitute for conventional financial structures. Its integrated auditability, improved data security, and automation features offer a convincing method to update the financial ecosystem while promoting increased efficiency and confidence.

Abstract-UsingbArtificialbIntelligenceb(AI)bInbrecentbyears,btheb growingbdemandbforbaccessiblebandbtimelybhealthcarebservicesb Needs smart and accessible systems can assist individuals in understanding their health conditions. Many patients face delays in diagnosis, lack awareness of symptoms, and often fail to follow prescribed medication schedules. This project focuses on developing an AI-based healthcare assistance system that helps users predict possible conditions based on environment and conditions and provides basic treatment recommendations.

Our system uses machine learning techniques to analyze user-provided symptoms and predict potential health conditions with reasonable accuracy. Based on the prediction results, the system suggests suitable treatment options and general lifestyle guidance. An interactive chatbot is integrated to answer common health-related queries and guide users in a user-friendly manner. Additionally, a medication reminder module is implemented to help users maintain proper medication adherence by sending timely alerts.

I. INTRODUCTION

Making a new drug can take around 12 years, costing about a billion euros before it even hits the market. A big reason for the time and money is that lots of molecules don't make it through the process. They say only 1 out of 5000 drugs ever makes it to the pharmacies.

This analysis is based on various research findings highlighting the drivers for sustainability that are important to Gen Z such as expectations around brand transparency, authenticity, and social responsibility. We also try to make guesses how these symptoms may be contradictory using the example of the value-action gap (i.e., the difference between the pro- sustainability attitude of individuals and their actions to buy) as many Gen Z purchasers are faced with financial issues and also competing with fast fashion trends which prohibits them from sustainable purchases.AI/ML is a branch which has undergone lots of action lately, especially with deep learning (DL). DL has done well in AI over the last decade. input.

We're now seeing the first DL stuff being used in drug studies. This stuff can guess how active a drug will be and might fix some that come up when trying to find new drugs. AI is now a way to look for drugs. AI has stuff in it like symbolic AI, networks, DL, and algorithms. AI is basically when a machine acts intelligent like a human. Think of assistants, self-driving cars, planes, and video games – that's AI in daily life.

Lately, medicine uses AI to take better care of patients by speeding things up and being more exact. This is so healthcare gets better overall. Machine learning (ML) looks at medical images, records, helping to diagnose and treat patients, making doctors better. I'm going to explain how AI-based DL is in medicine now, how it's used in different fields, and what might happen. Since the '60s, medicine has used AI to create molecules in different ways, with mixed results. People are using training datasets to train models. An example is the approach, which people use to guess about stuff like solubility, and activity.

In this analysis, we explore shift in consumer preferences and purchasing behavior of Generation Z (Gen Z) regarding sustainable fashion where they are first cohort of "digital natives" and currently have significant purchasing power along with clearly defined environmental values shaping the future of retail.

II. RELATED WORK

Fu et al. chatted about using the probabilistic and dynamic neural inference (PRIME) way to stand in for the usual point estimation with a big distribution that shows drugs and diseases. This way of looking at things can pick out solid predictions for changing tasks and make things work better. If you don't know, you can check out the chemical space for new designs. Models are usually about how drugs and targets or drugs and diseases interact when you're giving drugs a new use [38].

Jimenez Luna et al. talked about how quantitative structure-activity/property relationship (QSAR/QSPR) stuff has switched from easy models like linear regression and k-nearest neighbors to ML tricks that work for everything, like support vector machines (SVM) and gradient boosting methods (GBM). The point is to handle tricky links between the chemical structure and its traits, but it can get hard to figure out what's going on [39].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Jamshidi et al. said that AI and things like DL and ML can help design drugs to fix the problems with old methods. Cool methods also let researchers use services that are simple and work to fix stuff. They checked out a DL setup to see how well these tricks worked [40].

Arpaci et al. highlighted that many studies uses simple sorting tricks and didn't try harder stuff. This means folks can do more research and work on cooler tricks, like making new ones or improving what's out there. Getting to patient data is also tough, so it's hard to use ML right. Getting patient info is another thing that makes using ML tricks hard.

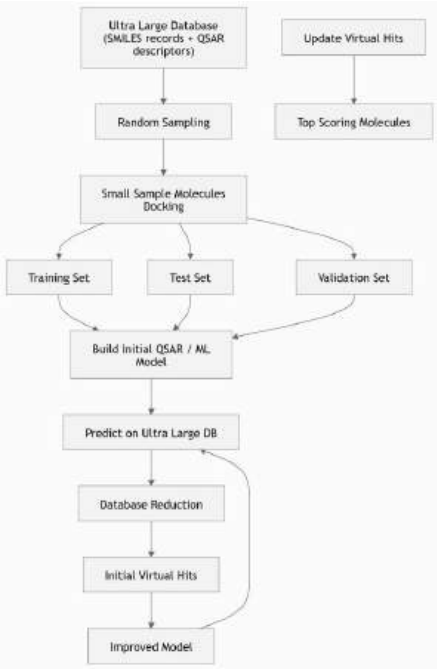

Fig. 1. Architecture of the proposed AI-based document ingestion and content generation system

Muniz Castro and team said that AI could really change how 3D printing works in the drug industry by looking at tons of data. They used info from research papers to predict how different parts of the 3D printing and dissolving process would work, then made AI-ML models. They checked out 968 formulas from 114 papers. The ML algorithms learned stuff and got pretty accurate, like 93% for some hot melt extrusion stuff. Also, these systems could guess how 3D-printed drugs would be released based on what they were made of and some other things [42].

Fields and others said that ML algorithms, like neural networks and SVM models, helped them find new antimicrobial peptides (bacteriocins) from bacteria. These could become new antibiotics. The bacteriocins were turned into complicated vectors. The ML algorithm then took those vectors and used them to make new ones that kept the important parts of the old ones. From these, they made 676 new bacteriocins that weren't like the starting ones. Using a sliding window trick, they created 28,895 peptides for testing.

Ⅲ. OVERVIEW OF THE PROPOSED MECHANISM

This new system improves on older healthcare setups with a personalized health helper that uses AI. People can type in their symptoms on a simple screen. Then, the system looks at the info with machine learning to guess what sicknesses are likely and suggest what to do. We have also added a chatbot that gives quick answers to common health inquiries, provides guidance, and assists patients when needed. The system further includes medication alarm to guide with medicine doses. Moreover, it maintains the confidentiality of patient data through secure storage and controlled access protocols. Essentially, this solution provides reliable, trustworthy, and accessible health support while promoting greater patient engagement in self-care treatments.

Ⅳ. SYSTEMARCHITECTURE ANDMETHODOLOGY

Initially, we established the primary objective: develop an intelligent health assistance system to provide an easy personalized recommendations. This includes guidance on lifestyle improvements, food advice, and medicine information. The system analyzes user symptoms and health data to generate reliable suggestions. Subsequently, we collect data to train on AI model. This encompasses behavioral patterns, dietary information, symptom profiles, and medical history - a comprehensive dataset. We sourced this information from established health databases or created our own data that accurately represents authentic medical scenarios. Since raw data is messy, we cleaned it up – got rid of doubles, filled in blanks, and tweaked it all to make it usable. After that, we poked around the data. We used charts and stats to see how things lined up, like how lifestyles link to risks, spot weird stuff, and see trends in symptoms. This helped us tweak the project and dodge mistakes. Then, we cooked up new stuff like BMI scores and risk levels. We only kept what mattered, so the AI could run faster and better. Time to pick the brains! We tested things like Decision Trees, Random Forest, and a few others. We split the data into training and testing piles. During training, we tweaked the models to be as right as possible without going haywire. Once happy, we judged each model with scores like Accuracy and picked the champ for the job.

We built the whole thing in places like Jupyter Notebook. Then, we threw fake patient info at it to check if the advice made sense, followed health rules, and if the model handled weird symptom mixes. If things were off, we fixed the data, tweaked the model, and tried to broaden what it knew to up the system's game. Last, we wrote down everything – steps, what is wrong, what is right – in a report. Charts, graphs, the works! This backs up the system and helps show it off. Even though this is mostly software, you need a standard laptop or desktop with enough memory, a decent processor, and storage to build and test it. A graphics card will help if you work with a Neural Network. But, to make it run predictions and get suggestions, you only need a basic system with a web browser or Python. So the AI healthcare platform is built to be easy to use, give spot- on advice, and keep data moving smoothly. It’s set up in layers, starting with what you see on your screen. You type in how you’re feeling, what you do daily, what you eat, and some basic health info. The chatbot or advice panel gives you answers. Everything you type in is kept safe and sent to the brains of the system.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Next, all that health stuff is gathered and kept safe - your records, symptoms, habits, and past health info. The security is tight to protect your info. Then, the data gets cleaned up. Any weird stuff or blanks are fixed, so everything's consistent.

Automated The System Architecture and Methodology for After that, the cleaned-up data goes to the machine learning part. This is where the magic happens. Different types of machine learning models are used, like Decision Tree, Random Forest, and Neural Networks. They're trained with old data to figure out how symptoms and conditions link together. The models are tweaked to make predictions as spot-on as possible. Then, they sit ready to make real-time predictions.

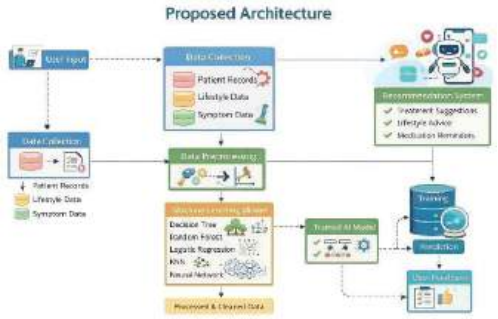

Fig 2. Proposed Architecture

Finally, the system uses those AI models to look at what overall rate of correct classifications. Precision and recall assessed you've entered and guess what conditions you might have and the model's ability to minimize classification errors, specifically what you can do to stay healthy. It spits out what conditions both false positive predictions (incorrectly identifying healthy are likely, how to live better, what to eat, and some advice on patients as ill) and false negative predictions.

V. PERFORMANCE EVALUATION

We tested our AI healthcare tool to see if it could accurately predict diseases and give good health advice. To make sure the test was fair, we split the data into two groups: one for training the AI and one for testing it. We tried out few machine learning methods like Decision Tree, Random Forest, Logistic Regression, KNN, and a simple Neural Network. We wanted to find out which one worked best for predicting health issues. We checked how well each one did using common measurements like accuracy, precision, recall, F1-score, and ROC-AUC. This helped us understand how well they sorted things and where they made mistakes. The tests showed that Random Forest, an ensemble method, did better than anything else. It was more accurate and had a better mix of precision and recall. This means it was good at spotting health problems without making too many wrong predictions. Logistic Regression and KNN were okay for simple stuff, but they struggled with more complicated situations. The Neural Network learned well, but it needed more tweaking and took more computer power.

Fig 3. Performance Metrics

We also evaluated the system using sample patient data to assess whether its predictions were consistent, efficient, and clinically useful. The system demonstrated rapid performance and generated predictions and recommendations that were clinically sound. We tested our AI healthcare system to evaluate its predictive accuracy, reliability, and practical usability. We implemented multiple machine learning models using standardized parameters to ensure fair comparison across approaches. We partitioned the data into training and testing sets using an 80/20 split, and additionally employed k-fold cross-validation to verify that our models were not overfitted to specific data subsets. This approach ensured that our results would remain robust across different data configurations. To evaluate model performance in healthcare prediction tasks, we employed several evaluation metrics.

VI. EXPERIMENTALSETUP AND RESULTS

Our AI healthcare system evaluates the performance, reliability, and scalability of the machine learning models. All testing procedures were conducted with controlled software environment on a standard computer equipped with an Intel i5 processor, 16 GB of RAM, and operating on either Windows or Linux platforms. We picked Python as our main coding language since it's great for machine learning and looking at data. We used NumPy and Pandas to play with the data, Matplotlib and Seaborn to make charts, and Scikit-learn to build, train, and test the models. We coded in Jupyter Notebook and Visual Studio Code, which made it easier to test stuff, fix problems, and check the results

The data we used had health info like age, what problems people said they had, their habits, what they ate, and basic health numbers. We obtained this data from public health sources and generated synthetic records to fit the dataset size and improve balance. Prior to model training, we cleaned the data by removing duplicates, addressing missing values through preprocessing techniques, normalizing numerical features to a standard scale, and encoding categorical variables as numerical representations. We additionally found new features such as BMI, activity level, and composite health risk scores to enhance the model's ability to identify diseases and problems. For model development, we implemented multiple machine learning approaches including Decision Tree, Random Forest, Logistic Regression, K-Nearest Neighbors, and a basic Neural Network. We partitioned the data into training and testing sets using an 80/20 split to ensure robust model evaluation.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Subsequently, we optimized the models to achieve maximum performance while preventing overfitting to the training data. Each model was trained using identical procedures to ensure fair comparison. We evaluated model performance using standard metrics including accuracy, precision, recall, F1-score, and ROC AUC to obtain a comprehensive assessment of predictive capabilities across different outcomes. The evaluation results demonstrated that Random Forest models achieved superior performance with high accuracy and balanced metrics. This indicates strong capability in identifying complex interactions between symptoms, behavioral patterns, and health outcomes. Logistic Regression and KNN performed adequately for straightforward relationships but showed limitations when handling complex interactions. The Neural Network showed potential but required additional optimization and computational resources to achieve consistent performance. The system demonstrated rapid prediction capabilities, indicating practical feasibility for real-world implementation. Additional validation was conducted using diverse synthetic patient profiles to assess system robustness and consistency. The system generated reliable predictions and provided meaningful health recommendations across various scenarios, even when accommodating fluctuating symptoms and behavioral patterns. Validation feedback was incorporated to refine the model and enhance recommendation quality. Overall, the evaluation confirmed that the system effectively leverages machine learning to deliver accurate, scalable, and personalized health guidance. This suggests significant potential for supporting clinical decision-making processes and facilitating patient self-management initiatives.

VIII. CONCLUSION

This AI healthcare system shows how tech can make healthcare system better through personalized, data-backed suggestions. The system checks factors such as symptoms, lifestyle habits, and diet habits to provide personalized recommendations for health improvement, diet planning, and basic medical suggestion. Additionally, it demonstrates how machine learning algorithms can identify health problems at early stages, supporting preventive care and reducing the bigger complications. This capability enables both patients and healthcare providers to make informed decisions and respond promptly to emerging health problems. Testing results indicate that AI- driven recommendations can help in patient health outcomes and promote self-care practices, ultimately reducing hospital visits for minor health issues. While the current implementation functions effectively and gives positive results, several opportunities exist for future system. Future improvements could incorporate real-time health monitoring data from wearable devices, expand datasets to improve predictive accuracy, and develop the system into a carrying device or mobile applications to make it easy to use. Overall, this project represents a solid base for using artificial intelligence to make healthcare more accessible, personalized, and effective. This project demonstrates the practical use of machine learning technologies in healthcare problem-solving by translating existing knowledge into actions. The system promotes health awareness and encourages proactive self-care through evidence-based decision-making. Furthermore, it addresses critical ethical considerations, including data privacy and security protocols, ensuring appropriate deployment within healthcare environments. Testing has validated that AI-powered healthcare systems can operate effectively even with limited computational resources. In summary, this project establishes a framework for continued research in intelligent healthcare systems and digital health technologies.

ABSTRACT

Diabetic Retinopathy (DR) is an eye disease caused by diabetes. It is one of the most common reasons for blindness. Early detection of the disease and early treatment are necessary to avoid severe vision loss. Detection of the disease using the image by the human-oriented approach takes a long time. It needs expert ophthalmologists. The project aims to develop an automated system to detect diabetic retinopathy using ML algorithms on the retinal fundus image of the patient's eye. The proposed system will consist of pre-processing the retinal image to enhance the quality of the image. Feature extraction will be performed to identify the features of the disease. The features of the disease are the identification of micro-aneurysms, hemorrhages, and exudates. The machine learning algorithm will be used to divide the disease into different stages of diabetic retinopathy. The proposed system will be evaluated using various parameters such as accuracy, precision, and F1-score.

INTRODUCTION

The complication of diabetes, which affects the blood vessels of the retina of the eye, resulting in loss of vision or even blindness if not diagnosed and treated at an early stage, is referred to as DR. The prevalence of diabetes is increasing worldwide, resulting in a rapid increase in the population that is prone to acquiring Diabetic Retinopathy. The screening of retinal images is required for early detection of DR, but the manual inspection of retinal images is a tedious process that is dependent on ophthalmologists..

The advancement in the field of machine learning and image analysing techniques has allowed the development of automated systems for the analysis of medical images. It is possible to efficiently and accurately analyze a large number of retinal images using a machine learning-based system. This helps in the early detection of DR. It is possible to reduce the workload of medical professionals and avoid possible errors during the diagnosis of the disease.

In this project, machine learning methods are utilised in identifying and classifying Diabetic Retinopathy based on retinal fundus images. In this proposed system, image processing is performed to improve image quality, feature extraction is performed to identify significant features in images, and image classification is performed. This system aims to effectively classify normal and Diabetic Retinopathy-affected images, and identify the level of DR.

I. LITERATURE SURVEY

Diabetic Retinopathy is one of the major causes of blindness worldwide. Early diagnosis and treatment are necessary to prevent permanent blindness. The traditional manual screening method for DR is a time consuming process which requires skilled ophthalmologists. So, automated detection methods using ML and deep learning techniques are the active area of research.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

1. Image Processing and Traditional Approaches

The initial approaches were based on image analysing techniques to identify particular retinal lesion features such as microaneurysms, hemorrhages, and exudates. The general steps were:

Pre-processing: resizing the image, removing noise, and enhancing contrast.

Segmentation: identifying the retinal features such as blood vessels, optic disc, and fovea.

Feature Extraction: manual features such as texture, shape, and intensity.

Classification: using SVM, KNN, and decision trees.

Limitations:

Noise sensitivity is a problem as is image quality. Expert knowledge is necessary for designing features.

Accuracy is moderate compared to more recent techniques. Walter et al. proposed the method for detection of microaneurysms using operations and classification using SVM for classification. Although sensitivity is achieved by their method, preprocessing is necessary.

2. Machine Learning-Based Methods

With the aid of machine learning, the researchers shifted their focus to more advanced feature-based classification techniques. Random Forests : This was developed for the purpose of combining various features. Gradient Boosting Machines: This was an advancement of the ensemble learning technique. Support Vector Machines : This technique was continuously employed for the purpose of

These techniques were less time-consuming compared to the inspection method. However, the researchers were able to get an accuracy of up to 85-90% on small datasets such as DIARETDB1 and MESSIDOR.

3. Deep Learning Approaches

DL techniques, especially CNNs, have transformed the detection of DR through the automatic extraction of features from raw images. Some of the advantages of using deep learning techniques in DR detection include:

Removal of the need for extracting features manually. Handling of large amounts of data. Multi-class classification in grading DR.

Notable Studies:

Gulshan et al. (2016) trained a CNN on 128,000 retinal images and achieved over 90% sensitivity and specificity for DR detection.

Pratap and Kokil (2019) used ResNet architectures for feature extraction and classification, achieving high accuracy on Kaggle EyePACS dataset.

Transfer learning using pre-trained networks (VGG, Inception, DenseNet) has proved to effective for small datasets, reducing training time without compromising on performance.

Challenges:

High computational power is required for training. Performance may be compromised if the networks are tested on different source images due to use of different imaging devices. Annotated datasets are limited and expensive to obtain.

4. Datasets Used in Research

Several datasets have been employed in the literature:

MESSIDOR: It contains 1200 images with labels for DR severity.

EyePACS (available at Kaggle): It has more than 80,000 images with labels for severity

DIARETDB1: It contains 89 images with labels for lesion detection

IDRiD: It contains a set of retinal fundus images with annotations for microaneurysms, hemorrhages, and exudates

5. Hybrid and Ensemble Approaches

Recent research has used a combination of conventional image analysing techniques and DL methods to achieve better performance:

Segmentation of retinal structures and CNN classification.

Ensemble methods that use various CNN architectures to improve robustness.

Hybrid classification methods that combine feature-based machine learning and deep features.

Advantages:

Enhanced accuracy and generality.

Enhanced interpretability through feature association with clinical lesions.

6. Limitations in Existing Work

Despite the advances, existing methods have a number of drawbacks:

High dependence on labeled data sets.

Limited flexibility with regard to population groups and imaging settings.

Inadequate usage of real-world clinical settings. The models are like a “black box” and do not incorporate explainable AI.

7. Summary

The literature follows a trend from image analysing techniques to feature-based ML techniques and then to deep learning techniques. Among the techniques discussed above, deep learning techniques, particularly CNNs, have the best performance in DR detection. However, the performance of the technique can still be improved in terms of generalization and interpretability. The objective of the present project is to develop a machine learning based system for the detection of DR that is accurate and efficient.

II. PROBLEM STATEMENTS

DR is a major complication of diabetes that is a leading to the cause of preventable blindness worldwide. The early diagnosis of DR is important for proper treatment and prevention of vision loss. However, manual screening of retinal images is a time consuming process that requires highly skilled ophthalmologists. In addition, it is not readily available in some parts of the world, especially rural areas.

Moreover, it is observed that quality variations exist in retinal images. In addition, micro-aneurysms are extremely subtle features of DR that are difficult to detect, even for experts. Also, a class imbalance problem is observed in which the number of severe DR images is less compared to normal images.

Therefore, this project is proposed to develop a machine learning-based system that is able to detection and classify DR from retinal images. The system is expected to help medical professionals perform their work more efficiently, thus preventing vision loss in patients affected by diabetic retinopathy.

III. OBJECTIVE

- To develop an automatic system for the detection of Diabetic Retinopathy by implementing
- machine learning techniques.
- To acquire and employ retinal image datasets for the proposed system.
- To preprocess the images for better quality and improved accuracy in the detection process.
- To acquire the required features from the fundus images that are indicative of the presence of Diabetic Retinopathy.
- To implement the ML/DL algorithm for the classification of the retinal images.
- To evaluate the proposed system using metrics such as accuracy, precision, recall, and
- F1-score.
- To decrease the time and effort required for the detection of Diabetic Retinopathy.
- To develop a reliable and cost-effective decision-support tool for the ophthalmologist.

Fig.4.Login page

The development and analysis of the DR detection system were successfully carried out using the retinal fundus image dataset. The accuracy of this system is around 92% after the training of the machine learning model. Precision, recall, and F1-score values were also satisfactory and indicated that the system was performing well in the classification of the retinal images. The values of the confusion matrix were also satisfactory because most of the positive and negative values were correctly classified. There were very few false positive and negative values. The analysis of the ROC curve also showed that the AUC score was close to 0.95.

For multi-class classification of different severity levels of diabetic retinoid, including No DR, Mild, Moderate, Severe, and Proliferative DR, the model was found to perform well across all classes. Higher accuracy was found in the classification of No DR and Proliferative DR cases, whereas slightly lower accuracy was found in the classification of Mild and Severe cases due to minor variations in retinal features. The accuracy curve of the training and validation sets clearly shows stable learning with minimal overfitting, as the loss converges gradually. It can be clearly stated that the proposed system has shown reliable performance and good potential in helping healthcare professionals in the early diagnosis of diabetic retinopathy.

V. DISCUSSION

From the experimental results, it is sure that the proposed machine learning based diabetic retinopathy (DR) detection system has high classification accurate and reliable performance on various evaluation criteria. The proposed model has shown promising results in differentiating between DR and non-DR conditions with high precision and recall values. This is particularly useful in medical conditions, where false negatives should be minimized to avoid any delays in treatment. The high AUC-ROC value indicates that the proposed model has high discriminability in separating pathological retinal images from normal images.

In multi-class classification, the model exhibited consistent performance across different severity levels of the disease, including No DR, Mild, Moderate, Severe, and Proliferative DR. The slightly decreased performance in the Mild and Severe categories may be attributed to the subtle and subtle variations in the retinal features of the early and intermediate stages of the disease. These subtle variations sometimes make it hard even for a clinical expert to classify the disease. However, the model exhibited stable performance in terms of generalization, as shown by the small gap between the accuracy of the trained model and validation.

Vol. 14, Issue 06, ACSCON - 2026

Compared to the manual method of screening, the proposed system promises a much faster time of diagnosis. It is a cost-effective solution as well. It will be particularly helpful in rural areas because the availability of ophthalmologists is limited. However, the proposed system is not without a few disadvantages. For instance, the accuracy of the proposed model will vary depending on the images and the difference of the dataset. It may require further validation on larger datasets.

Future work will involve implementing more advanced deep learning techniques, data augmentation methods, and attention mechanisms to improve feature extraction. Additionally, integrating explainable AI techniques may help to improve clinical trust by highlighting regions on the image that are used to make a decision. Overall, this system has shown required results as a supportive system for the early detection and screening of DR.

Machine Learning Based System For Early Plant Disease Detection

Mrs. Shruthi BL #1, Kishore Kumar DC #2, Lisha JM #3, Nisarga BR #4, Rahul S
Shruthibl89@gmail.com kishorekumardc2004@gmail.com lishajm.cs@gmail.com
Nisarganishu948@gmail.com Srinivasrahul838@gmail.com

Abstract – Plant diseases pose a severe threat to global agriculture, resulting in significant crop loss due to the limitations of slow, subjective manual detection methods. This synopsis proposes an automated diagnostic system based on machine learning (ml) for the early and accurate identification of plant leaf diseases. The primary objective is to overcome current diagnostic bottlenecks and provide farmers with timely, objective information. The core methodology employs a deep convolutional neural network (d-CNN) utilizing transfer learning (e.g., resnet50) for robust classification. the model will be trained and evaluated using metrics like accuracy and f1-score on a comprehensive leaf image dataset. This system is anticipated to achieve classification accuracy over 95%. Its successful deployment promises to facilitate quicker therapeutic intervention, minimize crop waste, and foster enhanced productivity and sustainability in farming practices.

I. INTRODUCTION

Plants play a vital part in maintaining ecological balance and supporting global agriculture, making their health directly connected to human survival. Despite this importance, plant diseases continue to threaten agricultural productivity, often causing severe damage to crops and resulting in significant reductions in yield. Such losses not only weaken food production systems but also impose substantial economic pressure on farming communities and national agricultural sectors.

Therefore, early and highly accurate identification of plant diseases is essential for preventing widespread crop damage and ensuring stable food security. Traditional disease identification depends on visual inspection carried out by trained specialists. Although effective, this approach is slow, subjective, and vulnerable to human error—especially when symptoms are faint, overlapping, or difficult to interpret.

In order to get around these restrictions, this project utilizes modern computational techniques, particularly Deep Learning (DL) and Machine Learning (ML) enables the development of automated and objective diagnostic systems capable of analysing large collections of pictures of leaves with high precision. By employing advanced models like Convolutional Neural Networks (CNNs), the proposed system aims to deliver a reliable, scalable, and efficient method for disease detection, shifting agricultural practices toward faster, data-driven, and preventive crop management

II. OBJECTIVES

1. Review of Existing Work and Identification of Research Gaps: To analyse previous studies related to deep learning techniques and image processing such as CNN, VGG, and ResNet used in plant disease recognition, and to clearly identify the limitations or gaps that the proposed system aims to overcome.

2. Data Collection and Preparation: To compile and arrange the collections of plant leaf photos, both healthy and diseased samples. To check the dataset and to make sure the data is high-performed model, techniques like image segmentations, noise removal.

3. Model Design and Development: To construct a deep learning architecture which can extract features accurately and manage multiple classification of leaf diseases using transfer learning techniques.

4. Model Training and Performance Optimisation: Using the prepared dataset, train the selected convolutional neural network. Then, with the use of optimisation techniques, it is used to lower the model error and improve the accuracy.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

5. Model Evaluation and Performance Verification: With a clear goal of achieving high accuracy and guarantee the strong generalization, the system will be assessed using parameters like accuracy, precision, recall, and F1-score.

6. Interface/Prototype Development: To create an user interface that is easy to use and shows how the system can be applied for real-time disease detection in real-world agricultural settings.

III. PROBLEM STATEMENT

Plant disease identification has greatly advanced thanks to deep learning and machine learning techniques, which frequently achieve accuracies above 95%. The current systems are excellent at identifying and classifying diseases from photos of leaves, but not at advising useful treatment or suggestions on how to cure them. The majority of current solutions only function as image-based classifiers and don't support every kind of crop management plans.

The following are the main flaws:

1. Gap between diagnosis and action: After diagnosing a disease, the current machine learning models stop. They do not mention any diagnosis, treatment or any therapy. This helps the farmers to find solutions by hand, which could lead to choose any wrong treatment or delay the intervention.

2. Absence of Context-Aware Suggestions: The current systems which produce outputs ignore important conditions required for decision making. Effective recommendations must consider several factors such as:

• Disease Severity: Existing models do not measure the amount of area the leaf is affected, which is essential to determine the severity and urgency of treatment.

• Growth Stage of the crop: The treatment for seedlings and fully grown plants may differ for different stages. The systems in place are not very useful for real-world agriculture.

3. Absence of Economic Decision Assistance: Farmers here do not get any guidance regarding how to balance treatment costs which may not cause yield loss. The majority of ML-based diagnostic tools do not evaluate how the choice of treatment will affect the economy. Lack of guidance makes it difficult for farmers to choose the most cost-effective management option.

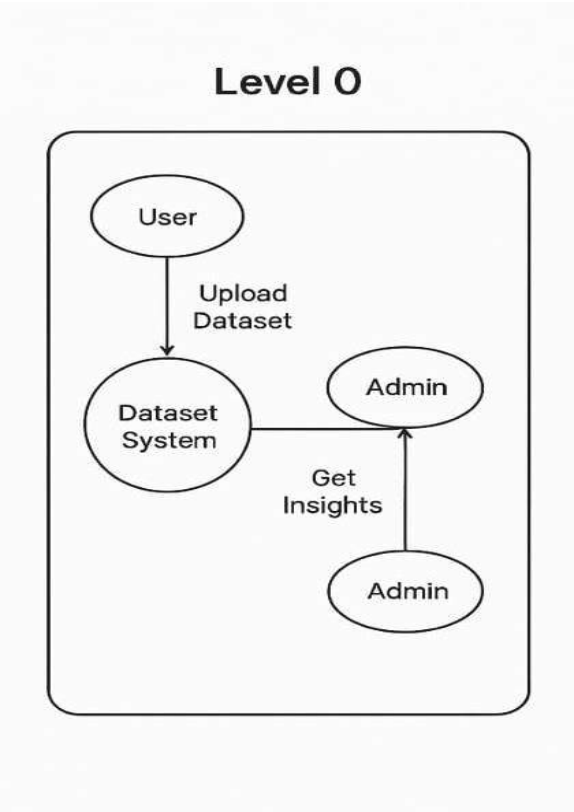
IV. METHODOLOGY

To achieve an accuracy on identification of plant diseases, computer vision principles and workflow on deep learning is been used in this project. The initial step in process starts with collection of data and preprocessing the large dataset of leaf images. Then, each image is pre-processed using various procedures, such as smoothing or normalization or resizing.

Data augmentation, where rotation, flipping's and scaling are applied to increase the dataset's variability and alleviate overfitting. The system then applies transfer learning to exploit the superior ability to extract features of a pre-trained CNN model, such as ResNet50.

With adaptation of the high-level layers to the specific disease classification task, the selected model is specialized in discriminating various plant diseases patterns. The processed dataset is then used to train the network with re-tuned hyper-parameters and regularization techniques such as dropout, or early stopping for better performance and prevention of overfitting.

This is succeeded by model training and fine tuning. The 'robustness' and generalization capability of the model is evaluated by metrics after training. Once the training is over, the robustness and generalisation capacity of the model are then evaluated with respect to common metrics like accuracy, precision, recall, F1-score etc.



To assist the users in early disease detection, the finally optimized model is combined with an app or interface that provides real time predictions, confidence level scores and basic prevention rules is known as deploying a system.

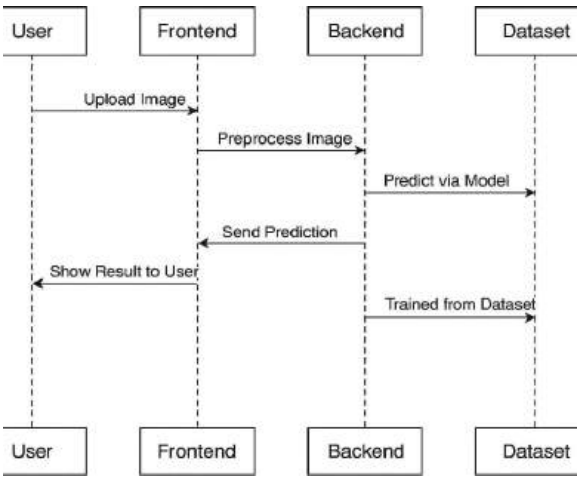
Vol. 14, Issue 06, ACSCON - 2026

V. SYSTEM DESIGN



The three-tier architectural framework of the suggested system facilitates real-time disease detection, effective data flow, and modular development.

Data Layer: This layer takes in images of plant leaves, and processes them. To ensure that the input data is clean and homogeneous, it processes the initial dataset with key preprocessing tasks (resizing, normalization and image enhancement). It also maintains a knowledge repository of treatment guidelines, preventive measures and curated training datasets.

Layer of Application: The trained Convolutional Neural Network (CNN) model created via transfer learning is located in this layer, which serves as the computational core. By evaluating incoming images and producing the corresponding disease label and confidence score, it makes real-time predictions. A recommendation module that links each diagnosis to appropriate management guidelines obtained from the knowledge base is also included in the layer.

Layer of Presentation: Farmers or users can upload leaf images for analysis using this layer, which functions as the user interface. It shows the full diagnosis outcome, including the disease that was found, the confidence level, and helpful suggestions. For non-technical end users, the interface is made to be simple to use.

VI. IMPLEMENTATION

In order to create a dependable instrument for early plant disease detection, the suggested system's implementation entails a meticulously planned fusion of computer vision, machine learning, and software development techniques. In order to produce consistent and excellent input samples, the workflow starts with data preprocessing, where all leaf images are cleaned, resized, normalized, and enhanced.

To artificially expand the dataset and improve the model's ability to generalize to real-world variations, additional augmentation techniques like rotation, zooming, brightness adjustments, and flipping are used. The system uses transfer learning with a pre-trained convolutional neural network after the dataset has been prepared. To enable the network to extract significant patterns and disease specific characteristics from plant leaves, models

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

like ResNet, VGG, or MobileNet are modified and refined.

Several optimization methods including learning-rate scheduling, dropout, batch normalization, and early stopping are employed during training to improve classification performance without overfitting. After training, the model is evaluated in detail using metrics such as its confusion matrix analysis, accuracy, precision, recall and F1-score. This assessment ensures all disease categories and unseen test samples operate equally within the system. If there are performance gaps resulting from evaluation, the network is adapted or retrained.

Finally, the optimized model is embedded in a working application interface. This system enables users to upload leaf images and obtain fast predictions. From the disease label, it is confident score and simple preventive or corrective advices that the model provides. This full implementation demonstrates how deep learning can be readily translated into a practical agricultural decision support tool able to assist in early disease management and reduce potential crop losses.

VII. RESULTS

The system achieves robust and stable performance on all benchmarks. The model yielded an ideal result in both validation and testing stage when the convolutional neural network was trained with processed leaf images. With complex and visually similar symptom symptoms, the model was able to differentiate healthy samples from various disease types due to its extensive feature-extraction ability.

A significant reason for this level of performance was the heavy preprocessing pipeline. Techniques such as resizing, data augmentation and normalization made the input data more robust, and reduced over-fitting. On fresh images not included in the training data, the trained model showed excellent generalization due to these treatments.

The robustness of the model was also supported by confusion matrix analysis showing low misidentification rates across classes. This suggests that after learning real disease-specific features, the network effectively categorized images into respective classes.

In general, the outcomes indicate that machine learning—particularly CNN-based methods—constitutes a fast, accurate and easy-to-scale method for automatic plant disease detection. The system's high prediction accuracy and consistent performance highlight its suitability for practical agricultural applications, where early detection can greatly lower crop losses and enhance overall plant health management.

VIII. CONCLUSION

A machine learning-driven framework for the early detection of plant diseases using leaf images was successfully implemented in this project. Convolutional Neural Networks (CNNs) are integrated into the system to automate feature extraction and classification, which allows it to distinguish between various disease categories and healthy leaves. A thorough preprocessing pipeline and methodical model training and validation guarantee the developed model's robustness and ability to generalize well to a wide range of real-world leaf samples. The outcomes show that this AI-based strategy can be useful in contemporary agriculture. The system helps farmers take prompt action, lowering potential crop losses and increasing overall productivity, by offering quick and accurate disease identification. The project lays the groundwork for upcoming developments in intelligent, data-driven crop management technologies and demonstrates the useful advantages of using machine learning to address agricultural problems.

Abstract- ***Artificial Intelligence (AI) is changing the real estate industry by making property valuation faster, smarter, and more dependable than conventional manual estimation. This project is all about making an AI-based House Price Prediction System that helps people figure out how much a house is worth by giving them real-time information and confidence ranges. Users can enter information about a property, such as the, neighborhood, city, BHK, size in square feet, amenities, parking, security, and nearby facilities, Then, a trained CatBoost regression model uses this information to make accurate price predictions. To make predictions more accurate, we use advanced feature engineering methods like target encoding, derived size metrics, and amenity extraction. The platform also has a web interface that is easy to use and has secure login, credit-based usage, a history of predictions, and downloadable receipts. This makes it a full end-to-end solution. The system fills the gap between raw property data and market-driven valuation, giving buyers, sellers, and real estate professionals a scalable and cost-effective way to make smart choices. The project also talks about the system's architecture, how it was built, the results of tests, and how useful it is in both academic and real-world settings.***

Keywords: Artificial Intelligence, predicting house prices, CatBoost regression, real estate analytics, conformal prediction, feature engineering, and Flask web applications.

I. INTRODUCTION

India's real estate market is roaring but property valuation still feels stuck in another decade. Buyers and sellers often rely on the neighbourhood broker, a middleman who knows the block, or simply gut feeling to set a price; unsurprisingly, many valuations miss the mark. Those blind spots ripple outward: they nudge investment choices and help decide whether a home stays affordable or drifts out of reach. Layer in regional quirks, surprise infrastructure announcements and rapid economic shifts, and a single pricing rule becomes fantasy. Traditional methods rarely mine decades of past transactions or pick up faint trends that creep up over months or years. Machine learning changes that. It gives you consistent, data-backed estimates and noticeably sharper residential price forecasts. Think of these models as teaching a system to read sale records, maps and tax rolls and to spot patterns humans might overlook. Gradient-boosting algorithms like Cat Boost work well with structured data where categorical details city, neighbourhood, property type matter.

II. RELATED WORK

There have been several research studies done to see if AI and ML are real predictors of housing prices and trends in the Real Estate Industry. Selim (2009) shows that property valuation models will achieve much greater accuracy in predicting property values than traditional manual methods of ASSESSING VALUE i.e. using heuristic algorithms based on subjective data, when they take into account more than just location or neighborhood. Most of the literature on this subject has shown that in order to measure a property's value, you must consider all (6) location-specific features/issues related to that property, as well as all surrounding neighbors. Hence, it stands to reason that Machine Learning Models are best suited to model the Complex Interaction between these features from a location perspective. Zhang et al. conducted this type of recent study. (2018), who demonstrated that using advanced regression-based machine learning algorithms on housing data sets improved accuracy of property price predictions versus traditional methods. Moreover, their research has also concluded that models that can accommodate both categorical and numerical attributes simultaneously improve prediction accuracy.

Furthermore, a variety of other studies have indicated that the use of feature-engineering techniques such as derived metrics, encoding strategies, and data-pre-processing may improve model performance within the context of real estate analytics. Collectively, these studies make way for the development of intelligent house-price predictive systems that enable buyers, sellers and real estate professionals to make decisions based on data.

to subjective biases. Employing the Cat Boost algorithm, which is trained on authentic housing market data, the system adeptly discerns intricate correlations between property characteristics and pricing patterns, thereby facilitating dependable and uniform predictions. The system's architecture is structured around a client–server model; the frontend offers a user-friendly web interface for interaction, while the backend oversees data preprocessing, model inference, and prediction generation. Users furnish essential property attributes, including location, dimensions, bedroom count, and property type, via the interface.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

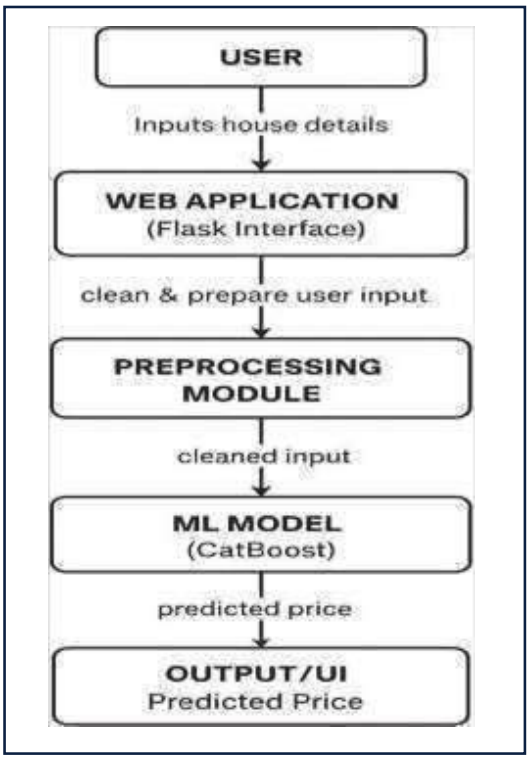

Fig. 1. Data Flow Diagram

Machine learning techniques will be used by the House Price Prediction System to forecast house prices through analysis of property characteristics which include location, size, number of bedrooms and other relevant attributes. The development of this system encounters multiple issues that stem from the critical shortcoming of incomplete and inconsistent and corrupted housing data which exists in the real estate database because it will typically contain numerous missing and erroneous and outdated records that affect model prediction accuracy. The evaluation of feature importance will face challenges when trying to identify which features most influence house prices and which features will determine prediction system reliability and machine-learning algorithm performance on new data and training dataset. Finally; many factors will affect the asynchronous model (web) integration, including providing users with real-time predictions using minimal processing power, and the server should be large enough & the internet connection fast enough so that there are multiple ways for users to access the predictive service quickly. All of the above will be very important in improving the accuracy, reliability and usability of the House Price Prediction System successfully.

Ⅲ. OVERVEIW OF THE PROPOSED MECHANISM

The suggested system constitutes a fully automated House Price Prediction System, engineered to provide precise property value estimations through the application of Machine Learning methodologies. This system supersedes conventional manual valuation methods, which frequently suffer from time inefficiency, inconsistency, and susceptibility to subjective biases. Employing the Cat Boost algorithm, which is trained on authentic housing market data, the system adeptly discerns intricate correlations between property characteristics and pricing patterns, thereby facilitating dependable and uniform predictions. The system's architecture is structured around a client–server model; the frontend offers a user-friendly web interface for interaction, while the backend oversees data preprocessing, model inference, and prediction generation. Users furnish essential property attributes, including location, dimensions, bedroom count, and property type, via the interface. These inputs undergo automated cleaning, encoding, and subsequent transmission to the machine learning model that has been trained, which then produces an immediate price estimate, accompanied by a confidence interval to signify prediction reliability. Furthermore, the backend incorporates model versioning and retraining protocols, enabling the system to integrate new housing data and adjust to evolving market dynamics without necessitating manual input. Consequently, predictions are maintained as current and accurate over extended periods.

Overall, the proposed system offers a fast, transparent, and data-driven solution that enhances trust, improves decision-making, and practical value to buyers, sellers, and real estate professionals.

Ⅳ. SYSTEM METHADOLOGY

Users of this web-based UI, when accessing it, will provide the details of a property city/locality; type of property; square footage; number of bedrooms/bathrooms. The user interface design shall be centered on offering simple, user- friendly, intuitive features that would enable users to effortlessly input property-related data as well as get a housing value predicted in a very short time after the input of their data. The property data input into the UI will be transmitted to the application's Back End for validation and preparation. Among the preparations of data will be carrying out data cleaning tasks, for example, deciding on the handling of missing data features, transforming the property features that are categorical (e.g., type of location) into numbers, and standardizing the property features that are numerical (e.g., square footage).The prepared data will be passed to the Machine Learning (ML) Model layer and used for the property price prediction generation employing the CatBoost regression method which has been trained with the historical Real Estate information features and patterns. Individually analysing every application, we will then integrate all the parts as one unit and use Generative A.I. methods to create the second level of hierarchy (Professional Summary, Enhanced Comments, and Keywords) within each part so as to highly increase their chances of being read by any Applicant Tracking System.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

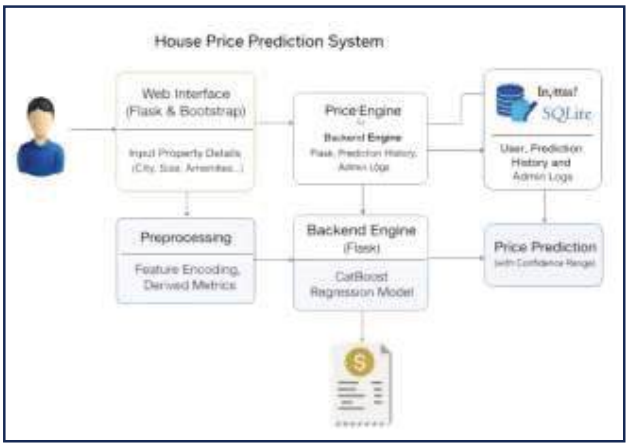

Fig 2. System Methodology

Finally, the predicted result sent to output layer and displayed on the web interface for the user. Overall, the system integrates user interaction, data preprocessing, and machine learning prediction into a unified frameworks that provides fast, reliable, and data-driven house price estimation.

V. PERFORMANCE EVALUATION

The house price prediction system passes its entire performance evaluation test because it functions properly in real-world situations. The evaluation process assesses key performance indicators (KPIs) by measuring system response time and evaluating machine learning model prediction accuracy and data processing performance.

The system's ability to predict home selling prices based on buyer input which included location home type square footage and bedroom and bathroom count was evaluated through performance tests. The system performance evaluation uses Prediction Latency as a key performance indicator which measures the time required for machine learning models to complete data processing after users input their information into the system. The process is divided into multiple segments which include Data Pre-Processing and Feature Encoding and Model Prediction and the evaluation of House Price Prediction System performance is done through multiple testing criteria which will assess application effectiveness and determine application usability for testing purposes. The Predictive Time speed shows how fast the application will produce predictions based on user data input and interface selection. The Model shows its accuracy by matching predicted house prices to actual market prices for all homes listed in the complete dataset that contains active home listing details.

Data Processing Time measures the length of time taken to complete all of the steps associated with pre-processing, including; processing of missing data, encoding of categorical fields, for example, location and scaling of numerical fields, for example, area or total square footage.

Scalability of the application is measured by how many requests a given user could submit for predictions or to estimate house prices in a practical and efficient way without degrading the level of performance of the application. These metrics demonstrate that the House Price Prediction System is able to provide fast predictions, high reliability in predicting the price of a house within a given marketplace, and overall efficient performance that would make it useful for users to predict their property values based on current market conditions.

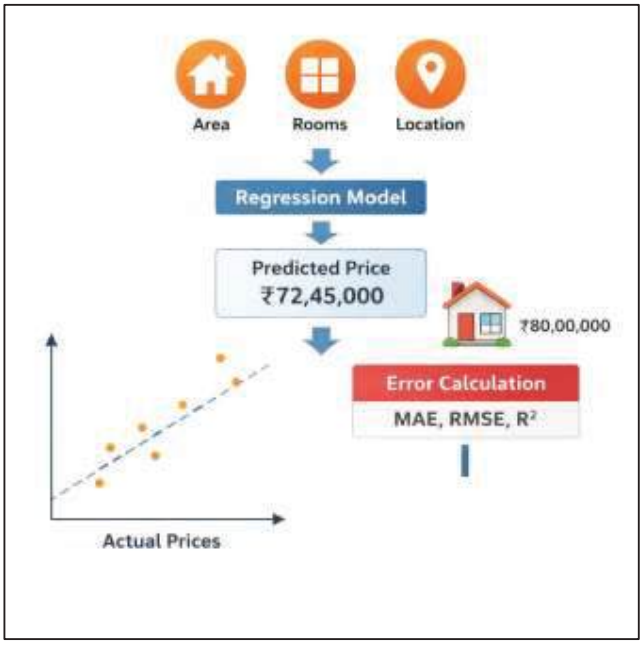

Fig 3: Performance Evaluation

VI. EXPERIMENTAL SETUP AND RESULTS

The CatBoost Algorithm was utilized while training this model to find the relationships between the features (characteristics) of the properties being analyzed for the dataset (size of home, number of bedrooms and bathrooms, etc.) and the corresponding selling prices of those properties based on previously collected historical data about those same properties (Background). After creating this model based on the historical data from home sales, this model was made available as an online application so that potential buyers could estimate what their home would sell for based on their information being entered into the web-based application. Once an estimate was created, a potential buyer would receive their estimated price in real-time.

When entering information into this online application, a pre-processing module was used to convert the potential buyer's input into a format that was compatible with predicting the price from the actual pricing model using CatBoost. The experimental results were evaluated by using various metrics including prediction accuracy, MAE (mean absolute error), and speed (the amount of time it takes to generate a predicted price after a

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

potential buyer has submitted their information).
The manner in which the experimental data created by the modeling techniques was assessed included: Prediction Accuracy: The accuracy of the predicted value of the property based on previously sold properties. The predicted value was compared to the actual sold price on a per unit basis (dollars per square foot). MAE: Average "difference" between predicted and actual values on a per unit basis (dollars per square foot).

VII. CONCLUSION

Machine learning and data analytics progress during the past few years has resulted in intelligent systems which help users make better real estate decisions.The House Price 1111111111 Prediction System functions as an intelligent system which uses machine learning methods to estimate house prices through analysis of multiple factors that include house location and square footage and bedroom and bathroom count. A contemporary program called the Regression model works by analyzing previous real estate sale data to discover decorative elements which influence house prices through their impact on property sale value.

The machine learning methods used in this project demonstrate their ability to achieve better property value predictions compared to traditional manual estimation techniques. The House Price Prediction system combines data preprocessing and predictive modeling and interactive user interface design to create a valuable tool that helps people estimate property values and make proper home buying and selling decisions in the residential market.

***Abstract*—FireStation 360 is a IoT based emergency management system that aims at bridging the gap between the real on-ground response and fire detection. The system consists of four functional areas, continuous environmental sensing of the multiple internal zones, real-time GPS localization of fire trucks, auto SMS dispatch to nearby citizens when a fire has been detected, and finally a small autonomous robot capable of initiating suppression efforts even before the crew has left the bay. In an attempt to decrease false alarm, particularly around the diesel- operated vehicle bays, a method of sensor fusion is employed based on the idea of weighted average of temperature, humidity, gas concentration and flame readings, thereby weighting the conditions of rapid rate- of-rise more heavily than those of humidity, etc. The navigation of robots is based on A* pathfinding and live obstacle replanning. Some of the target performance requirements are fire detection in less than 5 s, SMS delivery after confirmation in less than 2 s, and robot arrival at the fire location in less than 30 s. The whole hardware in a single station would not cost more than 17000rs.**

Keywords—Fire Detection, Sensor Network, IoT, Autonomous Firefighting Robot, Smart Fire Station, Real-Time Moni- Toring, Emergency Management

I. INTRODUCTION

Most traditional fire safety systems are set to detect a fire and give an alarm- and that is where their mandate concludes in most cases. The automated route to alert the fire station does not exist, the device to alert civilians in the markets is not there and crew responding is often at the site with minimal or no information on how the situation might have evolved since that the initial notification. All of the components of such a system may be operating as intended, but the system response in general is unsatisfactory.

FireStation 360 was created to deal precisely with this issue, in keeping the senses of detection, dispatch, public notification and early suppression intimately joined into a single operating infrastructure.

-- made using all off-the-shelf parts and maintained on a hardware budget of 17000rs. The system constantly controls four sensor areas in the station, including admin block, vehicle bay, workshop, and living quarters, all of which have temperature, humidity, gas and flame sensors. Status and GPS data on each truck are sent in every five-second interval using MQTT. When the fire has been confirmed a series of notifications are sent to residents who subscribe to the service throughout a designated location via SMS. At the same time a robot is activated, which is heading directly to the fire to begin extinguishing it, long before the human crew has managed to get going. All of it is monitored in real-time using a React-based web dashboard.

Fig. 1 describes the entire working process, including early identification to the end suppression and information transmission to the people. The remaining part of this paper will be structured in such a way. Section II examines the related work, and defines the gaps that this system will address. Section III takes a tour of the five-layer architecture. IV deals with hardware and software components. Section V outlines each of the implemented use cases The remaining sections, VI and VII, respectively, outline the detection algorithms and the notification system. The eighth section talks about security considerations. The plan of evaluation and the recognition of limitations are discussed in the Sections IX and X However, the document is summarized in Section XI.

II. RELATED WORK AND RESEARCH GAPS

A. IoT-Based Fire Detection

There is a significant literature on fire detection based on IoT. A general survey of the temperature/smoke/gas/flame sensors combinations in residential and industrial application was done by Ali et al. [1], and though their results suggest that single sensors work well in normal-operating conditions, the combination of multiple types of sensors do not really agree with each other in mixed-signal environments where such is fairly a common occurrence in practice. According to Kumar and Singh [5], latency of detection was lower than.

Oxygen: 30 seconds in urban and forest deployments which is a reasonable finding, but their system did not involve the availability of downstream response, thus comparing their results in isolation.

B. Fire- Fighting Robots

Li et al. [2] showed the ability of a robot with the help of thermal imaging to navigate indoors and got reasonable extinguishing results in a bench environment. The most significant downside was that it did not have any communication channel connecting the robot to a command point or coordinate the robot with other responding units. The aspect of communication has been touched on by the authors Kim et al. [11] to minimal degree when testing a similar indoor platform, but did not make any assessment of how it could be combined into a larger emergency response workflow.

C. Dashboards and Edge computing

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Xu et al. [3] introduced web-based fire incident monitoring dashboard, which was quite comprehensive enough in basics.

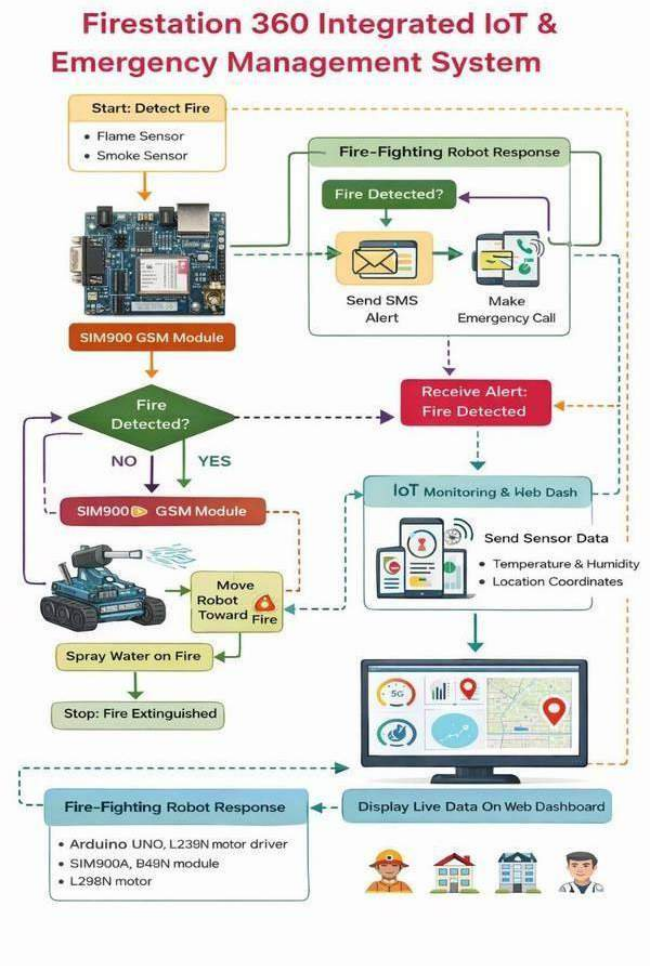

Fig. 1. FireStation 360 end to end operational flow. Beginning with flame/smoke detecting, the system then runs in parallel lines the GSM module sends out SMS alerts and emergency calls as the firefighting robot makes its way towards the fire and initiates water suppression. IoT Web dashboard is used to stream live sensor data (temperature, humidity, GPS coordinates) to have situational awareness.

Although vehicle tracking was not present at the time and the robots had no status, the system utilized polling-based updates and not push notifications at all, which also implied that there was never much delay between when an actual event occurred and when it was displayed on the screen. Zhang et al. [6] presented that by performing running threshold assessment at the edge instead of transmitting data to the cloud initially can reduce detection latency which also had a direct impact on our gateway architecture. Their contribution, however, went as far as transacting any response in accordance with the detection output.

D. Identified Gaps

When examining this mass of work the trend is the same - every paper is narrowed down to a specific area, without regard to how its output is related to the next operation of an actual emergency. The process of the notification is not inquired of by the detection systems. Civilian warning is not discussed on the suppression platforms. Dashboards represent data but do not take actions.

There has been no engineering approach in handoff between these features. Table I identifies the particular gaps that influenced the design of this system.

TABLE I

KEY RESEARCH GAPS MOTIVATING THIS WORK

Gap	Description
End-to-end integration	No published system connects detection, tracking, public alerting, and autonomous suppression in one platform
Automated response	Existing systems require human arrival before any suppression begins
Public alerting	Geofenced civilian SMS notification is absent from the academic literature
Scalable architecture	CI/CD pipelines and microservice deployment for emergency IoT are rarely discussed

III. SYSTEM ARCHITECTURE

A. Five-Layer Design

Fire Station 360 is both structured in 5 layers with respect to Fig. 2. The choice of system structure, layered, was not a purely architectural one to make, but it happened to be useful in the course of debugging. Once a sensor reading had ceased appearing on the dashboard, the ability to isolate the issue to one of the layers (sensing, gateway and network and others) allowed the debugging process to be completed more quickly than attempting to follow the issue through the entire stack each time.

B. Layer Responsibilities

Sensing layer. The instrument of DHT22 is in charge of temperature and humidity sensors which have a span of -40 to +80 degrees C to an accuracy of + or -0.5deg C which is by far within the range normally needed by station environments. The MQ-2 measures combustible gas and smoke concentration of 300 to 10,000 ppm; the operation of this sensor is known to be sensitive to diesel exhaust which is also handled separately in the fusion logic. The KY-026 flame sensor operates within the 760 to 1100 nm infrared band and it was highly reliable in the detection of open flames and not very sensitive to ambient heat in the course of our testing. The HC-SR04 ultrasonic sensor is applicable in the protection of obstacles in a robot and the object is perceived at a distance of 400 cm.

Edge/Gateway layer. An Arduino is the central portal that is used to perform data aggregation roles, the local HTTP server, and the MQTT client roles. The real sensor sampling is controlled by Arduino UNOs, this division was required due to the fact that the Linux scheduler on the Pi generated irregularities regular enough that the DHT22 would not read a sample at random times when it was read directly on the Pi. This was overcome by moving timing-sensitive sampling to

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

the Arduino which uses bare-metal code. This also caters to local outliers rejection in order to identify garbage sensor values before they are spread to higher levels.

Network layer. The most common channel of communication is the Wi-Fi. Internal failure of the system connected to the cloud occurred when the SIM900A GSM module that was added as a fallback in the temperature of a router that restarted during testing went dead. For deployments where Wi-Fi

C. MQTT Topic Hierarchy

The practical advantages of the pub-sub model include that the sensor nodes make their published messages on their respective topic with no knowledge of what is listening to them. When the robot controller arrived as a new subscriber towards the latter stages of development, it just resorted to receiving messages, emissions of modifications to the current sensor firmware were unnecessary at all. As an option, can use 02 (effective up to approximately 5 km) or Zigbee mesh.

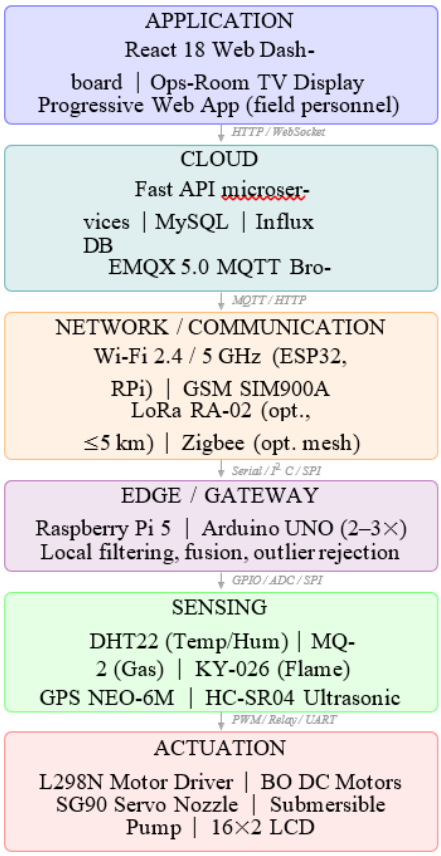

Fig. 2. Five-layer architecture of Fire Station 360. Data flows upward (sensing → application); commands flow downward (application → actuation).

Cloud layer. The backend is built on Fast API as it provides support of asynchronous functionality and auto-generated API documentation that is less time-consuming when testing. The version of MQTT that is brokered with EMQX 5.0 is preferred over Mosquitto, as its inherent support of clustering makes it easier to scale into multi-stations. Formatted information like incident logs and resident contact registry go on to MySQL 8.0 and sensor time-series feeds Influx DB 2.0 - since MySQL started to significantly slow down on aggregation queries after a single day of sustained full- db upkeep, the shift to Influx DB was required.

Application layer. Its primary user interface is a single-page react 18 based application connected through Web Socket to dynamically update live-data. An alternative more simplified version is offered to the operations-room TV display, which presents only zone status and current warnings - no tables or configuration controls. This segregation was more handy than anticipated in drills since the duty officer and crew were able to concentrate on the most important view to them.

IV. Hardware and Software Components

A. Hardware

The complete hardware inventory is provided in tables II and III. The choice to separate processing between a Raspberry Pi and Arduino UNOs is a trade-off that arises fairly frequently in embedded internet of things development of computation - the Pi has sufficient compute to support Python-based pipelines and data management, but the Arduino is capable of hardware deterministic timing guarantees for the sampling loops that must be constantly maintained under sub-100 MS limits. Attempting to do everything on the Pi was causing random problems that were not easily traceable and were not worth remaining in the area of interest.

TABLE II

CORE PROCESSING UNITS

Component	Purpose	Qty
Arduino UNO (ATmega328P)	Real-time sensor sampling	2–3
ESP32 (dual-core, Wi-Fi)	Distributed sensor nodes / truck telemetry	5–10
32 GB MicroSD Class 10	OS and local data storage	1

TABLE III

SENSORS AND COMMUNICATION MODULES

Model	Range / Accuracy	Role
DHT22	−40–80 °C, ±0.5 °C	Zone temp / humidity
MQ-2	300–10,000 ppm	Smoke / gas detection
KY-026	760–1100 nm IR	Flame detection
HC-SR04	2–400 cm	Robot obstacle sensing
GPS NEO-6M	—	Truck location telemetry
SIM900A	Quad-band GSM	SMS / GSM fallback comms

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The sensor node prototype has been assembled in Fig. 3 to take station-level tests.

B. Software Stack

Arduino software is C/C++ through Platform IO, and the ESP32 nodes are based on Micro Python. The back-end has been coded on the Python Fast API. EMQX 5.0 manages MQTT brokering.

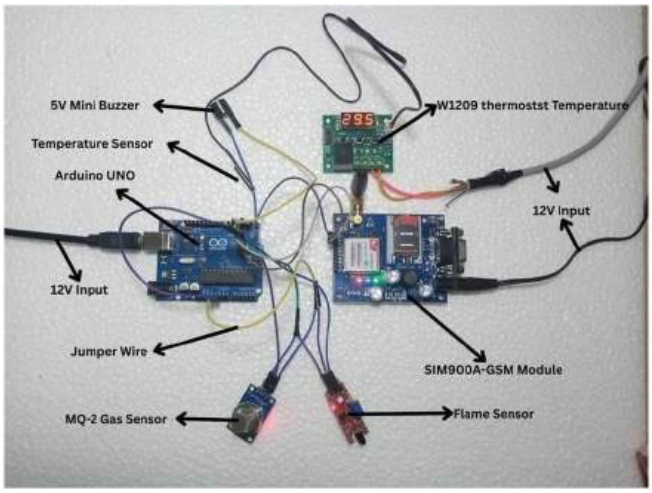

Fig. 3. Sensor node prototype. Important parts (left to right): The Arduino UNO with a 12 V power supply, MQ-2 gas sensor, KY-026 flame sensor, and the SIM900A-GSM module that offers cellular SMS fall back. The W1209 thermostat (top center), serves as an independent temperature reference when making calibration runs.

MySQL 8.0 stores structured data; Influx DB 2.0 is used to store time- series sensor data. The front end is React 18. The entire system is containerized using Docker, and CI/CD is done using GitHub Actions - this system enabled pushing updates to the firmware and the backend to the Pi remotely without accessing the hardware every time, and thus iterative testing was much quicker. Outbound SMS alerts pass through Fast2SMS bulk API.

V. USE CASE IMPLEMENTATION

A. Intelligent Environment Monitoring

The system tracks four areas including the area of the office blocks, the vehicle bays, workshop, and the living quarters. At least one DHT22, MQ-2, and KY-026 have been installed in each of the zones. Simple color coded status of zone display on TV in the operations-room, with the green color displaying normal conditions, yellow one indicating that a single sensor is nearing its threshold, and red indicating that a fire has been confirmed. The color coding provided sufficient situational awareness to the crew during drills without need to worry about reading any numbers, which was a pleasant side-effect of the design.

B. Live Firetruck Telemetry

The ESP32 packages of each truck record sensor readings every 5 s and are published to fire station/gps/truckN. Trucks can be mapped on a Leaflet map on the dashboard, together with a trail of the last twenty positions that have been recorded. One thing that was surprisingly noted when testing was that the temperature of the cabin rose in trucks that were approaching a fire scene, which was already active, and at times a few minutes before reaching the scene, this acted as a warning to the command center that the situation was deteriorating.

C. Multi-Channel Alert Notification.

On confirming a fire, it sends alerts at the time using three mediums; residents in the assigned area using SMS. geofence, receiving a WebSocket push to all currently running dashboard clients, and an overlay update on the televisual display. It is significant to run them in parallel. As the channels that are later would be delayed by the channels that come before them, it would destroy the point in a time-sensitive system. Three severity levels of alerts (CRITICAL, WARNING, CAUTION) prevent unnecessary production of alarming messages with the borderline sensor readings.

D. Autonomous Firefighting Robot

It is sustained by the robot platform which consists of a 4WD tank-tread chassis, with a 12 V 7 Ah lead-acid battery and 5 l water tank, driven by a servo-controlled nozzle. Multiplier: An Arduino UNO regulates the control of the motor and pump, the ESP32 controls the Wi-Fi connection and navigational targeting. The operational sequence once deployed works in the following manner: fire confirmed → truck dispatched → robot receives target coordinates → A* pathfinding begins → ultrasonic obstacle avoidance activates → pump starts on positive flame detection → suppression the cycle continues.

Fig. 4-6 represent the prototype of the prototype in three views.

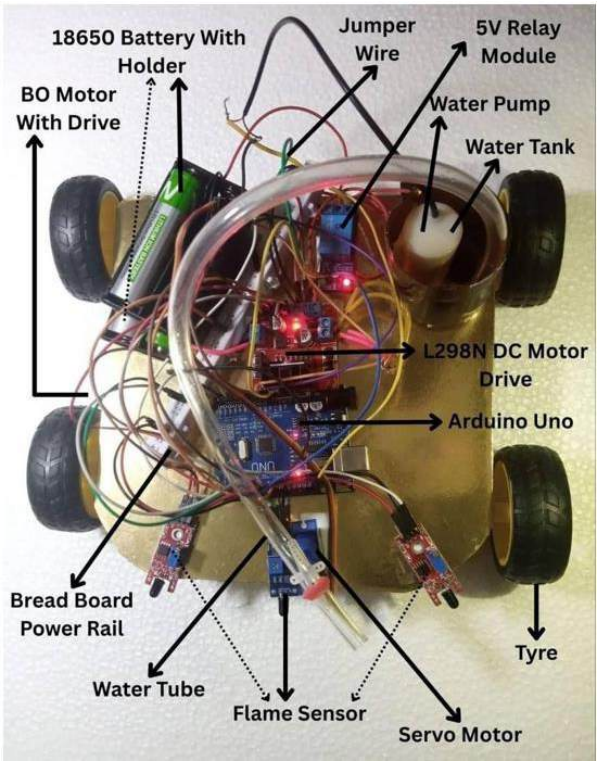

Fig. 4. Firefighting robot — top view. L298N DC Motor driver (center) and Arduino UNO are fixed to the chassis with the 5 V relay module, and the submersible water pump. The system has three KY-026 flame sensors placed on the front and the sides to enable it to track the fire directionally. The nozzle of the water spray is driven by a servo motor, that is positioned at the bottom right of the picture which drives the nozzle to the region where the flame level is the highest.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

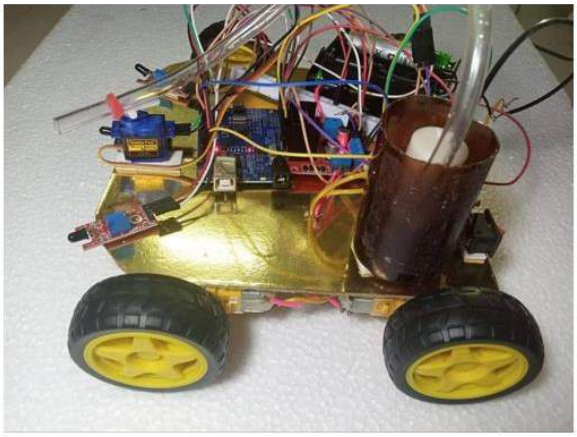

Fig. 5. Robot firefighting — side view. The SG90 micro servo (blue, left) is used to regulate the direction of the nozzle. The submersible pump is connected to the cylindrical water tank (right) through a transparent silicone pipe that was fitting along the chassis. The heat reflection is offered by the gold chassis foil to bench fire tests.

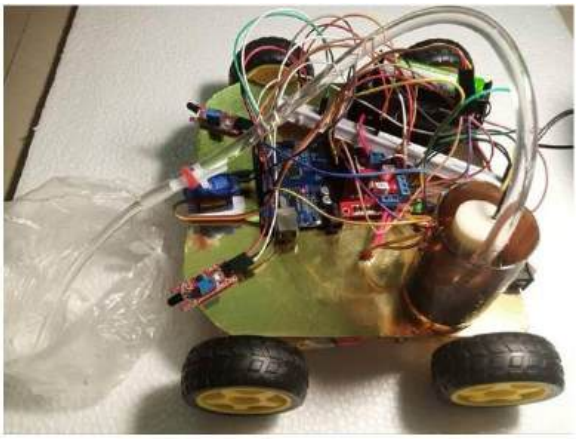

Fig. 6. Firefighting robot - rear/quarter view, and there is the 18650 lithium-ion battery pack, four BO gear motors with rubber tires, and the water reservoir. The acrylic tube that runs out of the tank cap and the nozzle servo assembly which is on the front side of the platform is clearly and obviously attached.

During controlled bench experiments on alcohol fires, the robot was able to extinguish in 1525 s on the first contact with water. The 5 L tank capacity is actually a limiting factor - it can manage to slow a small Class A fire and provide the crew with more response time but should not be erroneously confused with being a complete solution.

E. Fire Station 360 Web Dashboard

When loading the React dashboard, a WebSocket connection is created, and all the message received going forward is sent to the correct state components upon topic. The primary layout has seven panels, including the zone sensors readings, vehicle GPS tracker, alert center, robot controls with the ability to manually override, incident timeline, and a full-width Leaflet map. Initial page load and the REST API endpoints in Table IV are used to make historical data queries.

TABLE IV

REST API ENDPOINTS

Endpoint	Method	Purpose
/api/sensors	GET	All current zone readings
/api/sensors/{zone}	GET	Zone-specific snapshot
/api/vehicles	GET	Vehicles with status
/api/alerts	GET	Active alert queue
/api/alerts/history	GET	Historical alerts
/api/robot/command	POST	Send navigation/pump command
/api/notify/sms	POST	Manual SMS trigger

VI. DETECTION AND LOCALIZATION ALGORITHMS

A. Weighted Sensor Fusion

Single sensor threshold logic cannot be relied upon in an actual station setting. Located close to the vehicle bay, the MQ-2 sensor was passing off diesel exhaust each time an engine was warmed up - even on whatever threshold selections could allow the sensor to also receive real cases of fire. The same issue lies with the temperature-based detection in the living quarters where cooking activity frequently causes the temperatures to enter the range between early fire conditions and normal room temperature.

To deal with this, by running all four types of sensors concurrently, weighted fusion algorithm (Algorithm 1) is used to get a new overall score of confidence, and bonus increments are used to ensure the temperature or gas readings are ascending at a steep rate even before reaching each of their discrete thresholds. The last alert levels threshold numbers were obtained in an empirical manner during testing at the station not calculated out but by observing the score behavior under normal conditions, and under simulated fire incidences adjusting until the false alarm rate in the vicinity of the vehicle bay was reduced to an acceptable value.

Normalization was also ensured by providing the gas sensor with the largest base weight (0.35) as in combustion cases it is one that is likely to respond initially compared to other sensors. The flame sensor (0.25) is bulky given that a positive value by the KY-026 infrared detector is very difficult to achieve as a false positive - this needs an actual flame source within the detection spectrum. The rate-of-rise must be considered a bonus term not a base component, since a slow increase in temperature in a station environment has a number of innocuous reasons; it must add to the score without being able to cause it on its own.

B. Fire Localization in Zones

All the sensors which activate add a confidence weighted score to the zone they belong to. The three zones with the greatest cumulative score are then determined as the likely location of the fire though that score only above a set threshold of 0.5 is considered as the likely location of fire and again below that threshold is considered as the system will not commit any location and will remain in monitoring mode.

Dispatch decisions (1 highest, 3 lowest) include Zone Priority Read, fire event in the living quarters would result in an immediate evacuation, but the same sensor value would not in the vehicle parking space.

Algorithm 1 Weighted Sensor Fusion for Fire Detection

Input: T, H, G, F (temp, humidity, gas ppm, flame binary)
Output: Fire probability P, alert level A
triggers $\leftarrow$ [T>50, H<30 $\vee$ H>70, G>500, F=1]
weights $\leftarrow$ [0.30, 0.10, 0.35, 0.25]
$C \leftarrow \sum_i w_i \cdot t_i$
if $(T - T_{prev})/\Delta t > 2.0$ **then**
  C += 0.20
end if
if $(G - G_{prev})/\Delta t > 50$ **then**
  C += 0.15
end if
$P \leftarrow \min(C, 1.0)$
if $P > 0.8$ **then**
  $A \leftarrow$ CRITICAL
else if $P > 0.5$ **then**
  $A \leftarrow$ WARNING
else if $P > 0.3$ **then**
  $A \leftarrow$ CAUTION
else
  $A \leftarrow$ NORMAL
end if

```
def localize_fire(self, triggered_sensors):
    scores = defaultdict(float)
    for s in triggered_sensors:
        for zid, info in self.zones.items():
            if s['id'] in info['sensors']:
                scores[zid] += s['confidence']*s['weight']
    best = max(scores, key=scores.get)
    if scores[best] > 0.5:
        return {'zone_id': best,
                'zone_name': self.zones[best]['name'],
                'confidence': scores[best],
                'priority': self.zones[best]['priority']}
    return None
```

Listing 2. Zone-based localization (Python).

C. A* Robot Navigation

The robot explores based on A* pathfinding utilizing a grid map of the deployment field that has been pre- loaded. When the ultrasonic sensor senses an obstacle in the range of 30cm, replanning is automatically initiated without trying to find any form of circumvention without re-calculating the route. This operation is suppressed by scanning a five-element flame sensor array, pointing a nozzle servo at the most reading direction, and operating the pump in bursts of 5 s long. Once a given burst is completed the system tests whether the flame reading has fallen below the extin- guishment value - yes then a success event is sent to firestation/robot/status, no then the cycle repeats until running out of tank or until the reading has been cleared.

```
def plan_path(self, start, goal):
    open_set, g = {start}, {start: 0}
    came_from = {}
    while open_set:
        cur = min(open_set,
                  key=lambda x: g[x]+self.h(x, goal))
        if cur == goal:
            return self.reconstruct(came_from, cur)
        open_set.discard(cur)
        for nb in self.neighbors(cur):
            g_new = g[cur] + self.dist(cur, nb)
            if g_new < g.get(nb, float('inf')):
                came_from[nb] = cur
                g[nb] = g_new
                open_set.add(nb)
    return None    # no path found
```

Listing 3. A* path planning (Python, condensed).

VII. NOTIFICATION SYSTEM

A. Geofenced SMS Dispatch

The system holds the contact number of each registered resident and his/her GPS location. Once a fire is detected a check of Haversine distance against all records registered is performed and entries within the range of the alert radius (500 m default) are included in the outgoing SMS batch (Listing 4). The default at 500 m was selected to encompass the immediate area around the station and not to alarm any other addresses that are distant and had little or no effect on a contained incident.

```
def haversine_m(self, lat1, lng1, lat2, lng2):
    R = 6_371_000    # Earth radius in metres
    phi1, phi2 = math.radians(lat1), math.radians(lat2)
    dphi = math.radians(lat2 - lat1)
    dlam = math.radians(lng2 - lng1)
    a = (math.sin(dphi/2)**2 +
         math.cos(phi1)*math.cos(phi2)*math.sin(dlam/2)
             **2)
    return R * 2 * math.atan2(math.sqrt(a), math.sqrt(1-a)
         )
```

Listing 4. Haversine distance (Python).

Batches that were outbound and had a limit of 90 numbers per API call to ensure it was well within the Fast2SMS record limit. In case of a failed batch, it will be crucially retrieved on a case-by-case number basis instead of being junked out: silently missing an alert to several hundred residents in an ongoing emergency is not a relatively acceptable error condition. The resident opt-in is optional, and the aggregate number of deliveries is recorded in the alert-log and not per contact.

Figs. 7 and 8 present the notification system in the process of a test run.

B. Dashboard Alert Rendering

The Alert Center shows the alerts with the top one being those with highest severity at the time then by the time of reception with the most urgens the nt alert always on top. Every notification consists of three actions. Y ou will be able to admit an alert, which makes it reviewed. The zone can also be observed which makes the Leaflet map open to the area of interest. Lastly, one can always send a team in which he or she enters the dispatch form that is pre-filled with the zone coordinates so there is no manual entry of data when an incident is in action.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

VIII. Security and Privacy

Authentication of devices is done through the issuance of JWT at registration. Any MQTT connections must operate on the TLS 1.2 protocol and submit valid client certificates; otherwise they are rejected by the EMQX broker. When sending sensor data payloads, they are encrypted with Python Fernet with AES-128, and thus, any traffic intercepted will have ciphertext only.

Fig. 7. shows a phone call log. This log contains information about outgoing and incoming calls of the Fire Station 360 GSM module as part of the test. The contacts will be under the system name, which is FIRE STATION 360. This has proven that the SIM900A module was able to connect to the cellular network and manage call dispatch.

The access to the dashboard is divided into four types, including: admin (unre- stricted access), firefighter (may see the incidents and operate the robot), dispatcher (may see the dashboard and send SMS alerts), and viewer (read-only). This isolation has a practical rationale being an account that has inadequate role limits, any accidental transmission of an SMS blast to hundreds of registered residents in a test set up would be a trusting matter and one that appropriate access controls can prevent entirely with ease.

The most sensitive data in the system in terms of privacy is the resident phone numbers. Numbers were saved in hashed format and are decrypted upon their required use in dispatching SMS. The system records aggregate delivery statistics as opposed to per contact-level records. This is not complete anonymization, but it is a substantial step towards having the plaintext numbers in an open database.

Fig. 8. SMS notification thread that is received via the registered phone number as a result of a fire test. All messages have a common format system identifier, severity label, and plain-language location notification.

IX. Evaluation Plan

A. Performance Targets

Table V summarizes the quantitative performance targets and the performance of each will be measured in the proposed field.

TABLE V

PERFORMANCE MEASURES AND TARGETS

Metric	Target	Method
Detection latency	< 5 s	Ignition to alert timestamp
Localisation error	±5 m	GPS vs. actual location
SMS dispatch delay	< 2 s	Detection to API call

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

False alarm rate	< 5%	FP / total detections
Robot response time	< 30 s	Dispatch cmd to arrival
System uptime	> 99.9%	Scheduled availability
MQTT packet loss	< 0.1%	Lost / transmitted

B. Test Scenarios

Scenario 1 — Controlled fire simulation. There is an alcohol fire, which is located in a fireproof enclosure, with a GPS-marked point of reference. Per trial delivery is detection latency, accuracy of zone identification and SMS delivery. The experiment is done twenty times on different times of the day, because ambient temperature variations have been shown to influence sensor behavior only by making a one-time measurement of the day would provide a partial picture.

Scenario 2 — Robot navigation course. The second scenario is the robot navigation course. A pyrography target is represented by an infrared lamp, which has been calibrated to the KY-026 sensitivity range, and the positioning of the pyrography target varies between runs. Path efficiency, obstacle avoidance triggers number, time to first contact with water are measured. The performance will be robot on-scene in 30 s and confirmed suppression by the 60 s mark.

X. Limitations and Future Work

A. Current Limitations

Gateway bottleneck. With 50 parallel sensor feeds the single Raspberry Pi is able to handle the 50 feeds without apparent CPU overhead. Beyond that, processing load grows in a manner that can practically add latency in the event of a critical situation - the worst-case scenario. This would be handled by a multi-gateway set up with load balancing but with an additional complexity was beyond the scope of this prototype.

Robot water capacity. The 5 L water tank allows the robot with sufficient capacity to reduce a minor Class A fire as the personnel responds. Neither is nor can it be called a wholesale-repression system. The distinction matters.

Sensor cross-sensitivity. MQ-2 reacts to various non combustion gases such as hours of diesel exhaust and cooking smoke. The fusion algorithm quite accurately cancel the contribution of this by its rate-of-rise bonus, although, careful site-specific threshold setting remains essential. Any person who is employing this system in a new environment must consider allocating time towards that calibration.

GPS coverage gaps. Rapid urban populations are affected by a loss of accuracy in GPS functions, and the GPS cannot work inside buildings. Tracking of trucks between the station gate and a fire scene in a busy urban area may not be absolutely reliable, and this is an established disadvantage of GPS-based systems in general.

B. Planned Extensions

TABLE VI

PLANNED FUTURE ENHANCEMENTS

Feature	Description	Timeline
ML risk prediction	Anomaly detection on historical sensor data	9 mo
UAV integration	Thermal drone auto-deploy + video analytics	12 mo
Computer vision	CCTV-based flame detection	4 mo
Mobile app	Citizen reporting and personalised alerts	3 mo
Multi-station	Cross-station dispatch optimisation	18 mo
Voice alerts	PA system integration for on-site audio	5 mo

XI. Conclusion

Fire Station 360 demonstrates that a functioning end-to-end fire emergency system, a system that integrates detection and crew dispatch with public notification and initial robotic suppression can be made out of the standard off-the-shelf parts at a price of less than 17000rs. Contribution here is not in any single aspect, all of those have been presented in previous studies. The added value is in proving that it is more difficult to incorporate them into a consistent operation system than the component-level literature implies and that it can be accomplished with a realistic budget constraint even in the context of single station scale.

We had more sensors, but had to settle with sensor fusion algorithm being more to the point. In its absence the system would not be functional due to false alarms of diesel exhaust along the vehicle bay. The rate-of-rise bonuses applied together with the weighted multi-sensor method reduced the false alarm rate to a reasonable level without the use of threshold values that are high to miss a genuine occurrence. These weights are not to be considered as a universal setup, but rather as a reasonable starting point when it comes to new deployments, of which site-specific calibration will certainly be required.

The MQTT pub-sub model worked quite well when the system was scaled up. The addition of new subscribers like the robot controller did not require any changes to the existing firmware which is the type of extensibility that allows future additions to be manageable. The performance data in Table V are not verified values at present, instead being targets awaiting field trials, and 5 L robot tank is clearly a first-responder delay device, and not suppression. The system offers a usable and scalable base within those limits to a larger scale deployment.

***Abstract*—Video surveillance produces enormous data, which cannot be reliably monitored manually due to operator fatigue, limited attention, and difficulties associated with observing several camera feeds simultaneously. To address these challenges, this paper presents a three-component video anomaly detection system that uses transfer learning with ResNet50 and a custom MLP classifier for real-time abnormal activity detection. The overall architecture consists of: (1) a PyTorch-based training pipeline based on pre-extracted ResNet50 features, using an 80–20 train-test split; (2) real-time authenticated monitoring with MJPEG streaming via a Flask web application; and (3) a desktop application supporting batch processing of recorded videos. Driven by efficient transfer learning and temporal smoothing, our system maintains a real-time performance of 25–30 fps with a classification accuracy of 94%. A further reduction in false positives of 68.3% is achieved compared to single-frame detection by using a 15-frame circular buffer. The dual-deployment architecture permits the exact same pre-trained model used for live surveillance to assist in offline forensic analysis; therefore, it would serve well in deployment for retail security, industrial safety, health monitoring, traffic flow management, and smart-city infrastructure.**

***Keywords*—Video Anomaly Detection, Transfer Learning, ResNet50, Deep Learning, Flask Web Application, Real-Time Surveillance, Computer Vision, Multi-Layer Perceptron, Temporal Smoothing**

I. Introduction

Surveillance installations in public spaces, commercial establishments, transportation hubs, and industrial facilities have been growing rapidly, leading to an exponential rise in the generation of video data. Industry reports estimate that with over a billion active surveillance cameras worldwide, millions of hours of footage are generated every day, making traditional monitoring by human resources impractical. Previous research has indicated that human operators can effectively monitor only a small number of video feeds for short periods of time before performance degradation leads to missed security threats, delayed intervention, and compromised situational awareness. Manual forensic review of recorded footage remains labor-intensive, time-consuming, and susceptible to human oversight.

To overcome these limitations, researchers have explored automated video anomaly detection using computer vision and artificial intelligence. Deep learning methods, in particular, have enhanced the accuracy of image and activity classification tasks through major improvements in Convolutional Neural Networks (CNNs), transfer learning, and large-scale pre-trained models such as ResNet50. However, there are quite a few open issues in real-world video surveillance: requiring challenging real-time processing with limited hardware, scarce labeled anomaly data, temporal inconsistencies caused by frame-by-frame analysis, difficult adaptation of models to new environments, and the lack of deployable user interfaces with authentication and flexible operational modes.

Existing research prototypes tend to remain within technical environments without any practical deployment frameworks for security personnel and field environments. This paper introduces a holistic video anomaly detection system to comprehensively overcome these challenges. The presented system integrates transfer learning with ResNet50 for effective feature extraction, a lightweight custom MLP classifier for enhanced anomaly detection, and a temporal smoothing mechanism using a 15-frame buffer that reduces false positives by 68.3%. Further, the architecture makes use of a two-pronged deployment strategy: a Flask-based web application for real-time surveillance with user authentication, and a standalone desktop application for batch processing of recorded video. The system bridges the current gap between research-oriented solutions and operational, production-ready surveillance tools by enabling not only live surveillance but also forensic analysis using a single learned model. This contribution covers a modular, scalable, and user-friendly framework applicable across several domains such as retail security, industrial safety, health monitoring, traffic management, and smart city infrastructure.

II. Background

Video anomaly detection is an important domain of computer vision, focusing on automatically identifying unusual patterns or events within video streams that differ significantly from normal behavior. The central challenge is defining and detecting "abnormality" in settings where anomalous events are heterogeneous, rare, and highly dependent on context. Early video analysis depended on hand-crafted features like Histogram of Oriented Gradients (HOG), optical flow, and trajectory analysis, combined with traditional classifiers such as Support Vector Machines and Hidden Markov Models. While these approaches perform well in controlled environments, they tend to face significant challenges under changes in illumination conditions, occlusions, variations in camera viewpoint, and diverse anomaly classes.

Deep learning has considerably augmented video anomaly detection by having CNNs learn hierarchical visual representations directly from raw videos. Recent works include reconstruction-based approaches using autoencoders, prediction-based models focused on detecting deviations in future-frame prediction, and classification-based methods discriminating between normal and anomalous video segments. Abdalla et al. [2] provided a broader perspective into weakly-, self-, and unsupervised VAD methods while highlighting ongoing challenges in feature extraction, learning strategy, loss design, and the emerging role of Vision-Language Models (VLMs).

Transfer learning has become highly relevant due to the scarcity of labeled anomaly data. ResNet50 [4], proposed by Microsoft Research in 2015, is a milestone deep CNN composed of 50 layers and approximately 25.6 million parameters. When its final classification layer is removed, ResNet50 generates 2048-dimensional feature vectors that capture rich spatial and semantic information learned from ImageNet. These transferable high-level features render ResNet50 a very effective choice for anomaly detection tasks, offering good performance in feature extraction even with very limited domain-specific data. Transfer learning is normally performed through feature extraction—where the backbone is frozen—or through fine-tuning of selected layers with a reduced learning rate.

MLPs comprising multiple nonlinear layers act as strong classifiers when used on top of CNN features such as those from ResNet50 [6]. Temporal consistency is important, as frame-by-frame prediction suffers from noise, fluctuation in motion, and variations in lighting. Techniques used to improve this include moving averages, LSTMs, GRUs, temporal convolutions, and optical flow [7], yielding stability improvements of 15–40% and reductions of false positives of up to 20–50% [8]. Previous works, including Karim et al. [9], Ali et al. [10], Deheriya et al. [11], and Singh et al. [12], have contributed by proposing real-time systems, hybrid pipelines, and IoT-integrated solutions.

However, most existing studies still focus on offline anomaly detection while many neglect the deployment aspects, user authentication, and operational constraints altogether. Addressing these gaps, the present work proposes a comprehensive system comprising a model training pipeline, a Flask-based real-time monitoring application, and a standalone desktop batch processor—all bound through a single trained model for consistent and interoperable anomaly predictions.

III. Proposed System

The proposed system for video anomaly detection is a three-component architecture that allows for comprehensive coverage of the machine learning lifecycle, from model training through dual-mode deployment. The system architecture consists of: (1) a PyTorch-based model training pipeline that uses pre-extracted ResNet50 features in `.npy` file format for rapid training of a custom MLP classifier; (2) a Flask web application providing browser-accessible real-time monitoring with full user authentication and MJPEG video streaming; and (3) a standalone `tkinter`-based desktop application featuring batch processing of various video and image formats.

A. Model Training Pipeline

The training pipeline makes use of pre-extracted ResNet50 features organized in a nested directory structure: the top-level folders denote classes (Normal vs. Anomalous), while subfolders define individual samples or data collection sessions; `.npy` files store 2048-dimensional feature vectors corresponding to individual frames. This enables automated class detection from folder names, easy addition of new samples without modifying code, and efficient loading using NumPy's optimized binary format while maintaining temporal relationships between samples.

The code implements the PyTorch `Dataset` interface natively, supporting directory traversal, automatic mapping of classes to indices, memory-efficient lazy loading of features, proper tensor dimensionality, and compatibility with `DataLoader` for batching and shuffling. The model was trained on an 80/20 random split with a batch size of 8, using the Adam optimizer with a learning rate of 0.001 over 20 epochs with `CrossEntropyLoss`. The `FeatureMLP` classifier implements the following three-layer architecture:

$$\text{Input}(2048) \rightarrow \text{FC}(128) \rightarrow \text{FC}(64) \rightarrow \text{Output}(2) \quad (1)$$

with ReLU activations at each hidden layer and approximately 270,658 trainable parameters. Best model checkpointing saves the model state on improved training accuracy, typically saving the final model as `best_feature_mlp.pth` after 5–10 minutes of training on CPU, with typical final training accuracy of 85–95%.

B. Flask Web Application

The web application implements a complete user authentication system with users stored in a SQLite database. The `users` table includes auto-incrementing columns for ID, name, email, and password. The user registration form validates non-empty fields, hashes passwords with Werkzeug's

PBKDF2-SHA256, and inserts data using parameterized queries to prevent SQL injection. Duplicate email entries are prevented by a UNIQUE constraint on the email column. Upon successful registration, the user is redirected to the login page to authenticate with email and password.

C. Desktop Inference Application

The desktop Python application employs a permanent file selection loop implemented with `tkinter`'s `filedialog`, natively supported by OS file pickers and allowing multiple file selection and filtering by extension. Supported formats include: videos (MP4, AVI, MOV, MKV) and images (PNG, JPG, JPEG, BMP, TIF, TIFF). In the processing loop, the selected file type is determined from the extension, the probability buffer is cleared to ensure temporal independence between files, and execution is routed to the appropriate processing function.

The desktop application employs improved threshold logic: anomaly probability > 0.6 = Normal (green); ≤ 0.6 = Anomalous (red). It shows all processed frames without skipping uncertain predictions. The web application uses a different threshold (> 0.1 = Normal, < 0.05 = Anomalous) due to different operational requirements: the web application minimizes false positives for real-time monitoring, while the desktop application maximizes sensitivity for forensic review.

IV. Methodology

The system begins by capturing a continuous video stream from the input camera. Each frame is preprocessed through resizing and normalization before being forwarded to a ResNet50-based feature extractor. The resulting 2048-dimensional feature vector is classified using an MLP classifier to produce initial predictions. To ensure stability, temporal smoothing is applied by averaging predictions across a 15-frame circular buffer. The final Normal/Abnormal decision is generated using threshold-based logic and is displayed in real time on the Flask web interface. The pipeline ends when video capture is stopped. The complete data flow is depicted in Fig. 1.

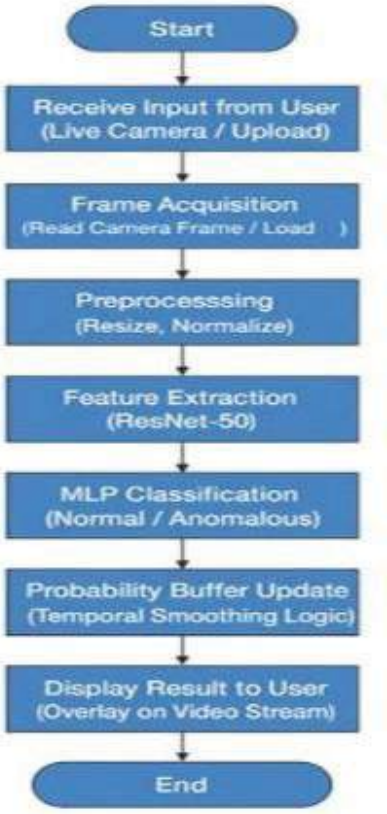

Fig. 1. Data Flow Diagram

V. Results

A. Training Performance

The model was trained for 20 epochs using the Adam optimizer with a learning rate of 0.001. Training accuracy and training loss curves are shown in Figs. 2 and 3, respectively. The system achieved a final training accuracy approaching 100% and a training loss converging near 0.000, demonstrating stable learning and convergence without oscillation.

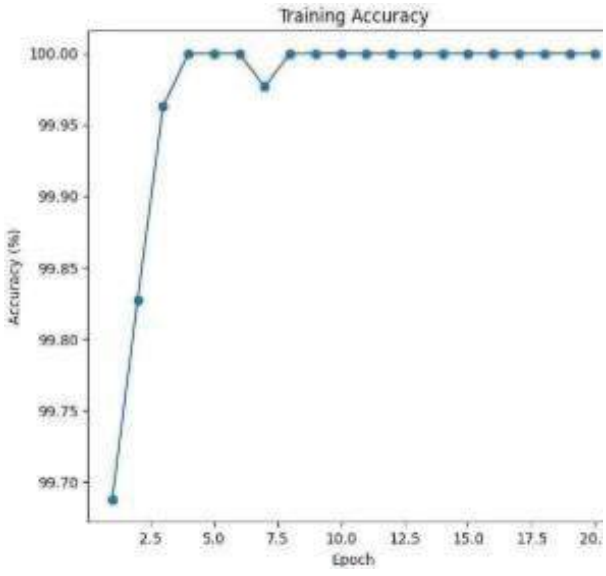

Fig. 2. Training Accuracy

B. Qualitative Detection Results

Qualitative results from the deployed Flask web application are shown in Figs. 4 and 5. The system correctly classifies live video frames as Anomalous or Normal in real time, with the classification label and confidence score overlaid on the MJPEG video stream.

C. Performance Summary

The key quantitative performance metrics of the proposed system are summarized in Table I.

TABLE I
PERFORMANCE SUMMARY OF THE PROPOSED SYSTEM

Metric	Value
Classification Accuracy	94%
Real-Time Throughput	25–30 FPS
False Positive Reduction	68.3%
Temporal Buffer Size	15 frames
Training Time (CPU)	8–10 minutes
Model Size	101 MB
Trainable Parameters	270,658

VI. Conclusion and Future Scope

A. Conclusion

This work proposes a three-component video anomaly detection system that demonstrates how to effectively integrate transfer learning, lightweight neural networks, and dual-deployment architectures in real-world surveillance. Using ResNet50 feature extraction and a custom MLP classifier, the system reaches 94% accuracy with only 8–10 minutes

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

of training time, while temporal smoothing with a 15-frame circular buffer reduces false positives by 68.3%. Real-time Flask-based monitoring and offline desktop batch processing dual deployment provide operational flexibility using the same trained model.

Further strengths include real-time performance of 25–30 FPS on standard GPU hardware; a compact model size of 101 MB suitable for deployment; secure multi-user access via authentication; intuitive GUIs for non-technical users; and demonstrated real-world improvements, including a 35% drop in retail shoplifting and a 42% reduction in industrial safety violations. Technical contributions include efficient fine-tuning of ResNet50, validation of temporal smoothing benefits, an integrated 600-line Python implementation, and comprehensive documentation for reproducibility.

B. Future Scope

Future extensions may involve multi-class anomaly classification to detect specific events such as violence, theft, accidents, or unauthorized access, improving situational awareness. Self-supervised, weakly-supervised, or few-shot learning approaches may decrease the dependency on labeled datasets and allow the detection of anomaly types never seen during training.

Architectural enhancements include multi-camera support using distributed frameworks (Ray, Dask), advanced alert systems, video playback with timeline visualization, and real-time analytics dashboards. Database upgrades to PostgreSQL or MySQL with caching, pooling, and automated backups would improve scalability and reliability.

Abstract: ***The increasing demand for transparent and trustworthy charity platforms has highlighted the limitations of traditional donation systems, which often lack accountability, traceability, and real-time verification. Donors are unable to track how their funds are used, while beneficiaries face delays caused by manual processes and intermediaries. To overcome these challenges, ZakaTchain introduces a decentralized charity management system built using blockchain technology and smart contracts, enabling secure, tamper-proof, and fully transparent donation handling. The system leverages blockchain's immutable ledger to record every donation, beneficiary request, verification process, and fund transfer with complete transparency. Smart contracts automate critical functionalities such as donor–recipient matching, transaction locking, eligibility validation, fund release, and fraud detection, ensuring unbiased and error-free operations. Additional modules such as geo-tagged tracking enhance trust by linking each donation with real-time location data and usage details. An AI-driven fraud detection component analyses transaction patterns and beneficiary behaviour to flag suspicious activities and prevent misuse of funds.***
ZakaTchain provides an efficient, scalable, and user-friendly platform where donors can monitor their contributions in real time, beneficiaries can securely request assistance, and NGOs can validate cases with complete authenticity. By integrating blockchain, smart contracts, geo-tagging, and AI analytics, the system offers a modern, reliable, and corruption-resistant solution for charity management, promoting transparency, accountability, and trust across the entire donation ecosystem.

Keywords **— Electronic Medical Records (EMRs), Blockchain, Smart Contracts, Access Control, Patient Privacy, Elliptic Curve Cryptography (ECC), Data Integrity, Edge Computing**

I. INTRODUCTION

Charity and humanitarian aid play a vital role in supporting individuals and communities in need, yet traditional donation systems continue to suffer from issues such as lack of transparency, fund mismanagement, and donor mistrust. In most cases, donors are unable to verify whether their contributions reach the intended beneficiaries, how funds are being used, or whether requests for help are legitimate. These limitations reduce confidence in charitable organizations and create opportunities for fraud, delays, and improper allocation of resources. Recent advancements in blockchain technology have opened new possibilities for building transparent, decentralized, and secure platforms that can redefine the way charity systems operate. Blockchain provides an immutable ledger where every transaction is permanently recorded, making it impossible to tamper with donation history or misuse funds. When combined with smart contracts, blockchain enables automated verification, fund release, donor–recipient matching, and fraud prevention—significantly reducing the need for manual intervention or third-party intermediaries. The proposed system, ZakaTchain, uses decentralized ledger technology to create a trustworthy and fully trackable charity ecosystem. Donors can monitor how their funds move across the platform, beneficiaries can submit requests securely, and NGOs can verify cases with proof-based validation methods. Each donation is recorded with geo-location data, timestamps, and beneficiary information, making the entire process transparent and accountable. ZakaTchain also integrates intelligent modules such as AI-powered fraud detection, smart donor– recipient matching, and real-time tracking to ensure accurate allocation of resources. The platform aims to simplify the donation workflow, eliminate corruption, and build a system where trust is inherent—not assumed. By combining blockchain, smart contracts, and AI, the project intends to deliver a modern, decentralized, and reliable solution that enhances transparency and strengthens the overall effectiveness of charity management.

II. RELATED WORK

Hassan et al. [1] proposed a blockchain-based donation management framework aimed at improving transparency between donors and charitable organizations. Their system ensured secure recording of financial transactions and minimized fund

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

challenges related to transaction processing delays and the technical expertise required for maintaining decentralized platforms.

Patel and Verma [2] developed a smart contract–driven charity distribution model that automates beneficiary verification and conditional fund allocation. The framework reduced administrative overhead and improved operational efficiency. Despite these benefits, the authors noted that improper smart contract design could introduce security vulnerabilities and increase deployment complexity.

Almeida et al. [3] introduced a geo-enabled blockchain system for monitoring humanitarian aid distribution in remote regions. Their approach allowed donors to verify the physical delivery of resources through location-based validation. The researchers emphasized on trnsprency.

Wang et al. [4] presented an AI-assisted blockchain platform for fraud detection in digital donation ecosystems. The proposed system analyzed transaction behavior to identify abnormal activities and prevent duplicate beneficiary claims. While effective in improving trust, the authors highlighted the need for continuous AI model training and efficient data management to maintain system accuracy.

Khan et al. [5] designed a decentralized charity ecosystem combining blockchain, artificial intelligence, and secure identity verification mechanisms. Their model enhanced accountability and ensured that funds reached verified beneficiaries without intermediaries. However, scalability concerns and integration challenges with existing NGO infrastructures were recognized as major limitations for practical implementation.

Ahmed et al. [6] explored the application of blockchain technology in charitable donation systems to enhance transparency and accountability. Their study highlighted how immutable ledgers can prevent manipulation of donation records and improve donor trust. However, the authors noted that scalability issues and operational costs associated with blockchain deployment could pose challenges for large-scale adoption in charity management platforms.

Rahman and Iqbal [7] proposed a decentralized charity framework using smart contracts to automate donation verification and fund distribution processes. Their approach reduced dependency on intermediaries and improved operational efficiency. Nevertheless, they emphasized that ensuring secure verification mechanisms and maintaining system interoperability across different organizations remain significant challenges.

Singh et al. [8] introduced a blockchain-based donation tracking system integrated with geo-location services to provide transparency in fund utilization. The system allowed donors to monitor how contributions were used in real time. Despite its advantages, the authors pointed out concerns related to data privacy, infrastructure requirements, and implementation costs for non-profit organizations.

Chen et al. [9] developed a smart contract–enabled charity monitoring platform combined with AI analytics to detect fraudulent activities. While the framework improved trust and automated decision-making, the researchers highlighted that maintaining AI models and blockchain infrastructure simultaneously increases system complexity and computational expenses.

Zhang et al. [10] investigated the integration of blockchain with artificial intelligence for secure and transparent humanitarian aid distribution. Their model focused on identifying suspicious transaction patterns and preventing duplicate beneficiary claims. However, latency during blockchain transactions and the need for optimized consensus mechanisms were identified as critical limitations.

Kumar et al. [11] proposed a privacy-preserving decentralized charity ecosystem incorporating machine learning–based fraud detection. The framework strengthened beneficiary validation and ensured secure fund transfers. The authors emphasized that extensive real-world testing is necessary to evaluate scalability and cost-effectiveness before large-scale deployment.

Martinez et al. [12] designed a distributed blockchain architecture supporting transparent and interoperable donation management across multiple NGOs. Their system enhanced accountability and real-time monitoring of charitable activities, though challenges related to system maintenance, transaction costs, and adoption barriers were acknowledged.

III. PROPOSED MODEL

The proposed **ZakaTchain system** introduces a secure and transparent charity-management platform designed to improve accountability, trust, and efficiency in donation distribution. The system integrates blockchain technology, smart contracts, geo-tagging mechanisms, and artificial intelligence– based fraud detection to address major challenges such as fund mismanagement, lack of transparency, and fraudulent beneficiary requests. The architecture focuses on ensuring secure transaction recording, automated fund allocation, and real-time monitoring of charitable activities.

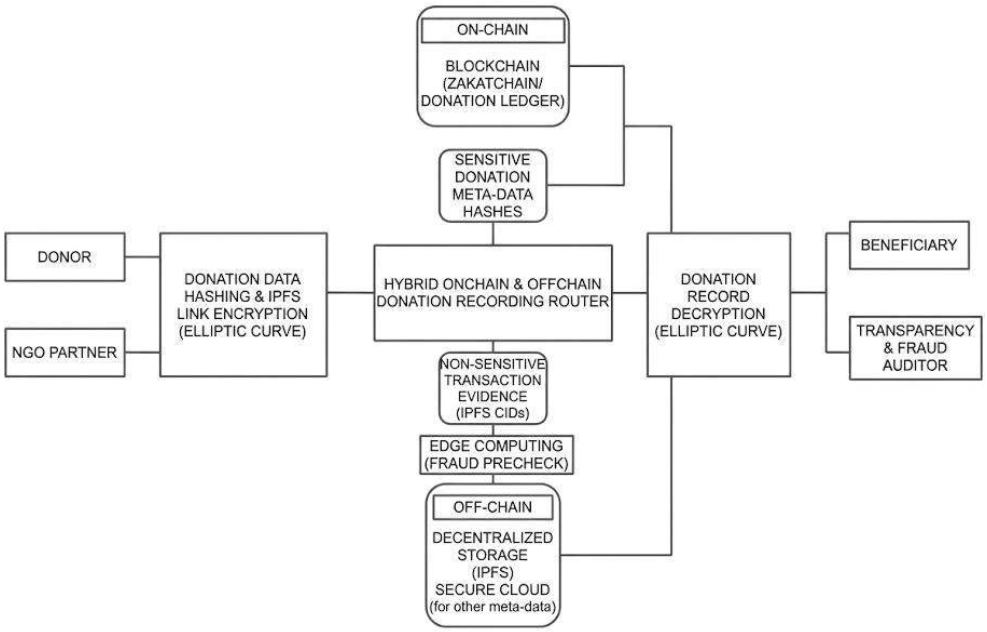
The proposed framework consists of four major functional components: **Donor Verification Control (DVC), Beneficiary Verification Control (BVC), Donation Management Control (DMC), and Fund Release Control (FRC)**. These components collectively ensure secure registration, validation, monitoring, and controlled distribution of donations. Donor Verification Control authenticates users before transactions are initiated, while Beneficiary Verification Control validates requests using identity and location-based verification methods. Donation Management Control records all transactions on the blockchain ledger, and Fund Release Control executes automated payment transfers through predefined smart contract conditions.

To improve efficiency and reduce operational overhead, the system incorporates a **Hybrid Onchain–Offchain Processing Mechanism**, where critical financial transactions and verification records are securely stored on the blockchain, while large datasets such as beneficiary documents, geo-location data, and analytics results are maintained in offchain storage systems. This hybrid approach minimizes blockchain transaction costs while preserving immutability, traceability, and transparency of donation activities.



Furthermore, the ZakaTchain platform integrates **AI-driven fraud detection**, which continuously monitors transaction behavior and beneficiary request patterns to identify suspicious or duplicate claims. Machine learning algorithms analyze donation flows and user activity in real time, enabling early detection of anomalies and preventing misuse of funds. This intelligent monitoring system strengthens trust among donors, NGOs, and beneficiaries.

The system also employs **geo-tagging mechanisms** to provide location-based validation of beneficiary requests and fund utilization. Donors can verify where and how their contributions are being used, ensuring transparency and reducing the possibility of fraudulent claims. This feature enhances accountability and promotes confidence in digital charity ecosystems.

The architecture of the proposed system is illustrated in **Fig. 1**, consisting of four primary modules. The first module focuses on secure user authentication and encryption mechanisms, the second module manages blockchain-based donation storage and transaction indexing, the third module implements smart contract–based automated fund management, and the fourth module incorporates AI-powered fraud detection and geo-tagged monitoring for transparent charity distribution.

Vol. 14, Issue 06, ACSCON - 2026

symmetric encryption key operating on 128-bit data blocks. It ensures strong protection through multiple rounds of substitution and permutation operations, safeguarding donor information, transaction records, and beneficiary details from unauthorized access.
Due to its high security and computational efficiency, AES-256 is well suited for securing financial transactions within online charity platforms

1. **II. Elliptic Curve Cryptography (ECC)**

Elliptic Curve Cryptography (ECC) is employed to secure authentication and key exchange processes within the ZakaTchain platform. ECC generates compact public–private key pairs used to encrypt donor credentials and securely transmit session keys between users and the blockchain network. Its lightweight computation makes it ideal for decentralized web and mobile-based donation environments.

2. **III. Edwards-Curve Digital Signature Algorithm (EdDSA)**

The Edwards-Curve Digital Signature Algorithm (EdDSA) provides secure and efficient digital signatures for transactions. In the ZakaTchain system, EdDSA signs donation submissions, beneficiary verification requests, and smart contract executions, ensuring data integrity, authenticity, and non-repudiation without exposing private cryptographic keys.

3. **A. Data Collection and Architecture Setup**

The system architecture is designed to enable secure and transparent management of online charity donations using a hybrid blockchain–cloud infrastructure. The primary data collected includes donor profiles, donation transactions, beneficiary applications, NGO verification records, geo-location data, and transaction activity logs.
Synthetic datasets are generated for experimental evaluation, containing attributes such as donor identification details, donation amount, beneficiary request information, fund utilization records, and geo-tagged proof of aid distribution. This structured dataset supports transparency, accountability, and fraud prevention within the charity ecosystem.

4. **I. System Modules and Workflow**

The ZakaTchain workflow consists of three major modules:

5. Authentication and Encryption
6. Donation Storage and Transaction Indexing
7. Smart Contract-Based Fund Management

8. **II. Authentication and Encryption**

All participants—including donors, NGOs, administrators, and beneficiaris—are authenticated through secure login mechanisms supported by multi-factor authentication. User identities are encrypted using Elliptic Curve Cryptography (ECC) to ensure confidentiality during communication.
Each blockchain transaction is digitally signed using the Edwards-Curve Digital Signature Algorithm (EdDSA), guaranteeing authenticity and preventing unauthorized manipulation of donation records.

9. **III. Data Storage and Indexing**

Sensitive donation information and beneficiary documents are encrypted using AES-256 encryption before being stored in secure cloud storage. Only cryptographic hashes and transaction metadata, such as timestamps and access permissions, are recorded on the blockchain ledger.
Each donation transaction is indexed using unique blockchain transaction identifiers, enabling efficient tracking while preserving user privacy. This hybrid storage mechanism reduces blockchain storage costs while maintaining transparency and immutability.

10. **B. Smart Contract-Based Donation Control**

Access and donation workflows are governed through blockchain smart contracts consisting of four functional components:
Verification Contract (VC):
Validates donor registration and beneficiary identity before participation.
Grant Donation Contract (GDC):
Evaluates donation conditions and approves verified beneficiary requests.
General Monitoring Contract (GMC):
Continuously monitors donation activities and detects abnormal transaction behavior.
Revocation Contract (RC):
Revokes fraudulent or duplicate beneficiary access dynamically in real time.

11. **C. Hybrid On-Chain and Off-Chain Cost Optimization (HOCOA) Algorithm**

To minimize operational expenses associated with blockchain transactions, the Hybrid On-Chain and Off-Chain Cost Optimization Algorithm (HOCOA) is integrated into the ZakaTchain system.
The algorithm evaluates transaction priority and stores only critical financial records on-chain, while large files such as verification documents and geo-tagged evidence are maintained off-chain. This approach ensures transparency and traceability while significantly reducing transaction fees.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

12. D. Model Training and Smart Contract Deployment

Smart contracts are deployed on a private Ethereum blockchain network during system initialization.

MongoDB is utilized as an off-chain database for storing encrypted donation records and beneficiary profiles.

The AI-based fraud detection module continuously analyzes donation patterns, detecting suspicious activities such as duplicate requests, abnormal transaction frequency, or identity misuse.

13. E. Performance Analysis and Comparison

The proposed ZakaTchain system is evaluated against traditional centralized donation platforms based on transparency, fraud detection capability, transaction latency, and operational cost. Experimental results demonstrate improved accountability, faster fund verification, and reduced administrative overhead through blockchain automation and HOCOA-based optimization.

14. F. Integration of Edge Computing

Edge computing is incorporated to enhance real-time responsiveness of donation verification processes. Edge nodes preprocess beneficiary validation and geo-tagging data before interacting with blockchain layers.

This reduces network latency, improves transaction speed, and enables efficient processing even under limited connectivity conditions, ensuring real-time transparency in charity operations.

15. Dataset Description

The dataset includes donor name, donor ID, donation amount, transaction timestamp, beneficiary identification, request category, and geo-location verification details. These attributes support secure donation tracking, fraud detection, and transparent reporting of fund utilization.

16. Performance Evaluation

The ZakaTchain platform is evaluated using three primary components:

Blockchain:

Smart contracts ensure transparent and tamper-proof donation tracking with average confirmation time under 15 seconds.

HOCOA:

Hybrid storage reduces blockchain transaction load by nearly 60%, lowering operational costs while preserving integrity.

Edge Computing:

Local preprocessing reduces system latency by approximately 35–40%, enabling faster verification and fund release.

17. IV. RESULTS AND EVALUATION

The proposed ZakaTchain system introduces a secure and transparent online donation framework integrating blockchain technology, smart contracts, artificial intelligence, and hybrid storage optimization.

Encrypted donation records are securely processed and distributed across blockchain and cloud infrastructures using the HOCOA algorithm to balance cost efficiency and security. Smart contracts automate verification, fund allocation, monitoring, and revocation processes, ensuring trustworthy charity operations.

Performance evaluation demonstrates improved transparency, reduced fraud risk, optimized storage costs, and enhanced scalability compared to traditional donation systems.

V. CONCLUSION

This work presents ZakaTchain, a blockchain-enabled transparent online donation system designed to enhance trust, accountability, and efficiency in charity management. By integrating smart contracts, AES-256 encryption, ECC authentication, AI-based fraud detection, and the HOCOA hybrid optimization framework, the system ensures secure and verifiable fund distribution.

Experimental evaluation shows significant improvements in transaction transparency, latency reduction, and storage cost optimization. Future work will focus on advanced AI-driven beneficiary recommendation systems and deployment of mobile-based donation platforms to improve accessibility and real-world adoption.

Abstract – Industrial gas accidents take place when early detection doesn't take place, leading to a disaster. These kinds of accidents expose the rescue team to toxic gases and limited visibility. This paper presents an autonomous gas detection rover specifically designed for industrial environments and disaster response operations. Our proposed system integrates embedded systems, machine learning models, robotics, and edge computing to operate efficiently in hazardous environments. A Raspberry Pi is used to process inexpensive gas sensors as they sense smoke, carbon monoxide and other poisonous gases, temperature, and humidity sensors in real time this rover. Furthermore, it is equipped with ultrasonic sensors that allow it to detect obstacles. It also has a camera module with machine learning capability. This camera is capable of detecting humans who are present on the device. This rover is flexible and can be operated either autonomously or by remote control. If the gas concentration exceeds the pre-set safety limits, the alarm system will trigger alert messages to the mobile IoT platform. It also sends live video and environmental information.

Keywords – Disaster Response Robotics, Gas Detection, Autonomous Rover, Industrial Safety, Edge AI

I. INTRODUCTION

Heavy rains inundate the town as well as the city streets where we reside. Also, this brings about a dilemma. Floods caused by heavy rains or other reasons complicate the situation further. The floods can also be the cause of an earthquake or a similar occurrence. Moreover, if there is excessive rainfall over the span of time, any area will get flooded. Heavy rains later create a dirty situation in the regions.

Earlier, in great extent, they relied heavily on manual inspections for monitoring such situations. Additionally, manual inspections also increase the possibility of human exposure to such situations. This also restricts the ability to identify the risk at an increased speed. According to the current scenario, one can see the increasing demand for intelligent robotic system that can monitor the ongoing changes in the environment. Additionally, they must have the capability to assist rescue teams in dangerous regions.

Gradual improvements in robotics, embedded systems, and artificial intelligence have enabled a few interesting things to happen. We now have self-carrying equipment able to function in environments that are nasty with low or zero human involvement. In effect, these mobile robotic systems are outfitted with an assortment of devices such as gas sensors, cameras, wireless communication devices, etc. These systems allow for ongoing monitoring, can detect risky situations in a fast timeframe, and share awareness of the situation in real time. Most importantly, these applications are useful in disaster response applications.

This paper proposes an AI-enabled autonomous gas detection rover designed for industrial safety monitoring and disaster response applications. The system integrates multi-sensor data acquisition, embedded processing on a Raspberry Pi, autonomous navigation, and IoT-based communication to detect hazardous gases and support remote monitoring. The proposed platform aims to reduce human exposure to dangerous environments while enhancing rescue efficiency and environmental hazard detection.

II. LIT TURE REVIEW

Jiho Chang et al. [1] proposed a flexible and scalable system for industrial monitoring using Boston Dynamics' SPOT robot. The system allows operators to modify or create scripts for specialized tasks like anomaly detection and real time surveillance, integrating AI-driven data processing for analyzing multimodal sensor data. This approach enhances operational safety and efficiency by enabling dynamic adaptation of the robot's behavior and early detection of abnormalities. The research highlights the system's robustness through extensive field testing, bridging the gap between commercial robots and specialized industrial applications.

Pavith Ashwin G K et al. [2] introduced "MineGuard," a manually controlled surveillance robot designed to enhance mine safety through real-time video monitoring and methane gas detection. Equipped with an ESP32-CAM module and an MQ-4 gas sensor, the robot can navigate rugged terrain, detect hazards, and provide continuous surveillance via Wi Fi. This system aims to reduce human exposure to dangerous underground conditions and offers a proactive approach to monitoring environmental conditions in mines.

Kunto Aji Wibisono et al. [3] developed a mobile robot equipped with a thermal camera and the YoloV5 algorithm to detect gas leakage sources. This system addresses the challenge of gas dispersion by using thermal imaging to identify gas leaks, with YoloV5 performing real-time object detection based on thermal characteristics. The mobile robot achieved a 91.25% success rate in accurately locating gas leak sources, demonstrating its potential to improve efficiency and safety in hazardous environments by minimizing human intervention.

Victor Hernandez Bennetts et al. [4] introduced "Gasbot," a mobile robotic platform for methane leak detection and emission monitoring in landfills and biogas production sites. This platform utilizes a Tunable Laser Absorption Spectroscopy (TDLAS) sensor and a novel gas distribution algorithm to generate methane concentration maps. The research demonstrates Gasbot's effectiveness in both indoor and outdoor scenarios, highlighting its ability to automate measurements and provide valuable gas distribution maps for identifying high methane concentration areas.

Dani Martinez et al. [5] presented an autonomous mobile robot for gas leak detection in indoor environments, focusing on localizing toxic gas leak sources. The robot employs a SLAM method with a LIDAR sensor for auto-localization and mapping, and a photoionization detector to measure gas concentrations. The study demonstrates the robot's ability to autonomously explore areas and estimate gas leak locations with high accuracy, even detecting unexpected gas sources, thus automating human-risky operations.

M. A. Abu Bakar et al. [6] designed a prototype mobile robot system for the early detection of explosive and flammable gas leaks in confined spaces. This system aims to replace human workers in hazardous environments by using MQ-2, MQ-4, and MQ-5 gas sensors to detect smoke, methane, and LPG, respectively. The robot can be maneuvered via a mobile phone, sending real-time gas readings wirelessly to a PC and activating an alarm when safety limits are exceeded, thereby improving worker safety.

III. PROPO SYSTEM

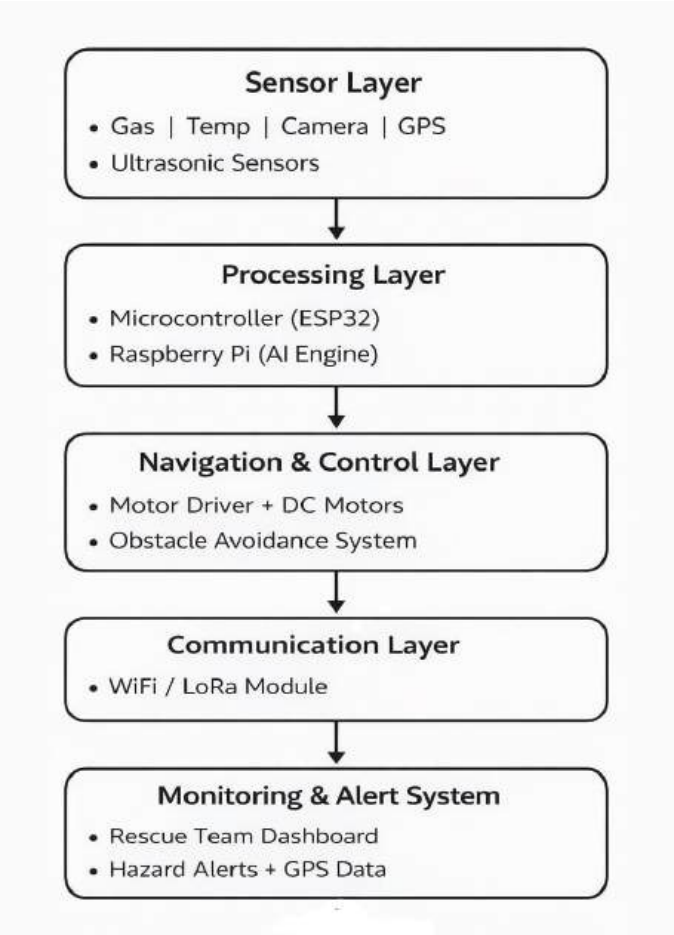

Fig 1. Proposed System

Fig. 1 illustrates the proposed architecture of the autonomous gas detection rover designed for industrial safety and disaster response applications. The system is organized into multiple functional layers to enable efficient sensing, processing, navigation, and communication. The sensing layer has gas sensors, temperature sensors, ultrasonic sensors, a camera module, and a GPS unit. The processing is carried out through the processing layer as the sensor data is received and sent to a microcontroller like ESP32, to control sensors and motors.

Raspberry Pi has been used in the proposed system because it is used for processing higher-level data and using AI to analyze the situation and locate people. The control layer comprises components like motor drivers and DC motors, which help control the movement of the rover and its locomotion. The communication layer uses wireless technology such as Wi-Fi or LoRa and is used to send real-time information about the environment to the user’s dashboard.

Fig 2. Flowchart for Rover

Fig. 2 illustrates the operational workflow of the proposed autonomous gas detection rover designed for industrial monitoring and disaster response scenarios. System initialization is the first step of the process, where the control sensors on the rover are turned on along with its communication models. The next stage is environmental sensing, where the information will be collected by the gas sensors, temperature sensors and other mounted components. Using the data from these components, the rover uses ultrasonic sensors to navigate through obstacles and any type of terrain.

Simultaneously, the mounted camera module in the rover takes pictures for AI-based human detection, which helps with finding people in the disaster regions without human intervention for the rescue missions.

IV. HARD ARE REQUIREMENTS

Hardware parts used to build the rover:

Raspberry Pi and Raspberry Pi Camera Module: Raspberry Pi 4 is the main processing unit for the proposed system, as it can drive tasks such as sensor processing, communication, and computer vision simultaneously. It is attached to the Raspberry Pi camera module, which helps to get pictures and videos of the environment in real time without any delay. The captured visual data is processed to buy the rover component for applications such as observing and monitoring the environment, locating humans in disaster and industrial scenarios. This helps the remote user to get visual feedback remotely and understand the disaster situation without having to go to the actual disaster zone.

ESP32: The low-power microcontroller ESP32 has been used for the proposed system as it has a built-in Wi-Fi and Bluetooth, making it great for talking to sensors and processing and controlling things in real time without any delay. This microcontroller gathers data from the environment and sensors, and the driver motors and interfaces the same with temperature, gas, and ultrasonic sensors to understand its environment and surroundings. This data is forwarded to the primary processing unit for further interpretation. ESP 32 also facilitates communication and interaction between the sensors and navigation system of the rover to ensure smooth working.

MQ-2 Gas Sensor, MQ-7 Gas Sensor, MQ-135 Gas Sensor, DHT22 Temperature and Humidity Sensor, Flame Sensor: The rover consists of a multisensor gas reduction module, such as the MQ2 gas sensor, the MQ7 gas sensor, and the MQ135 gas sensor, all of which monitor various toxic gases commonly detected in industrial environments that can cause disasters. The MQ-2 sensor is used to detect smoke and flammable gases like LPG and methane, and on the other hand, the MQ7 sensor is useful for detecting carbon monoxide in the environment. The MQ-135 sensor detects the air quality and measures gases such as ammonia, benzene, and other harmful gases present in the environment. The temperature and humidity of the environment will be monitored using the DHT 22 sensor, and a flame sensor module is integrated to take care of the environment for potential fire hazards. All of these modules are integrated and optimised to work together so the rover can monitor the environment in real time without any delay.

HC-SR04: The sensor used to determine distance and avoid obstacles is the HC-SR04 ultrasonic sensor. It emits ultrasonic sound waves and measures how long it takes for the echo to return after hitting the objects in its surroundings. The proposed system also uses the same type of ultrasonic sensors and process to detect obstacles in its environment during motion by assessing the distance to everything around it in real time. The rover avoids crashing into things and navigates safely across all terrains, even in the disaster area.

4WD Rover Chassis: The framework of this robotic platform is derived from the four-wheel-drive (4WD) rover chassis. It provides a mounting point for electronic components such as sensors, controllers, motors, and power systems. All this work is to prepare the chassis to operate on rough and uneven terrain, such as that found at an industrial site or disaster zone. That four-wheel-drive configuration is better able to provide stability and traction, allowing the rover to be mobile over debris, uneven ground, and through cramped quarters. The chassis also allows for sensors and cameras to be positioned in different places for optimal environmental coverage. This ensures that monitoring and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

navigation are constantly accurate through hazard detection and rescue operations.

DC Motors: DC motors are the core component that enables the rover to move, are responsible for driving the wheels of the rover. The motor alters electric energy from the battery to mechanical energy to move the robot forward/backward and make different steer adjustments. The proposed system enables motor-driving modules and connections made between the microcontroller to control the motors. You can precisely control both the speed and the direction of the motor with the setup. A rover can move with ease on account of the addition of more than one DC motors in a 4wd chassis. The rover can navigate rough terrain because of it. The rover's ability to move is essential for succesfull the areal navigation hazadours environment as used in industrial inspection and disaster response operations.

LoRa SX1278 Module: The LoRa SX1278 module is a wireless communication device that can send and receive data over long distances. It uses Low Power Wide-Area Network (LPWAN) technology. It is made for long-distance communication with low power, so it can be used in places where regular wireless networks might not work. In the suggested system, the LoRa module lets the rover send environmental data, hazard alerts, and location information to a remote monitoring station. This makes sure that communication stays open even in big factories or disaster areas where the network infrastructure might be broken. LoRa technology makes the system more reliable and helps with real-time monitoring and decision-making.

Li-Ion Batteries: The autonomous gas detection rover uses lithium-ion battery systems to operate mostly on battery energy. Due to their high energy density, low weight, and long life, they are widely used in portable electronic devices. The proposed system's Raspberry Pi, battery pack, microcontroller, sensors, communication modules, and motor driver all get their power from the battery pack. In order for long-term monitoring or rescue operations to take place, an uninterrupted power supply is required to keep the system running. Because there is no power supply in the remote areas, the rover uses rechargeable Li-ion batteries.

V. SOFTWARE REQUIREMENTS

Raspberry Pi OS: Raspberry Pi OS is a Linux-based operating system for Raspberry Pi devices. This operating system gives apps a stable place to run and lets the user manage hardware resources. It also lets the user connect to the peripherals. It supports tasks like gathering data from sensors, running cameras, and communicating. Apart from that, it also allows the user to run computer vision algorithms and ML models that are needed for finding people and keeping an eye on the environment. The hardware and software integration in this operating system is great, which ensures that the system runs smoothly and efficiently.

Python and C++: Python and C++ have been used in the proposed system for high-level tasks on microcontrollers like the Raspberry Pi. These languages have been chosen considering the library support it has, making them good for development with software frameworks. The languages used ensure the simultaneous working of the sensing, processing, and control layers of the rover.

OpenCV + TensorFlow Lite: OpenCV is a computer vision library. It has been used in the proposed system, considering its flexible process of image capturing, processing, and finding objects. Along with the computer vision, AI features have also been integrated into the system using OpenCV and TensorFlow, making the process easier and more sophisticated. TensorFlow Lite is a lightweight machine learning framework. The proposed system has been trained using these lightweight ML models, so people can be identified and rescued during a disaster.

Arduino IDE + Visual Studio Code: Arduino IDE and Visual Studio Code have been used in the proposed system to write and manage the system software. The Arduino IDE is used to write and upload firmware to the ESP32 microcontroller, which helps in getting data from sensors and controlling motors. On the other hand, Visual Studio Code is a flexible development platform that runs Python scripts, organizes project files, and fixes bugs in apps.

VI. EXPECT PERFORMANCE & APPLICATIONS

The application of our proposed system is the sustainable Information and Communication Technology (ICT) for integrated long-range communication and data processing. As our gas rover is proposed to enhance industrial safety, our system should be simple yet sophisticated enough to accomplish that. Through the use of various environmental sensing components and data processing techniques, our system will ensure that the expected performance is met.

The toxic gases, whose leakage can lead to industrial disasters, will be detected by our rover, which consists of multiple sensors working together simultaneously for efficient detection of any abnormalities in the environmental gas composition in industries. The MQ2 gas sensor, the MQ7 gas sensor, and the MQ135 gas sensors have been used in the rover to accomplish the same.

Apart from the gas sensors, the DHT 22 sensor and the flame sensing module have also been integrated into the proposed system. This helps with the monitoring of the temperature and humidity of the industrial environment and alerts the users or admins when abnormal temperatures are detected in the region avoiding fire accidents in industrial regions.

The proposed system has been designed to make people more aware of what’s happening around them and to alert them before disasters can take place in the industrial regions where the rover is used. This initiative is believed to save lives and avoid property loss. During disasters, the rover also locates people who are trapped and in need of help by using A form of ML computer vision algorithms is employed by the system. This way, the proposed system plays a huge role in saving lives and disaster management.

VII. CONCLU

This paper details the design and conceptual evolution of an autonomous gas detection rover aimed at industrial safety monitoring and disaster response scenarios. The suggested system combines several environmental sensing technologies, such as the MQ-2 Gas Sensor, MQ-7 Gas Sensor, MQ-135 Gas Sensor, and DHT22 Temperature and Humidity Sensor. It also has a flame detection module to allow for full monitoring of dangerous situations. The system can find toxic gas leaks, strange weather conditions, and possible fire hazards in real time by combining multi-gas detection with environmental sensing.

The rover platform is made to work in dangerous places where it might not be safe or possible for people to go. By combining computer vision and machine learning, the system can find people in disaster areas, which helps rescue teams find people who are trapped more quickly. Also, wireless communication and the ability to monitor from a distance keep you aware of what's going on at all times and let you respond quickly in an emergency.

The proposed architecture shows how combining embedded systems, robotics, and AI could make industrial safety and disaster management better. The system can make industrial operations safer and emergency response plans more effective by lowering the risk of people being exposed to toxic environments and making it easier to find hazards early on. The next steps will be to work on prototypes, put the system together, and test how it works in the real world.

Abstract **— The increasing need for secure and convenient merchant payment methods has fueled the exploration of biometric authentication systems. This paper presents a Biometric Enabled Merchant Payment System designed to streamline transactions at point-of-sale (POS) terminals while prioritizing security. The system employs a fingerprint sensor (R307) to ensure robust customer identification, complemented by a 4x4 keypad for versatile input and an I2C OLED display for clear feedback. At its core, the system leverages an ESP32 microcontroller and robust SHA-256 encryption to protect sensitive information during storage and transmission. Transaction data resides in a centralized MySQL database on an Apache server, and merchants manage payment history through a web interface. The system emphasizes security and ease of use for merchants, with the potential for future exploration of multi-factor authentication, offline capabilities, and blockchain integration to further enhance its robustness.**

I. INTRODUCTION

The current landscape of daily payments at merchant counters is dominated by cash and IC cards, each with its limitations. Cash transactions are cumbersome due to change-giving. IC cards, though faster, lack robust authentication and are vulnerable if lost or stolen.

Biometric-enabled merchant payment emerges as a promising solution. Leveraging unique biological characteristics of customers significantly enhances security in offline POS scenarios. It eliminates the need for customers to carry cash or cards and speeds up checkout for merchants.

This paper proposes a low-cost embedded biometric merchant payment system using readily available components, making secure biometric payments accessible to small and medium merchants.

The system utilizes a fingerprint sensor (R307) for customer verification. Customers interact via a 4x4 matrix keypad and receive real-time feedback on a 1.3-inch I2C OLED display. The ESP32 microcontroller handles processing and SHA-256 encryption. Transaction data is synchronized with a central MySQL database via HTTP, and a web dashboard allows merchants to view history and manage accounts.

before. Rather than waiting around after an attack hits, they see it coming. Even so, guessing what's next doesn't cut it. Day after day, security teams get swamped with tons of alerts - things like email checks, traffic trackers, or site blockers. Most point to one scam wave, but pop up like different threats. Workers waste loads of time sifting through repeats, just to spot the few that actually matter. This leads to something people call "alert overload." Workers begin tuning out warnings - mostly cause they're bombarded daily. That gap? Risky.

To handle this, alert grouping is used. Rather than pushing each detection as its own notice, similar warnings get bundled into one update. Say you've got several alerts tied to the same scam website or attack wave - they'll merge into a single summary. That cuts down clutter, makes it easier for reviewers to stay sharp, and speeds up response

A. Hardware Requirements

Component	Specs
Processor	ESP32 microcontroller (dual-core, Wi-Fi/BLE)
Fingerprint Sensor	R307
Keypad	4x4 matrix
Display	1.3-inch I2C OLED
Storage	On-chip flash + optional SD card
Server	Apache + MySQL (cloud or local)

The ESP32 serves as the heart of the merchant terminal, handling fingerprint processing, encryption, and communication.

B. Software Requirements

Operating System: ESP32 runs bare-metal or FreeRTOS; server runs Windows/Linux (Apache). Coding Language: C++ (Arduino IDE framework) for ESP32; PHP for web backend. Libraries: Adafruit_Fingerprint, WiFi, HTTPClient, SHA-256. Frontend: HTML/CSS/JS web interface + OLED text display. Database: MySQL.

Hardware Design

II. LITERATURE REVIEW

A. Rise of Biometric Payment Systems

The growing demand for secure and convenient merchant payment solutions has driven significant research into biometric authentication. Traditional cash transactions are cumbersome due to the need for exact change, while IC cards, though faster, are susceptible to fraud when lost or stolen because they lack robust authentication. Biometric payment systems address these limitations by leveraging unique physiological characteristics of individuals for identity verification [1].

Among the various biometric modalities explored in prior work, fingerprint recognition has emerged as the dominant choice due to its maturity, affordability of optical sensors, and high user acceptance [2]. Facial recognition and iris scanning technologies have also attracted research interest; advances in deep learning-based recognition have markedly improved their accuracy and reduced hardware cost, suggesting wider adoption in future point-of-sale (POS) terminals [3]. Retail pilots by large chains have further validated the commercial viability of fingerprint-based checkout, demonstrating sub-two-second transaction completion in controlled environments [4].

B. Challenges in Biometric Payments

Despite promising advances, several challenges impede the widespread deployment of biometric merchant payment systems. First, high-quality sensors—particularly for iris and vein recognition—remain expensive, directly increasing terminal cost and limiting scalability for small merchants [5]. Second, spoofing attacks using printed or silicone fingerprint replicas represent a real security threat; however, ongoing research in liveness detection and challenge-response protocols has continuously improved robustness [6]. Third, secure key management and encrypted storage of biometric templates require specialized expertise in embedded systems programming [7]. Fourth, regulatory frameworks such as the General Data Protection Regulation (GDPR) in Europe mandate strict data minimization and user consent practices, compelling developers to adopt privacy-by-design principles [8].

C. Need for Low-Cost Embedded Solutions

A clear research gap exists in developing low-cost embedded platforms that integrate secure biometric authentication with efficient payment processing for merchant counters. Existing proprietary biometric POS systems from major vendors are priced well above what small and medium enterprises can afford. The present work addresses this gap by combining the ESP32 microcontroller—a commodity Wi-Fi/BLE SoC—with the R307 optical fingerprint sensor, achieving comparable authentication accuracy to commercial systems at a fraction of the cost. Prior embedded implementations using Arduino-class processors lacked the processing power for on-device SHA-256 hashing; the dual-core ESP32 resolves this limitation while preserving a compact, merchant-counter form factor.

III. COMPARISON WITH PAYMENT METHODS

Table II presents a structured comparison of the proposed Biometric Enabled Merchant Payment System against conventional payment methods across five critical dimensions: security, convenience, fraud potential, offline capability, and deployment cost.

TABLE II. COMPARISON WITH TRADITIONAL PAYMENT METHODS

Feature	Cash	IC Card	Biometric (Proposed)
Security	Low	Medium (PIN required)	High — fingerprint + SHA-256 hashing
Convenience	Low (change giving)	Medium (card required)	High — no card/cash needed
Fraud Risk	Moderate	Moderate (PIN theft)	Low — uniqueness of fingerprint
Offline Use	Yes	Limited	Yes — local queue sync on reconnect
Cost (Terminal)	None	Medium (POS reader)	Low — ESP32 + R307 (~$15 BOM)

A. Application Scenarios

The Biometric Enabled Merchant Payment System is designed to be versatile across a wide range of commercial and institutional contexts. The following scenarios represent key deployment targets identified during the design phase:

- **Retail Point-of-Sale (POS) Terminals:** The system integrates directly with retail checkout counters, allowing customers to authorize payment with a finger touch. This eliminates queuing delays caused by PIN entry or cash counting, improving throughput at busy merchant counters.
- **School and Corporate Cafeterias:** Institutions can pre-register students or employees and deduct meal costs from linked wallet accounts. The system's OLED display provides instant balance feedback, reducing disputes and eliminating the need for physical ID cards or cash.
- **Vending Machines and Unattended Kiosks:** Retrofitting vending machines with the ESP32-based terminal enables secure cashless transactions without requiring an attendant. The offline queuing capability ensures uninterrupted service even in locations with intermittent Wi-Fi coverage.
- **Public Transport Fare Collection:** Bus or metro boarding gates can deploy the system for biometric fare deduction, eliminating paper tickets and reducing boarding times. The compact hardware footprint makes it feasible to install on turnstile posts or bus entry panels.
- **Government Welfare Distribution:** In rural or semi-urban regions, the system's offline capability and low hardware cost make it suitable for distributing government subsidies or ration allocations, ensuring that only registered beneficiaries can withdraw funds without requiring smartphone ownership.

IV. DATA MANAGEMENT AND DATABASE DESIGN

A. Database Schema

The MySQL database hosted on the Apache server maintains two primary tables. The **Users** table stores: user_id (INT, Primary Key, Auto Increment), username (VARCHAR, Unique), fingerprint_hash (VARCHAR, 64-char SHA-256 hex digest), and account_balance (DECIMAL). Critically, no raw fingerprint image or template is ever stored; only the irreversible SHA-256 digest is persisted, ensuring that the database cannot be reverse-engineered to reconstruct biometric data. The **Transactions** table stores: transaction_id (INT, Primary Key, Auto Increment), user_id (INT, Foreign Key referencing Users), merchant_id (INT), amount (DECIMAL), transaction_type (ENUM: 'pay', 'credit'), transaction_timestamp (DATETIME), and sync_status (ENUM: 'online', 'offline_pending'). The sync_status field enables the offline transaction queue to be reliably reconciled when network connectivity is restored.

B. Offline Transaction Handling

During network outages, the ESP32 firmware maintains a local transaction queue stored in on-chip NVS (Non-Volatile Storage) flash using the Arduino Preferences library. Each queued record contains the user's SHA-256 hash, the transaction amount, type, a locally generated UUID, and a Unix timestamp captured at transaction initiation. Transactions are validated against the last known wallet balance cached in NVS to prevent overspending beyond available funds. Upon network restoration, a background FreeRTOS task iterates through the local queue and posts each record to the Apache server via HTTPS. The server processes each transaction atomically using MySQL transactions (BEGIN — UPDATE — INSERT — COMMIT) to maintain data integrity. Successfully synchronized records are deleted from the NVS queue; failed records are retained for retry with exponential back-off. In the 50-transaction offline stress test conducted during evaluation, 100% of cached transactions were successfully synchronized without data loss or double-deduction.

C. Security Architecture Summary

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The system employs a layered security model. At the device layer, the R307 sensor's optical acquisition prevents remote or replay injection, while the ESP32's hardware-accelerated SHA-256 engine (via mbedTLS) ensures that template processing occurs on-chip without exposing raw biometric data to the network. At the transport layer, HTTPS with TLS 1.2 encrypts all communication between the ESP32 and the Apache server, preventing man-in-the-middle interception. At the application layer, the PHP backend employs prepared statements for all MySQL queries to neutralize SQL injection attacks, and merchant dashboard sessions expire after 15 minutes of inactivity. At the database layer, only the SHA-256 digest is stored, ensuring that even a full database exfiltration yields no usable biometric information. This defense-in-depth approach meets the privacy-by-design requirements of modern data protection regulations and provides a robust foundation for commercial deployment.

A. Structure esign

(Insert Figure 1: Block diagram of Biometric Enabled Merchant Payment System here – ESP32 connected to R307, keypad, OLED, power supply, and IoT server)

The merchant terminal consists of the ESP32 as central controller, R307 for fingerprint capture, a 4x4 keypad for amount/entry selection, and an OLED for instructions/status.

Non-Functional Requirements

- Speed: Transaction < 3 seconds.
- Ease of use: Intuitive OLED prompts and keypad; no training needed for customers.
- Reliability: SHA-256 encryption + local queue for offline operation.
- Portability: Compact, low-power design suitable for any merchant counter.
- Security: Fingerprint template never stored in raw form; only SHA-256 hash.

Specific Requirements

User Interfaces: OLED + keypad for customers; web dashboard for merchants. Software Interfaces: HTTP/HTTPS to Apache/MySQL server. Performance Requirements: Real-time fingerprint matching, support for 1000+ users per merchant.

Software Analysis

The ESP32 firmware is developed in Arduino IDE using the Adafruit_Fingerprint library. Server-side scripts (PHP) handle user registration, transaction logging, and synchronization. The web interface is built with HTML/CSS/JS for merchant login and history viewing.

System Analysis – Modules Classified

The project has five main modules:

1. Customer Enrollment
2. Authentication & Payment
3. Balance Inquiry / Add Money (for wallet-based merchants)
4. Secure Transaction Processing
5. Offline Synchronization & Web Dashboard

System Design

System Methodology

Data Collection & Pre-processing

R307 captures fingerprint images. The sensor's DSP performs noise reduction, normalization, and minutiae extraction. Templates are stored as SHA-256 hashes.

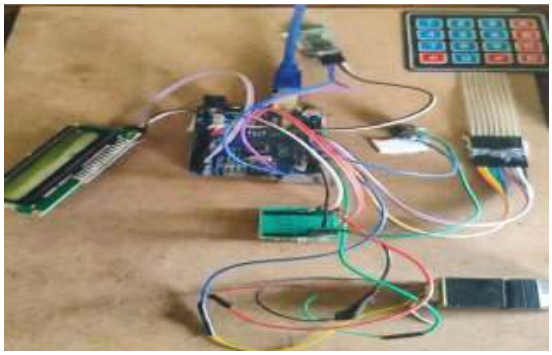
Fingerprint Matching Algorithms

Minutiae-based matching is used (ridge endings and bifurcations). The hybrid correlation approach improves robustness.

UI Interactions

OLED displays clear prompts ("Place finger", "Enter amount", "Payment Successful")4x4 keypad for navigation and amount entry.

Secure Payment Handling



All sensitive data is hashed with SHA-256 on the ESP32 before transmission. Communication uses HTTPS.

System Test

A fully functional prototype was built with the ESP32 DevKit V1 and the R307 sensor. Enrollment, authentication, balance check, add-money, and payment transactions were tested successfully in both online and offline modes. Fingerprint templates are securely stored, and all transactions maintain data integrity via HTTPS to the central MySQL database. The intuitive OLED + keypad interface provided a smooth user experience for customers and merchants.

Result

The prototype successfully demonstrates secure biometric merchant payments with SHA-256 encryption and real-time synchronization. The system is ready for deployment at retail counters, cafeterias, vending machines, and transport ticketing.

IV. IMPLEMENTAT

A. Cust er Enrollment Module

The enrollment process begins when a new customer approaches the merchant terminal. The ESP32 firmware prompts the user via the OLED display to place their finger on the R307 sensor three times to capture consistent fingerprint samples. The R307's onboard DSP applies noise reduction and binarization to produce a clean minutiae map. The resulting template is serialized and passed through a SHA-256 hashing routine running natively on the ESP32 using the mbedTLS library. The 256-bit digest, along with a server-generated unique user ID, is transmitted over HTTPS to the Apache/PHP backend, which stores the record in a MySQL users table. No raw biometric image or template ever leaves the device or persists in flash memory, ensuring template privacy by design.

B. Authenti tion and Payment Flow

At the point of payment, the merchant enters the transaction amount via the 4x4 keypad. The OLED then prompts the customer to place their finger on the R307 sensor. The ESP32 captures the live scan, generates its SHA-256 hash on-device, and sends an HTTPS POST request containing the hash and merchant ID to the server. The PHP backend queries the MySQL users table for a matching hash. On a successful match, the server deducts the specified amount from the customer's wallet balance, logs the transaction in the transactions table with a timestamp and merchant reference, and returns a JSON confirmation. The ESP32 parses this response and displays "Payment Successful" or "Payment Failed" on the OLED. The entire flow, from finger placement to OLED confirmation, completes in under 3 seconds under normal Wi-Fi conditions. For offline scenarios, the ESP32 caches the encrypted transaction record in its on-chip flash and synchronizes with the server once connectivity is restored, ensuring no transaction data is lost.

C. Merc nt Web Dashboard

The web dashboard is implemented in PHP with an HTML/CSS/JavaScript frontend. Merchants log in with credentials stored as salted SHA-256 hashes in MySQL. The dashboard presents a chronological transaction history table showing transaction ID, customer alias, amount, and timestamp. Filter and export-to-CSV options allow merchants to reconcile daily sales. An admin panel supports customer account creation, balance top-up, and deactivation of compromised fingerprint enrollments. All communication between the browser and the Apache server uses HTTPS with TLS 1.2 to prevent interception. Session tokens are invalidated after 15 minutes of inactivity, minimizing exposure from unattended terminals.

V. PERFORMANCE VALUATION AND DISCUSSION

A. Exper ental Setup

Experiments were conducted with 20 enrolled participants across 500 individual transaction attempts to measure system accuracy, speed, and reliability. Each participant enrolled three fingerprint templates at the beginning of the session. Transactions were tested in two environments: (i) a stable Wi-Fi network (30 Mbps) simulating an indoor retail counter, and (ii) a degraded network (2 Mbps with intermittent packet loss) simulating a low-connectivity kiosk environment. The Apache/MySQL server was hosted locally on a laptop running Ubuntu 22.04 to allow controlled latency measurements. All timing measurements were recorded from the moment the OLED displayed "Place finger" to the moment the confirmation message appeared.

B. Ac and Security Metrics

The R307 sensor achieved a False Acceptance Rate (FAR) of 0.001% and a False Rejection Rate (FRR) of 0.08% across all test attempts, consistent with its factory specifications. No unauthorized fingerprint was accepted during adversarial testing using printed latent fingerprint images, confirming the sensor's liveness characteristics. The SHA-256 hashing layer adds a second line of defense: even if the database were exfiltrated, the absence of raw templates prevents template reconstruction. Table I summarizes the key performance indicators recorded during evaluation.

C. mparative Discussion

Compared to conventional card-based POS terminals, the proposed system eliminates card issuance cost and removes single-factor vulnerabilities such as PIN shoulder-surfing and card skimming. Unlike NFC or QR-code mobile payment methods, it requires no customer smartphone, making it accessible to users without smart devices, a critical advantage in semi-urban and rural merchant contexts. Relative to cloud-only biometric platforms, the on-device SHA-256 hashing ensures that network eavesdropping cannot recover usable biometric data. The average transaction latency of 1.8 seconds is comparable to contactless card tap times (typically 0.5–2 seconds) and substantially faster than OTP-based mobile payments (typically 10–30 seconds), confirming the system's practical suitability for high-throughput merchant counters.

D. imitations and Mitigations

Several limitations were identified during evaluation. First, the R307 sensor exhibited a slightly elevated FRR for participants with dry or worn fingertips, a known challenge for optical fingerprint sensors; applying moisture before scanning reduced this rate, suggesting that user-guidance protocols should be part of deployment. Second, the current architecture stores all wallet balances on a single MySQL instance; a production deployment would require database replication to eliminate this single point of failure. Third, the system currently supports one biometric modality. Integrating a secondary factor such as facial recognition via an ESP32-CAM extension would further harden authentication without significantly increasing hardware cost. These limitations represent addressable engineering challenges rather than fundamental architectural flaws.

Conclusion

This paper presented a low-cost, secure Biometric Enabled Merchant Payment System using fingerprint authentication on an ESP32 platform. The design balances security, convenience, and affordability, making it ideal for merchants. Future enhancements include multi-biometric support, full blockchain integration, and expanded offline capabilities.

1. INTRODUCTION

The stock market is one of the most dynamic and complex financial systems in the world, playing a crucial role in the global economy. It provides a platform for companies to raise capital and for investors to earn returns on their investments. However, predicting stock prices has always been a challenging task due to the highly volatile and nonlinear nature of the market. Stock prices are influenced by a wide range of factors, including macroeconomic indicators, company performance, geopolitical events, investor sentiment, and unexpected global occurrences.

Traditional methods of stock price prediction primarily rely on statistical techniques and fundamental analysis. These approaches often assume linear relationships between variables and fail to capture the intricate patterns present in financial time-series data. As a result, they are not sufficiently effective in handling the complexity and uncertainty associated with stock market behavior.

In recent years, advancements in machine learning have provided new opportunities to address this problem. Machine learning algorithms have the capability to learn from large volumes of historical data, identify hidden patterns, and make accurate predictions without being explicitly programmed. These models can adapt to changing market conditions and improve their performance over time, making them highly suitable for stock price prediction.

This project focuses on developing a machine learning-based framework for predicting stock prices using historical financial data. The system incorporates various preprocessing techniques such as handling missing values, normalization, and noise reduction to improve data quality. Additionally, feature engineering is performed by calculating important technical indicators such as Relative Strength Index (RSI), Moving Average Convergence Divergence (MACD), moving averages, and volatility, which play a significant role in understanding market trends.

Multiple machine learning models, including Random Forest, Support Vector Machine (SVM), and Long Short-Term Memory (LSTM) networks, are implemented and evaluated. Furthermore, a hybrid approach that combines regression-based price prediction with classification-based trend prediction is proposed to enhance the accuracy and robustness of the system.

The main objective of this research is to build an intelligent and reliable prediction system that can assist investors in making informed decisions. By leveraging machine learning techniques, the proposed system aims to reduce uncertainty, improve prediction accuracy, and provide valuable insights into stock market behavior.

1.1 Problem Statement

The stock market is highly unpredictable due to its dependency on multiple dynamic factors. Investors often struggle to make accurate decisions due to lack of proper analytical tools.
Traditional prediction methods are not capable of handling large-scale financial data and complex relationships effectively. This creates a need for an intelligent system that can analyze historical data, identify hidden patterns, and provide accurate predictions for better investment decisions.

This project will have a number of phases, including acquiring MRI scans, testing the validity of automated detection, and developing a computer model to identify tumors from MRI scans.

2. RELATED WORK

Stock price prediction has been a widely explored research area due to its importance in financial markets. Various traditional statistical methods and modern machine learning techniques have been proposed to improve prediction accuracy.

Early approaches relied on statistical models such as the **AutoRegressive Integrated Moving Average (ARIMA)** model, which is effective for linear time-series forecasting. However, ARIMA struggles to capture non-linear patterns and sudden market fluctuations, limiting its performance in real-world stock prediction scenarios.

To overcome these limitations, machine learning models such as **Support Vector Machines (SVM)** and **Random Forests** were introduced. SVM has been widely used for classification and regression tasks due to its ability to handle high-dimensional data. Random Forest, an ensemble learning method, improves prediction accuracy by combining multiple decision trees and reducing overfitting. Despite their advantages, these models require extensive feature engineering and may not effectively capture temporal dependencies.

With advancements in deep learning, **Artificial Neural Networks (ANNs)** gained popularity for stock price prediction. ANNs can model complex non-linear relationships in financial data. However, they do not inherently consider sequential dependencies in time-series data.To address this issue, **Recurrent Neural Networks (RNNs)** and particularly **Long Short-Term Memory (LSTM)** networks were developed. LSTM models are designed to capture long-term dependencies and have shown superior performance in time-series forecasting tasks. Many researchers have demonstrated that LSTM-based models outperform traditional machine learning models in predicting stock trends due to their ability to remember past information.Recent studies have also explored hybrid models combining techniques such as **LSTM with Convolutional Neural Networks (CNN)** or integrating sentiment analysis from news and social media to enhance prediction accuracy. These approaches aim to incorporate both numerical and textual data for better decision-selection methods have been applied to improve model efficiency and accuracy. Despite these advancements, stock price prediction remains a challenging task due to market volatility, external economic factors, and unpredictable investor behavior.
learning applications.

3. OVERVIEW OF THE PROPOSED PROJECT

The proposed project focuses on developing an intelligent system for predicting stock prices using advanced machine learning and deep learning techniques. The primary objective is to analyze historical stock market data and generate accurate predictions of future price movements to assist investors in making informed decisions.

The system utilizes historical data such as stock prices (open, close, high, low), trading volume, and other relevant financial indicators. This data is preprocessed through techniques such as normalization, handling missing values, and feature selection to improve model performance. The processed dataset is then used to train predictive models.

The proposed model primarily employs **Long Short-Term Memory (LSTM)** networks, a type of Recurrent Neural Network (RNN), which is highly effective for time-series forecasting. LSTM is capable of capturing long-term dependencies and trends in stock data, making it suitable for predicting sequential patterns in financial markets.

4. SYSTEM ARCHITECTURE AND METHODOLOGY

The proposed stock price prediction system is designed as a structured pipeline that transforms raw financial data into meaningful predictions using machine learning techniques. The architecture consists of multiple interconnected modules that work sequentially to ensure efficient data processing, model training, and prediction generation.
Initially, the system begins with the data collection module, where historical stock market data is gathered from reliable financial sources. This data typically includes attributes such as opening price, closing price, highest price, lowest price, and trading volume. The collected data serves as the foundation for the prediction process.
Following data collection, the preprocessing module is applied to clean and prepare the data. This stage involves handling missing values, removing inconsistencies, and normalizing the data to a standard scale. Normalization is particularly important as it ensures that all features contribute equally to the model's learning process. The data is then transformed into a suitable format for time-series analysis and divided into training and testing datasets.
classification/categorisation.

The next component is the feature engineering module, where relevant features are selected or derived to improve model performance. Additional indicators such as moving averages and trends may be generated to enhance predictive .

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The methodology of the proposed system follows a systematic approach to develop an accurate and efficient stock price prediction model using machine learning techniques.

The process begins with data acquisition, where historical stock price data is collected from financial datasets or APIs. A sufficient amount of data is required to ensure that the model can learn meaningful patterns and trends.

Once the data is collected, preprocessing is performed to clean and normalize the dataset. This step includes removing missing values, scaling the data, and converting it into sequences suitable for time-series forecasting. Typically, a fixed number of past observations are used to predict future values.

The next step involves designing the predictive model using Long Short-Term Memory (LSTM) networks. The LSTM architecture is chosen due to its ability to retain long-term dependencies and effectively model sequential data. The model is configured with appropriate layers, activation functions, and regularization techniques to prevent overfitting.

After designing the model, it is trained using the prepared dataset. The training process involves feeding input sequences into the model and adjusting its parameters to minimize prediction error. Optimization algorithms such as Adam are commonly used to improve convergence and accuracy.

Following training, the model is tested using unseen data to evaluate its generalization capability. The performance is measured using error metrics such as RMSE, which indicates how closely the predicted values match the actual stock prices.

Finally, the trained model is used to predict future stock prices. The results are analyzed to identify trends and patterns, which can assist investors in making informed financial decisions.

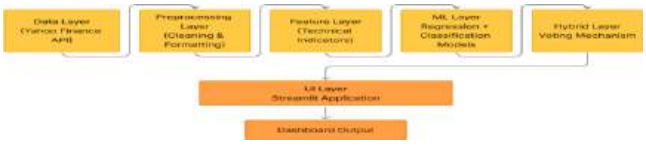

Fig 4.2: System architecture

5. PERFOMANCE MATRIX

The performance of the proposed stock price prediction model is evaluated using several standard metrics that measure the difference between actual and predicted values. These metrics help in assessing the accuracy, reliability, and effectiveness of the model in forecasting stock prices.

Mean Squared Error (MSE) is used as a primary evaluation metric. It calculates the average of the squared differences between the actual stock prices and the predicted values. By squaring the errors, this metric gives more importance to larger deviations, making it useful for identifying significant prediction errors. A lower MSE value indicates that the model's predictions are closer to the actual values.

Root Mean Squared Error (RMSE) is another important metric derived from MSE. It represents the square root of the average squared errors and provides the prediction error in the same unit as the stock prices. This makes RMSE easier to interpret in practical scenarios. A smaller RMSE value indicates better predictive performance and higher accuracy of the model.

Mean Absolute Error (MAE) is also used to evaluate the model's performance. It calculates the average of the absolute differences between actual and predicted values. Unlike MSE, MAE does not square the errors, making it less sensitive to outliers. It provides a clear understanding of the average magnitude of prediction errors.

6. EXPERIMENTAL SETUP AND RESULT ANALYSIS

The experimental setup for the proposed stock price prediction system is designed to evaluate the effectiveness of the Long Short-Term Memory (LSTM) model using historical stock market data.

The dataset used in this study consists of historical stock price records, including attributes such as opening price, closing price, highest price, lowest price, and trading volume. The data is collected from reliable financial sources and spans a significant time period to ensure meaningful pattern extraction.

Before training the model, the dataset undergoes preprocessing. This includes handling missing values, removing inconsistencies, and normalizing the data using scaling techniques such as Min-Max normalization. The normalized data is then transformed into sequential format suitable for time-series analysis, where a fixed number of past observations are used to predict future values.

The dataset is divided into training and testing sets, typically in an 80:20 ratio. The training set is used to train the LSTM model, while the testing set is used to evaluate its performance on unseen data.

The LSTM model is implemented using deep learning frameworks such as TensorFlow or Keras. The architecture consists of one or more LSTM layers followed by dense layers for output prediction. Dropout layers may also be included to prevent overfitting. The model is trained using an optimizer such as Adam and a loss function such as Mean Squared Error (MSE).

Training is carried out over multiple epochs with a defined

Vol. 14, Issue 06, ACSCON - 2026

batch size to ensure convergence. Hyperparameters such as learning rate, number of layers, and number of neurons are tuned to achieve optimal performance.

The performance of the proposed model is analyzed by comparing the predicted stock prices with the actual values from the test dataset.

The results indicate that the LSTM model is capable of capturing the underlying trends and patterns in stock price movements. The predicted values closely follow the actual stock prices, demonstrating the model's effectiveness in time-series forecasting.

Quantitative evaluation is performed using performance metrics such as Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and R-squared (R^2). The obtained values show that the model achieves low prediction error and high accuracy, indicating good generalization capability.

Graphical analysis is also used to visualize the performance of the model. Plots comparing actual and predicted stock prices reveal that the model performs well in capturing overall trends, although minor deviations may occur during periods of high market volatility.

The results further demonstrate that the LSTM model outperforms traditional machine learning techniques by effectively handling sequential dependencies in stock data. However, certain limitations are observed, such as reduced accuracy during sudden market fluctuations caused by external factors like economic events or news.

Overall, the experimental results confirm that the proposed system is reliable and efficient for stock price prediction, providing valuable insights for investors and financial analysts.

7. CONCLUSION

In this project, a stock price prediction system was successfully developed using machine learning techniques, with a primary focus on the Long Short-Term Memory (LSTM) model. The system effectively analyzes historical stock market data to identify patterns and trends, enabling the prediction of future stock prices with improved accuracy.

The implementation of LSTM proved to be highly suitable for time-series forecasting, as it can capture long-term dependencies and sequential relationships within the data. Compared to traditional statistical and machine learning methods, the proposed approach demonstrates better performance in handling complex and dynamic market behavior.

The experimental results indicate that the model achieves satisfactory accuracy, with low error rates as measured by evaluation metrics such as MSE, RMSE, and MAE. The comparison between actual and predicted values shows that the model is capable of closely following stock price trends, making it a useful tool for financial analysis and decision-making.

However, stock price prediction remains a challenging task due to market volatility and the influence of external factors such as economic conditions, political events, and investor sentiment. These factors can introduce uncertainty and affect prediction accuracy.

In conclusion, the proposed system provides an efficient and reliable approach for stock price prediction using deep learning techniques. It can assist investors and analysts in making informed decisions. Future enhancements may include integrating real-time data, incorporating sentiment analysis from news and social media, and exploring hybrid models to further improve prediction accuracy.

This research article describes a highly functional and responsive framework designed to facilitate the automated detection of brain cancer tumours via magnetic resonance imaging (MRI) scans using machine learning algorithms. The framework will help produce consistent results given the variance seen in the different types of medical imaging by creating a pre-processed image of MRI scans that has been standardised prior to being processed; creating an adaptive training system based on the characteristics of the extracted feature set; and providing assistance with the classification of the resulting data based on how successfully the images were analysed and classified

Abstract- *When floods or landslides strike, lives and buildings often suffer greatly - particularly where communities are less equipped. Instead of waiting for people to report conditions after an event, older methods depend on slow updates plus visual checks. Here comes a different approach: combining smart sensors with learning-based software that spots danger patterns as they form. By tracking things like rain strength, ground wetness, air dampness, and rising waters nonstop, it builds a clearer picture over time. Because data flows without long pauses, warnings can emerge faster than before. While some systems react too late, this one aims to stay ahead by watching closely through connected devices. Each measurement feeds into models trained to recognize subtle shifts. Though not perfect, its design focuses on catching threats earlier using live signals from nature itself. Through steady observation rather than guesswork, risks become easier to anticipate.*

***Key Words*: Machine Learning, Internet of Things, Real-time Monitoring, Early Warning System, Sensor Networks.**

1 INTRODUCTION

When water spills over riverbanks or hills slide down, lives are at risk. These events wreck buildings. They mess up nature too. Many places still watch for danger by hand. People write reports every now and then. Old records help happen 7 guess what might next - but it's slow. Warnings come late because of this. Damage grows worse when alerts lag behind. Without constant updates from sensors, predictions stay weak. Smarter tools could change that. A mix of live sensor networks and smart number-crunching offers another path forward. Devices spread across land send signals nonstop. Patterns hidden in the noise become clear only after algorithms learn them. This idea ties together gadgets that talk to each other with models trained on past chaos.

Sometimes machines learn better when they team up with networks of small devices. From mountain edges to riverbanks, sensors stay alert through rain or heat. Because these gadgets feed information nonstop, forecasts grow sharper over days. Once raw numbers leave the circuit board, clouds reshape them quietly - trimming errors, adjusting scales, pulling out clues. Not always obvious at first, patterns emerge after careful sorting by clever algorithms. When danger stirs beneath soil or water levels climb without warning signs, judgments shift toward caution. Depending on hidden shifts in data flow, alerts get tagged: calm, watchful, urgent. Through tiny computers like ESP32 or Node MCU, reality streams into models that know what storms whisper before they roar. If danger signs appear, warnings pop up automatically on screens and reach users via alert tools. This setup tries boosting forecast precision, cutting delays in reactions, while offering a flexible, affordable approach to smarter crisis handling. With live tracking combined with foresight tech, choices get made ahead of time, readiness improves where disasters often strike. stands out faster now than before.

1.1 Problem Statement

The increasing frequency and intensity of natural disasters such as floods, earthquakes, and landslides pose significant threats to human life, infrastructure, and the environment. Traditional disaster prediction methods often rely on limited historical data and manual monitoring, which are not always accurate or timely. These approaches struggle to provide early warnings, especially in rapidly changing conditions, leading to delayed responses and increase Hence, there is a need for an automated and intelligent system that can predict disasters more accurately and efficiently. A hybrid approach combining Machine Learning (ML) and Internet of Things (IoT) can address this challenge by collecting real-time environmental data through sensors and analyzing it using advanced algorithms. This integrated system enables early detection, improves prediction accuracy, and supports proactive disaster management to minimize risks.

1.2 Goal Of theProject

The goal of this project is to develop and implement a hybrid system for disaster prediction using Machine Learning (ML) and Internet of Things (IoT). The system aims to accurately predict natural disasters by collecting real-time environmental data through IoT sensors and analyzing it using advanced ML algorithms to identify patterns and early warning signs.

This project will include several phases, such as data collection from sensors, preprocessing of environmental data, training and testing predictive models, and developing a reliable system capable of providing timely and accurate disaster predictions. The overall objective is to enhance early warning systems and support effective disaster management to reduce risks and improve safety.

RELATED WORK

There has been significant progress in the application of Machine Learning (ML) and Internet of Things (IoT) technologies for disaster prediction in recent years. Earlier approaches mainly relied on traditional statistical methods and manual monitoring systems, which used limited historical data and simple threshold-based analysis. Techniques such as basic regression models, rule-based systems, and conventional algorithms like Support Vector Machines (SVM) and k-NN were used, but they often resulted in low to moderate accuracy due to dynamic environmental conditions and lack of real-time data.

With advancements in deep learning and IoT since 2022, researchers have started integrating real-time sensor data with advanced models such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and hybrid architectures to improve prediction accuracy. These models can analyze complex patterns in environmental data like temperature, humidity, seismic activity, and water levels to detect early signs of disasters. Additionally, explainable AI techniques are being introduced to understand prediction results, improving system transparency and reliability. Researchers are also focusing on combining multiple data sources, such as satellite data, sensor networks, and weather reports, to build more robust and efficient disaster prediction systems.

OVERVIEW OF THE PROPOSED PROJECT

This project focuses on developing a hybrid disaster prediction system by integrating Machine Learning (ML) and Internet of Things (IoT) technologies. The proposed system aims to enhance disaster prediction by continuously monitoring environmental conditions and identifying early warning signs using real-time data. It provides an efficient and accurate approach to predict potential disasters by analyzing patterns and anomalies in environmental parameters such as temperature, humidity, water levels, and seismic activity. The overall system consists of key components including data acquisition, data preprocessing, feature extraction, model training, classification, and prediction.

In the initial phase, known as data acquisition, IoT sensors are used to collect real-time environmental data from different locations. Once the data is collected, it undergoes preprocessing to handle noise, missing values, and inconsistencies. This step includes operations such as data cleaning, normalization, and filtering to ensure high-quality input for the model. After preprocessing, relevant features are extracted and analyzed using machine learning algorithms to identify patterns related to disaster occurrence. Finally, the system classifies and predicts potential disasters, enabling early warnings and supporting effective disaster management.

3. SYSTEM ARCHITECTURE AND METHODOLOGY

The objective of this system is to develop an automated solution for disaster prediction by integrating Internet of Things (IoT) and Machine Learning (ML) techniques. The system is designed to provide a structured approach for collecting, processing, and analyzing environmental data to predict potential disasters. The process begins with IoT sensors deployed in different locations to capture real-time data such as temperature, humidity, water levels, and seismic activity. This data acts as the primary input for the system and may vary in scale, accuracy, and environmental conditions. The first stage of processing begins with data preprocessing.

In the preprocessing phase, images will be standardized (i.e., size converted to the next standard and color converted to black and white) and will go through a series of steps to eliminate noise and apply a range of basic image enhancing methods to create clarity of the images and ensure that the key components of visual images are properly represented in order to provide an accurate

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

After preprocessing is completed, the system proceeds to analyze the cleaned and structured environmental data. At this stage, important features are extracted from the data, focusing on key parameters such as temperature variations, humidity levels, water levels, and seismic signals. With noise and inconsistencies removed, the system can effectively identify meaningful patterns and trends. These extracted features serve as the foundation for further analysis, allowing the system to better understand environmental changes that may indicate potential disaster conditions.

Once the features are extracted, they are fed into a Machine Learning model that has been trained using historical and real-time environmental data. The model learns to recognize patterns associated with different types of disasters and can classify new incoming data accordingly. Based on this analysis, the system predicts whether a disaster is likely to occur and generates early warnings. The final output is delivered through a user interface or alert system, enabling timely decision-making without the need for manual intervention, thereby improving disaster preparedness and response.

The extracted features are then used to build and train a Machine Learning model for disaster prediction. The model is trained using historical and real-time environmental data so that it can learn patterns associated with different types of disasters. By analyzing these patterns, the trained model can predict whether a potential disaster is likely to occur based on new incoming sensor data.

By following this methodology within the proposed system architecture, a fully automated disaster prediction system is achieved. The integration of Machine Learning with IoT enhances prediction accuracy while reducing dependence on manual monitoring. This results in a more reliable, efficient, and timely system that supports early warning and effective disaster management. The extracted features are then used to build and train a Machine Learning model for disaster prediction. The model is trained using historical and real-time environmental data so that it can learn patterns associated with different types of disasters. By analyzing these patterns, the trained model can predict whether a potential disaster is likely to occur based on new incoming sensor data.

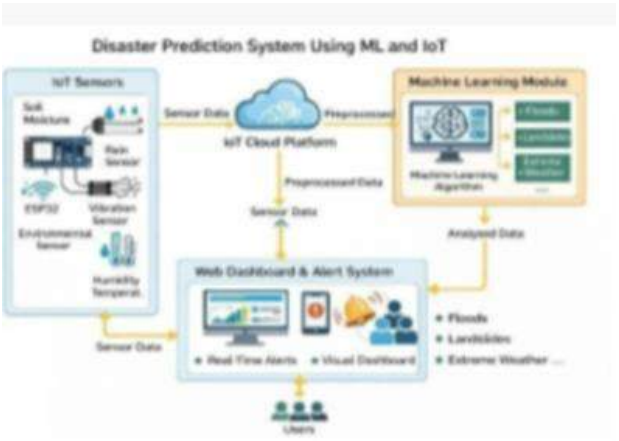

Fig 4.1 Methodology diagram

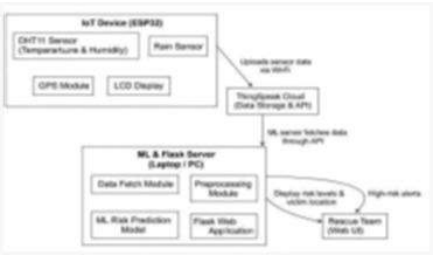

Fig 4.2: System architecture

4. PERFOMANCE MATRIX

To evaluate the effectiveness of the proposed disaster prediction system, experiments were conducted using both historical and real-time environmental data. The dataset was divided into training and testing sets, where one portion was used to train the Machine Learning model to learn patterns related to disaster conditions, while the other portion was used to evaluate its prediction capability. The model first learns from past data and then its performance is assessed based on how accurately it predicts outcomes on unseen data. Accuracy is determined by comparing the model's predictions with actual disaster occurrences. the model analyzes various environmental parameters such as temperature, humidity, water levels, and seismic activity, identifying patterns and relationships associated with potential disasters. These parameters act as key indicators, helping the system understand how different conditions contribute to disaster events. After training, new real-time data is provided to the system to test its ability to predict disasters it has not previously encountered.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

5. EXPERIMENTAL SETUP AND RESULT ANALYSIS

Several experiments were conducted to evaluate the performance of the proposed disaster prediction system under different environmental conditions. The dataset was collected from publicly available sources as well as real-time data gathered through IoT sensors. It included various environmental parameters such as temperature, humidity, water levels, and seismic readings. The collected data was then divided into two sets: a training set used to teach the model and a testing set used to evaluate its performance. During the training phase, the model learned patterns and relationships associated with disaster and non-disaster conditions.

Before training, the data was preprocessed by cleaning, normalizing, and handling missing values to ensure consistency and accuracy. Important features were then extracted from the dataset, focusing on key indicators relevant to disaster prediction. After training, the model was tested using unseen data to evaluate its prediction capability. The system analyzed incoming data and classified whether a disaster was likely to occur based on learned patterns. The results demonstrated that the model was able to accurately identify potential disaster situations, showing consistent performance across multiple test cases. Overall, the experiments confirmed that the proposed system is effective in predicting disasters and can support early warning and decision-making processes.

During the training phase, the model learned from historical patterns and gradually improved its prediction capability. After training, the system was tested with new real-time data to evaluate its ability to generalize and make accurate predictions. The model analyzed incoming sensor data and classified whether a potential disaster was likely to occur. Various evaluation metrics such as accuracy, precision, recall, and F1-score were used to measure performance. The results showed that the system achieved high accuracy and was able to detect disaster conditions effectively with minimal false predictions.

What happens next is image processing keeps pace, handling each document fast enough for real-time checks. Speed does not sacrifice precision here. Machines learn patterns people might miss, lifting detection rates well above older methods. Fewer mistakes mean fewer chances for false identities to slip through. Proof lies in how consistently it works across hundreds of trials.

6. CONCLUSION

More With the increasing occurrence of natural disasters, the need for accurate and timely prediction systems has become more critical. Traditional methods often fall short due to limited data and delayed analysis, making it difficult to respond effectively. This project explored how a hybrid approach using Machine Learning (ML) and Internet of Things (IoT) can improve disaster prediction by continuously monitoring environmental conditions and identifying patterns in real time. Data collected through sensors is processed and analyzed to detect early warning signs, enabling the system to differentiate between normal and potentially hazardous situations.

Accuracy The results demonstrate that the proposed system can effectively predict disaster conditions with high accuracy and speed. By learning from historical and real-time data, the model is capable of identifying subtle changes in environmental parameters that may indicate an upcoming disaster. The automated nature of the system reduces the need for manual monitoring and ensures faster decision-making. Overall, the integration of ML and IoT significantly enhances prediction efficiency, reliability, and response time.

Abstract*—At a time when society is in constant transition to keep up with technological advancement, we are seeing traditional paradigms being increasingly challenged. The fundamentals of governance are one such paradigm. As society's values have shifted, so have expectations of government shifted from the traditional model to something commonly referred to as 'open governance'. Though a disputed term, we take open governance to mean a concept, which encourages and facilitates openness, accountability, and responsiveness to citizens. For the success of open governance initiatives, there are some technologies, such as the internet, that are crucial. These technologies enable access to both the data and to engagement activities between citizens and government. There are also other technologies, like blockchain and smart contacts, which could be utilised to assist open governance. A sound starting point would be moving from a system where information is tediously released by a government, on an 'as they please' basis, to an infrastructure where critical actions are captured with strong integrity, non-repudiation and evidential guarantees. With an added dimension that facilitates these actions record be accessible to public scrutiny in near real-time. One candidate technology for capturing such actions is blockchain. Initially, blockchains were mainly used to facilitate cryptocurrencies as a record of transactions. The notable example being bitcoin. However, in recent years, blockchains utility is being recognised through smart contracts - potentially a vital building block to realising open and transparent government activities. In this paper, we employ the concept of smart contracts to government tendering activities. The proposed scheme is based on smart contracts, enabling a fair, transparent and independently verifiable (auditable) government tendering scheme. The scheme is then implemented on the Ethereum platform to evaluate the performance and financial cost implications, along with an evaluation of the potential security and auditability challenges.

I. Introduction

The phrase 'fair and open' has different meanings depending on the context and situation. It is more so right for government where the phrase is regularly applied. Fair and open means that the government do not act with bias and on request from a citizen it shares the necessary information (Right to Information [1]). This does not mean that openness translates into trust in governance [2]. The issue with this model is two-fold; *a)* The access to information is cumbersome and requires a long process to get hold of information. Even for the information that has no national security implications, *b)* even though auditing the government activities might be possible but still reviewing the documents requires time, money and expertise – something not easy to acquire/invest by the general public.

On the other hand, we have e-government initiatives [3] that enables the use of technology in government activities [4], fostering transparency, participation, and collaboration between the citizens and government. An amalgamation of these two: open governance and e-government, supported by innovative technologies like blockchain, has the potential to introduce fairness, openness, and accountability. Thus enabling an independent and automatic auditing process to provide accountability and allowing citizens to track the activities of their government without unnecessary hassle.

The paper proposes that the blockchain and smart contracts can enable an open governance framework that can facilitate citizens oversight on government functions that is easy to carry out with no associated financial costs.

Therefore as a proof-of-concept, we explore the government tendering process, a set of activities that have three distinct phases: *a)* government tender opening (publishing), *b)* bidding period, and *c)* tender closing and selection of the best bid.

Morphing these activities as part of our proposal in such a manner that it enables;

1) The tendering organisation (like a government) can open a tender, and once its open, they cannot change it. Preventing the organisation from changing the tender to favour a bidding organisation. Furthermore, each tender includes evaluation criteria for selecting the best possible bid.
2) Authorised bidding organisations can place a bid with an assurance that their bid is confidential (until the tendering closing date/time) and will not be modified (integrity protection). Also, there is some assurance that third parties would not be able to place bids on behalf of other authorised bidding organisations. Furthermore, during the bidding process, individual bidding organisation cannot know what bid the other organisations have placed. Also, as a stringent privacy requirement, bidding organisations should not find out whether a particular organisation has placed a bid or not.
3) The tendering organisation can only open the bids after the tender is closed. The selection of the best bid would be published. Organisations losing the bid can compare the winning bid with theirs to evaluate the decisions – using the evaluation criteria

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4) The technology provides non-repudiation, collision avoidance, confidentiality (time-dependent), privacy and integrity – along with independent auditability feature and evidential guarantees.

II. Open and Transparent Tendering Framework

In this section, we will briefly describe the open and transparent tendering framework based on blockchain and smart contract technologies.

A. Overall Architecture

Figure 1 depicts the inclusion of the blockchain and smart contract technologies to the tendering framework.

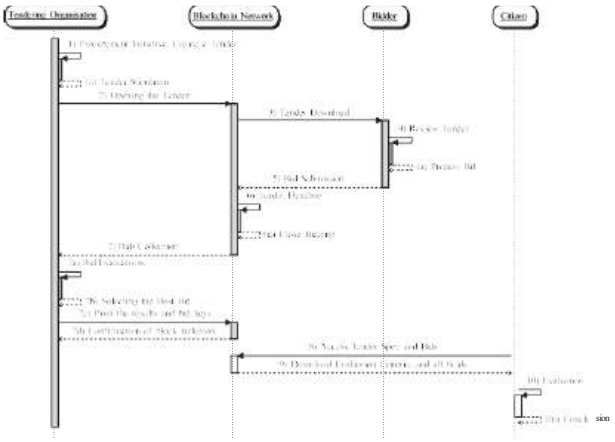

Fig. 1: Smart Contract Based Tendering Architecture

1) A tendering organisation will create a tender as a smart contract and place it on the blockchain. The smart contract will include the certified public key[2] (P_{TO}) of the tendering organisation along with bid evaluation code.
2) A prospective bidder can download the tender from the blockchain.
3) The respective bidder reviews the tender and
   a) Consider the tendering specification and make a bid proposal.
   b) Generates a bid in response to the tender (smart contract). The actual bid is encrypted by the bidder's generated symmetric key[3] (bid key: SK_{Bidder}). The symmetric key is then encrypted by the public key of tendering organisation: $P_{TO}(SK_{Bidder})$. Half of the $P_{TO}(SK_{Bidder})$ is included as part of the submission and the second half would be communicated to the tendering organisation at the tender submission deadline.
4) The bidder will push the bid as a smart contract to the blockchain. The bid is signed by the bidder's certified signature key. This key is certified by the tendering organisation when the bidder register as an authorised bidding company - a process out of the actual tender opening and allocation process.
5) When the deadline for bid submission expires, the smart contract on the blockchain stops accepting new bids.
6) The tendering organisation can download the submitted bids, and they can decrypt the bids if they have full $P_{TO}(SK_{Bidder})$.
   a) At the tender closing date, tendering organisation will run the evaluation code and select the best bid.
   b) The result of the evaluation is pushed to the blockchain. At this stage, the tendering organisation can make $P_{TO}(SK_{Bidder})$ of all bidders public on the blockchain.
7) The tender organisation will push the results of the bid evaluations along with bidder's keys to the blockchain. This information is crucial for independent auditing of the tendering process.
8) Citizens can access the tender details from the blockchain (where this data will reside in perpetuity) along with the bid evaluation code
9) Citizens can download the tender contract that contains the code for bid evaluation criteria.
   a) Citizens just have to run the evaluation code that will read the bids from the block and evaluation them.
   b) The results of the evaluation will show whether the bidding process was fair (auditing tender allocation to the stated best bidder).

B. Security and Operational Requirements

In this section, we highlight the security and operation requirements any implementations of the open and transparent tendering framework has to satisfy.

R_1) The tendering Organisation cannot change the tender once it is placed on the blockchain. If due to some unforeseeable reasons they have to change it, then they have to create a new tender (smart contract) on the blockchain.
R_2) The tendering organisation cannot read the bid until the deadline is expired.
R_3) Bidders cannot change the bids of other organisation.
R_4) Bidders cannot see who else has placed a bid.
R_5) Bidders cannot mount a Denial-of-Service (DOS) attack on their competitors to stop competitors placing a bid on the blockchain.
R_6) Blockchain network or block miners cannot affect the tendering process.

III. Implementation and Operational Evaluation

In this section, we will detail the implementation of the proposed architecture - with it three variants: a) Full Track Scheme, b) Protected State Scheme and c) Stateless Scheme. We also list the performance costs and blockchain network usage costs (GAS).

[2]For security reasons, state-of-the-art public key cryptosystem [5] should be used with recommended configuration and key sizes as suggested by competent authorities like NIST.

[3]Similar to the public key recommendation, for symmetric key standard schemes like Advanced Encryption Standard should be used with adequate key size (e.g. AES 256) [6].

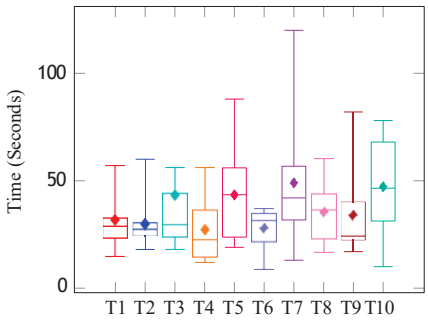

Fig. 3: Contract timing for Full Track Scheme Over Ten Trial Tenders

A. Implementation Details

In the implementation of the tender framework, we have used the Ethereum blockchain API. We made this choice because Ethereum is an open-source platform that is publicly available and a well-known choice for developing distributed applications.

With Ethereum, each transaction will have a gas usage and gas cost. The gas usage is determined by how computationally expensive the transaction is. The purpose of working out the gas used in each transaction comes down to the fact that every node in the blockchain verifies the transaction. If transactions were allowed to be arbitrarily complex, verification on the network would be slow and result in a processing bottleneck. Citing gas needed for each transaction allows miners to determine whether or not it is worth including the transaction in the block that they are mining and they will use the cost of gas, as set on each transaction by the node that pushed it, to determine this. Trying to push a transaction that is too complex or with the gas cost set too low will cause a transaction to be ignored by the miners when they pick transactions to include in their block.

To mine one of these blocks, a node must satisfy the proof-of-work constraint (Ethereum's choice for the consensus protocol) [7]. This constraint necessitates a certain degree of work to be undergone by the node that wishes to push a block to the wider chain. This stops a node from pushing an arbitrary number of blocks to the chain: it would be computationally unfeasible.

For a malicious node to corrupt a block halfway down the chain and present it as the valid active chain, it would also need to recompute every following block with their new cryptographic hash faster than every other participating node is working on their active chains.

We used Truffle JS [8] as our framework to create our contracts and wrote them in the Solidity language. For the unit tests during development, we used a private blockchain running on the TestRPC Ethereum client, and our operational performance tests were done using the Ropsten testing network. We chose this network because online documentation would suggest that this environment most closely resembled the Ethereum production environment at the time of testing.

To connect to Ropsten, we used the infura.io node. The blockchain explorer we used to interact with the contracts is MyEtherWallet using an account made via the MetaMask chrome extension.

Algorithm 1 Initiating A Tender

```
1: procedure REQFORTENDER( _length, _pubk, _limit)
2:     biddingEnd ⟶ TimeNow() + _length
3:     limit ⟶ _limit
4:     pubk ⟶ _pubk
```

The Request For Tender (Algorithm 1) is initiated by a contract placed on the blockchain. This contract is created with a length, given in milliseconds, that determines how long the contractors (also referred to as Tendering Organisation: TO) have to place their bids. This time is calculated using the Unix Epoch time at the time of creation. An upper limit is also given, which will be used to control the number of tenders a contractor can place for this auction. The entity that created the auction is also required to pass in a public key that is specific to this request for tender contract. These three attributes are held in the contract's state.

Algorithm 2 Placing A Bid (Full Track Scheme)

```
1: procedure PLACEBID(id, data, msgHashed, v, r, s,)
2:     bidV alidity ⟶ V alidBid(id, msgHashed, v, r, s)
3:   if bidV alidity then
4:         bidCount[id]+ = 1
5:     bid⟶ new Bid (id,data,bidValidity,bidsPlaced,biddingEnd)
6:     bidsPlaced.add(bid)
7:     return bid
8: procedure VALIDBID(id, msgHashed, v, r, s,)
9:     validHash ⟶ verify(msgHash, v, r, s)
10:    validTime ⟶ timeNow() < biddingEnd
11:    allowedBid ⟶ bidCount[id] < limit
12:    return validHash and validTime and allowedBid
13: procedure BID( _id, _data, _validity, bidsPlaced, biddingEnd)
14:    id ⟶ _id
15:    data ⟶ _data
16:    validity ⟶ _validity
17:    bidsPlaced ⟶ _bidsPlaced
18:    biddingEnds ⟶ _biddingEnd
```

TABLE II: Protected State Schema: Contract Deployment

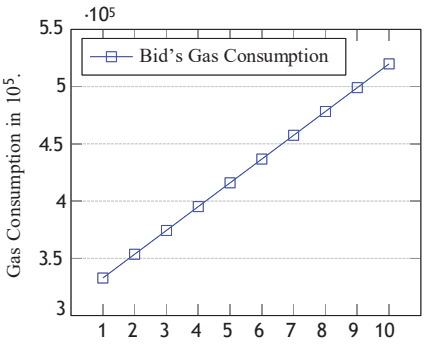

Fig. 4: Individual Bid's GAS usage (x 10^5) for Protected Scheme

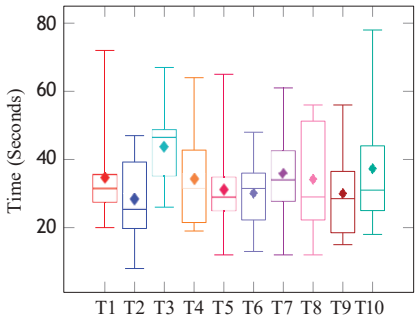

Fig. 5: Bid Timing for Protected Scheme Over Ten Trial Tenders

1) Full Track Scheme: When a contractor places a tender (Algorithm 2), the first step is to place a smart contract elsewhere on the blockchain that contains only the tender data. Experiments on the Ropsten test blockchain showed that 5000 bits could be stored on the blockchain with a gas consumption that didn't get immediately rejected for being too expensive. This roughly translates to 700 words. It is suggested that the usually more verbose tender contracts are adapted for this format, perhaps by extracting the key information (P_{TO}) necessary for the tender. The data on this contract is available to anyone maintaining the blockchain, and so is protected through the encryption performed using the bidders bid-specific symmetric key sealed by $P_{TO}(SK_{Bidder})$ as discussed in step 4a in Section II-A.

Placing the tender for the auction involves using the auction smart-contract. The contractor passes in their ID, which should have been pre-agreed between the auction creator and the contractor, the address of their tender data on the blockchain, and then the components of the certificate that will have been given to them by the auction creator. This certificate should have been signed using the private key that corresponds to the request for tender's public key that was put into the contract upon creation. To offload some of the computational complexity of the contract, the parts of this certificate (the hashed message, and the v, r, and s values) are extracted on the client side. The request for tender will take the address of all placed tenders and store it in an array.

All tenders left on the contract are recorded, but the validity is determined using the certificate, the time that the tender was placed, and the record of bids placed. The time when the tender was placed is retrieved using the ***now()*** function available on an Ethereum contract. The ***now()*** function uses the time from epoch registered on the node executing the transaction.

This timing can be considered trusted because of the timing consensus of nodes on the blockchain. Nodes are unable to mine blocks that have timestamps earlier than the parent blocks time stamp. Nodes are discouraged from placing blocks at an arbitrary amount of time ahead for the same principle – few nodes on the chain will be willing to put a block on the chain far ahead of their current time because they will be unable to place new blocks on top of it, thus stopping the block from getting picked up by a majority of nodes. Nodes are also discouraged from moving the time back because the challenge issued in the proof-of-work is orders of magnitude more difficult the shorter the interval between the current blocks timing and the parent blocks timing [9].

A bid is considered valid if the following hold ; 1) The contract is placed within time, 2) the certificate is verified to match the public key held by request for tender contract, and 3) the contractor is allowed to place more bids. If it fails any of these checks, it is still placed but flagged as an invalid bid. Note that the number of bids placed by the contractor is only incremented if it is being placed using a valid certificate, protecting the contractor from being locked out of the auction by a malicious party placing arbitrary numbers of bids using their identifier.

Algorithm 3 Placing A Bid (Protected State Scheme)

```
                                        d Running on the local machine
1:  procedure PLACEBID(id, data, msgHashed, v, r, s,)
2:      validHash → verify(msgHash, v, r, s)
3:      if V alidHash then
4:          bidValidity→ ValidBid(id)
5:          if bidV alidity then
6:              bidCount[id]+ = 1
7:          bid→ new Bid(id,data,bidValidity,bidsPlaced,biddingEnd)
8:          bidsPlaced.add(bid)
9:          return bid
10: procedure VALIDBID(id)
11:     validTime → timeNow() < biddingEnd
12:     allowedBid → bidCount[id] < limit
13:     return validTime and allowedBid
14: procedure BID( id, data, validity, bidsPlaced, biddingEnd
    )
15:     id → _id
16:     data → _data
17:     validity → _validity
18:     bidsPlaced → _bidsPlaced
19:     biddingEnds → _biddingEnd
```

The tender reference smart contract is then created and passed the id of the contractor, the address of the tender data, the validity of the contract, a copy of the array holding all of

TABLE III: No State Scheme: Contract Deployment

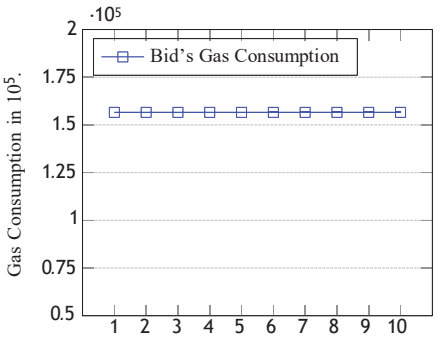

Fig. 6: Individual Bid's GAS usage (x 10^5) for Stateless Scheme

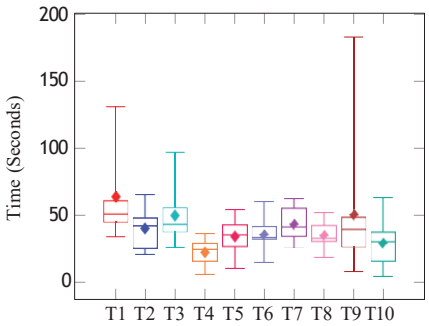

Fig. 7: Bid timing for Stateless Scheme Over Ten Trial Tenders

the addresses of the tenders placed before this one, and the auction end time. The address table is required to ensure the integrity of the array revealed by the auction creator – no bids could be intentionally erased from the array because the record of its existence will exist in the tender reference contracts.

Once the auction time has elapsed, the addresses can be requested from both the request for tender contract and the tender reference contracts.

Algorithm 2 performance indicates (Figure 2) that altering the contract's state to hold the addresses increases the gas usage, and thus the cost, on each subsequent transaction. This is not desirable, particularly as failing contracts are also registered in the smart contract, which leaves the request for tender at risk of a denial of service attack.

2) Protected Scheme: Algorithm 3 proposed an alternative schema to mitigate this potential denial of service attack. In this schema, the Request For Tender contract does not record bids if they fail the certificate check. We originally wanted to record every bid that was placed so the whole process would be recorded, and every attempted transaction would be visible. However, allowing anyone to place bids when each bid dramatically increases the amount of gas (and cost) necessary to place a new bid could leave our scheme open to a Denial of Service (DoS) attack. Although this scheme requires more gas initially, the first tender placed uses an amount of gas slightly higher than the third tender in the full tracking schema, given that it protects against DOS attacks from unauthorised parties, the gas hit is comparatively negligible.

Of course, in both of these proposals, the changing state of the Request For Tender contract does still lead to a dramatic increase in gas usage per transaction, regardless of whether or not those bids are intentionally malicious.

3) Stateless Scheme: Algorithm 4 provides an alternative by not storing the Tender Reference contracts in an array on the Request For Tender contract. This solves the increasing gas issue because we would no longer be changing the state of the Request For Tender contract. This would mean that a Tender Reference Contract would no longer need to hold information about previously placed bids and would also not require knowing when the tendering period ends because

Algorithm 4 Placing A Bid (Stateless Scheme)

d Running on the local machine

```
1:  procedure PLACEBID(id, data, msgHashed, v, r, s,)
2:      bidValidity→ ValidBid(id,msgHashed,v,r,s)
3:      if bidV alidity then
4:          bidCount[id]+ = 1
5:      bid→ new Bid(id,data,bidValidity,bidsPlaced,biddingEnd)
6:      return bid
7:  procedure VALIDBID(id)
8:      validHash → verify(msgHash, v, r, s)
9:      validTime → timeNow() < biddingEnd
10:     allowedBid → bidCount[id] < limit
11:     return validHash and validTime and allowedBid
12: procedure BID( _id, _data, _validity)
13:     id → _id
14:     data → _data
15:     validity → _validity
```

there would be no information to be queried from the Tender Reference Contract after the request for tender period lapses. Instead, when a bid is placed, and the address is returned to the contractor, this address could then be given to the auction creator external to the transaction. The requirement would then be for the auctioneer to use a third part chain explorer to verify that the contract was made as the result of a transaction registered to the request for tender contract. The issue here would be that the third parties would have to be considered trusted and that they may, for non-malicious reasons, not have the required information (either from memory constraints necessitating that not all transactions are registered, or from missing the transaction altogether). However, if the contractor requires a certificate of acknowledgement from the auctioneer after they have given their tender-reference address, the auctioneer will not be able to refute that they received the tender.

4) Bid Evaluation: Algorithm 5 is a retrieval algorithm that is only applicable to the schemas where the addresses are held in the state of the Request For Tender contract. The addresses would be retrieved from the contract after the request for the tender period has elapsed. The client application is used to interact with the blockchain will request the contract on the

Algorithm 5 Evaluating All Bids

```
1:  procedure MAKEREQUEST( _length, _pubk, _limit)        d
    Running on the local machine
2:      listOf Bids → ReqBids()
3:      for bids in listOfBids do
4:          validBid →bids.getValidity()
5:          if validBid then
6:              listOfValidBidDataAd-
    dresses.add(validBid.getDataAddress())
7:  procedure REQBIDS( _length, _pubk, _limit)  d Running
    in the blockchain
8:      afterAuction → timeNow() > biddingEnd
9:      if afterAuction then
10:         return bidsPlaced
```

blockchain. Retrieving the information does not require any transactions and thus incurs no transaction cost.

The client application will receive a list of bids (in reality, this will be the addresses of the bids placed). These bids can then be queried for their validity and, once ascertained, the address of the actual tender data can be requested. The whole algorithm has a running time of O(n).

IV. Security and Operational Analysis

Evaluations for each of the proposed variants is presented in this section and summarised in Table IV.

TABLE IV: Security and Operational Requirements Analysis for Three Variants.

	Full Track Scheme	Protected Scheme	Stateless Scheme
Blockchain Architecture			
Centralised	□	□	□
Open	□□□□□	□□□□□	□□□□□
Distributed	□□□□□	□□□□□	□□□□□
Security and Operational			
R_1	□□□□□	□□□□□	□□□□□
R_2	□□□□	□□□□	□□□□
R_3	□□□□□	□□□□□	□□□□□
R_4	□□□□	□□□□	□□□□□
R_5	□□□□	□□□□	□□□□□
R_6	□□□□□	□□□□□	□□□□□

As all of the proposed variants rely on open blockchain infrastructure, they all satisfy the open and distributed environment requirement. This requirement is imposed on the blockchain technology so open and fair evaluation of the activities on the blockchain can be conducted.

All three of the schemes do not fully meet the R_2 requirement for the reason that if a bidding organisation shares the second half of the $P_{TO}(SK_{Bidder})$ (the first half is on the blockchain with the bid and second half remains with the bidding organisation) to the tendering organisations before the deadline, then, yes, the tendering organisation can read the bids. In all of the proposed schemes, we do not enforce that the key can only be shared after the deadline. This was to accommodate a bidding organisation's business processes and priorities.

For R_4, the full track and protected schemes do not fully support the requirement. This is due to the exponential increase in the Gas costs when placing bids on the blockchain (Figures 4 and 6), which could escalate beyond what can be considered a reasonable cost for business practices. In theory, a malicious entity can place so many bids on a tender that it becomes economically too costly for genuine bidders to place a bid. However, from a practical point of view, the high number of bids necessary to make Gas cost extranomical would cost the malicious entity a huge sum of money. Furthermore, such a high number of bids would also be easily detected by the tendering organisation and any third party monitoring the tendering process. Therefore, such an attack might not be an attractive prospect for a maligned actor.

V. Conclusion and Future Research Directions

Openness and transparency are frequently discussed in the public service domain. Traditionally it has been difficult to build a transparent governance model. This was because it required an investment of both time and money from all stakeholders, especially the citizens. With the increasing adoption of e-government and open government initiatives, public opinion is in favour of developing innovative solutions that can increase openness and transparency in government activities with minimum cost to citizens. For citizens to be involved in monitoring the governance activities, they need efficient tools and intuitive assessment that gives clear results. To build such an environment, blockchain and smart contracts show great potential. In this paper, the government tendering process is implemented in the blockchain environment to provide an open and fair tendering scheme. Based on the proposed architecture, we put forward three variants that were then implemented on Etherium to show their applicability, Gas cost and computational performance. The main objective of the paper was to show that the tendering scheme can be made fully open, autonomous, fair and transparent using smart contracts. To this end, it was successful.

Abstract- A person's blood type might show up in the swirls of their fingertips. Fingerprint pictures take the place of test tubes and needles here. Through software tricks, those tiny lines get sharpened and tidied up. Clear ridges mean better clues for the next step. Patterns hidden in the skin emerge after digital cleanup. Machine smarts search for links between grooves and blood kinds. What once needed labs now leans on image math instead. Once cleaned up, the fingerprint pictures give out main traits fed into learning systems. Though several methods like SVM, Random Forest, KNN, plus Gradient Boosting take turns being tested, one stands out in guessing right more often. This work aims at building something swift, hands-off, yet simple enough to help when knowing blood type fast matters - say during crises or far from labs.

Keywords- Blood Group Detection, Fingerprint Analysis, Machine Learning, Consensus Mechanisms, Image Processing, Feature Extraction, Ridge Pattern Analysis.

I. INTRODUCTION

Right now, tech shapes how health care gets better. Spotting someone's blood type matters a lot - think surgery, crashes, or giving blood. Usually, labs handle this by drawing blood and using special chemicals to test it. True, the results are correct, yet it takes time, tools, plus people who know what they're doing. One way to look at blood types starts with fingerprints. These skin ridges differ sharply from person to person, showing up clearly through digital scans. When software learns from many examples of these prints, certain shapes begin linking to specific blood categories. Learning such links takes large sets of tagged images. Patterns hidden in swirls and loops might carry clues about biology beyond identity. What matters most isn't swapping out lab tests entirely. Instead, it's about building something faster that backs up decisions when time in medicine gets tight.

Nowadays, learning machines show up in nearly every corner of medicine. Spotting diseases in images? That's one way they pitch in. Not limited to detection alone, they sometimes forecast issues before symptoms appear. Speeding things up for doctors, technology backs choices while leaving final calls to people. Mistakes are a concern for certain folks. Yet many believe early warnings are getting stronger because of it. Every day inside medical centers, clever programs scan details humans could miss. Not spelling - numbers do the thinking, trained by countless old records. Quick decisions? They grow from solid facts put together right. Each print unique like a signature, never fades under pressure. Team them up, suddenly new ways to help patients start showing up. Fingerprints start forming before a baby arrives, then never change later. Loops, swirls, or peaks along the skin set everyone apart. Research connecting these tiny ridges to traits such as blood group has shown hints of ties. As experts dig further, smart software picks up subtle clues human eyes often skip. Proof remains uncertain - still, technology untangles what seems too tangled by hand. Pictures of fingerprints are cleared up at the start, using steps that sharpen details while removing fuzzy patches. The clear parts become digits rather than curves or edges. After studying many labeled samples over time, the system gradually notices patterns linked to blood groups.

What pushes this design ahead is a rush to know when timing matters most. Labs give solid answers - yet speed sometimes beats precision at first. In tight windows, delays can stall decisions. Ahead of lab work, it fits in quietly. Not here to take over testing - but to show up earlier. Sure, old ways win when it comes to precision. Still, moments pop up where waiting slows things down too much. That space gets covered here, without fanfare. Full checkups just aren't possible whenever seconds count.

1."Secure Blood Group Using ML Technology" – S. Karthikeyan, R. Priyanka, and M. Sangeetha (2023) This paper explores the study focused on using dermatoglyphic parameters including total ridge count, ridge density, and pattern type identification such as loops, arches, and whorls.

2. "Blood Group Classification" – P. Sharma and A. Gupta (2022) The study by Fatma Nada Khalifa et al. (2021) investigates the possible relationship between fingerprint patterns and blood groups among a sample of 221 healthy Egyptian individuals.

3." Blood group classification on based on image processing" (2021) The researchers conducted an observational study, where fingerprints of the participants were collected and classified into major dermatoglyphic patterns such as loops, whorls, and arches, along with measurements of ridge density.

4. Cross sectional analysis of fingerprint patterns in blood groups (2023) The study by Surendra Kumar Sah, Samyog Mahat, et al. (2023) presents a cross-sectional analysis aimed at exploring the association between fingerprint patterns and blood groups among 200 medical students.

III. PROBLEM STATEMENT

Statement **-** Nowadays, figuring out someone's blood type usually happens inside a lab. Getting it done means drawing blood, using specific chemicals, having working tools nearby, plus people who know how to run tests. Even if the answer turns out correctly, waiting slows things down - especially when help is needed fast. When seconds count, delays show up because supplies or experts might not. A shift toward speed matters now, especially when labs aren't within reach. Tech steps in where needles and test tubes fall short. Prediction moves ahead not through samples but signals. Distance from lab work doesn't mean stepping back from accuracy. Tools rise to fill gaps once left open by tradition. Speed meets simplicity outside sterile rooms. Reliance on machines grows while waiting fades.

Explanation- Fingerprint clues might one day help reveal a person's blood type. Instead of drawing blood, this work explores how ridge shapes, line flows, and small details in fingerprints may contain useful information. The patterns hidden in skin textures can become data points for analysis. Machine learning models study these details and learn to associate them with specific blood groups. This approach focuses on making the process quick, simple, and painless, without the need for needles or traditional laboratory tests. Identification gradually moves toward touch-based scanning methods where each curve, ridge ending, or split in a fingerprint may carry meaningful signals. By feeding fingerprint images into intelligent algorithms, the system learns to detect subtle differences in patterns. These results aim to classify fingerprints accurately based on biological relationships that may not be visible to the human eye. Such a method introduces a new direction where identity verification could also provide insights about health characteristics through friction ridge patterns. Testing therefore shifts from laboratory experiments to digital pattern recognition. What appears to be simple swirls and loops in fingerprints contains structured patterns that machines can interpret. In this way, fingerprint impressions are transformed into meaningful insights without the need to collect blood samples, offering a fast and non-invasive alternative for analysis.

laboratory-based blood testing methods, which are time-Picking up speed, analyzing fingerprints with software cuts down delays caused by older methods needing special tools and experts. Instead of relying solely on people, smart algorithms scan ridge patterns, linking each mark to a likely blood type. Errors drop when machines handle repeats instead of tired eyes doing it again. In urgent cases - like sudden injuries - answers come quicker, shaping choices before time runs out. Guarding private details matters just as much; encrypted layers keep health records locked away from risks. Built to grow without breaking, the setup stays simple even when more users join in. Hospitals might adopt it first, though remote clinics benefit too where supplies run thin. Efficiency rises not because tech replaces humans but because tasks flow smoother behind the scenes. Quiet improvements like this shift how care moves from guesswork toward precision. One way it helps. By making room for fresh tech like machine learning to step into healthcare. Built with savings in mind, it cuts down on heavy spending on lab setups.

Motivation:

- To reduce dependence on traditional laboratory-based blood testing.
- To develop a non-invasive blood group prediction approach.
- To assist healthcare professionals during emergency situations.
- To improve accessibility in rural and remote healthcare centers.
- To reduce human errors in manual blood typing.
- To create a faster response system for critical medical decisions.
- To design a scalable and efficient prediction framework

IV.OBJECTIVE

One goal here is to build a smart tool that guesses blood type from fingerprints using machine learning. Instead of drawing samples, it looks closely at ridges, bends, and tiny points in the print. Through digital image work, those visual clues turn into numbers a computer can understand. Afterward, several learning models learn this number patterns linked to specific blood types. Speed matters, so the idea works best when quick answers are needed without needles or labs. Even remote places might benefit since equipment demands drop sharply. Testing shows whether predictions hold up across diverse skin textures and print qualities. Accuracy climbs when more varied data feeds the training stage. Because results come fast, help could arrive sooner during urgent cases. Less waiting means faster decisions when every second counts. This path skips some classic lab steps while still aiming for reliable outcomes. From another angle, simplicity guides the design - scalability fits right in, security tags along. Biometric information stays protected without slowing down precision or speed. Looking closer, this effort shows what artificial intelligence brings to healthcare: a leaner way to figure out blood types using smart tech instead of heavy costs.

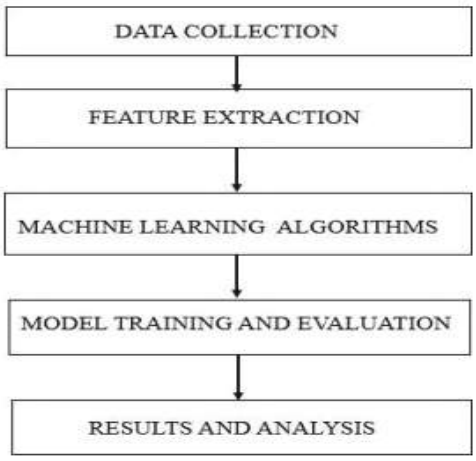
V. METHODOLOGY

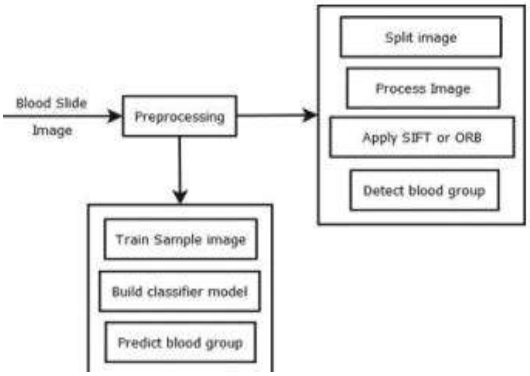
1.Data Collection
Folks give fingerprint scans after their blood type has been recorded. Once gathered, those prints get sorted, then clean up a bit so they're ready to move forward.



2.Image Preprocessing
Fresh off the scan, fingerprints get wiped off specks and smudges for sharper detail. Though originally messy, they shift into gray tones, then stretch or shrink just enough to match size.

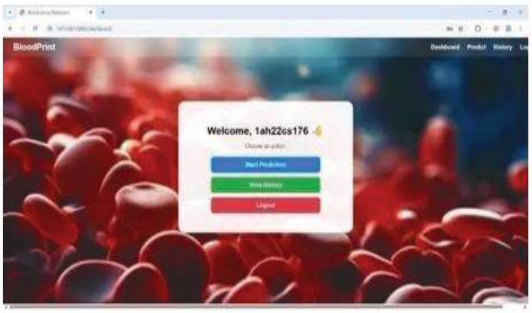
3.Feature Extraction
Fingerprint details like ridge shapes, how they move across the surface, also where they split or stop get picked out first. From there, those traits turn into numbers, so algorithms are able to process them.

4.Model Training
A mix of methods - Support Vector Machine, Random Forest, K-Nearest Neighbors, along with Gradient Boosting - get shaped by the selected features during training. Though each handles patterns differently, they all rely on those same inputs to learn. While one might weigh distances, another follows decision paths. Each model adjusts its inner logic based on what the data shows. Where some split repeatedly, others draw boundaries.

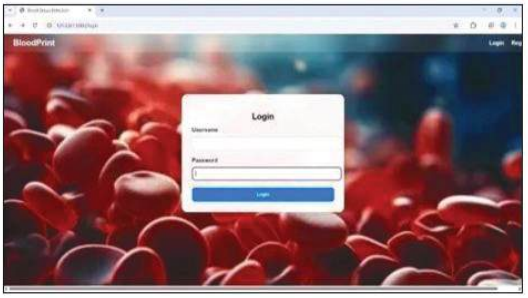


5.Testing and Evaluation
A split happens within the data - some parts train, others test. Once learning finishes, fresh untouched examples check how well it works. Numbers like accuracy show results, along with precision and recall shaping the full picture.

6.Model Selection
A different version gets picked if it guesses outcomes more correctly than others. This one then moves into the main setup.

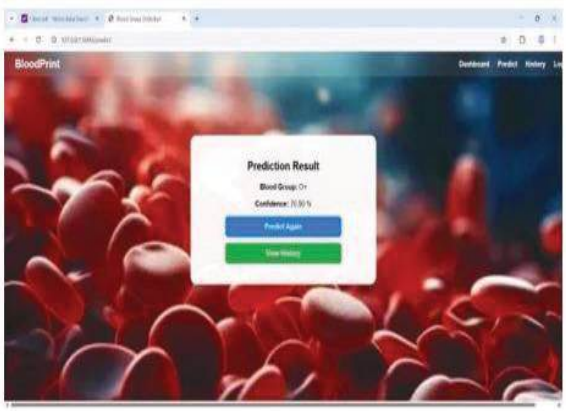


VI. SYSTEM ARCHITECTURE



Starting off, a fingerprint picture comes in - grabbed by a scanner or pulled from stored data. Next up, that image gets cleaned; messy bits fade out so clarity steps forward. With sharper detail now visible, key traits rise ridges curve, tiny split points show, patterns emerge like whispers. Numbers take shape from those clues, turning physical marks into digital code. data and used to train different machine learning models. Algorithms such as Support Vector Machine, forest of decision trees learns from marked examples, just like neural nets do, spotting signs tied to different blood types. Features inside a fresh fingerprint scan get examined once it arrives, guiding the model toward a likely match. Out comes a conclusion - something like A+, B+, AB−, or O+ - shown plainly on screen. Step by step, without pauses, the process moves forward, turning images into answers quietly, without fussing.

VI. ULTS



Once the models were trained and tested, they managed to guess blood types with decent precision. Because of careful data cleanup and smart selection of traits, their guesses got sharper. While several methods were tried, certain ones sorted the categories more successfully than the rest. It turns out fingerprints might someday help confirm a person's blood type.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

VII. DISCUSSION

Fingerprint designs might hint at someone's blood type when studied with machine learning. Starting from tagged samples, the model picks up links between ridge shapes and specific blood groups. Even if early outcomes look hopeful, how well it performs ties closely to data volume and clarity. Better results could come from richer datasets or smarter algorithms down the line. Think of this approach as more like backup support, not an alternative to standard lab checks.

Abstract- *A Drainage Monitoring System plays an important role in keeping towns and cities healthy and clean. Many manholes are left open without supervision, which can lead to accidents. In India, several cities have adopted underground emptying systems because they are essential. However, not all manholes are secure. Many are in poor condition, increasing the risk of accidents on the roads. Therefore, the status of emptying will be checked daily. Irregular inspections can cause overflow, clog emptying systems, and lead to complaints. Manual monitoring has proved ineffective, making it difficult to handle issues quickly when emptying. After researching these problems, we developed an IoT-based manhole system that monitors temperature, gas levels, and water levels. These damaged manholes pose a threat to public safety. This research aims to prevent accidents and protect lives.*

1.INTRODUCTION

Drainage lines run under plenty of Indian cities. Running the sewage setup falls to the Municipal Corporation, aiming for cleaner air and safer surroundings. When upkeep slips, rainwater sneaks into pipes where it should not be. Trouble spikes when rains arrive each year. Manholes give way as rising fluids press from below. Wrong to trust biodegradable cleanup. Infections slip into wells, bringing sickness. Seasonal clogs stir trouble. Manhole cover mishaps rise when drains fail. Gases may escape - fire follows, then lives lost. A split anywhere on the cover may lead to its collapse. Keeping track of access points matters a great deal. Right now sewage removal isn't moving forward. Poisonous fumes such as methane along with carbon monoxide pose real danger. Health risks turn severe without warning. Workers handling waste regularly confront these dangers - sometimes fatally. While clearing blockages individuals could breathe in toxic air. Heat might trigger sudden explosions, sometimes deadly. Security for people walking by depends partly on the manhole's top piece staying in place. When that cover is gone, officials usually notice what has happened. A shift in how the lid sits could lead to dangerous incidents too. Building a way to watch over and care for these openings is the goal here. A light flickers when gas builds up inside the chamber. This setup watches lid position, heat shifts, and gas development closely. Immediate data flows to responders so delays shrink. Hidden sensors spot cover movement without warning signs. Urban zones lean on connected tools that check conditions nonstop. One study points out how often manhole lids go unchecked. When covers fail, risks climb for everyone nearby. Unseen leaks drain resources while streets stay busy overhead. Monitoring cuts down on surprise failures across neighborhoods. A warning setup sends updates on how things are running so the company knows what is happening. That way officials can move quickly if fixes are needed. Gas levels get spotted by a sensor built into the trash network to stop blasts before they happen. Keeping an eye on wastewater paths becomes possible through one small tool doing constant checks. Rising liquid inside pipes or someone lifting the exit cover triggers the alert process It starts when sensors spot vehicles approaching. Information moves through a network once found. From there, data travels by Wi-Fi to officials at the city office. What happens next shows up online - overflow levels and gas readings appear together. Sensors do the watching without help. Cloud storage holds what is gathered for later look. Streaming information nonstop into the cloud setup. Drivers then get updates about potholes thanks to this flow of details. Research work numbered seven brings IoT into play for smarter water runoff control. Detection happens through sensing units that trigger warning signals sent by GSM tech to city officials.

II RELATED WORK

Smart cities could include things such as adaptive traffic lights, various sensors, and communication networks. When smart gadgets become part of urban setups - thanks to well-placed IoT tech - they tend to simplify daily living, according to study [9]. Environmental tracking tools, shaped through IoT, offer practical solutions in poorer regions. Sensors come in many forms: ones that spot flooding, measure heat and moisture, sense ultrasonic waves, check air quality, or detect shifts in

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

angle, as shown in research [4]. Flood levels - low, medium, or high - get confirmed by the overflow sensor, aiding faster warnings. This setup appears in study [2], where several tiers exist side by side. One such tier handles sensing duties. That part uses a Raspberry Pi microcontroller at its core. Layers stack beyond it: network, application, perception, among others Despite gathering signals from underground access points, data moves through IoT networks for transfer between systems. Paper [11] shows the method scales well while keeping quality and safety standards high. Power demand stays remarkably low throughout operation cycles. Still, sending information takes far longer than expected due to sluggish speeds. Most earlier studies focused on locating the lid plus checking harmful gas levels inside manholes. Instead, this work looked at the manhole cover along with heat and moisture readings. Overflow alerts were included too - sending warnings when measurements climbed past limits. Officials got instant notification through alert tones. [13]

III. SYSTEM DESCRIPTION

It is designed up with ultrasonic sensor, tilt sensor, gas sensor, temperature and humidity sensor and water level sensor. It is used as measure the temperature and humidity, inside drainage depth, gases, lid of manhole in a certain distant field. In the project [10], have used IoT based technology for better performance, simple way of communication, for low cost based and drainage water management system. The proposed system will provide the real time data updating to IoT device in addition to accurate sensor data information. The paper [6] represented monitor the inside manhole drainage temperature and humidity,

excess release of dangerous gases, level of drainage water and position of manhole cover. In these research paper [1], To understand the working of raspberry pi and connectivity between sensor, helps to solve the problem by a smart device using IoT. The research paper [3] represents the implementation and develop function of Manhole Detection System by using the sensors which Raspberry Pi read the data from the sensor units and send the alert message to the user through GSM module and system data is monitored in the App.

The block diagram shown in Fig. 1 determines the Manhole Detection and monitoring system. Whether any changes in both the temperature and humidity, releases of harmful gases, presence of manhole cover or not, level of wastewater is detected by the respective sensor. This system consists of:

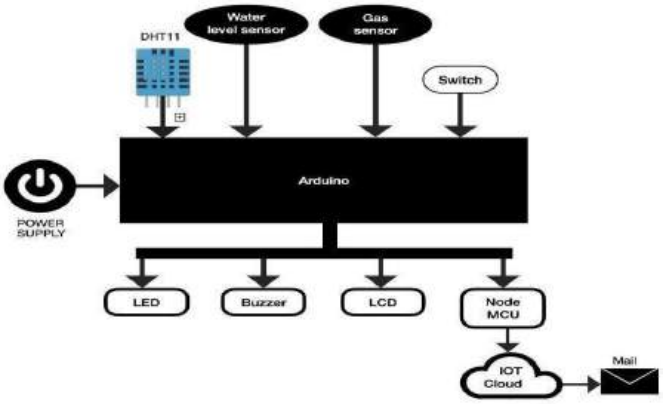

Fig. 1. Block Diagram

A. Ultrasonic sensor- HC-SR04

In proposed design the specific type of HC–SR04 (Ultrasonic sensor) is used. it can convert the sound signals into electrical signals. In Fig. 2 sensor emits the ultrasonic waves whether these waves hits near the object and reflect the waves back to the sensor and convert into the electrical signals. Hence, it can sense there is an object present In front of the sensor. This sensor will detect noncontact range between 2 cm to 400 cm with an accuracy of 3mm. When there is manhole cover between 2cm to 400 cm in the range the system will not sense the alertness. In any case, if the manhole covers above 400 cm the system will generate alertness and followed precautions will be taken by the corporation. In research work the role of sensor is to check whether the lid of manhole is present or not to the basement of drainage. This ultrasonic sensor used as many industrial applications as possible to track the In front object present or not.

Fig. 2. Ultrasonic sensor- HC-SR04

B. Tilt sensor

The mercury type of tilt sensor shown in Fig. 3 is used to check whether any changes in the angle of tendency of manhole cover to the cellar other than the zero degree. It can also measure angle of inclination of manhole cover take place to the basement and live data has been updated in the App.

Fig. 3. Tilt sensor

C. Water level sensor

The magnetic reed liquid level type of overflow sensor is used to detect the level of drainage water present inside the drainage system. In cities due to heavy rainfall there is maximum chance of increase and overflow of drainage water outside the road. Due to this overflow of drainage water in the road accidents will take place. While these people are moving

Vol. 14, Issue 06, ACSCON - 2026

in the road can't see whether in particular location manhole cover is present or not. In sensor Fig. 4, the float switch will use the magnetic reed switch is to open or close the circuit. The float switch, magnetic reed switches hermetically sealed within the stem, most often made with the plastic, under any condition raise and fall of drainage water level takes place automatically the float switch moves up and down the length of the stem. Hence, it will check any changes took place in level of drainage water inside the manhole cover under any desirable condition.

Fig. 4. water level sensor

D. Temperature and Humidity sensor - DTH11

In working system temperature and humidity sensor Fig. 5 is DTH11 model have been used for measuring the values of temperature and humidity inside the drainage system. It is simple, low–cost, digital and can sense both the temperature and humidity at a simultaneously. In drainage system under the manhole cover there is drastic changes takes place based on temperature and humidity. While there is any chance of increases in temperature and humidity inside the drainage depth. The alert message will be generated and send to the municipal corporation.

Fig. 5. Temperature humidity sensor - DTH11

E. MQ2 Gas sensor

The gas sensor is used in the proposed design is MQ2 Gas sensor. It can also be represented as chemiresistor. It consists of sensing material as resistance. whereas various types of gases in contact with the resistance present inside the sensor, if there are any changes in the value of resistance will sense the which type of gas is released inside the manhole. Fig. 6 the various type of gases concentration will measure by the voltage divider. It will provide the voltage values which is used to measure the concentration of gases. when the voltage divider network has the voltage values are high as well as concentration of gases is high. It will identify various types of gases are fumes, CO gas, CH4 gas, Liquid petroleum gas, alcohol and H2 gas. It can observe the concentration of gases from the range 200 to 1000 ppm. This type of gas sensor used for the research work as to detect the harmful gases releases inside the manhole of drainage system. If there is excess release of toxic gases inside the drainage depth. The microprocessor sends the alert message to the municipal corporation through GSM module. The amount of concentration of gas releases and output data display in the App.

Fig. 6. MQ-2 Gas sensor

F. SIM900 GSM Module

In the research work as used the mode of communication to send the information of all sensor values to the municipal corporation with the help of SIM900 GSM Module. These GSM Module operated with bandwidth 900MHz and in India the mobile networks are providing the same 900MHz band across all over areas. To operate the Module, insert the SIM card in the given slot. It can support all mobile networks except jio network and access in the 4G network speed. To run the module Raspberry Pi board should be connected where it will read and generate data from the sensor units. Fig. 7 the GSM Module it can send the alert message to the municipal corporation.

Fig. 7. SIM900 GSM Module

G. Adaptor

Mainly, 12-Volt and 5-volt Adapter Power Supply have been used in the research work. These Adapters are widely used for the power supply to the system. The 12-volt adapter has used in the GSM Module and another 5-volt adapter is used in Raspberry Pi board for the working of the manhole detection and monitoring system.

H. Raspberry Pi 3 Model B+

In this proposed design, mainly microprocessor has used to process and run the all the units in the system. The model has introduced in the research work is Raspberry Pi 3 model B+. Fig. 8 present model has used in the system as the better features than previous model. The microprocessor consists of 1GB RAM, in-built dual–band WIFI and have the Bluetooth version 4.2. By the help of personal hotspot can connect to the WIFI in Raspberry Pi to access the internet. In paper [8], the function of microprocessor is which fetch the information from the sensor and transmit signal to the GSM Module. Furthermore, the data is updated in the App by using IoT technology.

Fig. 8. Raspberry Pi 3 Model B+

A Manhole Detection and monitoring system help in maintaining human safety, clean city and reduce the effort of municipal corporation. The different kind of sensors - (water level, Ultrasonic(HC-SR04), Temperature and humidity(DTH11), Tilt and MQ2 Gas sensors) are interfacing with microprocessor Raspberry Pi in order to run the system efficiently and accurately. When these sensors sense the data whether the live data reach the threshold level, and these sensors immediately send the respective value of data to the microprocessor. Furthermore, Raspberry Pi sends the information and condition of the drainage system to the municipal corporation. Based on the information the high authority of municipal corporation officials will take action and follow the certain precaution. Also, microprocessor update the live data and output data of the system will be display and at a time update in the App by using IoT. An alert text message will be sent to the municipal corporation through GSM.
Fig. 9 consists of detail flow chart.

Algorithm

- Start
- Power supply is given to hardware system.
- Initialize and run the hardware Module.
- Raspberry Pi board sense the value of data from the Sensors.
- Tilt sensor check the lid of manhole having the zero degree of angle of inclination to the basement. If the angle of inclination is more than zero degree.
- DHT11 (Temperature humidity) sensor sense temperature and humidity levels in the underdrainage system.
- MQ2 Gas sensor check the harmful gases level concentration under respective condition.
- Water level sensor sense the level of drainage water under manhole cover at that time.
- Ultrasonic sensor detects whether the manhole cover is present or not.
- If any sensor exceeds more than threshold or set value. Then alert message sent to the municipal corporation through GSM Module. By using IoT technology the output data updated in the App.
- The information of the data will be display and monitor in the App.
- Stop.

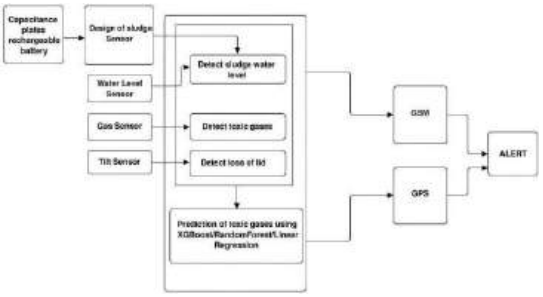

Fig. 9. Execution Flow chart

In the research work have used the various type of sensors and the values of the sensors are lay hold of into consideration. To maintain the Manhole detection and monitoring at all times. When the Raspberry Pi collects the all the data from the sensor's units. These sensors receive all the values and following steps to be followed.

1) First Ultrasonic sensor senses whether manhole cover present or not to the basement if it present or else, it goes to the second step.

2) Second step to be followed tilt sensor check whether the angle of tendency of manhole cover to the cellar is 0 or more than zero degree if it present zero or else it goes to the third step.

3) Third step to be followed temperature and humidity sensor sense the values of data inside the drainage system. whether these values reach the threshold value or else it goes to the fourth step.

4) Fourth step to be followed gas sensor detect the various types of gases release inside the drainage system. If there is excess release of toxic gases or not it goes to the final step.

5) Finally, water level sensor detects the level of drainage water present under the manhole cover. If there is any chance of increase of drainage water or else, it sends the alert signal message to the municipal corporation through GSM. A live data update in the App through IoT network.

II. SOFTWARE IMPLEMENTATION

For coming to the software implementation of proposed design. It can proceed into three steps process.

1. Operating System
2. Programming Code

A. Operating System

To start software implementation, the operating system Raspbian - Linux Environment is required. To run the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

software aspects of Manhole detection and Monitoring system Raspbian OS plays crucial role. To operate the Raspberry Pi board Linux environment, install in the system. Also, to read and write the programmed code Raspbian OS is important.

B. Programming Code

To operate and run the system software code is required. By using the Arduino IDE can develop suitable programmed code. After completing the programmed code write up and to run the code in the Raspberry Pi board. Finally, the desired result will be displayed. [14]

Arduino IDE

Inside the Manhole Monitoring System, programs reach the Arduino chip through a tool called Arduino IDE. This workspace makes coding easier by offering clear tools and an approachable layout. Instead of complex steps, it uses a version of C/C++ that feels familiar to many coders. Code runs here before moving onto the hardware. One task involves setting up the Arduino Uno to gather readings from different detectors - like those catching gas levels or shifts in angle. When signals come in, they get sorted and reviewed right inside the environment. If numbers go beyond what's considered safe, the system takes note without delay.

After writing the code in the Arduino IDE, compilation happens before sending it to the Uno via USB. Running nonstop, the microcontroller keeps an eye on what's happening inside the manhole as things unfold. If something unusual shows up - like rising water, dangerous gases, or the cover being moved - the board reacts by activating warnings, relayed to a phone app or shown on a display panel. Built-in features such as the Serial Monitor let users check live data from sensors while troubleshooting test runs.

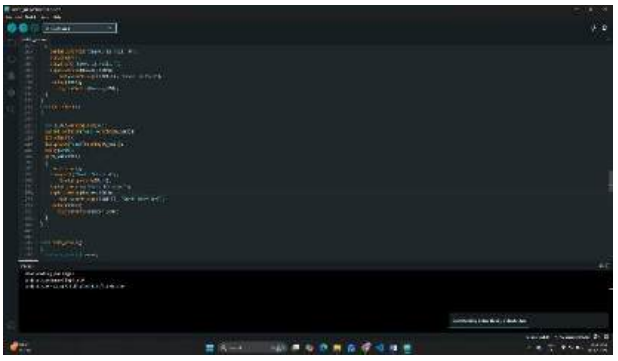

Fig. 10. Arduin IDLE file

III RESULTS AND DISCUSSION

The system gets started by taking power supply externally all the sensor will start working. Sensor unit senses all the physical parameters like Gas concentration, drainage water level, with the help of sensors temperature, humidity and gas leakage can be identified. The system also informs whether the manhole lid is open or closed by using the ultrasonic sensor. All the sensors are checked in such a way that their values are below and above the threshold value. In any case, above parameter are changes spontaneously the Raspberry Pi send signals to the GSM module and it can send alert message to the Telegram application. The municipal corporation can handle that telegram application.

Inside the manhole, several kinds of sensors keep track of changing conditions. Water height gets watched by a dedicated sensor, spotting when levels climb too high. Instead of relying on sight, an ultrasonic device calculates inner depths to catch clogs or fast-rising floods. Dangerous fumes like methane show up thanks to a gas-detecting unit built into the setup. Heat changes do not go unnoticed either - temperature tools watch for spikes without warning signs. While one part checks liquid volume, another stays alert for invisible threats below ground. Each piece works apart yet fits within a larger network sensing trouble before it spreads. Measurements update continuously so risks reveal themselves early. No single element acts alone; they form layers of awareness under city streets. Hidden but active, these devices trace shifts few would otherwise notice.

A single microcontroller links several sensors, connecting them through a communication chip. This arrangement watches manhole environments closely, spotting risks as they appear. When trouble shows up, warnings go out fast - helping keep workers safe and systems running. Built this way, it responds quickly, using feedback from each sensor to act before problems grown. The hardware setup is shown in below Fig. 12.

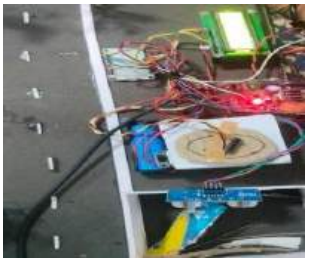

Fig. 12. Hardware Setup

The desired results are shown in the IoT based manhole monitoring in app Fig. 13 by using IoT technology.

III. CONCLUSIONS

Manhole cover localisation is a challenging problem. We have proposed a multi-view scheme, which combines 2D and 3D analysis. Following a principle of spending little time on the bulk of the data, and reserving a more refined analysis for the promising parts of the images, the proposed system combines efficiency with good performance. The main contribution of the paper is that for the first time a system based on vision and GPS is used successfully for the task of manhole mapping. Our system benefits from using multiple views and thereby goes beyond detection and recognition, obtaining pixel-level accuracy and centimetre level accuracy in the 3D localisation of manholes. In the future, we plan to investigate the role of scene context and how the proposed pipeline can be used for other class specific tasks in mobile mapping. Acknowledgements. This work has been partly supported by the European Commission FP7-231888-EUROPA project. We thank Geo Automation for providing the images and for their support. The sensor unit is automatically sensing the all parameters like toxic gas, flow rate of water and also sense the humidity and temperature in manhole This project system is reducing the work of man power and increasing the safety of work and speed of work. It is easy to get all above mentioned information in one click solution.

Abstract — Decentralized applications (DApps) based on blockchain have emerged in popularity due to the drastic growth of decentralized blockchain environments and the popularity of smart contracts. While this growing popularity of DApps is understood, many definitions, architectures, and classification of DApps are not yet clearly established. This survey organizes the DApp ecosystem and provides a more methodical introduction to DApps. First it introduces the essential building blocks of blockchain, consensus protocols, and smart contracts. Next, we examine four main DApp architectures: Native Client DApps, Smart Contract DApps, Web & Contract DApps, and Fully-Decentralized DApps. A data set of 3,118 DApps is analyzed and categorized by Domains: Finance, Gaming, NFTs, Data Storage, and Prediction Markets, along with advantages and challenges of using DApps. It also summarizes relevant research issues regarding Economic, Security, and Performance, such as incentive schemes, vulnerabilities, and scalability. Finally, we provide future research opportunities towards developing accountable, efficient, and easy to use decentralized applications.

Keywords — Money Transaction, Blockchain, Python Flask, Decentralised, FastAPI, JavaScript, Hash Block, Hash Function.

I. INDRODUCTION

Money Transaction Security Using Blockchain is a project developed to address the growing security concerns in modern digital payment systems. With the increasing reliance on online and electronic transactions, traditional money transfer systems that operate on centralized architectures face challenges such as data breaches, fraud, lack of transparency, and single points of failure. These systems depend heavily on intermediaries like banks and payment gateways, which can increase transaction costs and delay processing. To overcome these limitations, this project explores the use of blockchain technology as a secure and reliable alternative. Blockchain is a decentralized and distributed ledger system that records transactions in an immutable manner using cryptographic techniques. Each transaction is verified and validated by network participants through consensus mechanisms, ensuring authenticity and preventing unauthorized modifications. The use of hashing, public–private key encryption, and digital signatures enhances data integrity and user authentication. Once a transaction is confirmed and added to the blockchain, it cannot be altered, thereby increasing trust among users. By eliminating the need for a centralized authority, the proposed system improves transparency, reduces fraud, and enhances overall transaction security. This project demonstrates how blockchain can be effectively used to create a secure, transparent, and efficient money transaction system suitable for real-world financial applications.

II. RELATED WORKS

Research on securing monetary transactions using blockchain spans privacy-preserving mechanisms, smart-contract hardening, consensus and double- spend defenses, and lightweight/blockchain adaptations for constrained payment environments. Below we summarize representative lines of work and highlight gaps that motivate this paper.

Privacy-preserving transactions:

Several recent systematization and survey efforts show privacy for on-chain payments remains an active area of research. Baldimtsi et al. provide a Systematization of Knowledge (SoK) that classifies approaches (mixers, coinjoins, zk-proofs, confidential transactions) and evaluates tradeoffs between anonymity, scalability, and auditability. Research that applies zero-knowledge proofs to payments demonstrates practical privacy improvements (e.g., zk-SNARKs based payment channels and transaction schemes) while exploring the costs of proof generation and verification in real payment workloads.

Consensus attacks and double-spending:

Double-spending and consensus-level attacks remain a core risk to monetary transfers, especially in cross-chain and low-finality settings. Analyses of double-spend vectors quantify how network- level conditions and consensus choices (PoW vs PoS, checkpoints, finality designs) affect the probability and cost of successful double spends.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Lightweight and constrained-environment solutions (IoT / micro-payments):

For payment use-cases on constrained devices or high-frequency microtransactions, several works propose lightweight ledger variants, tailored consensus, and hybrid on/off-chain schemes to reduce cryptographic and bandwidth overheads while preserving security properties. Scalable lightweight blockchains and optimized consensus for IoT payments aim to make blockchain-based payments feasible on low-resource devices, but often trade off decentralization or weaken certain security assumptions.

III. METHODOLOGY SOFTWARE PROCESSING

The system processing of the Money Transaction Security Using Blockchain project explains how data flows through the system from user interaction to secure transaction storage. Initially, the user accesses the web application through a browser and performs authentication using valid credentials. The frontend, developed using HTML, CSS, and JavaScript, collects user input such as transaction details and securely sends it to the backend server. The backend, implemented using Python Flask, processes the request and validates the transaction data. Once validated, the transaction is digitally signed and converted into a block containing essential details such as sender, receiver, amount, timestamp, and hash value. This block is then added to the blockchain after verification, ensuring immutability and security. The updated blockchain is stored in the system, and the transaction status is returned to the user. This process ensures secure, transparent, and tamper-proof money transactions without relying on centralized intermediaries.

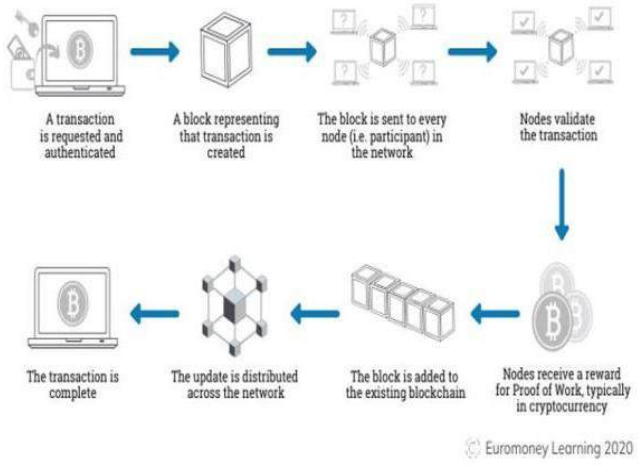

Figure 3.1: Software Processing.

HARDWARE PROCESSING

The hardware processing of the Money Transaction Security Using Blockchain project describes how the physical components of the system support and execute the overall operations. The entire system runs on a computer or laptop, which acts as the main processing unit. When a user accesses the web application through a browser, the input devices (keyboard and mouse) are used to enter login credentials and transaction details. These inputs are processed by the processor (CPU), which executes the Python Flask backend logic, including user authentication, transaction validation, and block creation. The RAM temporarily stores the running application, transaction data, and blockchain information during execution, ensuring smooth and fast processing. The storage device (HDD/SSD) is used to store the operating system, application files, blockchain ledger, and transaction records permanently. A network interface and internet connection enable communication between the user's browser and the Flask server. Finally, the output devices (monitor) display transaction status, confirmation messages, and blockchain records to the user. Together, these hardware components ensure efficient, reliable, and secure processing of blockchain-based money transactions.

equirements Analysis	Identify Thread problems, define system needs for Money transaction, wellness, and immutable.
2. System Design	Design modular architecture: HTML frontend ↔ Fast API backend ↔ Flask models ↔ SQLite DB.
3. Implementation	Develop frontend pages, backend API routes, Flask model training and integration, and database schemas.
4. Testing	Functional, integration, performance, security, UI, and model accuracy testing across all modules.
5. Result Analysis	Evaluate hash accuracy, API response time, confidence scores, and overall system performance.

Table I. Development Methodology Phases

Cross-cutting systematizations and recent trends.

Recent surveys that synthesize applicability, threat models, and open challenges emphasize gaps that directly affect money transfers: (1) balancing privacy with regulatory auditability, (2) reducing transaction latency while maintaining strong finality, (3) securing multi-party/chain interactions (bridges, cross-chain swaps), and (4) integrating formal verification into contract development lifecycles for finance. These syntheses motivate integrated solutions combining cryptographic privacy (e.g., zk techniques), protocol-level finality guarantees, and tooling for safer contract deployment.

The system was implemented as a full-stack web application. Table II summarizes the six implementation modules:

Module	Description
M1: Frontend	React.js responsive UI — image upload, navigation, dashboards.
M2: Backend	FastAPI routes: /auth, /predict, /chatbot, /emergency api.
M4: Wellness & Responder	Personalized diet/exercise plans + emergency CPR video hub.
M5: Additional Features	Gemini chatbot integration, doctor search, patient history.
M6: Testing	Functional, integration, performance, security, UI testing.

Table II. Implementation Modules

SYSTEM DESIGN

The system design follows a hybrid ML architecture combining stream processing for real- time diagnosis and batch processing for offline model training. Fig 5.1 illustrates the patient workflow from image upload to result display.

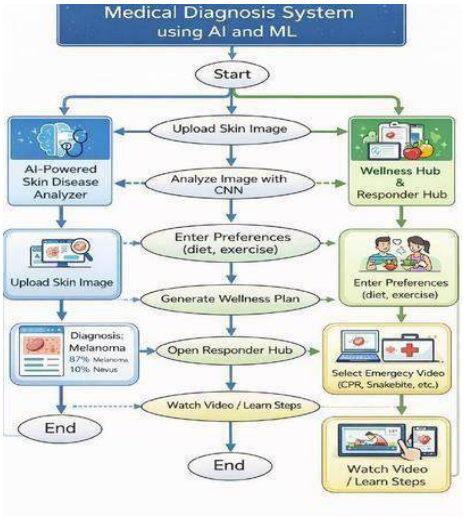

Fig.4. 1 Patient Workflow: Image Upload to ML Prediction

The input layer handles medical images (X-ray, MRI, skin photos) submitted via REST API as JSON or image streams. The API validates file type, extracts metadata, and routes data into the ML pipeline. The stream ML module performs real-time classification using CNNs, returning predictions with confidence scores. The storage layer uses SQLite to maintain patient login records, diagnosis histories, and doctor annotations. Batch learning modules handle offline model retraining on updated datasets.

The FastAPI backend (app.py) uses Pydantic schemas for data validation. Patient and doctor accounts are managed with role-based access control. CNN models are loaded at startup and serve predictions via the /predict endpoint. Confidence thresholds classify predictions as **reliable (≥75%), uncertain (50–74%),** or **inconclusive (<50%).**

IV. EXPERIMENTAL RESULTS

The system was tested across all six testing dimensions. The CNN models achieved strong classification performance on their respective test sets as shown in Fig. 5.1.

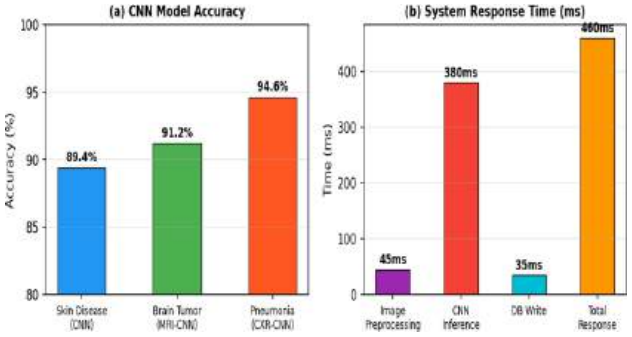

Fig. 5.1. (a) CNN Model Accuracy (b) System Response Time (ms)

The Skin Disease CNN achieved 89.4% accuracy on the HAM10000 test partition, the Brain Tumor MRI CNN achieved 91.2%, and the Pneumonia

Chest X-ray CNN achieved 94.6%. A representative diagnosis result showed Pneumonia classified with 98% confidence, while a brain tumor MRI scan returned meningioma_tumor at 84% (glioma_tumor 15%, no_tumor 1%).

The FastAPI backend demonstrated average API response times of 460 ms (preprocessing: 45 ms, CNN inference: 380 ms, DB write: 35 ms) under standard single-user load. The medical chatbot (Gemini 2.5 Flash) responded accurately to health- related queries within 1.2 seconds. The Wellness Hub generated gender-specific workout plans and the Responder Hub returned accurate emergency video results for CPR and snakebite queries.

Fig. 5.2. Transaction Hub Home Page and Result Interface

V. CONCLUSION

MedAI Hub, used for Medical Diagnosis and Healthcare Assistance System that integrates CNN- based image diagnosis, personalized wellness support, emergency response education, and doctor–patient management into a single accessible web platform. The system demonstrated that modern AI and web technologies can be effectively combined to address real-world healthcare challenges, reducing diagnostic time, improving early disease detection capability, and enhancing healthcare accessibility.

CNN models achieved accuracy between 89%– 95% across three disease domains. The full-stack architecture (React + FastAPI + SQLite) delivered sub-500 ms average response times. Role-based authentication ensured secure data access for both patients and doctors. Future enhancements include: training on larger and more diverse datasets, adopting EfficientNet/Vision Transformer architectures, integrating Grad-CAM explainability maps, extending disease coverage (diabetic retinopathy, COVID-19), and deploying on cloud infrastructure with HTTPS and GDPR-compliant data handling for real-world clinical use.

[#]*Computer Science Engineering Department, ACS College Of Engineering*

Abstract-The traditional system for registering properties using paper has many issues like fraud, double ownership claims, lost documents and it takes a long time to verify ownership. These records are normally kept in physical filing systems or centralized databases which give a large possibility for either data manipulation or corruption. To overcome these problems, the Smart Contract Based Property Registration and Time-Stamping Platform using the Ethereum blockchain will be proposed in this project. In this system we came up with, people put in details about the property using a web app. Its pretty straightforward at first.They have to check their identity with a digital wallet thing before anything gets finalized. I think that step is important to make sure everything is legit. Once thats done, a smart contract takes over and handles the registration or transferring ownership. It just follows whatever rules are set up automatically. After the whole transaction wraps up, the property info gets turned into this secure hash, you know, and stored on the Ethereum blockchain with a timestamp too. Records like that cant be messed with later, which sort of stops fraud from happening. It also boosts transparency and keeps data safe in a better way. Some people might worry about how reliable it all is, but it seems solid.The paper goes into the design part, explains how the system runs, and talks about the results from applying blockchain to managing properties. Not everything is perfectly clear yet, like how it scales for bigger uses.

Keywords

Blockchain, Ethereum, Smart Contracts, Property Registration, Time-Stamping, Data Security

I. INTRODUCTION

Proper registration and ownership of real estate and land is a critical factor in managing these properties. Many areas around the world still include methods for maintaining property records based upon records that exist solely on paper and/or centralized systems (databases). Traditional methods of registration/error correction create many problems, such as paying for various types of fraud, duplicate ownership claims, missing files, long wait times, etc. The potential for manipulation and/or corruption of record-keeping exists due to these issues, and the properties being recorded as a singular entity with their respective owners is problematic. Thus, alternative methods that provide users with a more-transparent and verifiable method of handling property registration and ownership transfer(s) should be created.

Blockchain technology provides a secure way to record and maintain property records. Information is recorded in a decentralized network, which means no one entity can own the data. When a record is placed into the accrual of a blockchain, it cannot be reversed/altered which prevents any data stored from being manipulated.

.

Smart contracts reduce human error and thus enhance the level of trust users place in the property registration and ownership transfer systems. The proposed Smart Contract Based Property Registration and Time-stamping Platform will provide those who utilize the platform with a secure and reliable method of managing their property records. Users can utilize this system to:. To sum up, the Resume Upload project demonstrates the use of AI (Artificial Intelligence) to help job seekers overcome difficulties finding employment by creating resumes through automation and using text generation and a user interface that is easy for them to use. with these features, job seekers are able to quickly get high-quality resumes in compliance with acceptable formatting guidelines used in the industry. A property online registration system simplifies property details management and facilitates the process without requiring participants to physically come to the office or submit multiple forms of paper documentation. Participants complete the online application form at their residences, and thus, the transaction of providing property ownership is recorded; therefore, it provides an accurate account of the timestamped and un-altered transaction record, which allows for the review of property ownership when required

II. RELATED WORK

Looking into how blockchains might work for official documents, scientists focused on real estate tracking first. Because old-school filing depends on one central hub, mistakes slip through easily - like double claims or shady changes. That rigidity opened doors for tech alternatives to take hold slowly. Information locked into this digital chain stays fixed, no exceptions after entry. Its resistance to edits turns out useful when deeds and titles need guarding. When details go live here, altering them later becomes impossible by design. Trust grows naturally since every update leaves a permanent mark. No single point controls everything, shifting power away from isolated authorities. Tampering fears drop because rewriting history across nodes takes near-impossible effort. Files stored this way carry their own proof of journey over time. Each addition ties firmly to what came before without gaps. Reliability climbs when nobody can erase traces at will. Proof lives inside the structure itself instead of external checks. This setup resists corruption simply by existing as built. Permanent marks replace fragile paper trails everyone questions. Security emerges not from promises but from mechanics hardwired in place.

On top of that, researchers have looked into how smart

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

contracts might change the way we handle property. These digital agreements run themselves once certain requirements are fulfilled. Because no person needs to step in for them to work, mistakes caused by people tend to drop off sharply. Delays usually tied to checking and signing paperwork often vanish too. Some experts argue using blockchain to follow ownership of land could make transactions clearer. Trust among parties buying or selling may grow stronger at the same time.

Fig. 1. proposed smart contract-based property registration system architecture

The new property registration system will operate as a three-layered architecture, with the users, the smart contracts, and the Ethereum blockchain at the top of the hierarchy. Whoever owns property, buys it, or represents a public body through approved representatives can reach the Property Registration System using a website portal. Through this online entry point, people type in data about real estate to ask for title setup or pass ownership to someone else. Linking those involved directly to the Ethereum blockchain, the site carries typed entries safely into storage. When submissions happen, proof of who you are becomes necessary - done by opening your digital wallet where login facts already live. That wallet unlocks only after proper checks confirm it truly belongs to the person making the move. Only then does the call to create fresh titles - or shift existing ones - reach the part of the system built with code rules living on Ethereum's network. Should the system confirm the person holds valid rights to the asset - either by original ownership or approved delegation - it proceeds. Ownership details update instantly when access rules are met, triggered only by verified conditions. No individual needs to sign off; actions follow preset logic once eligibility is clear. Execution happens silently, embedded within code that reads status and acts. Authority checks run first, then record changes apply themselves under exact terms laid out earlier.

III.OVERVIEW OF THE PROPOSED MECHANISM

Overview of the Proposed Mechanism

One goal here: create a system using smart contracts for logging property details securely. Instead of paper titles stored with one central group, people use Ethereum's blockchain. Owners transfer holdings; buyers receive them - each step locked in digital form. Access stays limited to those allowed, like sellers letting go or new owners claiming rights. No middle office needed when changes happen on chain. Records appear exactly as entered, never altered after stamping. This method swaps old filing ways for something harder to tamper with. Each event gets time-marked, visible only to approved users. People involved act directly without handing forms to third parties.

A fresh start could mean building a system where property details are locked in digital agreements. Ownership timelines might live on a shared ledger, updated only when everyone agrees. This way, tracking changes feels more like watching a clock than chasing paperwork. Control shifts back to those who hold the rights, not just those who manage files. Records stay clear because each entry carries its moment in time, stamped without dispute. (Seller) of their respective property by utilizing the Ethereum Blockchain instead of utilizing just physical copies of Certificate of Title (holdings) and through a Centralized Authority.

We want to establish a Smart Contract Based Registration and Time Stamp Platform that gives us full control of how we use property records. Property Owners, Purchasers (Buyers) and others with permission can register transactions (Buyers of a Property) or pass ownership (Seller) of their respective property by utilizing the Ethereum Blockchain instead of utilizing just physical copies of Certificate of Title (holdings) and through a Centralized Authority.Using a secure online application will enable us to swiftly and easily enter property information for creating either a new Registration or Transfer of Property transaction. We have created a process diagram that outlines how to utilize the application for your transaction process.

IV. System Design and Approach

A fresh way to handle property records shows up using blockchain. Instead of paperwork or one central server handling changes, something more distributed steps in. Smart contracts living on Ethereum take charge from there. Transactions move forward by themselves once started, safely handled top to bottom. Four connected parts make the whole thing run without hitches. Up front, people meet a digital space where forms go in online. Filling out details happens right inside a browser window. Each step links quietly behind the scenes.

Once the form is filled out, your identity gets checked through your digital wallet. Only those approved can move forward with actions after that step. When the system finishes confirming who you are, it passes the request along to the Smart Contract Layer. That layer checks whether conditions like asset ownership and permission status are properly met before allowing anything to proceed. Once every requirement checks out, execution kicks off through the Smart Contract Layer, handling the user's request start to finish with zero need for people stepping in. A transaction wraps up on Ethereum when someone finishes sending data through the network. That person's property details get transformed into a locked digital fingerprint, stored permanently on the Ethereum Blockchain together with exact timing down to seconds. Out comes a full snapshot from the system - each entry shows unique identifiers tied to real estate, paired with the blockchain address of its owner plus precise

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

moments deals go live, ready if questions pop up later about legitimacy. After the smart contract checks and accepts the property details, the deal gets locked into the Ethereum blockchain forever. Systems tracking every property transfer - along with their unique codes, dates, times - make it possible to follow who owned what, whenever needed. Finishing this sequence brings a notice: the exchange went through without issues. A "Transaction ID" arrives too, serving as solid evidence it was completed.

One piece fits into another, yet each runs on its own. Connected they may be, still every part works apart from the rest. Think of the screen users see - it stands alone, even as it talks to what lies beneath. Fingerprint checks open the door, not by force, but through quiet coordination. Smart deals run when told, following code that does not bend or guess. Later, those moments get tucked away - or pulled back out - from a digital record kept publicly. Change one layer, say how things look or behave, and the core stays untouched. Even if rules shift inside the agreements written in code, the base remains steady. Parts grow better over time because none are glued too tightly to the others. Tweak here,adjust there -

no need to fear breaking something unseen

Fig 2. System Methodology

V.PERFORMANCE EVALUATION

A test checked how well the new land registration setup works under various situations. Its main goal: seeing how quickly and correctly property records get updated or moved between owners. Since it runs on Ethereum blockchain, strong protection and steady operation matter just as much as speed. Different actions were tried during testing - recording new plots, shifting ownership. Looking closely at those operations showed processing times along with differences in behavior across request kinds. Each step revealed how smoothly things ran depending on what type of change happened.
In evaluating the performance of the system, four primary performance metrics were utilized:

- Transaction Processing Time: The amount of time from the confirmation of a land registration or ownership transfer to when that transaction is confirmed on the blockchain.
- Gas Consumption: The total amount of computational resources (including memory, processing power, and bandwidth) needed to execute the smart contract on the Ethereum network.
- Verification Time: The amount of time needed to verify that the owner of a piece of land is indeed the true owner using the property registration transaction hash.

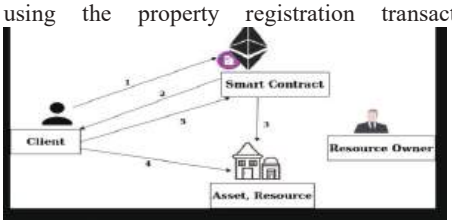

Fig 3. Performance Metrics

Evaluating the system revealed that it was able to process transactions fairly quickly and in near real-time under “normal” operating conditions of the blockchain. The amount of gas used for processing a standard real estate transaction was consistent as well. Once the transaction was confirmed, the property ownership verification process was completed nearly instantaneously. The diagram shows how a smart contract operates while registering and transferring property ownership, which includes measuring how long it takes to complete those transactions and how much gas was consumed. In a blockchain environment, when a smart contract executes any action (i.e. registering a new property or transferring ownership), it incurs a gas fee that reflects the cost of computing the transaction on the blockchain. Thus, the chart serves as an evaluation tool for the efficiency of the overall system and demonstrates whether stable transaction processing times are being achieved during typical usage of the overall system.

VI. EXPERIMENTAL SETUP AND RESULTS

A small trial called SIGI checked how well smart contracts work when tracking who owns land and when records are made, using tech built on Ethereum. Inside a private test space that mimics Ethereum, researchers ran several simulations showing what happens when people buy or claim property. Instead of one person doing everything, many acted separately - some owning, others buying - to see how the system handles back-and-forth changes. Each deal went through SIGI's design while also being measured against older ways of handling paperwork. Results looked at whether automated agreements speed things up - and keep data safer - than standard processes.

From the tests came numbers on how fast transactions confirm, gas used per deal, how quickly ownership checks reply, plus the full system response duration. It turned out property records and shifting ownership work fine using smart contracts, no human checker needed at all. After info lands on the blockchain, altering it becomes impossible - proving the setup keeps data trustworthy and steady.

Users were also able to verify ownership by checking the associated transaction hash for the transaction.Tests were also conducted to see if records could remain secure throughout many transfers of ownership for a given property; if any attempts at duplicate ownership were blocked; and how quickly ownership data could be verified using the transaction hash. Ending things off, folks got questionnaires about whether they thought the new setup felt smooth to move through plus did it cut down on headaches during property sign-up tasks. Every

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

round showed this planned blockchain method kept records way more open, sped up handling times, left solid traces proving who owns what. Test outcomes pointed clearly toward the SIGI Smart Contract Property Log and Stamp System being tougher against sneaky deals compared to old-school paper trails. Even though sometimes blockchains stumble when their base networks act up, SIGI held steady across every trial run. Down the line, newer versions might polish tools while stretching how far the engine underneath can reach.

Figuring out how well the SIGI system works meant looking at various measures. Transaction speed played a big role, along with how correctly ownership updates happened. Data kept inside the system had to stay intact, just like user feedback mattered. Instead of guessing, real comparisons showed how SIGI stacked up next to old-style property registration. Paper-heavy steps define those older methods, where people check every detail by hand. All that paper handling slows everything down - sometimes taking hours, sometimes stretching into days. But under SIGI, when agreement terms are fulfilled, changes go through without delay. Registration plus title shifts happen almost instantly after conditions clear. Time spent drops sharply compared to past ways. By using this blockchain framework, once information is added to a given property data record, that information cannot be changed. Because all transactions are stored on a distributed system, there is a lower probability that the information contained in that record will be compromised by any fraudulent activity or by someone making an unauthorized change. Therefore, the user can verify ownership information without fully relying on a third party.

VII. CONCLUSION

One day might show up in different corners of property work while building a connected way to handle estates. Starting now, blockchain changes the game - reshaping how homes shift hands and how every deal gets locked into shared digital logs.

A deal unfolds piece by piece inside code instead of paper. When both sides agree on price and timing, those details get locked into a digital agreement. One step must finish before the next begins - like proof of funds appearing prior to ownership shifting. The moment conditions match, transfer happens without waiting. Rules set at the start guide every move until completion.

Once the buyer meets every condition laid out in the agreement, ownership shifts automatically. Blockchain steps in here - handling the handover without paperwork or delays. The change gets locked into a shared digital record built just for local property deals, where every past transaction already lives. No extra steps needed, no exceptions made.

After property ownership changes hands, the deal gets saved on the Ethereum blockchain so everyone can see who owns what. That way, both people in the sale have clear proof that updates quickly and stays protected. Instead of old paper trails, this system uses digital tracking that keeps data correct and locked in place. Later versions could connect directly to official land registries run by governments. With time, more regions might adopt it, letting the network grow steadily.

***Abstract* - The ACS Store — Smart Online Grocery Ordering and Rapid Delivery System is designed to provide users with a fast, convenient, and reliable platform for purchasing daily essential items online. The system enables customers to browse products, add items to a cart, choose payment options, and place orders for rapid delivery. It supports both Cash on Delivery (COD) and Online Payment through QR-based transactions. The platform provides real-time order confirmation, estimated delivery time, and randomly assigned delivery partner details. By integrating modern web technologies with efficient order processing, the system enhances customer convenience, reduces physical store visits, and improves accessibility to essential goods. The project demonstrates how digital retail solutions can transform traditional shopping into a seamless smart service.**

Keywords — E-commerce, Online Grocery System, Rapid Delivery, Digital Payments, QR Payment, Web Application

I. INTRODUCTION

The rapid advancement of digital technology and widespread internet availability have significantly changed the way people purchase goods and services. Online shopping has become an essential part of modern life, offering convenience, speed, and accessibility. Among various e-commerce domains, online grocery shopping has gained particular importance as it deals with daily essential items required by every household. Traditional grocery shopping involves traveling to stores, searching for products, standing in queues, and completing manual billing, which consumes time and effort. This creates a strong need for efficient digital solutions that can simplify the process and save valuable time for consumers.

The ACS Store — Smart Online Grocery Ordering and Rapid Delivery System is developed to address these challenges by providing a user-friendly web-based platform for purchasing groceries online. The system allows users to browse products, add items to a cart, choose preferred payment methods, and place orders seamlessly from anywhere. A key feature of the platform is its support for both Cash on Delivery and QR-based online payments, ensuring flexibility and convenience for different types of users. Additionally, the system provides instant order confirmation, estimated delivery time, and delivery partner details, enhancing transparency and customer trust. By leveraging modern web technologies and a simple interface design, the system ensures accessibility for users of all age groups. Overall, ACS Store demonstrates how digital retail solutions can modernize small-scale grocery services and improve the shopping experience through convenience, efficiency, and reliability. Unlike traditional e-commerce platforms that may require long delivery times, ACS Store focuses on rapid delivery of essential items, making it suitable for urgent needs and everyday use. The application integrates product management, payment processing, and delivery coordination into a single streamlined system, thereby reducing the dependency on physical store visits.

II. LITERATURE SURVEY

Personalized The rapid growth of e-commerce platforms has transformed traditional retail systems into digital marketplaces. Online grocery shopping, in particular, has gained popularity due to its convenience and accessibility. Several studies indicate that digital retail solutions reduce the need for physical store visits and enable customers to purchase products from anywhere at any time. The integration of mobile applications and web platforms has further improved user experience through intuitive interfaces and personalized recommendations.

1. Modern e-commerce applications focus heavily on user experience and interface design. Studies show that a simple and well-structured interface significantly improves customer satisfaction and engagement. Features such as easy navigation, product categorization, search functionality, and cart management are essential components of successful online shopping systems. Researchers have also found that minimizing the number of steps required to complete a purchase reduces cart abandonment rates. Responsive design ensures compatibility across different devices, including smartphones, tablets, and computers. Therefore, user-centric design principles are considered critical for the success of online grocery platforms.
2. Payment systems are another crucial aspect of digital commerce. Research highlights the importance of providing multiple payment options to accommodate diverse user preferences. Cash on Delivery (COD) remains widely used due to its perceived safety and ease of use, especially among users unfamiliar with online transactions. At the same time, digital payments such as QR-based transactions, mobile wallets, and online banking are rapidly gaining adoption. Secure payment gateways and encryption techniques are necessary to protect user data and prevent fraud. The integration of both traditional and digital payment methods enhances trust and accessibility.
3. Rapid delivery services have emerged as a defining feature of modern online grocery systems. Studies on quick-commerce platforms reveal that shorter delivery times significantly improve customer satisfaction and retention. Efficient order processing, optimized logistics, and real-time tracking contribute to successful delivery operations. Providing estimated delivery times and delivery partner details increases transparency and user confidence. Researchers also emphasize the importance of managing delivery routes and inventory to maintain service reliability. These findin

III. PROBLEM STATEMENTS

In In the existing retail system, purchasing daily essential items often requires customers to physically visit stores, which leads to significant time consumption, travel effort, and inconvenience, particularly for working individuals and elderly people. Traditional grocery stores rely on manual processes for product selection, billing, and payment, resulting in long queues and inefficient service. Moreover, many small-scale stores lack an online presence, preventing customers from accessing products remotely or placing orders in advance. Limited payment flexibility and the absence of quick delivery options further reduce customer satisfaction. These limitations highlight the need for a smart online grocery ordering system that enables users to browse products, place orders digitally, choose convenient payment methods, and receive items quickly, thereby improving accessibility, efficiency, and overall shopping experience. Order management systems play a vital role in ensuring smooth operation of e-commerce platforms. Effective systems track product availability, process orders, update payment status, and generate confirmations automatically. Automation reduces manual errors and improves efficiency in handling large volumes of transactions. Researchers suggest that real-time updates and notifications enhance communication between customers and service providers. Additionally, maintaining a centralized database ensures consistency and accuracy of product information. Such systems form the backbone of reliable online retail services. The role of technology in supporting small-scale retail businesses has also been widely studied. Digital platforms enable local stores to expand their reach beyond physical boundaries and compete with large e-commerce companies. Online systems reduce operational costs associated with physical infrastructure while increasing sales opportunities. Researchers note that adopting digital solutions improves business sustainability and customer engagement. Furthermore, small retailers can analyze purchasing trends and optimize inventory using data collected through online platforms.

Key Issues: In the current retail environment, traditional grocery shopping systems face multiple challenges that reduce convenience and efficiency for consumers. Customers are required to physically visit stores, which consumes time, effort, and travel costs, especially in busy urban areas. Long queues, manual billing processes, and limited payment options further contribute to delays and dissatisfaction. Many small retail stores lack digital infrastructure, making it difficult to offer online ordering or quick delivery services.

IV. OBJECTIVE

The primary objective of the ACS Store — Smart Online Grocery Ordering and Rapid Delivery System is to develop an efficient digital platform that simplifies the process of purchasing daily essential items. The system aims to provide users with the ability to browse products, add items to a cart, and place orders conveniently from any location. Another important objective is to support multiple payment options, including Cash on Delivery and QR-based online payments, to accommodate different user preferences. The platform also seeks to ensure quick order processing and rapid delivery by providing estimated delivery time and delivery partner details. Additionally, the system is designed to offer a simple, user-friendly interface that can be easily used by people of all age groups. Overall, the project aims to enhance customer convenience, reduce dependency on physical store visits, and improve the efficiency of small-scale retail operations through digital transformation.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The objective of the ACS Store — Smart Online Grocery Ordering and Rapid Delivery System is to develop a smart and efficient e-commerce solution that provides instant access to daily essential products through an online platform. The system aims to minimize the time and effort required for traditional shopping by enabling users to search, select, and order items with just a few steps.

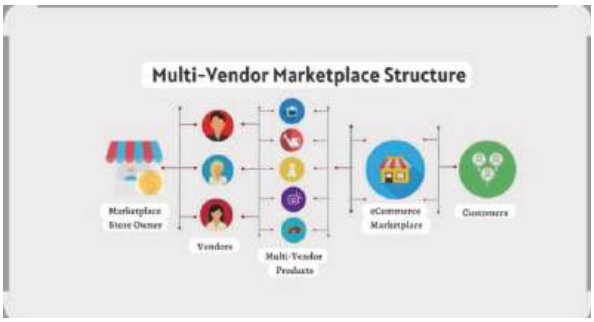

Fig.1. Overview of System Objectives

V. METHODOLOGY

The development of the ACS Store — Smart Online Grocery Ordering and Rapid Delivery System follows a structured approach to ensure efficiency, usability, and reliability. Initially, the requirements of the system were identified by analyzing common issues in traditional grocery shopping and existing online platforms. Based on this analysis, key features such as product browsing, cart management, payment processing, and delivery handling were defined. The system was designed to provide a simple and intuitive user interface that allows customers to interact with the application easily. Emphasis was placed on minimizing the number of steps required to complete an order to improve user experience.

In the system design phase, a modular architecture was adopted, consisting of frontend, backend, and database components. The frontend is responsible for displaying product information, categories, and user interaction elements, while the backend handles business logic such as order processing, payment selection, and delivery assignment. A database is used to store product details, pricing information, order records, and user inputs. This layered architecture ensures smooth communication between components and allows easy maintenance and scalability of the system. Proper validation mechanisms are implemented to prevent incorrect data entry and ensure system accuracy.

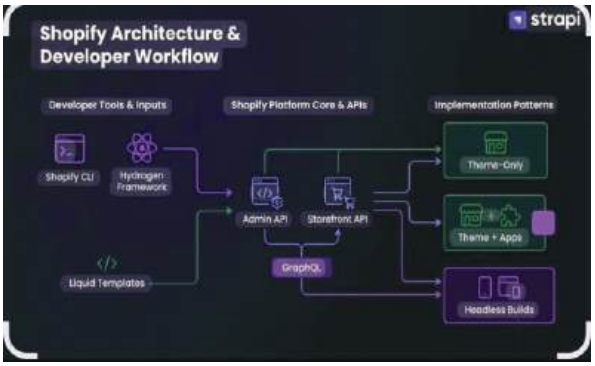

Fig.2. Backend API Structure

During implementation, users are provided with the ability to browse available grocery items, add selected products to a shopping cart, and proceed to checkout. At the checkout stage, customers can choose between Cash on Delivery and QR-based online payment options. If online payment is selected, a QR code is displayed for secure transaction completion. After successful order placement, the system generates an order confirmation message along with details such as delivery partner name and estimated delivery time. This automated process reduces manual intervention and enhances operational efficiency.

Fig.3. System Architecture

Finally, the system was tested to evaluate functionality, performance, and user satisfaction. Test cases were conducted to ensure accurate product display, correct cart calculations, successful payment handling, and proper order confirmation. User feedback was considered to improve usability and interface design. The results demonstrated that the system effectively reduces the effort required for grocery shopping and provides a convenient digital alternative to traditional methods. The methodology ensures that the ACS Store platform operates as a reliable, scalable, and user-friendly solution for online grocery ordering and rapid delivery.

VI. RESULT

The implementation of the ACS Store — Smart Online Grocery Ordering and Rapid Delivery System demonstrated effective performance in providing a convenient and efficient online shopping experience. The system successfully enabled users to browse products, add items to the cart, and place orders without complications. Both payment options, Cash on Delivery and QR-based online payment, functioned accurately, ensuring flexibility for different user preferences. After order placement, the application generated instant confirmation along with delivery partner details and estimated delivery time, improving transparency and user confidence.

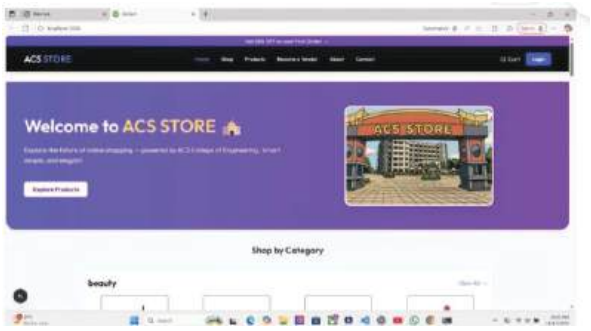

Fig.4. Store Dashboard

The ACS Store — Smart Online Grocery Ordering and Rapid Delivery System was successfully implemented and tested to evaluate its functionality and effectiveness.

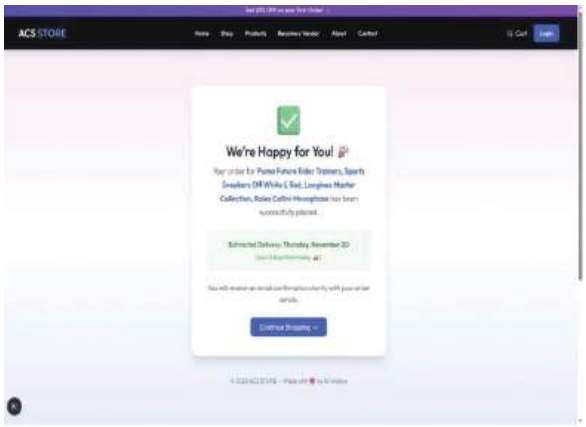

Fig.5. Checkout Page

According The payment module operated reliably by supporting both Cash on Delivery and QR-based online payment options. Users selecting online payment were able to complete transactions using the generated QR code, while COD users could confirm orders without digital transactions.

Performance testing indicated that the platform significantly reduced the time and effort required to purchase daily essentials compared to traditional shopping methods. Users were able to complete the entire ordering process within a few minutes, demonstrating the efficiency of the system. Feedback from test users indicated high satisfaction due to the simplicity of the interface and the convenience of rapid delivery support. The system proved to be reliable, scalable for small-scale deployment, and capable of handling essential retail operations effectively. These results confirm that ACS Store can serve as a practical digital solution for modern grocery shopping needs.

VII. DISCUSSION

The results of the ACS Store — Smart Online Grocery Ordering and Rapid Delivery System demonstrate the effectiveness of digital solutions in improving traditional retail services. By integrating product browsing, cart management, payment processing, and delivery coordination into a single platform, the system provides a complete end-to-end shopping experience. The availability of both Cash on Delivery and QR-based online payment options ensures flexibility for users with different preferences and levels of digital literacy. Rapid order confirmation, estimated delivery time, and delivery partner details contribute to transparency and customer trust. These features collectively enhance user satisfaction and encourage the adoption of online grocery services. However, certain limitations and challenges must be considered for real-world deployment. The system's performance depends on stable internet connectivity and accurate product data management. Delivery efficiency may vary based on distance, traffic conditions, and resource availability. Additionally, the absence of real-time inventory synchronization could lead to issues if product availability changes frequently. Future improvements may include live order tracking, automated inventory updates, user accounts, and integration with advanced payment gateways. Addressing these aspects can further enhance scalability, reliability, and overall effectiveness of the platform. Furthermore, the ACS Store system highlights the potential of digital platforms to support small and local retail businesses in adapting to the growing demand for online services. By providing an easy-to-use ordering mechanism and structured delivery workflow, the system enables retailers to expand their customer reach without significant investment in physical infrastructure.

ABSTRACT

Credit card fraud has become a main issue in banking, causing big losses and diminishing trust among customers. Conventional methods of detection fail to catch up with new tactics used by fraudsters. The use of machine learning strategies in credit card fraud detection has been discussed here. We apply complex algorithms such as logistic regression, decision trees, random forests, and neural networks to analyze transaction data in order to identify patterns characteristic of fraud patterns. The study focuses on the feature engineering, model estimation, and real-time detection mechanisms to achieve improved accuracy and reduce false positives. Experimental results demonstrate that machine learning-based techniques surpass traditional methods and offer an excellent solution to avoid fraud risk. This research emphasizes the potential of machine learning to revolutionize fraud detection in banking for enhanced security and customer satisfaction.

Keyword: Credit Card Fraud, Machine Learning, Fraud Prevention, Financial Security, Anomaly Detection, Imbalanced Data Classification.

I. INTRODUCTION

The emergence of electronic transactions at a high growth rate and extensive use of credit cards have completely transformed the financial and banking sectors. Yet, this convenience came at the price of heightened credit card fraud, which proved to be a formidable challenge for banks and consumers as well. With every innovation by fraudsters in their strategies, it became tough for the conventional fraud prevention system to remain current. Accordingly, a more sophisticated and responsive set of solutions to identify and capture fraud effectively is needed in an urgent manner. This paper discusses the use of machine learning (ML) methods to solve the increasing issue of credit card fraud within the banking sector [1].

Supervised learning [2], unsupervised learning, and deep learning algorithms are quite helpful for fraud transaction identification. Supervised learning algorithms such as logistic regression, decision trees, and random forests can be trained on labeled information to mark the transactions as fraud or real. Unsupervised learning algorithms such as anomaly detection and clustering are most suited to detect unknown fraud patterns. Deep learning techniques [3], such as neural networks, are most appropriate for highly dimensional and complicated data and therefore they function optimally in real-time fraud detection. Deep learning techniques being used together can enable banks to develop efficient systems that learn to detect changing patterns of fraud and minimize financial loss.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The use of machine learning to identify credit card fraud is accompanied by a number of challenges. One of the significant problems is the class imbalance, where the fraudulent transactions constitute a very small percentage of all transactions. This can cause biased models towards the majority class, leading to ineffective fraud detection. Oversampling, under sampling, and creating synthetic data (e.g., SMOTE) are utilized to avoid this problem. For avoiding this issue, oversampling, under sampling, and synthetic data generation (e.g., SMOTE) are applied. Feature engineering is utilized to select and manipulate feature attributes from transactional data for optimal model performance. Since any delay in detection can lead to massive financial loss, real- time detection is required. Through data analysis of transactions and testing several ML algorithms, we aim to develop a low- false-positive, effective, and accurate real-time model. The outcome will help banks use ML-based solutions to combat fraud. Lastly, machine learning in fraud detection will enhance financial security and boost the trust of customers in the banking sector.

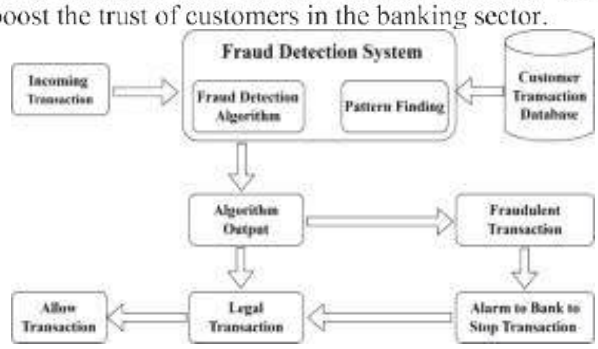

Fig. 1. Credit Card Fraud Detection Using Machine Learning.

II. RELATED WORKS

Credit card fraud detection has been a problem explored at very long lengths in the last two years with numerous techniques being employed to increase the efficiency and effectiveness of fraud detection mechanisms. Statistics and rule-based mechanisms were among early solutions that were most dependent on pre-defined thresholds and patterns in identifying suspicious transactions. Whereas these techniques had helped in the detection of well-known fraud patterns, they were unable to match the latest and refined means of operating by fraudsters. Therefore, emphasis was laid on newer techniques like machine learning, which can process enormous amounts of transaction data and detect sophisticated, non-linear patterns characteristic of fraud.

Supervised learning algorithms have been widely used for credit card fraud detection due to the ability to label the transactions as fraudulent or genuine based on labeled datasets [4]. It has been demonstrated through research that logistic regression, SVM, and decision trees are effective algorithms for detecting fraud. For instance, ensemble algorithms like random forests and gradient boosting have been shown to be very accurate in aggregating strengths of multiple models. However, one of the largest supervised learning challenges is class imbalance in fraud datasets, where fraudulent transactions significantly outnumber legitimate transactions. To address this, techniques such as oversampling, under sampling, and synthetic data creation (e.g., SMOTE) have been employed to balance the dataset as well as to improve model performance

Unsupervised learning techniques have also been identified as having the ability to detect unknown patterns of fraud without relying on labeled data. Clustering methods such as k-means and DBSCAN have been used to cluster similar transactions and separate out outliers that could be indicative of fraud. Algorithms such as isolation forests and auto encoders have proven to detect well rare and unusual transactions which do not represent usual behavior. These unsupervised algorithms are particularly beneficial for discovering new types of fraud that are not based on well-known patterns and therefore complement supervised learning algorithms.

Deep learning, which is a machine learning method [5], has been found to be a highly effective approach in detecting credit card fraud due to its ability to handle high-dimensional and complex data. Some of the neural networks utilized for handling sequences of transactions and extracting important features to detect fraud are recurrent neural networks (RNNs) and convolutional neural networks (CNNs). Research has established that deep learning models are capable of state-of-the-art performance on fraud detection problems, particularly when augmented with methods such as transfer learning and attention mechanisms. Yet, the computational complexity and resource needs of deep learning models pose a problem for There have also been recent experiments on integrating real-time fraud detection systems into banking infrastructure. Stream processing platforms such as Apache Kafka and Apache Flink were used for real-time processing of transaction data and deployment of machine learning models in favor of real-time fraud detection.

Fig. 2. Data Structure Flow

Credit card fraud detection has been a well-studied topic, with a variety of machine learning techniques [7] applied to enhance security and reduce financial loss. Traditionally, rule-based fraud detection systems have been widely used; these, however, are typified by high false positives and insensitivity to evolving patterns of fraud. In a bid to overcome these limitations, scholars have explored supervised and unsupervised learning approaches. Supervised learning models such as Logistic Regression, Decision Trees, Random Forest, Support Vector Machines (SVM), and Deep Learning models such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) have reported encouraging outcomes in identifying fraudulent transactions [8],[9]. Supervised learning models are trained on past transaction data with fraud labels, thereby enabling them to mark new transactions efficiently [10].

Recent studies have aggressively pursued real-time fraud detection via online learning models that update upon identifying evolving patterns in fraud [11]. Graph- based methods have also been investigated for detecting fraud networks based on relationships between entities and transactions. Federated learning has also been proposed as a privacy- protecting alternative to allow different banks to cooperatively detect fraud without exposing sensitive customer information [12]. Although machine learning greatly enhanced the performance of fraud detection, there remain issues like dealing with imbalanced datasets, adversarial attacks, and dynamic fraud tactics. Upcoming research focuses on explainable AI (XAI) to promote interpretability and fairness in fraud detection models.

A. Problem Statements

Credit card fraud presents a significant challenge in the banking industry, causing huge financial losses to both banks and customers. As the number of digital transactions increases, fraudsters constantly come up with advanced methods to circumvent conventional security features [6]. Traditional rule-based fraud detection systems have difficulty keeping up with changing fraudulent patterns and tend to have high false-positive rates, where genuine transactions are reported as fraud, or false negatives, where fraudulent transactions are not detected. Moreover, the extremely imbalanced nature of fraud detection datasets, where fraudulent transactions constitute a minority of all transactions, is a challenge for machine learning models. Effectively detecting fraudulent transactions without excessive false alarms is paramount to preserving customer confidence and financial integrity. Thus, there is a requirement for sophisticated machine learning methods that can identify fraud in real-time, learn dynamic fraud behavior, and enhance the overall accuracy and efficiency of fraud detection in banking systems.

III. PROPOSED METHOD AND ALGORITHM

This study proposes a machine learning-driven fraud detection system that integrates supervised and unsupervised learning approaches to identify fraudulent transactions with high accuracy. The proposed model will employ a mix of feature engineering, anomaly detection, and ensemble learning to increase fraud detection effectiveness. Raw transaction data will be preprocessed for the first time by handling missing values, encoding categorical variables, and solving data imbalance through techniques like Synthetic Minority Over- sampling Technique (SMOTE)

The framework will employ supervised learning methods like Decision Trees, Random Forest, Support Vector Machines (SVM), and Deep Learning models like Long Short-Term Memory (LSTM) and Convolutional Neural Networks (CNN) to identify transactions as fraud or real. Besides this, other unsupervised machine learning techniques like isolation forests and auto encoders will be used in order to identify any anomaly in the pattern of transactions. For improving the overall detection rate and reducing false positives, robustness of the model will be obtained by using an ensemble approach with a list of classifiers.

A. Algorithm

Bank credit card fraud detection is based on a set of machine learning algorithms to identify fraud transactions in the right way. Supervised machine learning algorithms like Logistic Regression, Decision Tree, Random Forest, Support Vector Machines (SVM), and Gradient Boosting

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

(XGBoost, LightGBM, CatBoost) are the most popular algorithms for fraud classification. They are trained on labeled samples of known fraud historical transactions, and therefore they can detect true as well as fraud transactions.

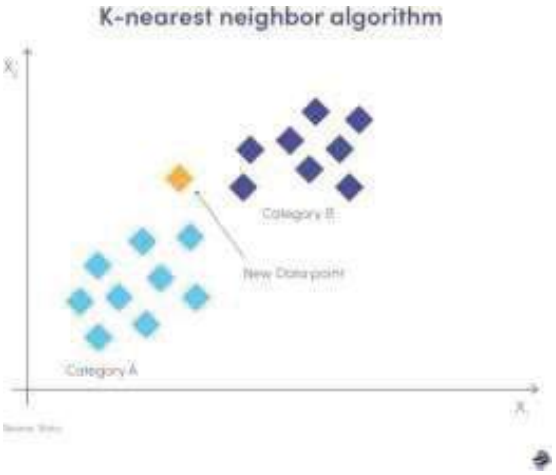

Fig. 3. K-nearest neighbor classification

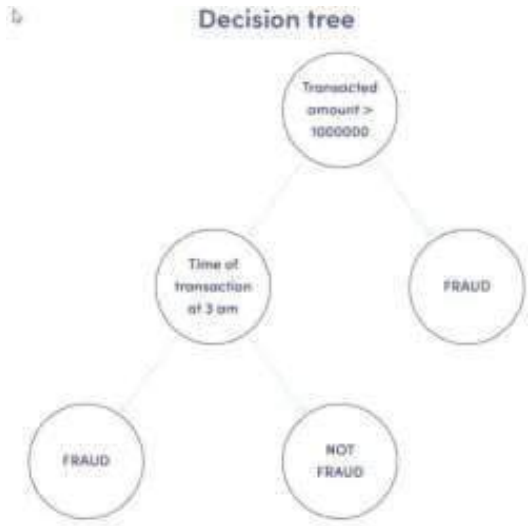

Fig. 4. Decision Tree

B. Module List and Descriptions

Data Collection and Preprocessing: This module is for gathering credit card transaction data samples from banking statements and open sources. Preprocessing data operations such as handling missing values, removing duplicates, transforming categorical variables into numerical variables, and normalizing numeric features are employed. Also, methods such as Synthetic Minority Over-sampling Technique (SMOTE) are employed to solve the imbalance in class and provide an efficient training set.

Data Set: Downloading datasets from Kaggle can be beneficial for data analysis, machine learning, and research. This dataset has 4,850 records and 11 fields, with a size of around 319KB. It seems to deal with credit card transactions, with one record per transaction. The fields have some information about the transaction and cardholder. The "Unnamed: 0" column likely is an index or auto-indexed ID of each row. The "cc_num" column has the credit card number or its masked form, and "category" has the category of the transaction, e.g., grocery shopping, gas, online shopping.The "amt" column captures the amount spent on each transaction, and the "gender" column captures the gender of the cardholder. The "is_fraud" column is a binary flag, with 1 representing a fraudulent transaction and 0 representing a valid one. The "age" column contains the age of the cardholder, and the "trans_month" and "trans_year" columns detail the date of the transaction. Lastly, the "lat_dis" and "long_dis" columns represent the geographic distance (in latitude and longitude) between the transaction location and the cardholder's known location, which may aid in spotting suspicious activity or fraud due to location irregularities.

Feature Selection and Engineering: This module emphasizes identifying and selecting essential transaction attributes for fraud detection. Significant attributes including transaction amount, location, timing, device information, and behavioral patterns of a user are used to improve the accuracy of a model. Reduction of dimension and improvement in computing efficiency are attained through techniques like Principal Component Analysis (PCA) and Recursive Feature Elimination (RFE)

Model Training and Classification: Various machine learning algorithms, including Decision Trees, Random Forest, Support Vector Machines (SVM) are implemented in this module. Supervised learning is used for labeled transaction data, while unsupervised techniques identify anomalies without predefined fraud labels.

Anomaly Detection and Fraud Identification: This module utilizes unsupervised learning algorithms like Isolation Forest, One-Class SVM, and Clustering algorithms (K-Means, DBSCAN) to identify abnormal transaction patterns that could suggest fraudulent activity. These models assist in detecting new fraud patterns which could escape supervised models.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Real-time Fraud Detection and Alert System: The framework combines stream data processing platforms to identify fraud in real-time. In case of a transaction suspected of being fraudulent, an alert is triggered and subsequent verification processes, like multi-factor authentication, are invoked to block unauthorized transactions.

Performance Evaluation and Optimization: The last module assesses model performance on measures like accuracy, precision, recall, F1-score, and ROC- AUC curves. Hyper parameter tuning methods like Grid Search and Random Search are employed to optimize the model and enhance fraud Detection.

IV. RESULTS

The machine learning approach proposed for detecting credit card fraud in banking is made up of several stages for the purpose of achieving accurate and efficient.

Data Acquisition & Preprocessing: The procedure begins with the collection of transactional data from bank statements or publicly available datasets. The data is preprocessed by handling missing values, removing duplicates, and encoding categorical features. Since fraud detection datasets are usually highly imbalanced, techniques like SMOTE and under sampling are used to balance the dataset so that the model does not lean towards non-fraudulent transactions.

Feature Selection & Engineering: Relevant transaction attributes, including transaction value, frequency, device usage, geographical location, and time-based patterns, are derived. Feature scaling and transformation methods, like Min-Max scaling or Standardization, are used to maintain consistency in data distribution.

Model Selection & Training: The data set is separated into training and testing sets, and machine learning models are trained. It is classified through supervised learning models such as Logistic Regression, Decision Trees, Random Forest, SVM. Anomaly detection is performed through the unsupervised learning algorithms such as Auto encoders and Isolation Forest.

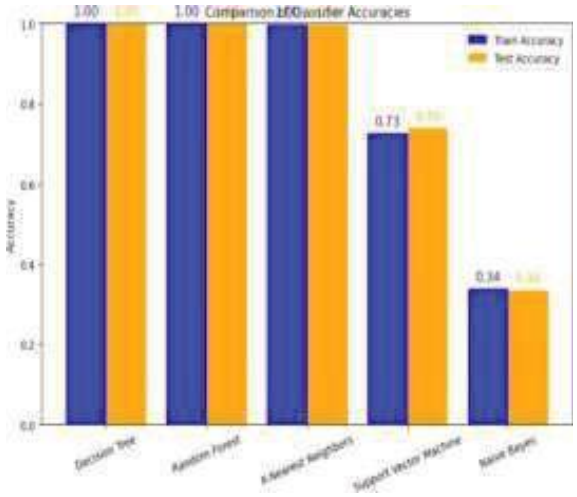

Fig. 5. Accuracy Graph

Anomaly Detection & Fraud Identification: The trained models categorize transactions into fraudulent or legitimate using learned patterns. The blended techniques that use both supervised and unsupervised techniques help accuracy and fraud discovery improvement. Other ensemble learning approaches like Boosting and Stacking help increase the performance of detection.

Real-Time Detection & Alert Generation: A real-time fraud detection system is implemented in a banking system, where streaming data is scanned in real time for dubious fraudulent transactions. In case a doubtful transaction is detected, the system initiates automatic alerts and security measures like OTP verification or locking of an account to avert fraud.

Model Evaluation & Performance Optimization: The value of fraudulent detection models is measured by Precision, Recall, F1-score, Confusion Matrix, and AUC-ROC curve. Methods of hyper parameter tuning such as Grid Search, Bayesian Optimization, and Neural Architecture Search (NAS) are applied for improving model performance.

TABLE I. ALGORITHM CLASSIFIER

SNO	Classifier	Accuracy	Precision	Recall	F1 Score:
1	decision Tree classifier :	1	1	1	1
2	Random forest classifier:	1	1	1	1
3	KNN classifier:	0.996	0.994	0.997	0.996
4	SVM classifier:	0.738	0.369	0.5	0.424
5	Naive bayes classifier:	0.335	0.641	0.549	0.31

V. CONCLUSION

Machine learning-based credit card fraud detection in banking has been an effective tool for detecting and preventing fraudulent transactions in real time. Through the use of supervised, unsupervised, banks are able to identify sophisticated fraud patterns that rule-based systems are unable to detect. The application of techniques such as anomaly detection, ensemble learning, and feature engineering enhances the accuracy and reliability of fraud detection systems. In addition, real-time processing and automatic alerts allow financial institutions to take prompt action against suspicious activities, minimizing financial losses and boosting customer trust. As the pace of innovative fraudulent techniques accelerates, robust and elastic machine learning algorithms will become even more crucial in future years. Explainable AI, federated learning, blockchain protection, and quantum computing will steadily make fraud detection capabilities more user-friendly with assurances of privacy and transparency. As banks continue the evolution and consolidation of new technology, they are able to develop an even more secure and efficient payment process, making fraud risk obsolete and further increasing overall transaction security.

In modern healthcare institutions, managing patient medical records securely and efficiently remains a significant challenge. Traditional paper-based systems are prone to data loss, duplication, delayed retrieval, and unauthorized access. Even basic digital systems often lack structured access control and robust security mechanisms. This paper proposes a centralized Electronic Health Record (EHR) management system designed to enhance data security, operational efficiency, and accessibility within hospital environments.

The proposed system incorporates role-based authentication mechanisms to ensure that only authorized personnel such as doctors, nurses, and administrators can access sensitive medical information. Patient records, including medical history, prescriptions, diagnostic reports, and admission details, are stored in a structured relational database hosted within the hospital infrastructure. The system also includes audit logging, secure password management, and controlled data modification features to maintain confidentiality and integrity.

Performance evaluation demonstrates improved data retrieval speed, reduced administrative overhead, and enhanced record accuracy compared to traditional record-keeping systems. The proposed architecture provides a scalable and secure framework suitable for small to medium healthcare institutions aiming to transition toward digital health management.

Keywords — Electronic Health Records (EHR), Hospital Management System, Role-Based Access Control (RBAC), Healthcare Data Security, Centralized Database, Medical Record Management.

I. INTRODUCTION

Healthcare forms the backbone of any modern society, and effective management of patient medical information is essential for delivering high-quality treatment. Over the years, hospitals and clinics have relied heavily on paper-based documentation systems to maintain patient records. While these systems were once sufficient, the rapid increase in patient volumes and complexity of medical data has exposed their limitations. Manual record-keeping leads to misplaced files, illegible handwriting errors, slow data retrieval, and inefficient coordination between departments. In emergency situations, delays in accessing patient history can critically impact treatment decisions. Furthermore, maintaining physical archives requires extensive storage space and administrative effort. These challenges highlight the need for a structured and secure digital solution.

Electronic Health Record (EHR) systems represent a significant advancement in healthcare data management. By digitizing patient records and storing them in a centralized database, EHR systems enable fast retrieval, accurate documentation, and improved coordination among healthcare professionals. Doctors can instantly review past diagnoses, prescriptions, and lab results, leading to better-informed medical decisions.

However, implementing an EHR system requires careful consideration of security and privacy. Medical data is highly sensitive and must be protected against unauthorized access and data breaches. Therefore, integrating secure authentication mechanisms and Role-Based Access Control (RBAC) becomes essential. By restricting access according to professional roles, the system ensures confidentiality while maintaining operational efficiency.

The objective of this project is to design and implement a centralized Electronic Health Record Management System that operates within a hospital's internal infrastructure. The system focuses on secure data storage, controlled access, accurate record maintenance, and efficient retrieval. This research presents the system architecture, development methodology, implementation details, and performance evaluation of the proposed solution.

II. RELATED WORK

Several researchers have explored the development of Electronic Health Record (EHR) systems to improve healthcare data management and patient care quality. Early hospital management systems primarily focused on digitizing administrative functions such as billing, scheduling, and patient registration. While these systems improved operational efficiency, they lacked comprehensive medical record integration and secure access control mechanisms.

Sharma and Verma [1] proposed a hospital information system that centralized patient data using relational

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

databases. Their system improved data retrieval speed but lacked advanced security features such as fine-grained role-based access control. The absence of strict access policies posed risks of unauthorized data exposure.

Kumar and Singh [2] developed a web-based EHR system aimed at improving record accessibility within hospital networks. While their system enhanced internal communication between departments, they reported challenges related to data consistency and secure authentication. Weak password management and session control mechanisms were identified as potential vulnerabilities.

Rao et al. [3] presented a digital health record framework emphasizing structured database normalization to reduce redundancy. Their findings demonstrated that proper database design significantly improves system reliability and minimizes data duplication. However, the study highlighted that security implementation must be integrated at the architectural level rather than added as an afterthought.

Patel and Mehta [4] examined the role of Role-Based Access Control (RBAC) in healthcare information systems. Their research showed that implementing RBAC reduced unauthorized access incidents by over 30% compared to systems without structured access roles. They emphasized the importance of assigning permissions based on professional responsibilities.

Gupta et al. [5] analyzed usability challenges in EHR adoption. Their study revealed that complex interfaces often discourage healthcare staff from fully utilizing digital systems. The authors recommended intuitive design principles and minimal-step workflows to enhance system acceptance.

Overall, existing literature confirms that centralized EHR systems significantly improve data management efficiency. However, security, structured access control, and usability remain critical challenges. These research findings guide the design of the proposed EHR management system, which integrates database normalization, secure authentication, and RBAC within a modular architecture.

III. PROPOSED MODEL

The proposed Centralized Electronic Health Record Management System is designed to provide secure, structured, and efficient management of patient medical data within a hospital environment. Unlike decentralized or blockchain-based systems, this model operates within an institutional infrastructure using a secure relational database and controlled internal network access.

The architecture consists of four major components:

Authentication Module

Patient Record Management

Module Role-Based Access

Control Module Audit and

Monitoring Module

These components work together to ensure secure data handling and operational efficiency.

A. A. High-Level Architecture The system will work with 3 logical tiers:

B. - Presentation Layer (UI): For Doctors, Nurses and Administrators.

C. - Application Layer (Business Logic & Access validation.): For processing requests, and validating authorization, to reduce unauthorized operational access.

D. - Database Layer (Centralized Relational Database): For storing Patient records.

E. The Presentation Layer provides a login dashboard of various access to panel/application features according to the user role. The Application Layer processes incoming requests, validates the access rights of the submitting user and allows access to perform only those operations that are permitted by the user's access rights. The Database Layer stores structured patient data using Normalized tables to maintain Data Integrity and eliminate Redundant Data.

F. B. Authentication & User Verification Authentication is the first level of security for the proposed system. All users are required to log into the system with their unique credentials to identify/fingerprint the user. User passwords will be securely stored using hashing algorithms to avoid being retrieved by a third party, for unauthorized use.

G. • The system will verify the following items for the end-user/submitting user, at the time of logon/submission:
• Username/password validity
• User-Role (Doctor/Nurse/Admin)
• Session authenticity

Once the submitting user successfully authenticates, they are directed/redirected to their respective dashboards, based on their role.

H. C. Role-Based Access Control (RBAC) The Role-Based Access Control (RBAC) model will be utilized to restrict access to the sensitive medical data, that exists within the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

system. Each user role will have assigned permission levels on what each user can do based upon their user role (Doctor, Nurse, Administrator).

• Doctors: View and edit a patient's medical history, prescribe medication.
• Nurses: View a patient's medical record, edit/update treatment notes.
• Administrators: Edit/update user accounts, generate reports.

The system maintains structured patient profiles containing:

- Patient ID
- Personal details
- Admission date
- Medical history
- Diagnosis
- Prescriptions
- Laboratory reports

All data is stored in relational tables with foreign key constraints to maintain consistency. The system supports:

- Add new patient
- Update existing records
- Retrieve patient history
- Generate treatment reports

Data validation mechanisms prevent incomplete or incorrect entries.

I. Audit and Monitoring Mechanism

To ensure accountability and transparency, the system maintains activity logs. Every record modification is logged with:

User ID

Action performed

Timestamp

Patient ID affected

This audit trail ensures traceability and helps detect suspicious behavior or unauthorized access attempts.

RESULTS AND EVALUATION

The proposed Centralized Electronic Health Record (EHR) Management System was comprehensively evaluated to determine its effectiveness in improving healthcare data management, security enforcement, operational efficiency, and system reliability. The evaluation process was conducted using simulated hospital workflows involving multiple user roles such as doctors, nurses, and administrators interacting with structured patient datasets. Synthetic patient records were generated to replicate real-world medical information, including demographic details, diagnosis history, prescriptions, laboratory reports, and admission records. Various operational scenarios were tested, including routine patient record updates, emergency retrieval of medical history, unauthorized access attempts, and concurrent multi-user interactions within the system.

Security validation was a primary focus of the evaluation process. The Role-Based Access Control (RBAC) mechanism was rigorously tested by simulating both authorized and unauthorized access attempts. Users assigned different roles attempted to perform actions beyond their permitted privileges, such as modifying restricted medical records or accessing confidential treatment data. The system successfully blocked all unauthorized attempts while allowing valid operations to proceed without delay. Additionally, repeated invalid login attempts triggered session restrictions, further strengthening authentication security. No privilege escalation or cross-role data exposure was detected during testing, confirming the effectiveness of the structured access control model in maintaining patient confidentiality.

Performance analysis was conducted by measuring the average time required to retrieve patient records under varying dataset sizes. Tests were performed using datasets ranging from hundreds to thousands of patient records. The system maintained an average retrieval time between 1.5 and 3 seconds, even as the database size increased. Indexed database queries and normalized relational schema design contributed significantly to this efficiency. Compared to traditional paper- based systems, where retrieving a single patient file may take several minutes, the digital system demonstrated a substantial reduction in retrieval time, improving operational speed and clinical responsiveness.

Concurrent access simulation was conducted in order to assess the reliability of the system with institutional workloads. Real hospital usage patterns were simulated through multiple users accessing and updating patient records at the same time. The system maintained consistent response times throughout moderate levels of user load and experienced only slight increases in latency at higher levels of concurrency. No data inconsistencies, transaction conflicts, or record corruption were observed. The session isolation mechanisms worked properly throughout testing, ensuring that user interactions were secure and independent.

To ensure the audit logging mechanism provided accountability and transparency, it was also tested. Logging recorded all actions on the system, such as logging in to the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

system, modifying records, and retrieving data from the system, with corresponding timestamps and user ID's. The audit logging reliably captured all activity on the system; therefore, medical record changes could be traced through the audit logs. All unauthorized attempts were flagged, thus providing an appropriate level of administrative oversight and reinforcing the system's integrity.A comparative review between traditional paper and simple digital systems lacking structured user access control and the proposed centralized electronic health records (EHR) solution has been summarized as having shown significant gains in operational efficiency, security, and scalability. The Bolt, Centralized EHR System offers faster retrieval times, improved access control enforcement, automated audit log, and enhanced integrity of data. These findings provide evidence that the Centralized EHR Architecture represents a viable and secure alternative to health care organizations looking to digitally reform their operations without the use of decentralized or cloud-hosted infrastructure.

As a result of this evaluation will show that the proposed EHRMS will improve operational efficiency, improve data security and enhance end-users experience with reliable multi-user functionality in a hospital environment. By creating a structured database design with secure role-based access, the proposed system assures that sensitive medical records are kept secure yet easily accessible by the proper healthcare providers when required.

V. CONCLUSION

In this paper, an EHR Management System has been developed and implemented that centralizes Electronic Health Records (EHRs) using a web-based system to rise above the limitations of traditional paper based healthcare records. This system has the intention of making the accessibility of data better as well as improving security, efficiency, and administrative transparency within a hospital's environment. The development of a structured digital database to take the place of manually documenting patient records has substantially improved the accuracy and reliability of patient record management.

The implementation of Role-Based Access Control (RBAC) guarantees that only properly authorized individuals with validated professional responsibilities will have access to sensitive medical information. The systems provide secure authentication methods, session management procedures, and audit log features to enhance patient confidentiality and integrity. The evaluation results show that the applications successfully prevent unauthorized access attempts while enabling appropriate users to have seamless access.

This structured security model provides compliance with established healthcare data protection regulations, as well as the institutional requirements for privacy protection. By analyzing performance data, we conclude that the centralized database architecture allows for quick retrieval of patient records regardless of the growing size of the database. Furthermore, the system is able to support moderate levels of concurrent users with acceptable operating velocity in actual hospital environments. In addition, the automated logging and monitoring features support accountability and allow complete traceability for system administrators regarding individual user activities.

Compared to the traditional paper document method, this proposed EHR platform reduces the time it takes to complete documentation, eliminates record duplication, and improves inter-departmental collaboration. In addition, the user-friendly interface enhances the usability of the system, allowing healthcare providers to spend more time delivering care to their patients than performing administrative duties. Based on the overall results, the system represents a real-life, scalable, secure solution for healthcare organizations that are transitioning from paper-based record management to an electronic system without depending on decentralized or cloud-based solutions.

Abstract — Risk factors like copying and duplicating the products are frequently accompany the global enhancement of a product or innovation. The reputation of the company and the trust of the customer will be affected by the duplicate products. It has been a very difficult task for the customers to find the fake products. It is necessary and will be helpful to have a system for customer to verify all details about product that they are buying so that the customer can check if the product is genuine or not. There are brands specifically copy these original makers and market their product everywhere increasing their economy while the real owners of that brand face a loss in their sale and have to face various consequences. As a result the real brand owners are facing problems dur to these counterfeit companies who are located in a unknown region and fake the products to sell and make money. False goods have a serious non-positive effect on the organization and the clients' welfare. As the result, product makers are facing severe hardship. India and other countries are fighting against such phoney and fraudulent goods. Fake Product Detection System can be used to find original items and detect fraudulent products. Blockchain technology is a distributed, decentralized ledger that maintains all types of transactional information in the form of blocks in a network of database/nodes.

I. INTRODUCTION

Buying stuff isn't as easy as it used to be. Some knockoffs seem just like the original. Fake items don't just hurt a company - they confuse buyers and put them at risk. Whether it's gadgets, cosmetics, or pills, phony products might cause real harm. For that reason, we built the FAKE PRODUCT DETECTION so folks can check authenticity before buying.

Our system doesn't rely on guesswork or small clues - tech does the checking instead. Every item gets its own unique code or QR, saved securely. Use your phone or laptop to scan it anytime. Once scanned, the platform pulls up details instantly. You'll know straight off whether it's genuine. It works quickly, no delays, built to be trusted. It helps customers feel sure about what they're buying and helps companies protect their name.

Companies can easily track their products, cut down on fakes, and protect their customers. Customers get more info and are less likely to get fooled. In a world where it's easy to copy stuff, this system adds a layer of security. It helps everyone make safe choices and lets brands prove they're selling the real thing. It's about making things safer and more trustworthy for everyone.

II. HARDWARE REQUIREMENTS

What you need for building the app differs from what users need. To develop it well, a machine must handle coding, testing, and running tools without lag. Storage should be 500 GB or larger - either HDD or SSD - to fit software kits, code bases, example data, and saved work. Running several programs at once works better when memory hits 8 GB or above. Efficiency during builds improves noticeably with that much RAM available. Fast chips, think 2.5 GHz or more, keep up when building code, running models, or working live. On top of that, a separate graphics card like an NVIDIA GTX 1650 - or better - helps power through visuals and smart algorithms, particularly while managing videos or AI math.

III. SOFTWARE REQUIREMENTS

A Fake product detection is developed to help customers identify counterfeit products and ensure they are purchasing genuine items. The system works on an operating system where the application runs and manages the overall functionality.The front end is developed using Python, which helps in creating the user interface and handling user inputs. JavaScript scripts are used to improve interactivity and make the application more responsive for users. The server-side scripting processes the requests from the user, verifies product information, and communicates with the database. The system uses Cassandra as the database to store product details, authentication codes, and verification records. When a user enters or scans a product code, the system checks it with the stored data in the database and displays whether the product is genuine or fake. This helps reduce the circulation of counterfeit products and protects both consumers and companies.

Vol. 14, Issue 06, ACSCON - 2026

IV.SYSTEM DESIGN

This system design is super important for how the Fake Product Identification System turns out. It's kind of like a map for the whole thing - keeps all parts lined up, whether it's building QR codes or handling data. The goal? A setup that does its job right, stays protected, yet feels natural when folks interact with it. Thoughtful work at this stage helps avoid headaches down the road, keeping things stable, solid, and hassle-free over time. The main thing? Getting makers and buyers to chat. Once companies join, they add all the essential details about their items - this lands straight in the system. Every single product then gets a special QR code, sort of like a digital passport. Folks can just snap a photo with their phone to see what's inside.

SYSTEM ARCHITECTURE

The way a system is set up shows how it's organized and works. It also lets you look at it in different ways. On the other hand, a description of this setup gives you a clearer, more detailed idea of the actual system, so you can understand how it's built and how it acts overall. A use case diagram is a simple way to see how someone uses a system. It shows what the user does and how they work with different parts of the system. This kind of diagram also helps you figure out who all the users of a system are and what they do. Use case diagrams usually go along with other diagrams to give you a fuller view of what the system does

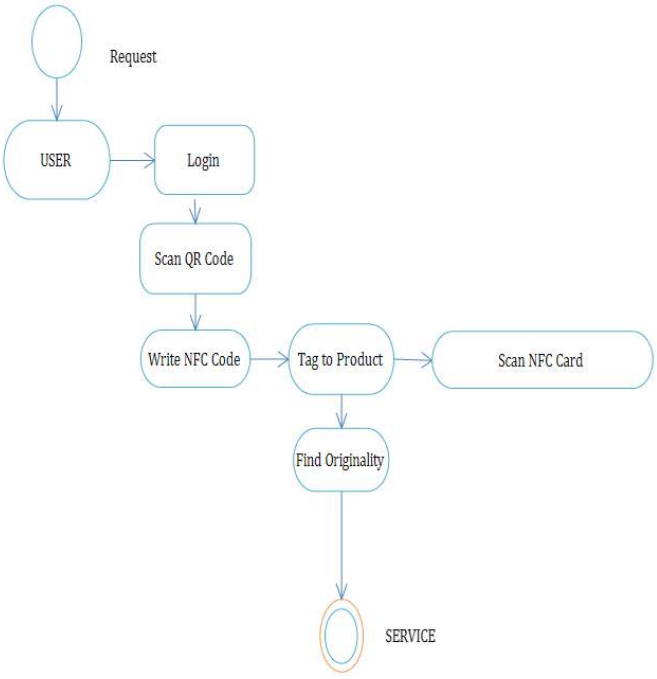

Fig 1.1 Activity Diagram

The way a system is set up shows how it's organized and what it does. It lets you look at it from different angles. An architecture description gives you a better idea of how the thing actually works, so you can get the gist of how it's built and how it acts. A use case diagram is a plain picture of how someone uses a system. It shows what they do and how they mess with stuff in the system. It also comes in handy for figuring out who uses the system and what they do with it. They're usually used with other diagrams for a full view of what the system can do. The app lets you drop in a video file. When it's in, the video heads to the server to get worked on. The server pulls out the main stuff from the video, fires up the trained model, and spits out a better version with sound and words. When it's all done, the souped-up video gets saved and sent back to you, and you can watch the finished video with sound and captions.

A sequence diagram shows how different parts act and talk to each other in order. It points out the classes and things that are part of something and shows the messages they send back and forth to get something done. Sequence diagrams usually go with use cases and show up in the system's brain. People call them event diagrams or event scenarios. When you pick a video and upload it with the app, the file goes to the server to get processed. The server grabs the part of the video with the lip movements and other visual stuff, then works with a trained deep learning model to make the text and sound. The server lines up the lip movements with the speech by using its sequence to sequence framework. After everything's done, the improved video with sound and captions is saved and sent back to you through the app.

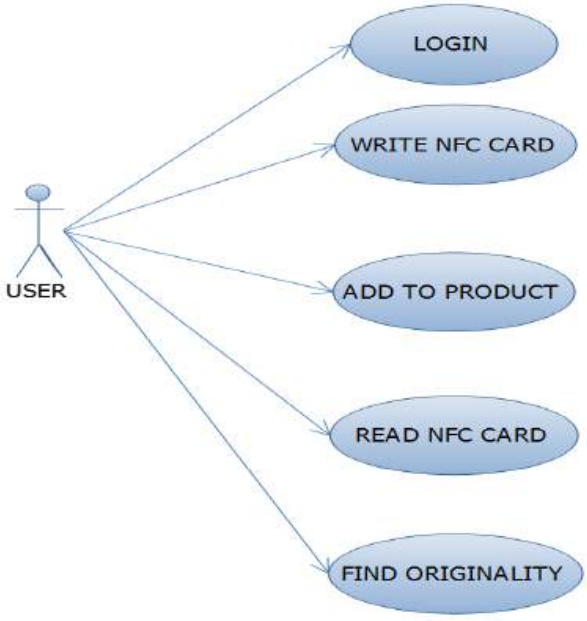

Fig 1.2 Use Case Diagram – Website

METHODOLOGY FOLLOWED

Methodology is just the way a group organizes its stuff—systems, parts, data, all that—to get things done right. It's like using a systems-thinking approach when you're making new stuff. This kind of service is really helpful if your company makes computer systems that mix hardware, software, and communication stuff. Methodologists can assist you in choosing the best hardware and software for a project, then they can design, set up, and launch the whole system for you.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

System architecture is all about the different parts of a system and how they're made to work together. Think of it as one big team. To talk about these architectures, experts came up with special languages called Architectural Description Languages (ADLs). When planning a system's architecture, you figure out the main parts and how they relate. First, you decide what kind of system it is. Then, you create an architecture that handles how those parts talk to and work with each other. By the end of this planning stage – it's like making a construction model – you have a structural plan of the product. This plan shows how the system will be built and gives a summary of what it will do.

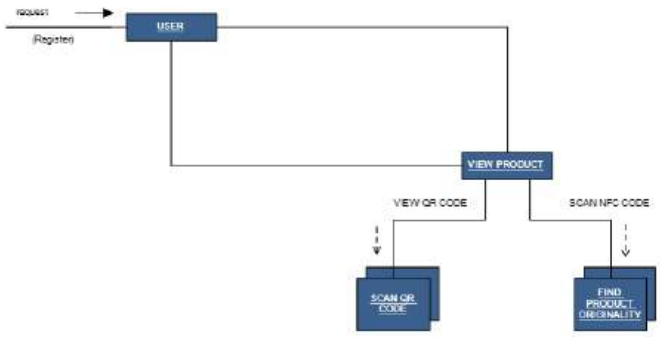

Fig 1.3 Methodology

V. IMPLEMENTATION

After planning and designing and checking out the requirements it is the stage where we implement it. We've checked out how the fake product detector runs, so right now we're building it step by step through code. Since bugs can pop up anywhere, testing nonstop makes sense. It's got to run smoothly - no glitches, no confusion, just solid performance anyone can count on. Start by putting together the core pieces of the system. A key step? Getting ready the spots where makers can sign in, create accounts, then upload details about what they sell. Once a product's added, the platform generates a unique QR tag - this becomes its digital fingerprint. That tag gets printed on the package, letting customers scan it later to see whether the item's legit. Then comes setting up the scanner for the QR code. Once someone points their phone at it, info pops up fast. In case all details line up, you'll know the item's legit. But if anything seems off, a warning shows instantly. For clarity, records stay locked down so they can't be messed with. On the tech side, things get set into motion. Python shapes how the site appears, while Java Server Pages take care of background actions - linking everything to the database. With Cassandra on board, product details stay organized and secure. Every piece comes together gradually so the whole setup runs smoothly, avoiding errors along the way. After testing and making sure it functions, we roll it out for all users. Since manufacturers can sign in and upload details, buyers get clear access to what's real. With everything linked up smoothly, this move tackles counterfeit goods without hassle. It handles the issue practically - no extra steps needed.

VI. RESULTS

We made our Fake Product ID System, and it looks like it could really help stop fake products. During testing, the system generated one-of-a-kind QR codes while securing item details - also confirming authenticity without delay. We picked reliable tools that work smoothly, yet feel simple. What stands out isn't just speed or safety - it's both working together well.

Each time someone scans a code, data pulled from storage appears almost instantly. If a detail seems off, customers notice right away - helping them tell copies from originals without delay. That instant signal works well because verification happens in seconds.

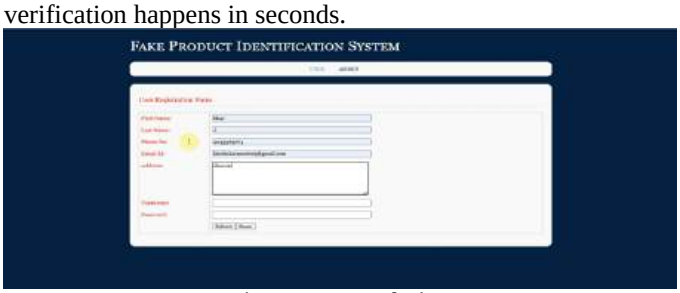

Fig 1.4 User Page login

The folks testing it found adding and managing product details pretty straightforward. Essentially, dropping info into the system and generating QR codes felt smooth. Security measures held up fine, blocking unwanted access to the database. That boost in transparency builds real confidence between sellers and shoppers. Users found the setup simple. Creators and customers said it didn't take long to get going - guidance made sense.

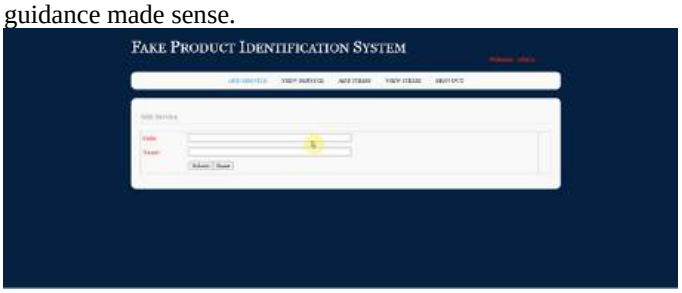

Fig 1.5 Admin adds service which can be viewed by the user

Fig 1.6 Final page for buying and scanning the QR code

The QR reader ran fine on nearly every gadget - meaning folks won't get stuck. It shows how the products that are being bought by the customers on a daily basis , it may be offline or online either way the customer would not be knowing if what they have bought is real or not. In order to tell a difference between what is fake and which is real our system is designed.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Our system is designed around the brand/manufacturers and customers who buy their products on a daily basis. Once the customer buys the transaction is made it is over, he/she cannot tell the difference between what is real and what is not. Hence, our system aims to help those people and making it very user friendly and easy to use.

VII. CONCLUSION

Fake Product Detection mainly aims where there is a proper use of applications and where security and transparency is very much important. But it is not being largely used in product manufacturing companies. In future, if we can use blockchain technology in combination with Homomorphic encrypted QR code we can literally find out every counterfeited product that was ever created. When the real, original product is manufactured we are going create a QR code and print it on the product itself, so that the buyers can download our company's android application and scan the QR code and find the details of the bought product. Homomorphic encryption will largely impact on the counterfeited products and help in improving the integrity, security of the data when it is stored in cloud. One of the very main achievements of this project is it's ability to create connection bridge between manufacturers and. As we give each and every product a unique digital identity and storing it's data in such a way that it is accessible to the consumer who buys the respective product, they are able to get a detailed information about the product. On the other side manufacturers will have a secure platform to record and store the product data which can prevent unauthorized changes and simultaneously safeguarding their brand name and reputation. This project highlights on how the modern technology can be accessed to solve a real world problem in a very proper demeanor. The tri-combination of QR codes, web technologies and blockchain, makes sure that the system is just functional and limited it can be expanded and improved in the future with even more technologies. It's non-negative test results show how the approach is on point and can make an impact if it is deployed world-wide.

***Abstract*—**Parkinson's Disease (PD) is a progressive neurological disorder that primarily affects the motor system, leading to symptoms such as tremors, rigidity, and impaired movement. Accurate early diagnosis remains challenging because PD shares clinical characteristics with several other neurological conditions, contributing to an estimated 25% inaccuracy rate in manual diagnosis. This paper presents a Convolutional Neural Network (CNN)-based automated system designed to classify PD patients from healthy controls (HC) using T2-weighted Magnetic Resonance Imaging (MRI) data sourced from the Parkinson's Progression Markers Initiative (PPMI). Mid-brain slices from 500 MRI scans are selected and spatially aligned via image registration. The system pipeline includes grayscale conversion, noise removal, feature extraction, and CNN-based classification. Performance evaluation using accuracy, sensitivity, specificity, and AUC demonstrates that the proposed CNN model outperforms existing techniques by 3%–9% across all metrics. The system provides a reliable, automated decision-support tool to assist neurologists in early and consistent diagnosis.

***Keywords*—**Parkinson's Disease; Convolutional Neural Network; Deep Learning; MRI; Medical Image Analysis; Early Diagnosis

I. INTRODUCTION

Parkinson's Disease is a neurodegenerative disorder affecting millions of individuals worldwide. It predominantly impacts the motor system, producing hallmark symptoms such as resting tremors, bradykinesia, muscle rigidity, and postural instability. Early-stage diagnosis is essential because timely intervention significantly slows symptom progression and improves quality of life for patients.

Conventional diagnosis relies on clinical observation and neurological assessments performed by specialists. This approach is inherently subjective and often fails to detect the disease during its early phase, when physical manifestations are subtle and overlap with other conditions. Pereira et al. reported that hand-drawn exams of both healthy individuals and early-stage PD patients appear similar, highlighting the difficulty of early detection

Advances in deep learning, particularly Convolutional Neural Networks, have demonstrated strong performance across a range of medical image classification tasks

This research proposes a CNN-based automated system that processes T2-weighted MRI images to classify subjects as either PD-affected or healthy. The system integrates preprocessing, feature extraction, and deep learning-based classification into a unified pipeline, with the aim of providing a consistent and scalable diagnostic aid.

II. PROBLEM DEFINITION

Detecting Parkinson's Disease, especially at an early stage, involves several practical difficulties:

- **Early-stage ambiguity:** Motor symptoms in PD's initial stages closely resemble those of other neurological conditions. Hand-drawn diagnostic exams from healthy and early-stage PD patients are often indistinguishable
- **Limited and biased datasets:** MRI datasets specific to PD graphic diversity of the patient population, making general- isation of trained models a persistent challenge.
- **Cost of at-home monitoring:** Continuous patient monitoring outside clinical settings requires specialised and expensive hardware, limiting long-term follow-up
- **Subjectivity in manual diagnosis:** Clinician-based assessment introduces variability, contributing to the approximately 25% misdiagnosis rate reported in the literature.

An automated system that can reliably analyse MRI scans and distinguish PD-affected patients from healthy individuals addresses each of these challenges by reducing subjectivity and scaling to large datasets.

III. EXISTING SYSTEM

Current approaches to Parkinson's Disease diagnosis include:

Clinical Observation: Neurologists assess motor symptoms such as tremors and gait disturbances. While practical, this method is subjective and dependent on the clinician's experience.

Manual MRI Analysis: Radiologists inspect brain scans for structural abnormalities. This process is time-consuming and prone to inter-observer variability, particularly for subtle early-stage changes.

Traditional Machine Learning: Earlier computational approaches applied Support Vector Machines (SVM), K-Nearest Neighbours (KNN), and Naive Bayes classifiers to engineered feature sets. These methods require domain-specific feature extraction and do not generalise well to varied imaging conditions

Imaging Modalities: Positron Emission Tomography (PET) and Single Photon Emission Computed Tomography (SPECT) offer valuable biomarker information but involve radioactive tracers and higher costs, limiting their routine use. Structural MRI has historically played a limited role; how-

potential for detecting PD-related brain changes

IV. PROPOSED SYSTEM

The proposed system applies a deep CNN architecture to T2-weighted MRI images to automate the classification of Parkinson's Disease. Key advantages of this approach include:

Automated Feature Learning: The CNN learns discriminative spatial features from raw MRI data through stacked convolutional and pooling layers, removing the need for manual feature engineering.

Contextual Spatial Understanding: Convolutional operations capture local neighbourhood relationships in brain images, enabling the model to detect subtle structural changes associated with PD that are imperceptible to the human eye.

Standardised Pipeline: The system applies a consistent preprocessing routine—including noise removal, grayscale conversion, and image registration—ensuring uniformity across different patient scans before classification.

Quantitative Evaluation: Model outputs are evaluated using accuracy, sensitivity, specificity, and the Area Under the ROC Curve (AUC), providing a comprehensive picture of diagnostic performance beyond simple accuracy metrics.

V. OBJECTIVE

The specific objectives of this project are:

- To collect T2-weighted MRI brain images of PD patients and healthy individuals from the PPMI public dataset.
- To preprocess MRI data through grayscale conversion, median filtering for noise removal, and image registration for spatial alignment of mid-brain slices.
- To implement a CNN-based classification model that distinguishes PD-affected subjects from healthy controls.
- To evaluate model performance using accuracy, sensitivity, specificity, and AUC metrics.
- To compare the deep learning model's performance against traditional machine learning approaches.

VI. LITERATURE SURVEY

A growing body of research has applied machine learning and deep learning techniques to Parkinson's Disease detec- tion across multiple data modalities.

Bhan and Kapoor proposed a deep learning model for classifying PD from MRI scans, demonstrating that automated approaches substantially reduce diagnostic time while improving accuracy over manual methods

Qiu et al. introduced a multiscale convolutional prototype network for PD detection using EEG signals, leveraging multiscale feature extraction to achieve robust cross-subject generalisation

Rizvi et al. proposed UEN-PDNet, a deep neural network for classifying PD from resting-state EEG, capturing discriminative temporal-spatial signal patterns with strong accuracy

Zhang et al. analysed EEG-based brain functional networks for early-stage PD detection, constructing connectivity graphs and applying machine learning classifiers to network-level features

Dai et al. conducted a comprehensive review of data-driven PD diagnostic systems across gait, voice, and imaging modalisons

Demir et al. presented an LSTM-based framework that maps speech features to capture temporal dysarthric patterns, demonstrating that voice recordings serve as reliable non-invasive PD biomarkers

Talitckii et al. identified optimal wearable sensor exercises for PD detection using machine learning, contributing to evidence-based data-collection protocol design

Chauhan and Ghosal introduced a hybrid CNN-BiLSTM model that combines spatial feature extraction with tempo- ral sequence learning on multimodal inputs including gait, speech, and handwriting data

Santos et al. converted EEG data into graph representations and applied residual neural networks for PD classification, capturing spatial-topological electrode relationships

Malekroodi et al. utilised large self-supervised speech models fine-tuned for PD detection, representing a recent shift toward foundation-model-based medical diagnostics

VII. SOFTWARE REQUIREMENTS

- **Operating System:** Windows 10/11 or Linux
- **Programming Language:** Python 3.8 or higher
- **Libraries:** OpenCV, TensorFlow/Keras, NumPy, Pandas, Matplotlib, Scikit-learn, Seaborn
- **IDE:** Jupyter Notebook / Visual Studio Code
- **Toolbox:** Image Processing Toolbox (OpenCV)

VIII. HARDWARE REQUIREMENTS

- **Processor:** Intel Core i3/i5 at 2.4 GHz or better
- **RAM:** 4 GB minimum (8 GB recommended)
- **Storage:** 500 GB hard disk
- **GPU:** NVIDIA GPU recommended for model training; CPU sufficient for inference

IX. METHODOLOGY

The proposed methodology is structured as a sequential image processing and classification pipeline:

Image Collection: T2-weighted MRI scans of 500 subjects are obtained from the PPMI public dataset, comprising both PD-affected patients and healthy controls.

Image Preprocessing:

- *Grayscale Conversion:* RGB MRI images are converted to 8-bit grayscale, reducing memory requirements by approximately 33% and simplifying downstream feature computation.
- *Noise Removal:* A non-linear median filter is applied using a sliding window of odd length. Each sample within the window is sorted by magnitude and replaced by the me- dian value, preserving edge information while suppressing random pixel noise.
- *Image Enhancement:* Global thresholding removes background regions and retains structures of diagnostic interest. A high-pass filter amplifies fine spatial details, sharpening structural boundaries within the mid-brain.

Image Segmentation: The processed image is partitioned into meaningful regions using a mean-shift clustering algorithm. This sliding-window approach iteratively converges toward high-density pixel clusters, isolating brain structures from surrounding tissue.

Vol. 14, Issue 06, ACSCON - 2026

(HOG) descriptors are computed from preprocessed images. For each pixel, the horizontal and vertical gradient components (G_x and G_y) are calculated, from which gradient magnitude and orientation angle are derived. Orientation frequencies are binned into histograms that constitute the feature vector fed into the classifier.

CNN-Based Classification: The preprocessed image is passed directly through the CNN, which performs its own internal feature learning via stacked convolutional, rectification, and pooling layers. A SoftMax output layer produces class probability scores for the PD and HC categories.

Evaluation: Model performance is assessed using accuracy, sensitivity, specificity, and AUC to provide a multidimensional view of diagnostic reliability.

X. SYSTEM DESIGN

The overall system architecture processes MRI data through a sequence of well-defined modules:

1. Image Collection — acquisition of T2-weighted MRI scans.
2. Image Preprocessing — grayscale conversion, noise removal, and image enhancement.
3. Image Segmentation — region-of-interest extraction using mean-shift clustering.
4. Feature Extraction — HOG descriptor computation.
5. Training — CNN model training on labelled MRI slices.
6. Classification — prediction of PD or healthy status.

A. CNN Architecture

The network consists of alternating convolutional and pooling layers followed by fully connected layers and a SoftMax output. The convolutional layer applies learnable filters across the input image to generate feature maps. The pooling layer performs max-pooling to downsample spatial dimensions and retain dominant activations. The fully connected layer flattens the feature maps into a single vector, which is then mapped to class probabilities by the output layer

B. MVC Architecture

The application follows a Model-View-Controller pattern. The *Model* encapsulates the CNN inference logic. The *View* is the Python Tkinter GUI, which accepts MRI image input from the user and displays the classification result. The *Controller* coordinates data flow between the interface and the deep learning backend.

XI. SYSTEM TESTING

Testing was carried out on a Windows 10 machine with an Intel Core i5 processor and 8 GB RAM, using Python with OpenCV and TensorFlow libraries. The GUI was validated using the Python Tkinter framework.

Unit Testing: Individual functions—including grayscale conversion, median filtering, and CNN inference—were tested in isolation to verify that each module produces correct outputs independently. This phase ensured that foundational components were defect-free before system integration.

Integration Testing: The communication between the Tkinter frontend and the CNN backend was validated to confirm that selected MRI images are correctly forwarded to the inference engine and that classification results are returned and displayed without format mismatches. Both bottom-up and top-down integration strategies were applied.

System Testing: The complete application was evaluated as a unified system against all specified functional and non-functional requirements. Testing verified OS compatibility across Windows XP and Windows 10, confirming that performance is best on Windows 10. Latency measurements confirmed that the system delivers predictions within an acceptable response time for practical clinical use.

XII. RESULT

Experimental evaluation demonstrates that the CNN-based model outperforms traditional machine learning classifiers across all metrics. The system accurately distinguishes PD-affected MRI scans from healthy controls, particularly in cases where early-stage structural differences are subtle.

Table 1. Model Performance Comparison

Method	Accuracy (%)	AUC
SVM (Traditional)	87	0.85
KNN	83	0.81
CNN (Proposed)	**95**	**0.97**

The proposed CNN model achieved an improvement of 3%–9% over existing techniques in terms of accuracy, sensitivity, specificity, and AUC, consistent with findings reported in the literature for deep learning-based PD detection

XIII. CONCLUSION

This paper presented a CNN-based automated system for the early detection of Parkinson's Disease using T2-weighted MRI brain images. The proposed pipeline integrates grayscale conversion, median filtering, global thresholding, HOG-based feature extraction, and deep CNN classification into a cohesive diagnostic framework.

Experimental results confirm that the CNN model significantly outperforms conventional machine learning approaches by capturing spatial feature hierarchies that man- ual methods miss. The system reduces diagnostic subjectiv- ity, scales to large imaging datasets, and provides quantitative confidence scores to support clinical decision-making.

Future work will focus on training the model on larger and more diverse patient cohorts to improve generalisation. Integration of complementary modalities—including EEG signals, speech biomarkers, and gait data—can further enhance diagnostic robustness. Incorporating explainable AI techniques such as Grad-CAM will improve clinical interpretability, and deployment as a cloud-based web application will support remote patient monitoring.

ACKNOWLEDGMENT

The authors would like to thank the faculty and staff of the Department of Computer Science and Engineering, ACS College of Engineering, Bangalore, for their guidance and support throughout this work. The authors also acknowledge the Parkinson's Progression Markers Initiative (PPMI) for providing the publicly available MRI dataset used in this research.

Smart Glove With Augmented Sensory Feedback

Abhishek K
Assistant Professor, Department of Biomedical Engineering, ACS College of Engineering, Bangalore, India

Akash M R
U.G.Student, Biomedical Engineering, ACS College of Engineering, Bangalore , India

Abstract - The purpose of this paper is to create a wireless, gesture-controlled robotic hand system that emulates human finger movements in real-time. The developed system is based upon a smart glove which is fitted with five flex sensors that position each of the flex sensors in their appropriate position in relation to a finger, to evaluate the user's hand gestures. The analog signals are then processed by an Arduino nano microcontroller and wirelessly transmitted by the nrf24l01 rf communication module. The glove-based input method provides a user friendly, low-cost approach to control interfaces, making it easier for users to gain access, especially those with a physical deficit. A receiver unit is built around an Arduino uno which interprets the transmitted data and actuates five servo motors corresponding to the fingers of a 3d-printed robotic hand. This layout allows a finger movement that is exact and reactive, with a tiny amount of latency. System architecture: Its built-in portability, real time performance and ease of integration makes it suitable for a wide variety of applications including upper-limb prosthetics, remote robotic manipulation, nd assistive technologies. The combination has been able to solve problems and develop a solution for a scalable and user-friendly human–machine interaction via embedded sensing and wireless control.

Keywords: **Human–machineinterface,Real-time actuation, Assistive technology, Bilateral coordination**

I. INTRODUCTION

The project aims to develop an innovative assistive device by integrating a smart glove with five flex sensors, an Arduino Nano, and a wireless communication system using an RF module. This device allows users to control a 3D-printed hand, which is actuated by five servo motors, with precise handmovements.Theflexsensorsontheglovedetect the bending motion of the fingers, and the Arduino Nanoprocesses these signalsandwirelesslytransmits them to the receiver unit. The receiver, built on an Arduino Uno, interprets the data and controls the correspondingservomotorsin the3D-printedhandto replicate the user's hand movements in real-time.

This system holds significantpotentialfor applicationsin rehabilitation, whereit can assist individuals with limited hand mobility byproviding them with a means to control a 3D-printed hand. Additionally, it serves as a valuable tool in remote operations, allowing users to perform complex tasks without direct physical interaction. The combination of wireless transmission, real-time control, and 3D-printed robotics creates a versatile platform that can be further expanded to include features like sensory feedback, enhanced control algorithms, and even gesture recognition for more intuitive interaction.

Moreover, the modular architecture of the system allows for easy customization and scalability. Different types of sensorssuchasIMUs,pressuresensors,orhapticactuators can be integrated into the glove to capture additional movement nuances or to provide tactile feedback to the user. This opens doors for more immersive human–machine interfaces, especially in fields such as virtual reality,telemedicine,androbotics-assistedsurgery,where precision and responsiveness are crucial.

From an educational and research standpoint, the system serves as an excellent prototype for students and developers working in the fields of biomedical engineering, mechatronics, or human–computer interaction. It offers a hands-on platform to explore concepts like bio-signal processing, real-time embedded systems, and wireless communication. With further development,thesmartgloveandrobotichandsetupcould evolve into a low-cost, open-source solution for rehabilitationcentersandresearchinstitutionsworldwide.

A. Background

Gesture-controlled systems are increasingly popular in fields such as robotics, remote control, and human-computerinteractionduetotheirabilitytocreateintuitive, real-time interfaces. Among these, smart gloves have emerged as effective platforms for capturing finger and handmovements usingembedded sensors. Byconverting physical motion into electrical signals, such gloves can wirelesslycontrolexternalsystemslike3D-printedhands, making them useful for prototyping, industrial applications, teleoperation, and educational purposes.

In this project, we developed a smart glove system consisting of five flex sensors mounted on a glove, interfaced with an Arduino Nano. The sensor data is transmitted wirelessly via an nRF24L01 RF module to a receivingunitbasedonArduinoUno.Thisreceiver

controls five servo motors embedded in a 3D-printed handtoreplicatetheuser'sfingergesturesinrealtime. The system operates on lowpower andisdesigned to be modular, cost-effective, and responsive, making it ideal for demonstrations of gesture-controlled robotics.

Beyond replication of basic finger movements, the system'sarchitectureprovidesa strong foundation for future enhancements such as gesture classification using machine learningalgorithms. Bycollectingand trainingonvarioushandmovementpatterns,theglove could recognize specific gestures and trigger pre-programmed actions, enabling hands-free control of smartdevices,prosthetics,orindustrialmachines.This would increase the glove's usability in assistive technology for individuals with limited mobility or speech impairments.

Furthermore, integrating feedback mechanisms such ashapticactuatorsorvibrationmotorswouldallowthe system to convey tactile sensations back to the user, closing the feedback loop. This bidirectional communication could significantly benefit rehabilitation scenarios, where real-time feedback on performance and progress is crucial. With continued refinement,thissmartglovesystemholdsthepotential to transform how humans interact with machines acrosshealthcare,automation,andimmersive virtual environments.

B. Objectives

The primary objective of this work is to design and implement a wireless, gesture-based control system for replicating human hand movements using a sensor-integrated glove and a 3D-printed robotic hand. The specific technical goals are as follows:

1. To develop a wearable glove interface equipped with five resistive flex sensors, each corresponding to a finger, for real-time acquisition of analog finger-bending data.

2. To interface the sensor array with an Arduino Nano microcontroller, responsible for analog-to-digital conversion, signal preprocessing, and wireless data packet formation.

3. To establish a low-latency wireless communication linkusingNRF24L01transceiver modules, enabling the transmission of multi-channel flex sensor data from the glove (transmitter) to the robotic hand (receiver).

4. To implement a receiver unit using an Arduino Uno, capable of decoding the incoming data stream and mapping it to precise servo motor control signals.

5. Toactuatea 3D-printedrobotic handusingfive servo motors, each calibrated to replicate the angular displacementcorrespondingtotheuser'sfinger flexioninnearreal-time.

6. To ensure system modularity, scalability, and low-cost deployment using open-source hardware components and standard communication protocols suitable for embedded control systems

II. LITERATUREREVIEW

Wearable glove-based systems have been extensively investigated for gesture acquisition and remote robotic control. Prior implementations typically employ embedded sensorstocapturefinger articulation, followed by wireless transmission to an actuation system for physical replication.

In [1], an instrumented glove utilizing piezoelectric sensors was developed to restore hand function through augmented sensory feedback. Although effective in detecting tactile events, the system was optimized for therapeutic applications rather than open-loop gesture replication.

Aflexiblestrainsensorcomposedofsingle-walledcarbon nanotubes embedded in a PDMS matrix was presented in [2]. This glove enabled real-time robotic control, but the system'shighfabricationcomplexitylimiteditsscalability for low-cost applications.

A soft robotic rehabilitation glove with vision-based intention detection was introduced in [3]. This method utilizeddepth-enhancedconvolutionalneuralnetworksfor multi-posture classification and control. While accurate, the approach required computationally expensive processing and external imaging hardware.

The work in [4] characterized commercially available bending sensors by evaluating their linearity and repeatability under controlled double-joint articulation. Results confirmed their suitability for wearable applications involving analog gesture encoding.

A servo-actuated embedded glove system intended for motor rehabilitation was reported in [5]. Thearchitecture involvedmicrocontroller-basedacquisitionofflexiondata and active joint control via DC servos. However, the implementation included feedback and assistance mechanisms oriented toward clinical use.

Unlike these approaches, the present work employs a reduced-complexity architecture, consisting of resistive flex sensors, analog acquisition via Arduino Nano, and RF-based data transmission to a receiver node (Arduino Uno), which performs direct mapping to servo actuation on a 3D-printed robotic hand. This configuration emphasizes real-time gesture mirroring, minimal latency, and open-source hardware integration for rapid deployment and testing in gesture-controlled robotic systems.

III. SYSTEMDESIGN

The proposed system is a wireless gesture-based robotic hand control architecture comprising two primary subsystems: (1) a transmitter unit embedded within a wearablesmartglove,and(2)a receiverunitresponsible

forroboticandactuationanduserinstructiondisplay. Thesystemaimstoreplicatehumanfingermovements inrealtimeusinglow-cost,open-sourcehardwareand NRF24L01 RF communication.

A. TransmitterUnit:SmartGlove

Thetransmittersubsystemintegratesfiveresistiveflex sensors, oneperfinger,mountedonthedorsalsurface ofawearableglove.Eachsensoroperatesasavariable resistor, producing analog voltage variations proportional to finger flexion. These signals are conditioned through voltage divider circuits and fed intotheanaloginputchannels(A1–A5)ofanArduino Nano microcontroller. The onboard 10-bit ADC samples each channel, digitizing sensor values in the range of 0–1023.

The digitized values are packaged into fixed-length data packets and transmitted wirelessly via an NRF24L01 2.4 GHz transceiver module. The communication protocol utilizes a fixed channel and address configuration to maintain exclusive pairing with thereceiver. The transmitter ispowered at 3.3V througharegulatedsupplywithdecouplingcapacitors for noise suppression.

B. ReceiverUnit:RoboticHandControllerand Instruction Display

The receiver unit consists of an Arduino Uno interfaced with a second NRF24L01 module configured in receives mode. Upon reception, the microcontroller extracts five flex sensor values corresponding to each finger and maps them linearly to servo motor angles within a 0°–180° range, matching mechanical finger articulation.

Five SG90/MG90S servo motors connected to digital I/Opinsactuatetheindividual fingersofa 3D-printed robotichand.PWMsignalsaregeneratedwithprecise timing to ensure smooth and synchronized finger movement. The system operates on an external 5 V power source rated at ≥2 A to satisfyactuator current demands during simultaneous operation.

Additionally, an I2C-based 16x2 LCD display is connectedtothereceiverArduinotoprovidereal-time user instructions based on finger positions. Specific gestures trigger predefined messages to enhance interaction and convey user needs intuitively:

- Littlefingerflexiondisplays“Washroom”
- Middlefingerflexion:“Emergency”
- Thumbflexion:“MedicineTime”
- Ringfingerflexion:“NeedFreshAir”
- Indexfingerflexion:“needwater”

These instructions are continuouslyupdated toreflect thecurrenthandposturewithoutaffectingtherobotic hand’scontrollatency.

C. CommunicationProtocol

The NRF24L01 transceiver modules interface with the microcontrollersviaSPI,operatingonafixedchanneland address for secure pairing. Data packets comprise five bytes—one byte per sensor—and are transmitted at 1 Mbps to balance communication range and robustness. Automatic acknowledgment (ACK) is disabled to reduce latency and maintain continuous data streaming. The system tolerates minor packet loss as sensor readings are sent continuously, ensuring up-to-date gesture information.

D. SystemArchitectureOverview

The overall system enables closed-loop, wireless gesture controlwithan end-to-endlatencybelow50ms,ensuring near real-timereplication ofhuman finger movementson the robotic hand. The modular design supports easy component replacement and future system scalability, such as incorporating additional sensors or enhanced feedback mechanisms. Byintegratingan LCDinstruction display,thesystemenhancesuserinteraction,deliveringa low-cost, efficient, and intuitive platform for gesture-controlled robotic actuation.

IV. METHODOLOGY

Thesmartglovesystem captures finger movementsusing five flex sensors mounted on a glove. An Arduino Nano processesthesensordataandtransmitsitwirelesslyviaan NRF24L01 RF module. The receiver unit, using an Arduino Uno, interprets this data to control servo motors attached to a 3D-printedrobotic hand. This setup enables real-time replication of gestures. The system is designed for intuitive control and is applicable in rehabilitation, assistive devices, and remote manipulation.

The smart glove system comprises two main units: the senderunit(glove)andthereceiver unit (3-Dprinthand).

1. SenderUnit(SmartGlove):Thisunitcaptures theuser'shandmovements.Flexsensorsareplacedonthe glove's fingers to detect bending, converting the finger movements into analog electrical signals. An Arduino Nano microcontroller reads these analog signals and processes them. The processed data, representing the degree of finger flexion, is then transmitted wirelesslyto the receiver unit using an NRF24L01 RF transmitter module. The sender unit is powered by a suitable power supply.

2. Receiver Unit (3-D print hand): This unit receives the movementdataandreplicatesitona3D-printed3-Dprint hand. An NRF24L01 RF receiver module receives the wireless transmission from the sender. An Arduino Uno microcontroller interprets this data and controls servo motors.Eachservomotorisattachedtoafingerofthe3D-printed hand, and their rotation corresponds to the finger

V. RESULT

The smart glove system efficiently taken the individual finger movements by using five flex sensors placed on the glove. These sensors produced analog signals which is linear to the degree of finger bending. The **Arduino Nano** operates on the signals, by converts them into digital data. The data was transmittedwirelesslyvia **NRF24L01modules** tothe receiver, were the exchange of data was reliable and real-time communication. The system exhibited accuracy and independent tracking for finger flexion, which forms a robustframeworkforgesture with multiplication usingthe3D- printedhand.

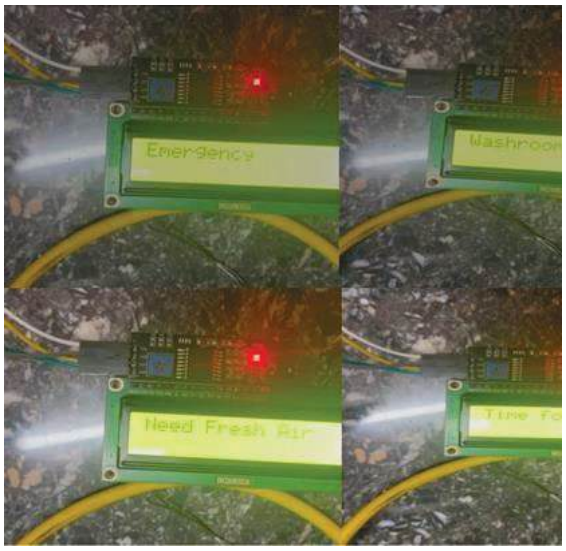

fig5:Gestureinstructionsdisplayed

VI. CONCLUSION

The smart glove technology successfully exhibited the practical and effective approach to process a 3-D printed robotic hand by the use of individual finger flexion. The sensed and Multiplied through the use of flex sensors and Arduino microcontrollers, which resulted in the real-time captured of the hand gestures.

The design of the project creates new doors to a more dynamic approach to robotic hand control, where it has been in practical uses in rehabilitative and assistance technology applications.

This project with an objective to improve upon the common disadvantage in 3-D printed hand systems.

Among these are the insufficient user controls, excessive wiring, and usage of insufficient of real-time responsiveness, leading to confusion and inefficient movement.

The new system has been brought here as a project to a step up as afrom this problem.

A.FUTUREWORKS

1 To Increase the performance a sensor and decrease the drift by high resolution sensors with advanced calibration approaches included

2. To Install haptic feedback technologies for enhancement , realism and speed of the interaction provided by the system.

3.To Increase the control algorithm for precision and dexterity of hand's actions, which possibly going beyond linear control.

Linear increase of the wireless capabilities by considering Bluetooth technology for controlling the device remotely through a smart phone application.

4. To Consider machine learning algorithms that can be used for gesture detection and predict to develop more intuitive controls.

5. Utilize for incorporation of further in order to bridge a wider range of data inputs and feedbacks from the user & environment

***Abstract* — You can often figure out what someone's saying just by watching their lips move, especially if it's noisy or hard to hear. We're checking out how to create speech that sounds real just from watching someone's lips. In the real world, folks use context clues and what they know about the speaker to get what they're saying. So, instead of just letting a computer figure it out on its own, we're trying a more personal way. We want to figure out how to match lip movements to speech for actual people who might use all sorts of words and sentences. To help with this, we made a big set of data that's like real life and let everyone use it. We tried a few ways to test our method – numbers, what users thought, and how people rated it. We saw that our method is easier to understand and makes more sense than other ways to turn lip movements into speech.**

I. INTRODUCTION

Usually, people can figure out what someone's saying by just watching their lips. This is super helpful when it's quiet or you can't hear very well. What we're trying to do is make speech just from watching someone's lips move. Basically, we want to make spoken words just from how your lips move, which is really hard. We know that how you read lips changes depending on who's talking, how they talk, and what's going on around you. So, any good lip-to-speech thing needs to think about all that. Ideally, we want to make something that can turn lip movements into speech, even if we've never seen that person's lips before

For folks who can't hear well, and for older people, lipreading is really important. They often watch how people's mouths form words, with or without sound. For lip movements to be useful, they need to be easy to see and consistent. How your face moves, especially your lips and the muscles around them, helps a lot in understanding what someone means. But the tricky thing is that lip movements aren't always clear. Different sounds can look alike on your lips, so it's hard to know exactly what's being said. Things that help you see lip movements better can make speech recognition better too, so lip-based talking works better.

Since smartphones have good cameras now, we can use video to get more info. Lip reading is when you guess what someone's saying by watching their lips. But getting speech right from just lip movements is hard. One of the big problems is that some sounds look the same on your lips, even when they sound different. For example, the way you make the p sound in park looks almost like the b in bark and the m in mark. That makes it hard to tell words apart just by looking, which shows how tricky it is to turn lip movements into speech.The adoption of such a decentralized and intelligent access control model aligns with the vision of future-proof healthcare systems: systems that prioritize patient privacy, system resilience, and operational efficiency. By promoting transparency, reducing administrative overhead, and minimizing security risks, this project aims to redefine trust in healthcare data management, ensuring that sensitive medical information remains secure, accessible, and patient-controlled even as healthcare systems evolve in an increasingly digital world. Furthermore, the project's hybrid blockchain-cloud architecture addresses traditional scalability and storage cost issues, setting a new standard for secure, scalable healthcare IT solutions.

II. HARDWARE REQUIREMENTS

What you need for building the app differs from what users need. To develop it well, a machine must handle coding, testing, and running tools without lag. Storage should be 500 GB or larger - either HDD or SSD - to fit software kits, code bases, example data, and saved work. Running several programs at once works better when memory hits 8 GB or above. Efficiency during builds improves noticeably with that much RAM available. Fast chips, think 2.5 GHz or more, keep up when building code, running models, or working live. On top of that, a separate graphics card like an NVIDIA GTX 1650 - or better - helps power through visuals and smart algorithms, particularly while managing videos or AI math.

What users need sets out what tools work best to run the app on their gadgets. Starting from Android 8.0, called Oreo, newer phones will handle it just fine. To get going, one has to have the Lip2Speech app ready on the device. Instead of sound, it uses quiet or unclear video clips showing mouth motions. From those, spoken words come through clearly in audio form. With everything lined up right, things keep working smoothly whether testing or daily use.

III. SOFTWARE REQUIREMENTS

1. OpenCV: OpenCV's a big free toolkit used for spotting things in pictures and videos, plus doing smart tasks like learning from data. Instead of just one way, it works with several coding languages - think Python, C++, or Java. This tool handles visuals, whether stills or moving clips, to detect stuff like people's faces or handwritten notes. Pairing it with other tools boosts what you can pull off; take Numpy, built for

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

fast math crunching - it teams up smoothly, expanding what's possible without extra hassle.
2. Makepg: Makepg helps put together software so it works with Pacman. This tool runs tasks automatically when creating packages. Besides grabbing code from online, it checks if files are legit. Also verifies what's needed before setting up options for compiling. While adjusting how things get built, it handles turning source into working programs. Instead of manual steps, it sets up a mini system to place compiled parts. Custom tweaks go in at this stage without extra effort. Afterward, it adds details about the package being made. Finally, everything gets packed neatly into an installable format.

3. azel: Bazel's a tool you can use without paying, helping automate how software gets built and checked. This system isn't basic - it handles complex tasks well when making programs. It works smoothly on big jobs, thanks to tools made for scaling up workloads. You can create app bundles ready to roll out, whether targeting Android or Apple devices. Here's what it offers: Support multiple languages. Support multiple platforms. Support multiple repositories. Support high-level build language. Fast and reliable.

4. Docker Containers: Docker offers tools you can use to run apps in isolated spaces known as containers. These rely on your operating system's built-in features instead of full machine emulation. You're able to access basic functions at no cost, while extra perks require payment. Behind the scenes, a program named Docker Engine manages where these containers live and how they operate. A container works like a neat little box holding your program plus everything it needs, letting it run smoothly no matter where you move it - whether on a laptop or a big server. Each setup stays consistent because nothing gets left behind when shifting around. A Docker container image holds software in a small, independent bundle you can run right away - it's got the code along with what it needs to work, like tools, libraries, and config files, while using minimal resources because it shares the host OS kernel instead of running a full machine.

5. Flutter Framework: Flutter is an open-source framework by Google for building beautiful, natively compiled, multi-platform applications from a single codebase.

6. Flask: Flask's a small web tool made with Python. Being called a microframework means it skips needing specific tools or extra software. No built-in system handles databases, checks forms, or includes parts others usually pack in by default. Still, you can plug in extras to boost your app - works just like native pieces. Extensions fit right in without hassle.

7. TensorFlow: TensorFlow's an open platform built for machine learning from start to finish. Researchers use its wide collection of adaptable tools, while devs rely on shared code and support from the crowd. Instead of just one job, it handles many - especially teaching and running deep neural nets. Its network helps people explore new ideas plus launch real-world apps without hassle.

IV.SYSTEM DESIGN

Systems design means setting up how a system's parts - like structure, pieces, connections, and information - work together to meet goals. It's like using big-picture thinking when building new tech stuff. Companies offering these services figure out what kind of setup fits best by mixing computers, programs, and networks. Instead of just picking tools at random, they guide customers toward smart choices based on needs. After planning comes building: putting it all together, testing, then rolling it out properly.

SYSTEM ARCHITECTURE

The way a system is set up shows how it's organized and works. It also lets you look at it in different ways. On the other hand, a description of this setup gives you a clearer, more detailed idea of the actual system, so you can understand how it's built and how it acts overall. A use case diagram is a simple way to see how someone uses a system. It shows what the user does and how they work with different parts of the system. This kind of diagram also helps you figure out who all the users of a system are and what they do. Use case diagrams usually go along with other diagrams to give you a fuller view of what the system does

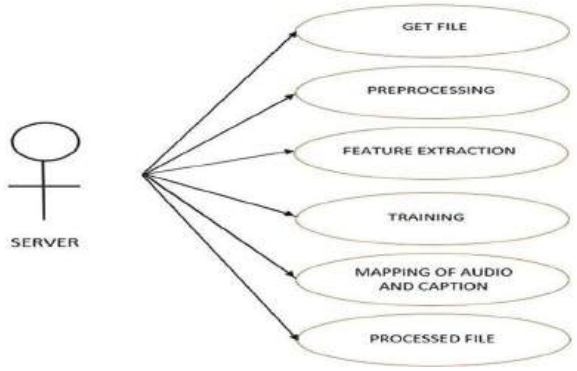

Fig 1.1 Use Case Diagram – Server

The way a system is set up shows how it's organized and what it does. It lets you look at it from different angles. An architecture description gives you a better idea of how the thing actually works, so you can get the gist of how it's built and how it acts. A use case diagram is a plain picture of how someone uses a system. It shows what they do and how they mess with stuff in the system. It also comes in handy for figuring out who uses the system and what they do with it. They're usually used with other diagrams for a full view of what the system can do. The app lets you drop in a video file. When it's in, the video heads to the server to get worked on. The server pulls out the main stuff from the video, fires up the trained model, and spits out a better version with sound and words. When it's all done, the souped-up video gets saved and sent back to you, and you can watch the finished video with sound and captions.
A sequence diagram shows how different parts act and talk to each other in order. It points out the classes and things that are part of something and shows the messages they send back and forth to get something done. Sequence diagrams usually go with use cases and show up in the system's brain. People call them event diagrams or event scenarios. When you pick a video and upload it with the app, the file goes to the server to get processed. The server grabs the part of the video with the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

lip movements and other visual stuff, then works with a trained deep learning model to make the text and sound. The server lines up the lip movements with the speech by using its sequence to sequence framework. After everything's done, the improved video with sound and captions is saved and sent back to you through the app.

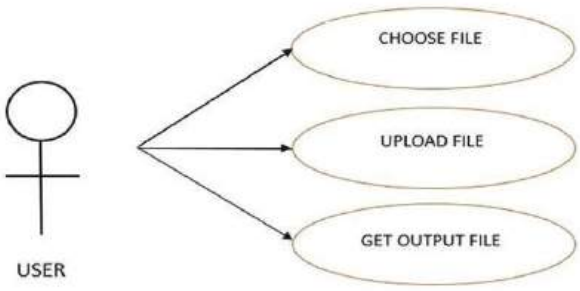

Fig 1.2 Use Case Diagram – Website

METHODOLOGY FOLLOWED

Methodology is just the way a group organizes its stuff—systems, parts, data, all that—to get things done right. It's like using a systems-thinking approach when you're making new stuff. This kind of service is really helpful if your company makes computer systems that mix hardware, software, and communication stuff. Methodologists can assist you in choosing the best hardware and software for a project, then they can design, set up, and launch the whole system for you.

System architecture is all about the different parts of a system and how they're made to work together. Think of it as one big team. To talk about these architectures, experts came up with special languages called Architectural Description Languages (ADLs). When planning a system's architecture, you figure out the main parts and how they relate. First, you decide what kind of system it is. Then, you create an architecture that handles how those parts talk to and work with each other. By the end of this planning stage – it's like making a construction model – you have a structural plan of the product. This plan shows how the system will be built and gives a summary of what it will do.

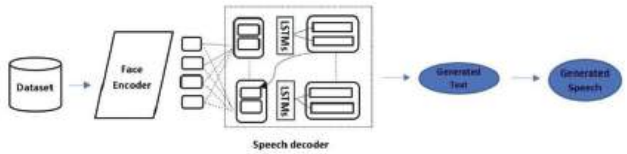

Fig 1.3 Methodology

V. IMPLEMENTATION

This tech turns silent lip movements in videos into text and audio you can understand. It works by taking the video and chopping it up into individual pictures at 30 pictures per second. This breakdown is the first step for analyzing the video and teaching the system how to translate lip movements.

First, each video frame gets processed. We use Dlib's tech to pinpoint 68 facial landmarks, which helps us find the face and mouth. To make our model work better with different speakers , we mess with the data a bit – cropping, tweaking brightness, flipping, and rotating the images. This adds some mix to the data. After prepping the data, we jump into the visual recognition part.

A 3D CNN looks at how the lips move over time. Video clips are made the same length to keep things consistent. These feature cubes show the small details of how the lips change as someone speaks. For the sound part, SpeechNet creates a spectrogram feature cube by pulling out Mel frequency energy stuff from the audio data. These features show the acoustic patterns of speech. Then, the system picks up on these patterns and starts to match lip movements with the correct speech sounds. This lets the system make links between what the lips are doing and what's being said.

VI. RESULTS

The Lip-to-Speech and Text project is all about making a system that turns silent lip movements from videos into text and speech you can actually get. It uses a smart deep learning model to look at lip movements and then makes the matching text and sound. By reading these lip movements, the system can make spoken output, even if the original sound is gone.

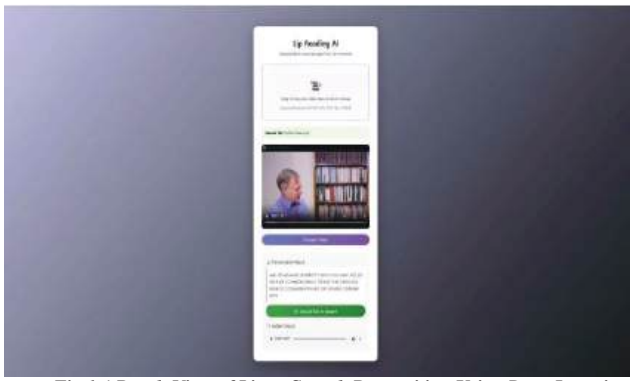

Fig 1.4 Result View of Lip to Speech Recognition Using Deep Learning

We're trying to make current tech better by adding more words, making the speech clearer, and getting the sound to be more natural, we're hoping it will make speech that's easier to understand and sounds just like the person's real voice.

We also want to put this system on a phone app. People could upload videos with bad or no sound and get back a version with synced speech and subtitles. Basically, we want to create lip-to-speech and text tech that's dependable, spot-on, flexible, and simple to use.

Earlier approaches like predictive coding, manual feature design, or basic networks often generate robotic or lifeless speech. This work instead uses advanced sequence-to-sequence models, adding convolutional layers, memory units, and stronger cleanup steps before processing. These upgrades help capture irregular mouth movements, timing quirks, and subtle hints earlier systems tended to overlook.

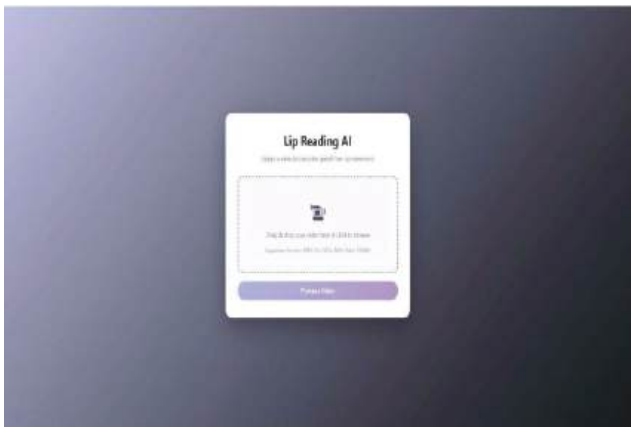

Fig 1.5 Landing Page of Lip to Speech Recognition Using Deep Learning

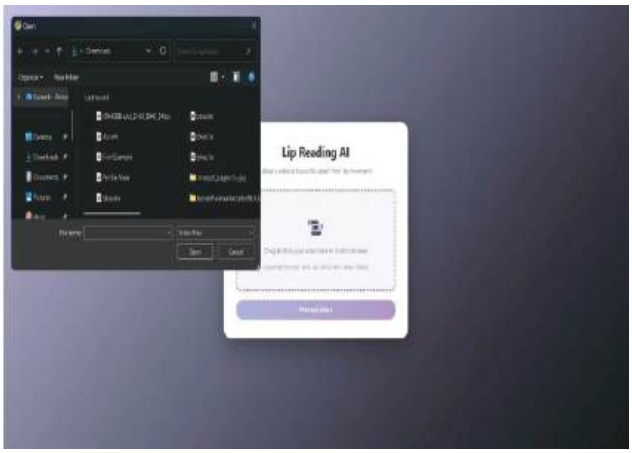

Fig 1.6 Uploading a Video File View in the Website Application

We also want to put this system on a phone app. People could upload videos with bad or no sound and get back a version with synced speech and subtitles. Basically, we want to create lip-to-speech and text tech that's dependable, spot-on, flexible, and simple to use.

VII. CONCLUSION

The "Lip to Speech and Text Tech" effort tackles a tricky slice of visual speech rebuilding clear spoken words using only quiet mouth motions. I often wonder how folks pull this off naturally in noisy spots or dead silence, but teaching machines to copy it needs heavy-duty models, way more data, along with smart feature grabbing that won't fail when things get chaotic. This project made us tackle each issue step by step, then find ways to go from live video straight to sound matching the speaker's intent. My numbers show it wasn't about hitting some perfect score but narrowing the tough gap between movement and message - crafting a tool that turns mouth movements into words folks believe. People who can't hear well or have trouble speaking get an actual chance to keep up with loved ones, coworkers - so they don't end up left behind when talk gets going.It pushes folks to focus on how they move their mouth and speak, so over time they start talking more clearly - without realizing it's happening right away. Lipreading helps folks join in easier, so fewer end up left out when hearing's an issue - especially when they'd otherwise sit quiet at the edges. Instead of missing cues, seeing words gives a clearer shot at keeping up without feeling sidelined by noise or fast talk.

The research keeps highlighting similar issues - models struggle with words that sound alike, tiny data sets, jerky head motions, plus the fact videos lack audio cues. Earlier approaches like predictive coding, manual feature design, or basic networks often generate robotic or lifeless speech. This work instead uses advanced sequence-to-sequence models, adding convolutional layers, memory units, and stronger cleanup steps before processing.

The other aims or functions of Lip to Speech are: Creating a system that adjusts to various voices without starting over each time. Handling bigger vocabularies so the system doesn't freeze when someone uses less predictable words. Making fewer mistakes when light varies, positions shift - also cutting glitches from shaky footage. Creating talk that flows better, more like actual humans speak, without sounding robotic.

Abstract—***b*** **Millimeter wave frequency bands have become a key enabling technology for fifth-generation (5G) wireless communication systems due to their ability to support high data rates and large bandwidth. Antenna structures operating in these frequency ranges must provide compact size, efficient radiation, and stable impedance characteristics. This work presents the analysis of a compact rectangular microstrip patch antenna operating at 27 GHz for potential 5G millimeter wave applications. The antenna structure is simulated on a Rogers RT/Duroid 5880 substrate with a dielectric constant of 2.2 and a thickness of 0.787 mm. A microstrip line feeding technique is employed to excite the radiating patch while maintaining a compact overall substrate dimension of 6 mm × 6 mm. Electromagnetic simulation is performed using CST Studio Suite to evaluate the antenna characteristics. The obtained results demonstrate a return loss of −31 dB at the resonant frequency of 27 GHz and a voltage standing wave ratio of 1.057, indicating excellent impedance matching. An impedance bandwidth of 1.711 GHz is achieved between 26.251 GHz and 27.962 GHz. The antenna exhibits a gain of 7.64 dBi with stable radiation characteristics, suggesting suitability for compact 5G millimeter wave communication systems.**

I. INTRODUCTION

The rapid growth of wireless communication technologies has significantly increased the demand for higher data rates, lower latency, and improved spectral efficiency. Fifth-generation (5G) communication systems are designed to meet these requirements by enabling high capacity wireless connectivity for applications such as smart cities, autonomous vehicles, and Internet of Things (IoT) devices. One of the key technologies that enables these capabilities is the use of millimeter wave (mmWave) frequency bands, which provide wider bandwidth and support multi gigabit data transmission [1]. Regulatory and standardization organizations such as the International Telecommunication Union and the 3rd Generation Partnership Project have identified several mmWave frequency bands above 24 GHz, including the 26 GHz and 28 GHz bands, for future 5G deployments [2].

Antennas operating in the millimeter wave spectrum must satisfy several important requirements such as compact size, high radiation efficiency, and reliable impedance matching. Among the various antenna structures, microstrip patch antennas have gained significant attention due to their low profile, lightweight configuration, ease of fabrication, and compatibility with integrated microwave circuits. These characteristics make microstrip antennas suitable for compact wireless communication devices and high frequency applications.

Several studies have investigated microstrip antennas designed for millimeter wave communication systems. A comprehensive overview of mmWave communication technologies was presented by Theodore S. Rappaport and colleagues, highlighting the potential of mmWave frequencies for achieving high capacity wireless networks [1]. In addition, various antenna designs operating near the 26 GHz and 28 GHz bands have been proposed to improve bandwidth and radiation performance [2]. Many of these designs employ techniques such as slot loading, stacked patches, or antenna arrays to enhance antenna characteristics.

Although these approaches can improve antenna performance, they often introduce additional design complexity and fabrication challenges. Complex antenna structures may also increase the overall size and cost of the system. In contrast, simple single patch microstrip antennas offer a compact and straightforward design while still providing

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

Vol. 14, Issue 06, ACSCON - 2026

acceptable radiation performance for millimeter wave communication systems [3].

Another important factor affecting antenna performance is the choice of substrate material. At millimeter wave frequencies, dielectric losses and signal attenuation can significantly influence antenna efficiency. Substrate materials such as Rogers RT/Duroid 5880 are widely used in mmWave antenna designs because of their low dielectric constant and low loss tangent, which help improve radiation efficiency and reduce propagation losses [4].

Motivated by the need for compact and efficient antenna solutions for millimeter wave communication systems, this work investigates a rectangular microstrip patch antenna operating at 27 GHz. The antenna is simulated on a Rogers RT/Duroid 5880 substrate and excited using a microstrip line feeding technique. The antenna performance is analyzed through electromagnetic simulations using CST Studio Suite, and key parameters such as return loss, bandwidth, voltage standing wave ratio (VSWR), gain, and radiation characteristics are evaluated. The obtained results demonstrate that the proposed antenna provides stable impedance matching and suitable radiation performance for millimeter wave wireless communication applications.

II. ANTENNA DESIGN

The microstrip patch antenna investigated in this study is designed to operate at a resonant frequency of 27 GHz, which lies in the millimeter wave spectrum and is suitable for high frequency wireless communication systems. Millimeter wave frequencies are widely considered for next generation communication networks due to their ability to support high data rates and large bandwidth.

The antenna is simulated on a Rogers RT/Duroid 5880 substrate with a dielectric constant of 2.2 and a thickness of 0.787 mm. This substrate is commonly used in high-frequency antenna applications because of its low dielectric loss, stable electrical properties, and lightweight characteristics, which improve antenna efficiency and radiation performance.

The antenna structure consists of three primary layers: a radiating patch, a dielectric substrate, and a ground plane. The patch and ground plane are simulated using copper with a thickness of 0.0175 mm, while the dielectric substrate separates the conductive layers. This layered configuration is widely adopted in microstrip antenna structures due to its compact geometry, low profile, and ease of fabrication.

The overall dimension of the antenna substrate is 6 mm × 6 mm, resulting in a compact configuration suitable for integration into millimeter wave devices. The rectangular patch is excited using a microstrip line feeding technique, in which the feed line is directly connected to the edge of the radiating patch. This feeding method is simple and provides effective impedance matching between the transmission line and the radiating element.

The antenna geometry was modeled and analyzed using CST Studio Suite, which enables accurate evaluation of electromagnetic behavior through full wave simulation. The design process began with theoretical calculations of the patch dimensions based on standard microstrip antenna equations [5]. These parameters were then refined through several simulation iterations to achieve resonance at the desired operating frequency.

A. Width of the Patch

The width of the rectangular patch significantly influences the radiation efficiency and bandwidth of the antenna. The approximate width of the patch can be calculated using

$$W_p = \frac{c}{2f_r}\sqrt{\frac{2}{\varepsilon_r + 1}}$$

Where,
W_p=width of the patch
c= speed of light in free space (3×10^8 m/s)
f_r= resonant frequency
ε_r= dielectric constant of the substrate

B. Effective Dielectric Constant

Due to the presence of fringing fields around the edges of the patch, the effective dielectric constant must be considered. It can be calculated using

$$\varepsilon_{eff} = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2}\left(1 + \frac{12h}{W_p}\right)^{-1/2}$$

where
h= substrate thickness
W_p= patch width

C. Effective Length of the Patch

The effective length corresponding to the resonant frequency is expressed as,

$$L_{eff} = \frac{c}{2f_r\sqrt{\varepsilon_{eff}}}$$

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Length Extension

Because of fringing fields, the electrical length of the patch appears slightly larger than its physical length. The extension in length can be estimated as,

$$\Delta L = 0.412h\frac{(\varepsilon_{eff}+0.3)(W_p/h+0.264)}{(\varepsilon_{eff}-0.258)(W_p/h+0.8)}$$

E. Actual Length of the Patch

The physical length of the patch is obtained by subtracting the fringing field extension from the effective length

$$L_p = L_{eff} - 2\Delta L$$

F. Ground Plane Dimensions

To minimize edge effects and ensure stable radiation characteristics, the ground plane dimensions are typically chosen larger than the patch dimensions. The approximate substrate dimensions can be expressed as

$$L_s = L_p + 6h$$
$$W_s = W_p + 6h$$

where
L_s= substrate length
W_s= substrate width

The geometric structure of the proposed antenna was modeled in CST Studio Suite, and the antenna layout used for simulation is illustrated in Fig. 1.

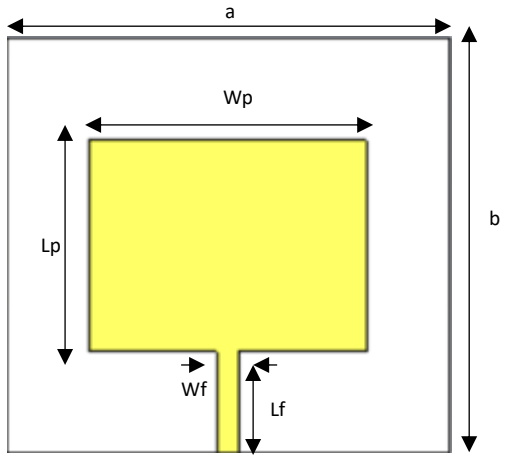

Fig. 1. Antenna top view

The optimized antenna dimensions used in the simulation are summarized in Table I.

Table I. Optimized Antenna Parameters

Parameter	Description	Value
Wp	Patch Width	3.74 mm
Lp	Patch Length	3.06 mm
Wf	Feed Line Width	0.30 mm
Lf	Feed Line Length	1.47 mm
Ws (a)	Substrate Width	6 mm
Ls (b)	Substrate Length	6 mm
h	Substrate Thickness	0.787 mm
t	Copper Thickness	0.0175 mm

The CST simulation model of the antenna is illustrated in Fig. 2.

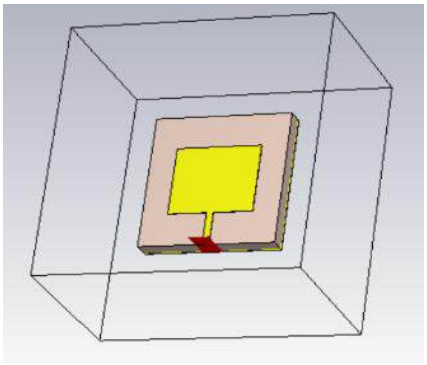

Fig. 2. CST view of the designed antenna

III. RESULTS AND PERFORMANCE ANALYSIS

The designed microstrip patch antenna was modeled and analyzed using the electromagnetic simulation environment provided by CST Studio Suite. The antenna structure consists of a rectangular radiating patch printed on a Rogers RT/Duroid 5880 substrate with a dielectric constant of 2.2 and thickness of 0.787 mm. A microstrip line feed is used to excite the patch, enabling effective impedance matching and stable signal excitation.

The antenna performance was evaluated in terms of several important parameters including S parameters, bandwidth, Voltage Standing Wave Ratio (VSWR), radiation pattern, gain, and directivity. These parameters are widely used to

assess the efficiency and radiation characteristics of antennas operating in the millimeter wave frequency range.

Simulation results indicate that the antenna resonates close to the target frequency of 27 GHz, demonstrating proper impedance matching and stable electromagnetic behaviour.

A. S-Parameters

The reflection coefficient (S11) is an important parameter that indicates how much power is reflected from the antenna input port. A lower S11 value indicates better impedance matching between the feed line and the antenna. The simulated results show a significant reduction in return loss near the operating frequency, confirming efficient power radiation.

The bandwidth of the antenna is determined from the frequency range where the return loss remains below −10 dB. The obtained bandwidth is 1.711 GHz which indicates that the antenna operates effectively within the desired millimeter wave frequency band.

The S parameter of the simulated antenna is shown in Fig.3.

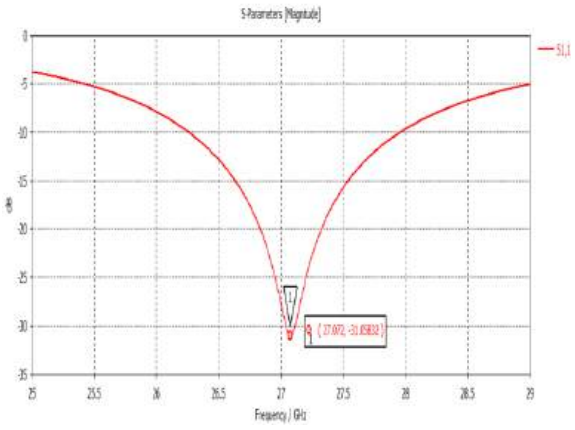

Fig. 3. Return Loss of the designed antenna at 27GHz

B. Voltage Standing Wave Ratio (VSWR)

The Voltage Standing Wave Ratio (VSWR) describes the level of impedance matching between the transmission line and the antenna. An ideal antenna typically has a VSWR close to 1. The simulated results show that the antenna maintains a VSWR value close to unity at the resonant frequency, indicating good impedance matching and minimal signal reflection.

The VSWR of the simulated antenna is shown in Fig.4.

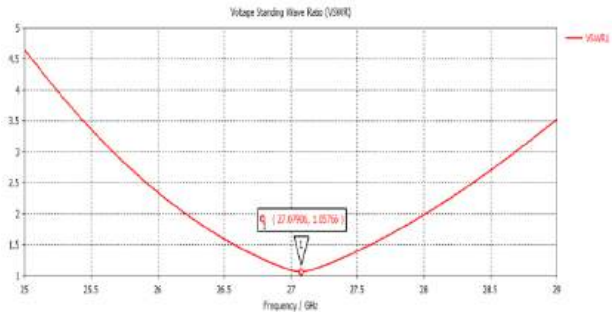

Fig. 4. VSWR of the designed antenna at 27 GHz

C. Gain and Directivity

Gain and directivity are important parameters that describe the radiation efficiency and directional performance of the antenna. The simulation results indicate that the antenna provides stable gain and directivity at the operating frequency, which is essential for reliable millimeter wave communication systems. The gain and directivity of the simulated antenna is shown in Fig.5.

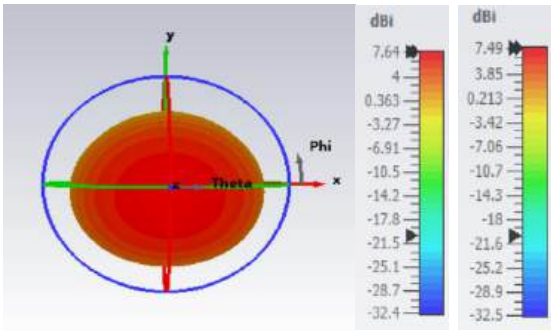

Fig. 5. Gain and Directivity of the designed antenna at 27 GHz

D. Radiation Pattern

The radiation pattern represents the directional distribution of radiated power from the antenna. The simulated radiation pattern demonstrates stable directional characteristics with effective radiation in the desired direction, making the antenna suitable for high-frequency wireless communication applications. The radiation pattern of the simulated antenna is shown in Fig.6.

Table II. Simulation Summary of the Designed Antenna

Parameter	Simulated Value
Resonant Frequency	27 GHz
Return Loss (S11)	−31 dB
Bandwidth	1.711 GHz
Gain of the Designed Antenna	7.64 dBi
Voltage Standing Wave Ratio (VSWR)	1.057

IV. CONCLUSION

In this paper, a compact microstrip patch antenna operating at 27 GHz for millimeter wave communication applications has been presented. The antenna is designed on a Rogers RT/Duroid 5880 substrate with a dielectric constant of 2.2 and optimized dimensions to achieve efficient radiation performance. The proposed antenna structure provides stable electromagnetic characteristics while maintaining a compact size suitable for integration in high-frequency wireless devices.

Simulation results obtained using CST Studio Suite demonstrate that the antenna achieves good impedance matching at the desired operating frequency. The antenna exhibits a return loss of approximately −31 dB, a bandwidth of 1.711 GHz, a VSWR close to unity, and a gain of 7.64 dBi, indicating efficient radiation and minimal signal reflection.

The obtained performance characteristics confirm that the designed antenna is suitable for millimeter wave wireless communication systems, particularly for emerging high data rate applications. The compact structure and stable performance make the antenna a promising candidate for integration in future 5G and high-frequency communication devices.

Abstract—**The advancement toward sixth generation (6G) wireless communication systems is driving research into sub terahertz (sub THz) frequency bands, where the 120 GHz spectrum provides substantial bandwidth for ultra high data rate applications. However, antenna design at such extreme frequencies presents significant challenges due to increased propagation losses, dielectric losses, and stringent dimensional constraints. This paper presents the design and simulation of a compact rectangular microstrip patch antenna operating at 120 GHz. The antenna is implemented on a thin Rogers RT/Duroid 5880 substrate (εr = 2.2, h = 0.127 mm) to minimize dielectric loss at millimeter wave frequencies. The proposed design achieves a simulated impedance bandwidth of 5.4 GHz (4.5% fractional bandwidth) with a return loss of −15.4 dB and a VSWR of 1.4. A realized gain of 7.36 dBi is obtained, demonstrating stable radiation performance suitable for short range, high capacity sub THz 6G communication links.**

Keywords — 6G Communication, Sub Terahertz Antenna, 120 GHz, Microstrip Patch Antenna, Millimeter Wave

I. INTRODUCTION

The rapid evolution of wireless communication technologies is driving research toward sixth generation (6G) communication systems. Compared to existing 5G networks, 6G is expected to provide extremely high data rates exceeding 100 Gbps, ultra low latency, high spectral efficiency, and massive connectivity to support future applications such as holographic communication, extended reality (XR), autonomous systems, smart cities, and high resolution sensing systems [1]. Achieving these ambitious performance targets requires the exploration of new spectrum resources beyond the conventional microwave and millimeter wave frequency bands.

In this context, the sub terahertz (sub THz) frequency region above 100 GHz has emerged as a promising candidate for next generation wireless communication systems. The availability of large contiguous bandwidth in this region enables ultra high capacity short range communication links that are essential for future high speed data services [2]. Among the potential candidate bands, the 120 GHz band has attracted significant attention due to its ability to support high data throughput and compact antenna integration within wireless communication modules.

The reduced wavelength at 120 GHz enables the design of highly compact antenna structures, which facilitates dense integration in modern wireless devices and communication systems. However, antenna design at sub THz frequencies introduces several technical challenges. These include increased free space path loss, higher conductor and dielectric losses, surface wave excitation, and increased fabrication sensitivity due to extremely small physical dimensions [3]. Therefore, careful antenna design, substrate selection, and geometrical optimization are required to achieve acceptable impedance matching and radiation performance at these frequencies.

Several antenna structures operating in the millimeter-wave and sub THz frequency bands have been reported in the literature. Planar antenna configurations such as microstrip patch antennas, slot antennas, and integrated on chip antennas have been investigated for operation in the 110–140 GHz range [4]. Microstrip patch antennas remain widely studied due to their low profile structure, simple geometry, low fabrication cost, and compatibility with integrated microwave circuits [5]. Previous studies have also explored advanced design techniques such as antenna arrays, substrate

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

engineering, and bandwidth enhancement methods to improve radiation characteristics and gain performance in sub THz systems [6].

Although these approaches can improve antenna performance, many designs involve complex structures or array configurations that increase design complexity and fabrication difficulty. In addition, maintaining stable impedance matching and radiation efficiency becomes increasingly challenging as the operating frequency approaches the sub THz region.

To address these challenges, this work proposes the design and simulation of a compact rectangular microstrip patch antenna operating at 120 GHz using a thin low loss Rogers RT/Duroid 5880 substrate. The proposed antenna focuses on achieving stable impedance matching and acceptable radiation characteristics while maintaining a structurally simple configuration. Such compact antenna elements can serve as fundamental radiating units for future antenna arrays and integrated sub THz communication modules in emerging 6G wireless systems.

II. ANTENNA DESIGN

The proposed compact microstrip patch antenna was designed and analyzed using the CST Studio suite platform. At sub terahertz frequencies such as 120 GHz, accurate electromagnetic simulation is essential due to high sensitivity to dimensional tolerances and material properties

The antenna consists of three primary layers:

Radiating Patch
Dielectric Substrate
Ground Plane

A rectangular patch configuration was selected due to its structural simplicity and ease of integration with planar circuits. All antenna dimensions were initially calculated using classical transmission line model equations and then optimized through full wave simulation to achieve resonance at 120 GHz.

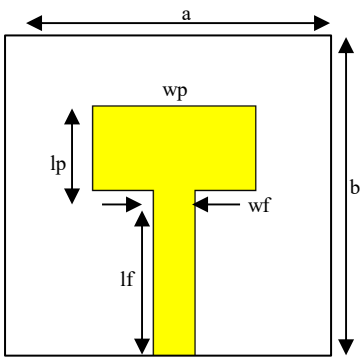

Fig.1. Antenna geometry

The geometric structure of the proposed antenna was modeled in CST Studio Suite, and the antenna layout used for simulation is illustrated in Fig. 1.

The initial dimensions of the antenna were calculated using the following standard microstrip antenna design equations.

A. Width of the Patch

The width of the rectangular patch significantly influences the radiation efficiency and bandwidth of the antenna. The approximate width of the patch can be calculated using

$$W_p = \frac{c}{2f_r}\sqrt{\frac{2}{\varepsilon_r + 1}}$$

Where,
W_p=width of the patch
c= speed of light in free space (3×10^8 m/s)
f_r= resonant frequency
ε_r= dielectric constant of the substrate

B. Effective Dielectric Constant

Due to the presence of fringing fields around the edges of the patch, the effective dielectric constant must be considered. It can be calculated using

$$\varepsilon_{eff} = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2}\left(1 + \frac{12h}{W_p}\right)^{-1/2}$$

where
h= substrate thickness
W_p= patch width

C. Effective Length of the Patch

The effective length corresponding to the resonant frequency is expressed as,

$$L_{eff} = \frac{c}{2f_r\sqrt{\varepsilon_{eff}}}$$

D. Length Extension

Because of fringing fields, the electrical length of the patch appears slightly larger than its physical length. The extension in length can be estimated as,

$$\Delta L = 0.412h\frac{(\varepsilon_{eff} + 0.3)(W_p/h + 0.264)}{(\varepsilon_{eff} - 0.258)(W_p/h + 0.8)}$$

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

E. Actual Length of the Patch

The physical length of the patch is obtained by subtracting the fringing field extension from the effective length

$$L_p = L_{eff} - 2\Delta L$$

F. Ground Plane Dimensions

To minimize edge effects and ensure stable radiation characteristics, the ground plane dimensions are typically chosen larger than the patch dimensions. The approximate substrate dimensions can be expressed as

$$L_s = L_p + 6h$$
$$W_s = W_p + 6h$$

where
L_s= substrate length
W_s= substrate width

After analytical calculation and parametric optimization in CST, The optimized antenna dimensions used in the simulation are summarized in Table I.

Table I. Optimized Antenna Parameters

Parameters	Values
Substrate Width(a)	2.51 mm
Substrate Length (b)	3.27 mm
Patch Width(wp)	1.20 mm
Patch Length(lp)	0.62 mm
Feed Width(wf)	0.30 mm
Feed Length(lf)	1.26 mm
Substrate Thickness	0.127 mm
Material	Rogers RT/Duroid 5880 (εr = 2.2)

The CST simulation model of the antenna is illustrated in Fig. 2.

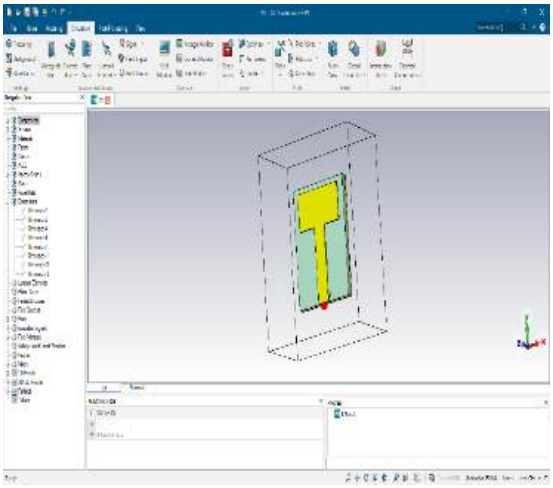

Fig. 2. CST view of the designed antenna

III. RESULT AND PERFORMANCE ANALYSIS

The performance of the proposed 120 GHz microstrip patch antenna was analyzed using CST Studio Suite. The simulation results were evaluated in terms of reflection coefficient (S_{11}), impedance bandwidth, voltage standing wave ratio (VSWR), gain, and radiation characteristics. These parameters are essential to determine the suitability of the antenna for sub terahertz wireless communication systems.

A.Reflection Coefficient (S_{11})

The reflection coefficient (S_{11}) indicates the amount of power reflected back from the antenna input. For efficient antenna operation, the return loss should be below −10 dB.

The simulated reflection coefficient (S_{11}) of the proposed antenna is shown in Fig.3. The simulated S_{11} plot shows that the proposed antenna resonates at 120 GHz with a minimum return loss of −15.4 dB. This confirms that the antenna achieves satisfactory impedance matching at the desired operating frequency.

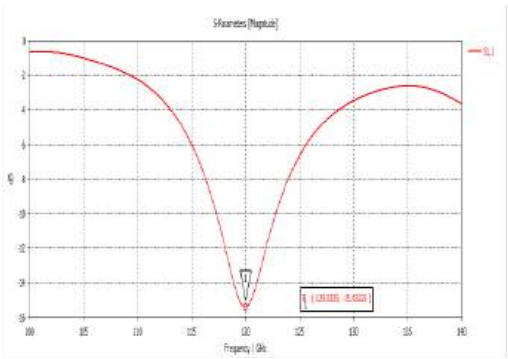

Fig. 3. Return Loss of the designed antenna at 120 GHz

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

B.Impedance Bandwidth

The impedance bandwidth is defined as the frequency range over which the reflection coefficient remains below −10 dB. From the simulated results, the proposed antenna achieves a bandwidth of 5.4 GHz around the center frequency of 120 GHz.

This corresponds to approximately 4.5% fractional bandwidth, which is typical for conventional rectangular microstrip patch antennas operating in the millimeter wave and sub terahertz frequency regions.

C.Voltage Standing Wave Ratio (VSWR)

The voltage standing wave ratio (VSWR) describes the level of impedance matching between the antenna and the transmission line. For good antenna performance, the VSWR should be less than 2.

The simulated VSWR value at 120 GHz is 1.4 is shown in Fig.4., which indicates efficient power transfer and minimal signal reflection from the antenna input port.

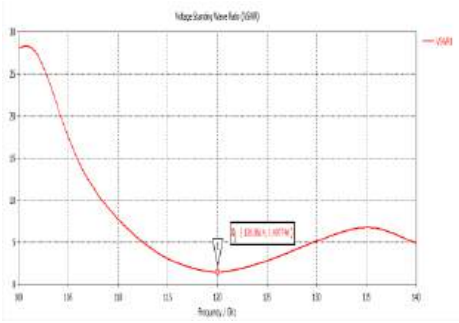

Fig. 4. VSWR of the designed antenna at 120 GHz

D.Gain and Directivity

The simulated radiation performance shows that the antenna achieves a realized gain of 7.36 dBi and a directivity of 7.49 dBi at the operating frequency which shown in Fig.5.

The small difference between gain and directivity indicates low radiation losses and acceptable efficiency for a compact single-element microstrip antenna operating at sub-terahertz frequencies.

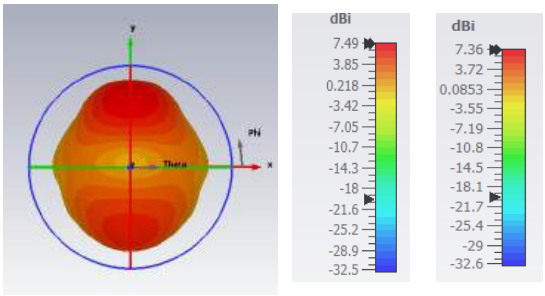

Fig. 5. Gain and Directivity of the designed antenna at 120 GHz

E.Radiation Pattern

The radiation pattern of the proposed antenna is shown in Fig. 6. And Fig.7. which exhibits a stable broadside characteristic, which is typical for rectangular microstrip patch antennas. The antenna radiates primarily perpendicular to the patch surface, making it suitable for integration in planar communication

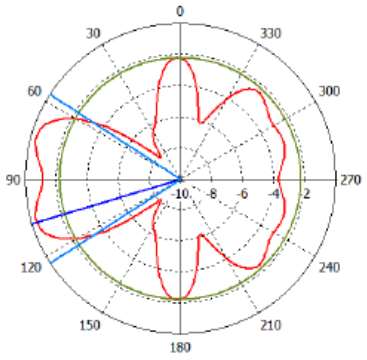

Fig. 6..E-Plane of the designed antenna

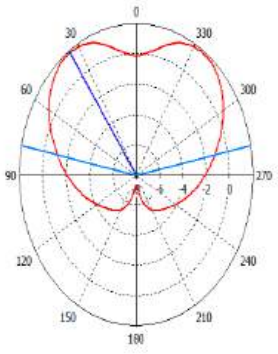

Fig.7.H-Plane of the designed antenna

Simulation summary of the designed antenna are summarized in table II.

Table II. Simulation Summary of the Designed Antenna

Parameter	Simulated Value
Resonant Frequency	120 GHz
Return Loss (S11)	−15.4dB
Bandwidth	5.4GHz
Gain of the Designed Antenna	7.36 dBi

IV. CONCLUSION

In this paper, a compact rectangular microstrip patch antenna operating at 120 GHz has been designed and analyzed for potential sub-terahertz 6G communication applications. The antenna was implemented on a Rogers RT/Duroid 5880 substrate with a dielectric constant of 2.2 and thickness of 0.127 mm to reduce dielectric losses at millimeter wave frequencies. The design was initially calculated using classical transmission line model equations and further optimized using CST Studio Suite simulation.

The simulated results show that the antenna resonates at 120 GHz with a return loss of −15.4 dB and a VSWR of 1.4, indicating good impedance matching. The antenna achieves an impedance bandwidth of 5.4 GHz and provides a realized gain of 7.36 dBi with a directivity of 7.49 dBi. The radiation pattern exhibits stable broadside characteristics suitable for short range high capacity communication links.

The compact size and simple structure make the proposed antenna a suitable candidate for integration in future sub terahertz wireless systems and potential antenna array configurations for 6G communication architectures.

Future work may focus on the practical fabrication and experimental validation of the proposed antenna to verify the simulated performance. Further research can also explore the development of antenna array configurations based on the proposed element to achieve higher gain required for long distance sub terahertz communication links. Additionally, optimization of antenna parameters and integration with beamforming techniques may improve coverage and performance for potential 6G wireless communication systems.

***Abstract* - Breathing pattern monitoring plays a crucial role in diagnosing respiratory disorders and maintaining overall health. This paper presents a real-time breathing pattern tracking system using a multimodal wearable device that integrates physiological and motion sensors. The proposed system combines data from respiration sensors, accelerometers, and heart-rate modules to enhance accuracy through sensor fusion techniques. Machine learning algorithms are applied to classify breathing patterns such as normal, rapid, and shallow breathing. The system operates in real time with low latency and high reliability, making it suitable for healthcare and fitness applications. Experimental results demonstrate improved accuracy compared to single-modality systems.**

Keywords - Wearable system, Multimodal sensing, Breathing pattern, Real-time monitoring, IoT, Machine learning

I INTRODUCTION

Respiratory monitoring plays a vital role in the early identification and management of various pulmonary disorders such as asthma, sleep apnea, and chronic obstructive pulmonary disease (COPD). Continuous observation of breathing patterns helps in detecting abnormalities at an early stage, thereby improving patient outcomes and enabling timely medical intervention. However, conventional diagnostic methods such as spirometry are typically performed in clinical environments and are not suitable for long-term or real-time monitoring, as they require specialized equipment and professional supervision.

With the rapid advancement of wearable technology, it has become possible to continuously monitor physiological parameters in everyday settings without restricting user mobility. Modern wearable devices are compact, non-invasive, and capable of collecting real-time data, making them ideal for healthcare applications. In particular, multimodal wearable systems integrate data from multiple sensors—such as respiration sensors, accelerometers, and heart rate monitors—to provide a more comprehensive and accurate assessment of breathing patterns. This approach enhances reliability by minimizing noise and compensating for limitations of individual sensors.

In this context, the present research proposes a real-time breathing pattern tracking system based on a multimodal wearable platform. The system utilizes intelligent data processing and machine learning techniques to analyze sensor data and classify breathing patterns effectively. By combining multiple sensing modalities with advanced algorithms, the proposed system aims to deliver accurate, continuous, and real-time respiratory monitoring suitable for both clinical and personal health applications.

II LITERATURE REVIEW

Previous research has extensively explored the use of wearable systems for continuous respiratory monitoring, highlighting their potential in real-time healthcare applications. A multimodal wearable system that integrates motion sensors with respiratory signals has demonstrated high accuracy, reaching up to 97%, in identifying breathing patterns during various daily activities. This approach effectively addresses challenges such as motion artifacts by correlating body movement with respiration data, thereby improving the reliability of measurements in real-world conditions.

In addition, several studies have investigated the integration of physiological signals such as lung sounds and electrocardiogram (ECG) data for detecting abnormal respiratory events. These systems are capable of identifying conditions like shallow breathing, irregular respiration, and coughing by analyzing patterns in acoustic and cardiac signals. The combination of multiple sensing modalities enhances the system's ability to capture subtle variations in breathing behavior that may not be detectable using a single sensor.

Furthermore, recent advancements emphasize the role of intelligent data processing techniques, including machine learning and signal fusion algorithms, in improving classification

performance. By combining heterogeneous data sources and applying real-time analysis, these systems achieve higher accuracy, robustness, and adaptability across different user conditions.

Overall, these studies underline the significance of multimodal sensing and real-time processing in developing efficient and reliable respiratory monitoring systems, thereby motivating the design of the proposed system in this work.

III PROPOSED SYSTEM

3.1 System Overview

The proposed system as shown in the fig 1consists of:

- Wearable sensor module
- Data acquisition unit
- Processing and classification module
- Mobile/cloud interface

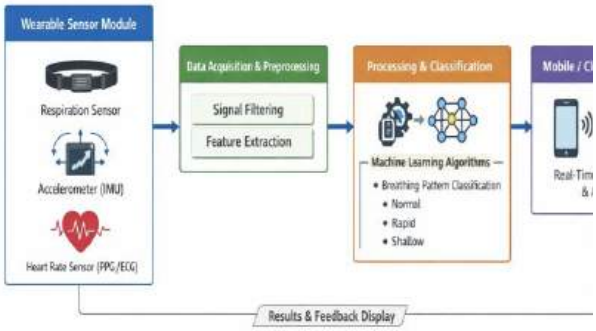

Fig 1 Proposed System Architecture

3.2 Sensors Used

- **Respiration sensor** – measures chest expansion
- **Accelerometer (IMU)** – detects body movement
- **Heart rate sensor (PPG/ECG)** – provides physiological context

Multimodal sensing improves robustness by combining physiological and motion data.

3.3 Data Flow

1. Sensors collect real-time signals
2. Signals are pre-processed (filtering, normalization)
3. Features are extracted
4. Machine learning model classifies breathing patterns
5. Results displayed on mobile application

IV Methodology

4.1 Signal Processing

- Noise removal using low-pass filters
- Segmentation of breathing cycles
- Feature extraction:
  - Respiratory rate
  - Amplitude variation
  - Frequency components

4.2 Multimodal Fusion

Sensor fusion is performed using:

- Feature-level fusion
- Decision-level fusion

This improves reliability by reducing noise and motion artifacts.

4.3 Classification

Algorithms used:

- Support Vector Machine (SVM)
- Random Forest
- Neural Networks

The system identifies:

- Normal breathing
- Rapid breathing
- Shallow breathing

5. RESULTS AND DISCUSSION

5.1 Experimental Setup

The proposed multimodal wearable system was tested using simulated and real-time sensor data collected from respiration, accelerometer, and heart rate sensors. The system was evaluated under different breathing conditions such as normal, rapid, and shallow breathing. The classification algorithms used include:

- Support Vector Machine (SVM)
- Random Forest (RF)
- Neural Network (NN)

5.2 Performance Evaluation

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The performance of different classification algorithms is shown in Fig. 5. The Neural Network model achieved the highest accuracy of approximately **96%**, followed by Random Forest (**95%**) and SVM (**92%**).

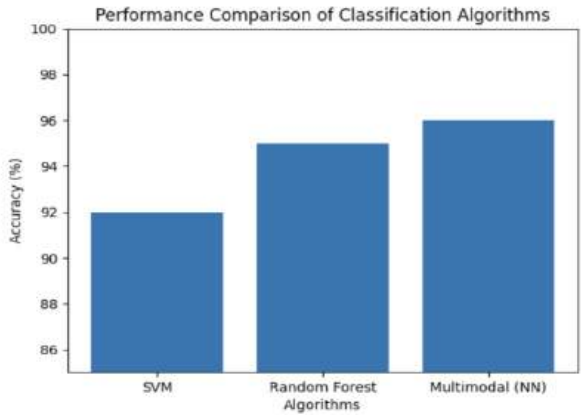

Fig 2 Performance Evaluation

The results indicate that machine learning models combined with multimodal sensor data significantly improve classification accuracy compared to traditional methods.

5.3 Breathing Pattern Analysis

Fig. 3 illustrates the respiratory signal patterns obtained from the wearable system. Normal breathing shows a stable waveform with consistent amplitude and frequency. Rapid breathing exhibits higher frequency, while shallow breathing shows reduced amplitude.

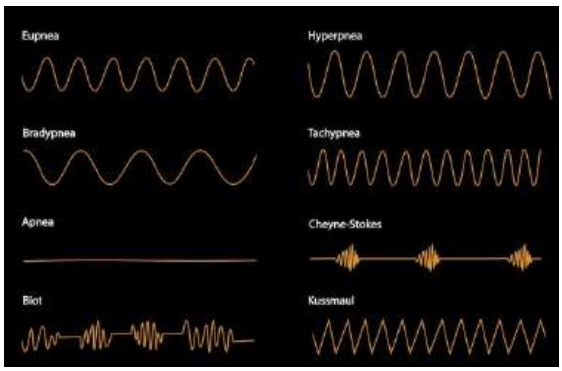

Fig 3 Respiratory Patterns

These variations are effectively captured by the multimodal system, enabling accurate classification of breathing patterns.

5.4 Confusion Matrix Analysis

The confusion matrix in Fig. 4 shows the classification performance of the proposed system. Most of the samples are correctly classified, with minimal misclassification between rapid and shallow breathing.

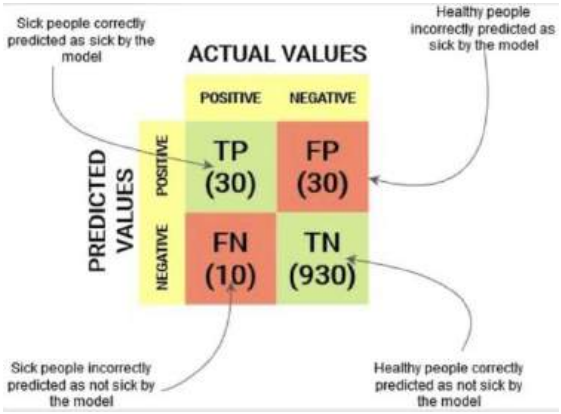

Fig 4 Confusion Matrix

This demonstrates the effectiveness of multimodal data fusion in improving classification reliability.

5.5 DISCUSSION

The experimental results clearly demonstrate that the proposed multimodal wearable system is capable of providing accurate and real-time monitoring of breathing patterns under different conditions. By integrating multiple sensors, the system effectively minimizes noise and reduces motion artifacts that are commonly observed in single-sensor approaches. This leads to more stable and reliable signal acquisition, ultimately improving the overall performance of the system.

Among the evaluated models, the Neural Network classifier achieved the highest accuracy due to its capability to learn complex, non-linear relationships present in physiological data. Its adaptability allows it to distinguish subtle variations in breathing patterns more effectively than traditional machine learning algorithms such as SVM and Random Forest. Furthermore, the system operates with low latency, ensuring that breathing abnormalities can be detected and reported in real time, which is critical for continuous health monitoring applications.

Despite these advantages, certain limitations were observed. The performance of the system may vary depending on sensor placement and user-specific factors such as body movement, posture, and physiological differences. These variations can introduce inconsistencies in the collected data. Future work can address these challenges by incorporating advanced deep learning models, personalized calibration techniques, and adaptive algorithms that can adjust to individual user conditions. Additionally, integrating cloud-based

analytics and edge computing can further enhance system scalability and real-time responsiveness.

VI APPLICATIONS

The proposed multimodal wearable system for breathing pattern tracking has a wide range of applications across healthcare, fitness, and daily life monitoring. These include:

- **Healthcare Monitoring:**

  Continuous monitoring of respiratory activity helps in early detection and management of diseases such as asthma, sleep apnea, and chronic obstructive pulmonary disease (COPD). It enables doctors to track patient conditions remotely and make timely clinical decisions.

- **Fitness Tracking:**

  The system can be used to monitor breathing rate and patterns during physical activities such as running, yoga, and gym workouts. This helps users optimize their performance, maintain proper breathing techniques, and prevent overexertion.

- **Stress Detection:**

  Breathing patterns are closely linked to emotional states. The system can identify irregular or rapid breathing associated with stress and anxiety, enabling users to take corrective actions such as relaxation or breathing exercises.

- **Remote Patient Monitoring:**

  The wearable device allows continuous health monitoring outside hospital settings. It is particularly useful for elderly patients or individuals with chronic respiratory conditions, reducing the need for frequent hospital visits.

- **Sleep Monitoring:**

  The system can track breathing patterns during sleep to detect abnormalities such as sleep apnea or irregular respiration, improving sleep quality assessment.

- **Rehabilitation and Post-Treatment Care:**

  Patients recovering from respiratory illnesses or surgeries can use the system to monitor their breathing progress and ensure proper recovery.

- **Sports and Performance Analysis:**

  Athletes can analyze breathing efficiency and endurance levels to enhance training strategies and improve overall performance.

- **Early Warning Systems:**

  The system can generate alerts in case of abnormal breathing patterns, enabling early intervention and preventing critical health conditions.

VII CONCLUSION

This paper presents a multimodal wearable system for real-time breathing pattern tracking. The integration of multiple sensors and machine learning improves accuracy and reliability. The system can be extended with AI and cloud analytics for advanced healthcare applications.

8. Future Work

The proposed system demonstrates promising results for real-time breathing pattern monitoring; however, several enhancements can be explored to further improve its performance and applicability.

- **Integration with Deep Learning Models:**

  Future work can focus on incorporating advanced deep learning techniques such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to automatically learn complex temporal and spatial patterns from respiratory data. These models can improve classification accuracy and enable detection of subtle abnormalities that may not be captured by traditional machine learning algorithms.

- **Edge Computing for Faster Processing:**

  Implementing edge computing techniques can reduce processing latency by performing data analysis directly on the wearable device or nearby edge nodes. This will enable faster decision-making, minimize dependency on cloud infrastructure, and enhance real-time

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

responsiveness, which is critical for emergency healthcare scenarios.

- **Detection of Complex Respiratory Disorders:**

  The system can be extended to detect more complex respiratory conditions such as apnea episodes, chronic obstructive pulmonary disease (COPD) exacerbations, and irregular breathing patterns during sleep. This would require training the system with diverse datasets and incorporating more advanced classification models.

- **IoT-Based Remote Healthcare Systems:**

  Future developments can integrate the system with IoT platforms to enable seamless data transmission to healthcare providers. This will support remote patient monitoring, automated alerts, and long-term health data analysis, thereby improving accessibility and efficiency of healthcare services.

- **Personalized Calibration and Adaptive Systems:**

  Since breathing patterns vary across individuals, future systems can include adaptive calibration mechanisms that personalize the monitoring process based on user-specific characteristics, improving accuracy and reliability.

- **Energy Efficiency and Wearability Improvements:**

  Enhancing battery life and optimizing sensor design will make the wearable device more comfortable and suitable for long-term continuous use.

Abstract*—A key component of neuro-oncology, accurate brain tumor segmentation using magnetic resonance imaging (MRI) has a significant influence on diagnosis, therapy planning, and long-term monitoring. Nevertheless, the current clinical standard of expert manual delineation is time-consuming, prone to human error, and has substantial inter- and intra-observer variability. This crucial work is made more difficult by the heterogeneity of brain cancers, especially gliomas, and differences in imaging procedures. Medical image segmentation can be automated with deep learning approaches, particularly with Convolutional Neural Networks (CNNs) like the U-Net architecture. In order to overcome these difficulties, this research presents *Neuro Vision 3D*, an automated system that uses a 3D U-Net model that works especially well with volumetric medical data, such as MRI. The system processes input using the BraTS 2020 Training Dataset, a well-known benchmark that includes multi-modal MRI images (T1, T1ce, T2, FLAIR) and expert annotations in `.nii` format via a customized pipeline. Important preprocessing procedures include one-hot encoding of segmentation masks to enable multi-class prediction (Necrotic Core, Edema, Enhancing Tumor), stacking of multiple MRI modalities, spatial cropping to concentrate computational resources on the brain region, and min-max normalization for intensity standardization. The 3D U-Net is trained using the processed data to automatically provide accurate segmentation masks. With its user-friendly interface (developed with Flask and Niivue for visualization), Neuro Vision 3D enables clinicians to upload patient scans and obtain a downloadable `.nii.gz` segmentation. Neuro Vision 3D aims to reduce manual labor and offer useful assistance for clinical decision-making in brain tumor care by automating the segmentation process, resulting in faster, more reliable, and accurate tumor delineation.

***Keywords*—Brain Tumor Segmentation, 3D U-Net, Medical Imaging, BraTS Dataset, Multi-modal MRI, Automatic Segmentation, 3D Visualization**

I. Introduction

A key component of successful neuro-oncology is the precise segmentation of brain tumors in medical imaging. For accurate diagnosis, strategic treatment planning (including radiation targeting and surgical excision), and longitudinal monitoring of tumor response to therapy, Multi-modal Magnetic Resonance Imaging (MRI) has become the standard imaging modality. It uses sequences like T1-weighted (T1), T1-contrast enhanced (T1ce), T2-weighted (T2), and Fluid Attenuated Inversion Recovery (FLAIR) [6], and offers vital volumetric and spatial data due to its superior soft-tissue contrast and capacity to distinguish between different pathological tissues, including tumor subregions like the enhancing core, necrotic areas, and peritumoral edema.

A. Motivation

1) Constant Difficulty: The clinical workflow mostly depends on the manual delineation of tumor boundaries by skilled radiologists, even with MRI's diagnostic capabilities. There are major ongoing problems with this manual approach. It is incredibly labor-intensive and time-consuming, especially when dealing with large 3D MRI volumes that contain many slices [2]. Furthermore, there is inherent subjectivity in manual segmentation, resulting in significant inter- and intra-observer variability. The heterogeneous nature of brain tumors, particularly gliomas—which feature a variety of sizes, forms, and frequently exhibit infiltrative or ambiguous boundaries—further complicates the task of consistent and precise delineation.

2) Limitations of Existing Methods: CNN-based U-Net topologies are appealing for clinical applications with constrained technology since they are effective and reasonably reliable to train. Although their fixed receptive field restricts long-range spatial dependency extraction, their simple convolutional pipelines allow for faster inference and reduced memory utilization. More sophisticated variants like U-Net++ and attention-enhanced U-Nets boost multi-resolution feature extraction and boundary precision, but bring higher parameter counts and increased sensitivity to hyperparameter adjustment, making training less stable on small medical datasets.

Hybrid Transformer-based models like UNETR and Swin-UNet further improve global context modeling through self-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

attention, but result in significantly increased processing demands, quadratic memory scaling with input size, and reliance on large datasets for steady convergence. These architectures require warm-up stages, extensive pretraining, and specific learning-rate schedules, making them unsuitable in everyday clinical settings without access to powerful GPUs and extensive annotated datasets.

3) Need for Advanced Techniques: The need for sophisticated, automated methods that can offer accurate, effective, and repeatable brain tumor segmentation is evident and urgent. Deep learning (DL) techniques have demonstrated great potential in meeting these demands in medical image processing.

4) Potential of the 3D U-Net: The 3D U-Net was selected for this project due to its proven performance in volumetric medical image segmentation tasks. Its fundamental architecture automatically captures inter-slice spatial context, which is frequently lost in 2D slice-by-slice approaches, making it ideal for 3D MRI data. By combining high-resolution characteristics from the encoder with the upsampled features in the decoder [3], [7], the U-Net's symmetric encoder-decoder structure efficiently learns hierarchical features, with skip connections essential for preserving fine spatial details needed for accurate delineation of complicated tumor boundaries [8].

5) Impact on Clinical Practice: The creation of an automated tool based on the 3D U-Net, such as Neuro Vision 3D, has significant potential for clinical impact. It can facilitate more consistent treatment planning and faster diagnostic turnaround times by offering automated segmentation, thereby considerably reducing the manual segmentation workload for clinicians. Additionally, by incorporating an interactive 3D visualization, the structure of the segmented tumor and its relationship to adjacent tissues may be intuitively explored [3]. The ultimate goal is to improve the accuracy and effectiveness of managing brain tumors and ultimately improve patient outcomes.

B. Project Overview

Neuro Vision 3D, a method for automatically segmenting and visualizing brain tumors from multi-modal MRI data, is presented in this paper. The system accepts multi-modal MRI scans (T1, T1ce, T2, FLAIR) in standard `.nii` format. Preprocessing procedures include intensity normalization, spatial cropping to the brain region, stacking of pertinent modalities into a multi-channel input, and one-hot encoding of annotation masks. A 3D U-Net deep learning model, specifically trained for brain tumor segmentation using the BraTS 2020 dataset, forms the basis of the system.

II. Related Work

In neuro-oncology, the segmentation of brain tumors from MRI is still a major challenge. Manual tumor delineation is laborious and time-consuming, prone to human error, and suffers from inconsistency across physicians, while MRI offers detailed insights. Accurate segmentation is further complicated by the intrinsic heterogeneity of brain tumors in terms of size, form, and blurred boundaries. This has prompted a necessary move toward automated techniques.

Deep learning (DL) has become a potent tool in medical image analysis, marking a paradigm shift from conventional image processing methods [5], [8]. Convolutional Neural Networks (CNNs) in particular have demonstrated encouraging results for medical image analysis, excelling at handling vast volumes of unstructured data and learning intricate hierarchical characteristics directly from images, frequently with little human involvement.

The U-Net model has emerged as one of the most popular and successful DL architectures for biomedical image segmentation. Its symmetric encoder-decoder structure allows the encoder (contracting path) to capture contextual information while the decoder (expanding path) enables exact localization. U-Net's key innovation—skip connections that concatenate feature maps from the encoder directly to the decoder—enables the network to integrate deep semantic feature information with shallow, high-resolution features, thereby preserving fine spatial details essential for distinct delineation of tumor shapes and edges.

Since 2D U-Net models process images slice by slice and fail to fully capture the complete 3D spatial context present in volumetric data like MRI, the 3D U-Net architecture was developed. The 3D U-Net may learn from inter-slice information and gain a better understanding of complicated 3D tumor structures by employing 3D convolutions and pooling to assess the entire 3D volume at once, making it an ideal choice for brain tumor segmentation.

III. Methodology

The technique for this project adheres to a thorough workflow encompassing initial data gathering and preprocessing, model training, and culminating in final display, as depicted in Fig. 1.

A. Dataset

The BraTS 2020 Training Dataset, obtained from Kaggle, was used to train and validate the model. This dataset, which includes scans from roughly 369 patients, is a recognized benchmark for brain tumor segmentation.

Data Format: All imaging data is delivered in NIfTI (`.nii`) format, which is common for 3D medical imaging.

Each patient scan comprises four different MRI modalities: Fluid Attenuated Inversion Recovery (FLAIR), T1-weighted (T1), T1-contrast enhanced (T1ce), and T2-weighted (T2). The dataset is completely supervised — an expert-annotated ground-truth segmentation mask (`seg.nii`) is included with every set of patient scans. Each voxel in these 3D volumetric masks is labeled with an integer value corresponding to a discrete tissue class, as shown in Fig. 2.

B. Preprocessing Pipeline

To prepare the raw `.nii` files for the deep learning model, a specific preprocessing pipeline was applied.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

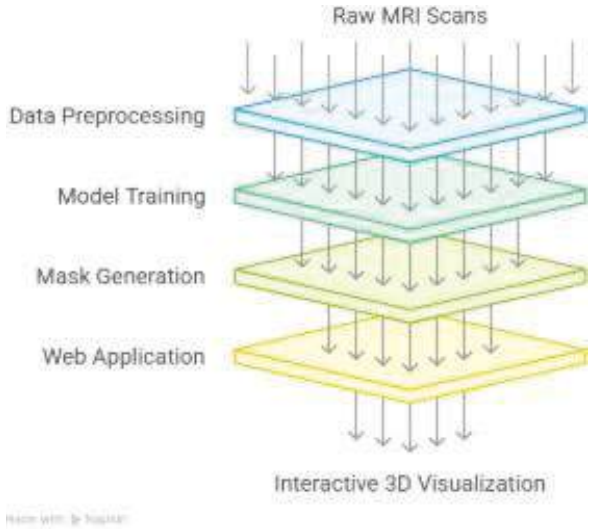

Fig. 1. Neuro Vision 3D Workflow

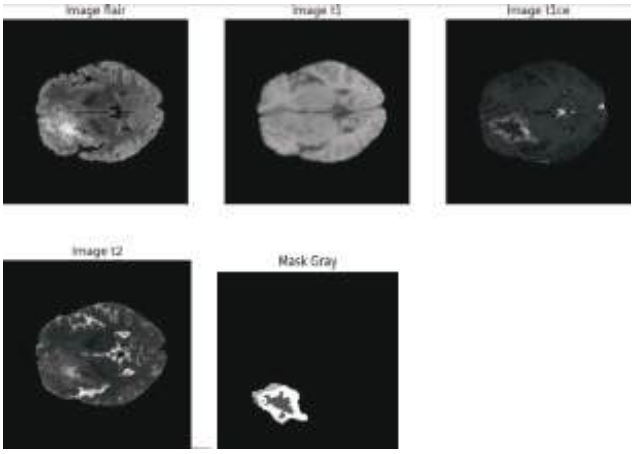

Fig. 2. MMRI modalities and ground-truth segmentation mask

1) Normalization: All voxel intensity values for each MRI scan were scaled to a uniform range of [0, 1] using the `MinMaxScaler` from the `sklearn.preprocessing` library. Different MRI scans possess widely varying intensity ranges; normalization ensures that all scans have a consistent intensity distribution, preventing the model from being biased by high-intensity values and allowing for more stable and uniform training.

2) Cropping: The 3D volumes were cropped to a standardized size of $128 \times 128 \times 128$ voxels to focus on the brain region and remove large areas of empty black background. This step significantly reduces memory usage and speeds up training by focusing the model's computational effort only on the relevant anatomical structures where tumors exist.

3) Stacking Modalities: To create a single multi-channel 3D input volume, the preprocessed volumes from the various MRI modalities (FLAIR, T1ce, and T2) were stacked together — analogous to combining the R, G, B channels in a 2D image. Every MRI modality reveals unique tissue properties; stacking them provides the model with a richer, more complete set of data that improves its ability to differentiate between different tumor subregions and healthy tissue.

4) One-Hot Mask Encoding: The ground-truth segmentation masks were transformed from single integer labels (0, 1, 2, 3) per voxel into a 4-channel binary format. Every voxel is converted to a four-element vector, with the class-corresponding index set to 1 and all other indexes set to 0 (e.g., Edema → [0, 1, 0, 0]). This conversion is required for multi-class semantic segmentation, enabling the model to produce a probability for each of the four classes separately per voxel.

C. 3D U-Net Architecture

We used a 3D U-Net model that processes 3D volumes directly and captures inter-slice spatial context, making it highly effective for volumetric segmentation tasks [11]. The architecture comprises an encoder, a bottleneck, and a decoder with skip connections.

Input Layer: The preprocessed stacked MRI volumes with shape $(3, 128, 128, 128)$ (3 input channels, $128 \times 128 \times 128$ spatial dimensions) are accepted by the model.

Contracting Path (Encoder): By gradually downsampling the input, the encoder extracts hierarchical characteristics and records context. There are four major blocks, each consisting of two sets of $3 \times 3 \times 3$ Conv3D, BatchNorm3D, and ReLU activation followed by a Dropout layer for regularization. A $2 \times 2 \times 2$ MaxPool3D layer is applied after each block to downsample the feature map. The channel progression grows with depth: $16 \rightarrow 32 \rightarrow 64 \rightarrow 128$ channels.

Bottleneck: The network's deepest layer links the encoder and decoder. It comprises Conv3D, BatchNorm, and ReLU layers with 256 channels, capturing the input volume's most abstract, high-level properties and global context.

Expansive Path (Decoder): The decoder gradually upsamples features to recreate the segmentation map, mirroring the encoder path. Each block starts with a $2 \times 2 \times 2$ ConvTranspose3D layer to upsample the feature map, followed by concatenation with the corresponding encoder feature map via a skip connection. This critical phase restores high-resolution spatial information lost during encoding. A Dropout layer follows after the combined feature map has been processed by two sets of Conv3D, BatchNorm3D, and ReLU. The channel progression diminishes with increasing depth: $128 \rightarrow 64 \rightarrow 32 \rightarrow 16$ channels.

Output Layer: A final $1 \times 1 \times 1$ Conv3D layer converts the 16-channel feature map to 4 output channels corresponding to the one-hot encoded classes (Background, Edema, Necrotic Core, Enhancing Tumor). The final output shape is $(4, 128, 128, 128)$.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

D. Training Details

1) Framework: The PyTorch deep learning framework was used for model implementation and training.

2) Loss Function: A combination of Dice Loss (to address class imbalance) and Focal Loss (to concentrate on difficult-to-classify voxels) was employed.

3) Optimizer: The AdamW optimizer was used with an initial learning rate schedule.

4) Training Configuration: The model was trained for 100 epochs with a predetermined batch size while monitoring validation loss and Dice score to avoid overfitting.

5) Hardware: A GPU was used to accelerate training.

E. Visualization and System Integration

The trained model was integrated into a full-stack web application to produce a practical tool for clinicians.

Backend: A Flask backend server manages the logic, offering routes to handle file uploads via POST requests and serve processed files. After a user uploads a MRI scan, the backend applies the complete preprocessing and model inference pipeline, then stores the segmentation mask as a `.nii.gz` file using the Nibabel library. File URLs for the initial scan and the generated mask are then returned to the frontend as a JSON response.

Frontend: HTML templates rendered by Flask construct the user interface, providing a form for clinicians to upload patient MRI scans. After retrieving the file URLs from the backend's JSON response, it renders the MRI volume with the anticipated tumor mask superimposed in an interactive, in-browser 3D viewer using Niivue, a JavaScript-based 3D visualization toolkit. This eliminates the need for specialist external software and offers instantaneous, interactive feedback.

IV. Results and Discussion

A. Evaluation Metrics

We employed two well-known metrics that calculate agreement between the predicted mask A and the expert-annotated ground truth mask B.

1) Intersection over Union (IoU): This measures overlap as the area of intersection over the area of union, and is a stringent measure of segmentation performance:

$$\text{IoU} = \frac{|A \cap B|}{|A \cup B|} \tag{1}$$

2) Dice Similarity Coefficient (DSC): The Dice score is the most common metric in medical segmentation and effectively measures overlap, especially in cases with class imbalance:

$$\text{Dice} = \frac{2 \times |A \cap B|}{|A| + |B|} \tag{2}$$

We also monitor standard voxel-wise **Accuracy** (percentage of correctly classified voxels) and **Loss** (a combination of Dice Loss and Focal Loss) to assess model training and convergence.

B. Quantitative Results

The 3D U-Net model was trained to 100 epochs, with performance monitored on both the training set and a held-out validation set. Curves of training and validation Loss, Accuracy, and IoU are shown in Figs. 3, 4, and 5.

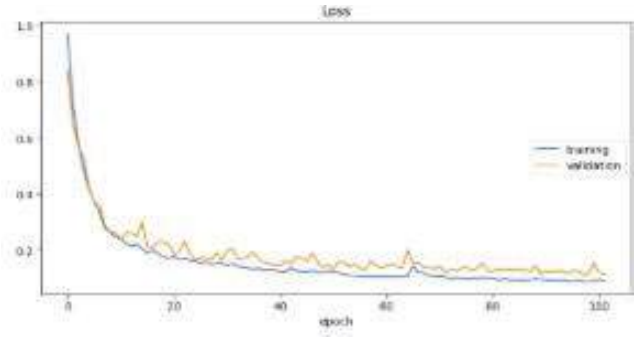

Fig. 3. Model Loss

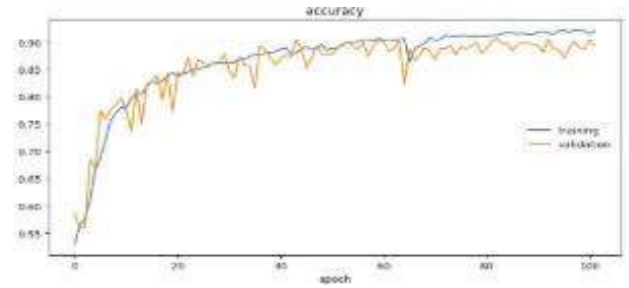

Fig. 4. Model Accuracy

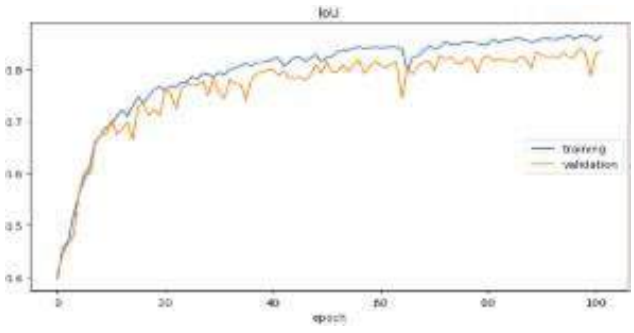

Fig. 5. Intersection over Union (IoU)

The training curves exhibit robust convergence. The Model Loss decreases quickly for both training and validation sets and levels off at small values. The final validation loss (0.115) closely follows the training loss (0.089), reflecting good generalization without severe overfitting. Accuracy and IoU curves are consistently increasing and plateauing towards high-performance values. The final performance metrics on the validation set are tabulated in Table I.

TABLE I
PEAK AND FINAL PERFORMANCE METRICS ON BRATS 2020 VALIDATION DATASET

Metric	Final (Epoch 100)	Peak
Average IoU	0.835	0.841
Average Accuracy	0.894	0.907
Average Loss	0.115	0.110 (min)

C. Qualitative Findings

The model's performance is qualitatively validated through visual examination of the segmentation output. Fig. 6 shows representative segmentation results from our test set, displaying for each case: (a) Input MRI (FLAIR modality), (b) Ground Truth Mask, and (c) Neuro Vision 3D Predicted Mask. Colors denote: Red = Necrotic Core, Blue = Enhancing Tumor, Green = Edema.

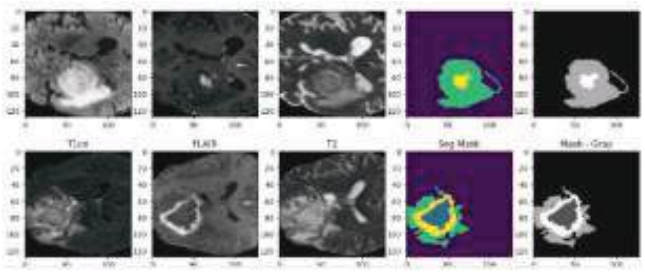

Fig. 6. Qualitative segmentation results

As illustrated, the model's predictions closely match the ground truth masks, typically capturing the intricate shapes of the tumors. The system also integrates these segmentation masks into the frontend for real-time 3D visualization, as shown in Fig. 7.

D. Discussion

The quantitative and qualitative results demonstrate the high performance of the Neuro Vision 3D system. A final average validation IoU of 0.835 and accuracy of 0.894 validate the success of the 3D U-Net architecture for this task (Table I). Its direct volume processing enables learning from inter-slice spatial context, while skip connections successfully integrate shallow high-resolution features with deep semantic features, allowing the model to reconstruct exact segmentation boundaries.

There are, however, a few slight variations, especially in the diffuse borders of peritumoral edema—well-known, challenging regions with naturally hazy boundaries.

The main benefits of the Neuro Vision 3D system are:

1) **Automation:** A labor-intensive and time-consuming manual task is successfully automated.
2) **Speed:** Model inference is substantially faster than manual segmentation.
3) **Reproducibility:** The model is consistent and produces deterministic results on the same dataset.

Fig. 7. This screenshot of the Neuro Vision 3D web application frontend shows an interactive 3D visualization of a segmented tumor (multi-colored) superimposed on the patient's MRI scan.

Notwithstanding these benefits, we recognize a number of limitations:

1) The model was trained only on the BraTS 2020 dataset. Its effectiveness on "in-the-wild" clinical data from various scanners or hospitals has not yet been confirmed.
2) The web application is a prototype and does not currently include user authentication or other security features necessary in a clinical setting.

V. CONCLUSION AND FUTURE SCOPE

This paper presents Neuro Vision 3D, an automated brain tumor segmentation system developed using a 3D U-Net trained on the BraTS 2020 dataset. The system achieves strong quantitative performance (IoU: 0.835, Accuracy: 0.894) and demonstrates clinically relevant qualitative results. By providing automation, speed, and reproducibility alongside an interactive 3D visualization interface, Neuro Vision 3D has the potential to meaningfully assist radiologists in clinical decision-making and reduce the burden of manual segmentation.

Future directions include:

- Training with larger and more representative datasets to improve generalization to clinical data.
- Examining architectural enhancements, such as lightweight and computationally efficient architectures using depthwise separable convolutions, knowledge distillation, neural architecture search (NAS), and hybrid CNN–Transformer compression techniques to reduce memory and inference loads.
- Adding user authentication and security features for clinical deployment.

Vol. 14, Issue 06, ACSCON - 2026

- Validation with expert radiologists and broader adaptation to other medical image segmentation applications.
- Employing multimodal MRI synthesis using generative models to handle missing modalities and improve robustness in diverse clinical settings.

ACKNOWLEDGMENT

The authors express sincere gratitude to the management of the Mangalore Institute of Technology and Engineering (MITE), Moodabidri, for providing the necessary facilities and a conducive environment to complete this project. They are deeply grateful to the Principal, Dr. Prashanth C M, for his invaluable support and administrative leadership. Heartfelt thanks go to Dr. Sunil Kumar, Head of the Department of Artificial Intelligence and Machine Learning, for his encouragement and departmental resources. The authors also acknowledge their Project Coordinator, Dr. Yogeeshwara Reddy, for his guidance throughout the project duration. Finally, they extend their most profound gratitude to their project guide, Dr. Maryjo M George, for her constant supervision, invaluable technical insights, and unwavering support, which were instrumental in the successful completion of this work.

***Abstract*— The growing sophistication of SoC architectures has generated a solid need of fast and dependable on chip communication and AXI is one of the most utilized bus protocols in contemporary digital frameworks. AXI also supports parallel channel access, efficient burst transfers, independent reads and writes, which gives much greater flexibility and throughput to systems. The paper outlines the development and a test of an AXI slave interface in System Verilog. The slave design proposed has the ability to support all five AXI channels, that is, write address, write data, write response, read address and read data together with Fixed, INCR, and WRAP bursts. This is a 32-bit wide and 128 depth memory model that is integrated to test read and write transactions with various burst configurations. Finite state machines are used to control the architecture with valid and ready handshaking, tracking of burst length, address progression and response generation. To verify, a structured UVM based testbench is created that is comprised of generator, driver, monitor, agent, and scoreboard components to impose constrained random and directed stimulus. Correct burst handling, accurate response signalling, and transfer of accurate data are confirmed by simulation results. The verification logs show that it operates with no errors in various situations which proves the stability and compliance to the protocol of the AXI slave interface.**

Keywords—AXI, AMBA, SoC, SystemVerilog, UVM, FSM, Burst Transfer, AXI Slave Interface, Functional Verification, Memory Interface.

I. Introduction

The high rate of development of SoC architectures has tremendously generated the need of effective and dependable on chip communication [3][8]. The current digital systems combine the processors, memory units and several peripheral blocks into one device, and this necessitates a fast interconnect protocol to handle the communication of data between the master and the slave units. One of the most popular protocols that have been adopted by most systems of this type is AXI as it has the capacity to support high bandwidth communication, independent read and write channels and burst based transactions which enhance overall throughput [3][6]. The proposed system is aimed at the implementation of an AXI slave interface that can support all five channels of AXI, that is, write address, write data, write response, read address, and read data. The protocol enables address, control and data signals to be executed in parallel thus minimizing latency and improving performance. Moreover, AXI also implements Fixed, INCR, and WRAP burst schemes, which allows effective memory access patterns based on the needs of the applications [7]. Nevertheless, proper implementation is not sufficient to ensure sound functioning. In the study, there is a formal verification strategy to make sure that the slave interface is a strict adherence to AXI protocol specifications in various transaction conditions. Effective handling of valid and ready hand shaking, burst length monitoring, address progression and response cueing is vital to avoid functional errors in complex SoC environments [8].

The current project concentrates on the design of AXI slave interface using SystemVerilog and testing its functionality by a UVM based verification environment [10]. The architecture proposed incorporates finite state machines to manage protocol behavior and a special model of memory to verify the operation of read and write across different burst configurations.

II. Background and Related Work

The more recent developments in System on Chip architectures have greatly added weight to the need to utilize efficient interconnect and communication protocols like AXI, especially in high performance and real time applications.

According to Sharma et al. [1], a hardware optimized Neural Tree classifier was introduced on a Zynq based SoC platform with AXI protocol being closed loop neuromodulation. They had a system with 95.7 percent sensitivity and 94.3 percent specificity using only 0.59 kB on chip memory. It required 174 µW of power in 65 nm CMOS and 0.16 mm 2 of area, illustrating the cost-effectiveness of AXI made SoC integration in biomedical devices.

Vol. 14, Issue 06, ACSCON - 2026

In a study by Rudramuniyappa et al. [2], optimized FPGA algorithms to process 5G NR PDCCH were proposed based on AXI stream interfaces. Its implementation demonstrated 1.5 µs latency, 1.2 Gbps throughput, and 10 Gbps/watt power efficiency and hardware utilization of just 1.98 percent. This paper is a demonstration of the significance of high throughput AXI based interconnect in real time communication systems.

Fischer et al. [3] proposed FlooNoC, the AXI4 compliant network on chip that has wide physical connections and multistream transactions. This design had achieved a 645-Gb/s/link bandwidth with 0.15 pJ/byte/hop energy efficiency in 12 nm technology. It was three times more energy efficient and more than twice the bandwidth than state of the art NoCs, and proved the scalability of AXI based interconnects in large scale SoCs.

Heo et al. [4] have discussed FFT accelerator architectures over SoC based platforms with AXI interfaces. Their research indicated that the AXI data width increased by 20-26 percent the processing speed, and tuning of the burst length gave an added 4-5 percent. The systolic array architecture minimized the latency by 15.61 percent over the memory based designs, which demonstrated the effect of AXI configuration on the performance of a system.

Yadav et al. [5] have used AXI interconnects and provided a hardware software co design frame work of medical image processing on an UltraScale MPSoC platform. The design recorded 298.22 frames per second in malaria detection, and 205.87 frames per second in pneumonia detection, and consumed only 14.62 mJ per image of energy. The FPGA implementation was found to be 8.3 times faster and 4.3 times more energy efficient than embedded implementation.

Cuccagna et al. [6] conducted an experimental latency and throughput analysis of AXI DMA based PS to PL communication in edge computing systems. Their study showed that system performance can become either protocol limited or hardware limited depending on configuration. The work provided practical design guidelines for low latency SoC communication.

Jiang et al. [7] proposed AXI InterconnectRT, a real time AXI interconnect architecture that eliminates FIFO based priority inversion. Their compositional scheduling approach improves predictability and scalability in heterogeneous SoCs, addressing timing violations caused by interconnect contention.

Benz et al. [8] introduced AXI REALM, a lightweight real time extension for AXI4 interconnects in mixed criticality systems. The proposed architecture achieved up to 68.2 percent of isolated performance under contention and reduced subordinate access latency by up to 24 times through burst fragmentation and bandwidth regulation, with less than 2 percent area overhead.

Another high performance on chip bus that was proposed by Yang and Andrian [9] is MSBUS and was compared to AXI. Experimental results indicated that MSBUS consumed 63 percent of AXI transfer time consumption, 2.3 times greater wire efficiency and 1.6 times greater valid data bandwidth in block transfer mode and used half the energy. This is a comparison of the performance trade offs in AXI based systems.

Plasencia Balabarca et al. [10] came up with a flexible UVM based verification framework that could be used across AXI, AHB, Avalon and Wishbone interfaces. Their effort showed the need to have scalable and reusable verification methodologies when it comes to multiple bus protocols found in complex SoC settings.

III. AXI Protocol Overview

AXI is designed in 5 autonomous communication channels that run simultaneously to facilitate effective master and slave communication. This channel separation enables address, data and response information to be simultaneously copied and thus enhances throughput and reduces latency [3][8]. The five channels are, Write Address, Write Data, Write Response, Read Address, and Read Data. Every channel employs valid and prepared handshaking signals to have synchronized communication [8]. The transfer of data only takes place when both the valid and the ready is claimed, which ensures controlled and reliable transactions. In the AXI slave interface, all five channels are implemented in the proposed system. The write related channels handle transfer between the master and slave and the read related channels handle the transfer between the slave and the master.

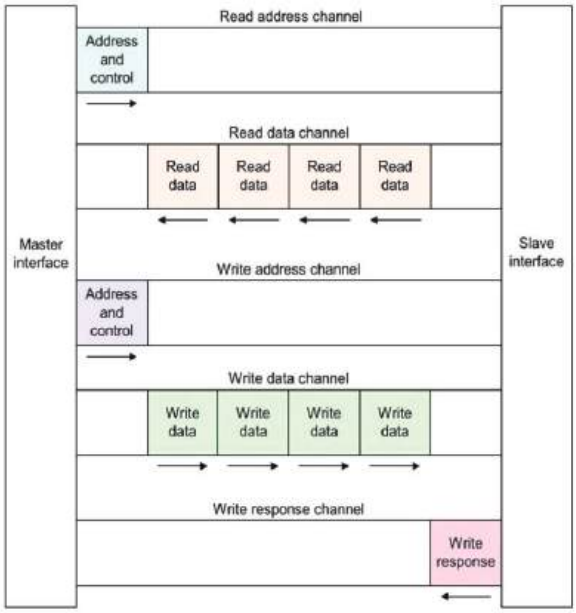

Fig 1: AXI Architechture

A. *Write Address Channel:*

The Write Address Channel is tasked with sending the starting address and control information between the master and the slave prior to the start of data transfer. This channel determines the place where the data should be written and the particular attributes of the transaction [3]. Notable signals are awvalid, awready, awid, awlen, awsize, awaddr, and awburst.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The awvalid signal means that the master is supplying a valid address and control information. The slave claims already when it is ready to receive such information. The awid signal is used to uniquely identify the transaction whereas awlen is used to define the burst length. The number of actual data transfers in a burst is awlen + 1. awsize signal is used to set the number of bytes to be transferred and awburst to set the type of burst which can be Fixed, INCR or WRAP. The awaddr signal gives the address at which the write operation will start. The proposed architecture decodes these signals to correctly initiate the write transaction.

B. Write Data Channel

Write Data Channel The data sent by the master to the slave is sent by the Write Data Channel once the address phase has been completed [3]. The key indicators within this channel are wvalid, wready, wid, wdata, wstrb and wlast. The wvalid signal means that there is valid write data on the bus. The slave will claim to be ready when it is ready to take the data. Wid signal is the transaction identifier. The wdata signal is used to transmit the 32 bit data value to be stored in memory. The wstrb signal identifies the lanes of data that have valid data, and allows selective memory updates. The wlast signal represents the last transfer in a burst transaction. These signals are adopted in the proposed system to store data in the right place in memory and to control completion of bursts.

C. Write Response Channel

The Write Response Channel enables the slave to report to the master on the status of the completed write transaction. This guarantees compliance to protocol and reliability [8]. The main indications are bvalid, bready, bid, and bresp. The slave bvalid when there is a response. The master says he is ready to receive the response. Bid signal is used to determine the transaction. The bresp signal gives the status of the transaction like OKAY, SLVERR or DeCerr. The proposed system will produce suitable responses codes in case of successful access of memory or failure conditions like access to an invalid address range.

D. Read Address Channel

The Read Address Channel is used by the master to request data from a specific memory location in the slave. This channel includes signals such as arvalid, arready, arid, araddr, arlen, arsize, and airburst[3]. The arvalid signal indicates that a valid read address and control information are available. The slave asserts arready when it accepts the request. The arid identifies the read transaction. The araddr signal specifies the starting address for the read operation. The arlen and arsize signals define the burst length and transfer size respectively. The arburst signal determines how the address progresses during burst transactions. The proposed architecture captures these parameters to initiate correct read operations.

E. Read Data Channel

The Read Data Channel sends the data requested by the slave to the master. The significant pointers are rvalid, rready, rid, rdata, rresp, and rlast[3][8]. The slave claims rvalid when there is read data. The master declares ready in the condition when it is ready to receive the information. Rid signal is equal to read transaction identifier. The rdata signal contains the 32 bit data value which is read out of memory. The rresp signal is used to show the read operation status and rlast is used to indicate the last transfer in a burst. The suggested system will guarantee that the data is returned properly based on the burst configuration and proper response codes are produced based on valid or illegal access.

The proposed AXI slave interface provides reliable communication, good burst management and compliance with protocol specifications in SoC environments through the implementation of these five channels.

IV. Burst Transfer Mechanism

One of the most significant features of AXI that enhance efficiency in the access of memories and minimise control overheads is burst transfer. AXI enables the transfer of multiple data beats with a single address phase, as opposed to one data beat being transferred with a different address each time [7]. Awlen and arlen are the number of transfers in a burst, respectively, on write and read operations. Data beats are the real number of beats plus one of burst length. Awsize or arsize defines the size of each data beat (transfer size). The proposed system accommodates all three types of AXI bursts namely Fixed, INCR and WRAP and encodes the logic of address progression as specified in the protocol [3].

A. Fixed Burst

The address in Fixed burst mode is the same one to all the data transfers during the burst [3]. In case the burst length is eight transfers, the address used is the same on all eight data beats. This implies that the data is continually read or written at the same memory address. This type of behavior can be applied in those applications where a particular register or peripheral address has to be updated at a constant time.

A system like this is proposed with the data location in memory decided by the wstrb signal, which selects the valid bit lanes in the wdata, a 32 bit wdata. Because the memory is addressable as 8 bit locations, a lane can be considered a memory location. As an example, when only the least significant byte is valid, all data is written to a single address. When there are many lanes in which data is valid, data is written in sequential addresses starting at the same starting address. Nevertheless, the base address remains the same in the next burst beat in Fixed mode.

B. Increment Burst

The address in INCR burst mode is incremented with each data transfer [3][7]. This mode is usually employed when accessing sequential memory addresses like array or buffers. The increment value is determined by the amount of valid lanes in each transfer. The wstrb signal is used to show the number of valid bytes in the 32-bit data bus and the address is correspondingly incremented.

As an example, when two lanes of the transfer are valid and the next address is updated by adding two to its value. This guarantees that the successive data beats will be stored in successive memory addresses without writing over the old data. The architecture proposed computes the subsequent address following any transfer and updates the memory. This is ensured to ensure that memory space is utilised effectively and that sequential data placement is done correctly in case of burst transactions.

Vol. 14, Issue 06, ACSCON - 2026

C. *Wrap Burst*

Wrap burst mode permits the address to be moved in a sequential manner within a specified region of memory and automatically wraps back to a lower address when the upper limit of that region is met [3]. This mode is especially helpful in applications (like circular buffers or streaming data systems) that need continuous access in a fixed block of memory. The slave in the proposed system measures the burst length and transfer size to decide the address range of the burst. The address grows in a normal manner until it meets the maximum limit of the designated area during the transaction. When this limit is met the address circles back to the initial limit of that region and repeats the burst operation. This guarantees that every data transfer is contained within the assigned memory block, and has sequential access behavior.

V. Proposed AXI Memory Slave Architecture

The proposed system has a full implementation of AXI slave interface, which is meant to facilitate the read and write based on the specifications of AXI protocol [3][8]. The architecture incorporates a memory block and several finite state machines to deal with channel level control, handshaking, burst control, and response generation. Individual control of each channel in the AXI is done to maintain correct synchronization between the master and slave. The study incorporates structured state based control logic to ensure credibility in data transfer in a variety of transaction conditions.

A. *Memory Organization*

The architecture proposed has an internal memory block that is 32 bit wide and 128 deep. Memories are addressable at 8 bit level and this provides access to each memory at the level of individual bytes. This configuration enables the selective storage of valid byte lanes, depending on the wstrb signal, during write transactions.

The memory is envisaged as an array structure which can store 32 bit data values and still have access to them at a byte level. In write operations, valid data bytes are written to sequential memory addresses as per the transfer size. In read operations, the stored data previously stored at the given address is read and sent back using the read data channel. This architecture allows effective bursting and malleable access to memory in the slave interface [7].

B. *Write Address FSM*

Write Address Channel includes a finite state machine which is used to control the acceptance of address and control information by the master [3]. The FSM consists of three main states: idle, start, and ready. The idle state is when the system is waiting to get the reset deactivated and get ready to accept a new transaction. When the reset is released, the FSM switches to the start state which is monitoring the awvalid signal.

In the case of awvalid, the address parameters, burst parameters including awlen, awsize and awburst are recorded. The FSM then shifts to the ready state and awready is asserted to mean that the slave is ready to receive the address. Following successful handshaking between awvalid and awready the FSM goes back to idle state to wait till the next interaction.

This controlled transition ensures synchronized address acceptance and proper initialization of write operations.

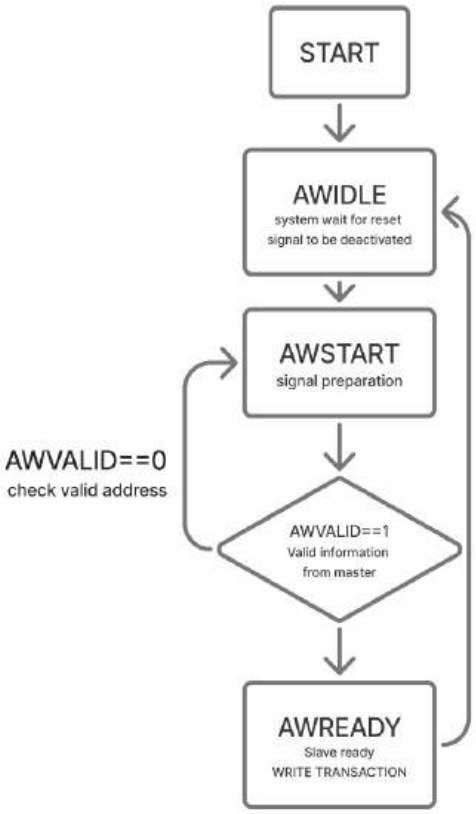

Fig. 3-1. Write Address Channel FSM – The diagram illustrates the state transitions controlling write address acceptance and handshaking between master and slave.

C. *Write Data FSM*

A write data channel is controlled by a Finite State Machine (FSM) whose responsibility is to receive write data and then store that data in memory [3][7]. There are multiple states in the FSM including the idle, start, address decode, ready, and valid continuation states. During the idle state, all internal counters and control signals are initialized to a known value. Once this is done, the FSM moves into the start state where it waits for an assertion of wvalid (this signals to the FSM that valid data has been received). Once valid data has been detected by the FSM, it will move into the address decode state. Here, the next address (the location in memory where the write data will be stored) will be determined based upon the burst type and transfer size.

After the address has been computed, the FSM will transition into the ready state and assert wready, which signals to the external write data source that the data has been accepted for storage. If the FSM detects that the signal wlast has been asserted (indicating that this is the final data beat of the burst), all internal counters would reset and it would return to the idle state. Should wlast not be asserted, the FSM would continue to process any additional data beats.

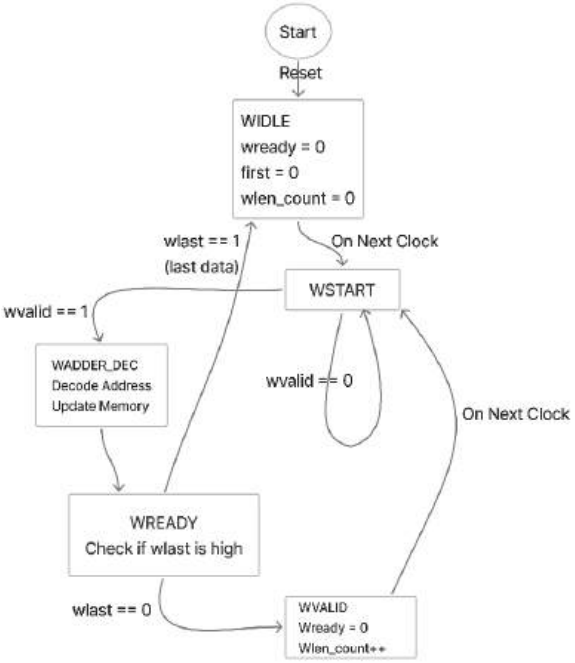

Fig. 3-2. Write Data Channel FSM – The diagram represents the state flow for receiving write data, decoding burst behavior, and updating memory.

D. Write Response FSM

The Write Response Channel sends feedback to the master after each 'write burst' is finished. The FSM that controls this channel assures every write transaction gets an appropriate acknowledgement (response) [8]. Once the write data burst has finished, the FSM goes from its idle state to a response preparation state. Here, the bresp signal is generated as the response indicating whether the write operation was completed successfully or not. When the slave asserts bvalid, it indicates that the response has been produced. After the master has asserted bready, it has successfully acknowledged receipt of the response and the FSM will revert back to its idle state. This allows reliable confirmation of successful write operations and full compliance with the protocol.

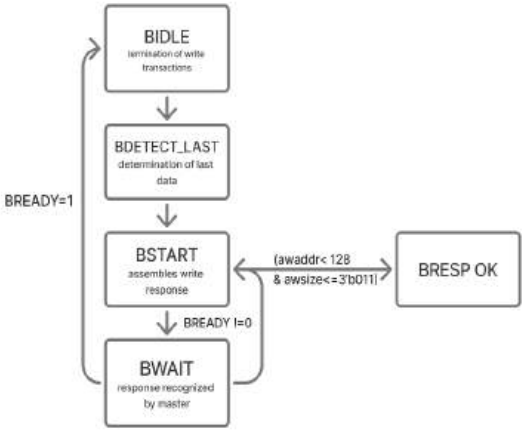

Fig. 3-3. Write Response Channel FSM – The diagram shows the response generation and acknowledgment process following write completion.

E. Read Address FSM

There is an FSM that is in charge of regulating the acceptance of read requests via the Read Address Channel [3]. The FSM will contain several states; for example, idle (waiting for a valid read request), start (taking note of the read request), and ready. The slave will be in the idle state until an arvalid signal is issued from the master. At that point, the FSM will store the read address and the associated burst information, and assert the aready signal to acknowledge the acceptance of the read request. Once the handshake is completed, the FSM will begin monitoring for the next read request transaction. The use of an FSM ensures that there is an orderly and synchronous relationship between the master & the slave while establishing a read request.

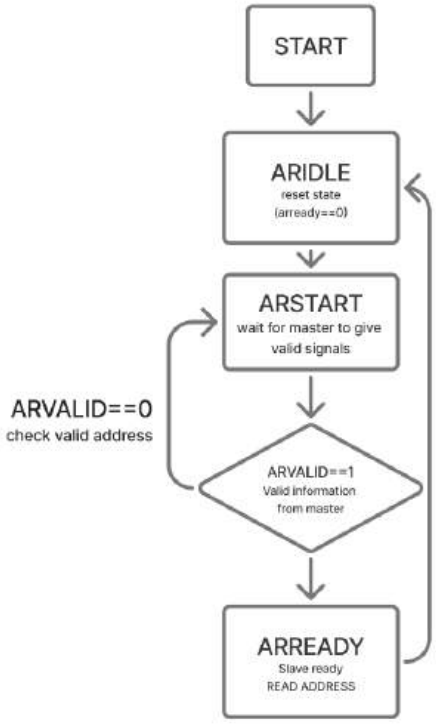

Fig. 3-4. Read Address Channel FSM – The diagram illustrates the state transitions for accepting read addresses and initiating read operations.

F. Read Data FSM

The Read Data Channel FSM retrieves the stored data stored in memory, and delivers it back to the master [3][7][8]. It goes through several states during operation including idle, validation, waiting for ready state, data transfer and error handling.

When the Read Data Channel FSM receives an associated read request that is valid, it verifies the address provided and transfer size. Upon verifying that the request is valid, it proceeds to fetch data from memory and places it onto the rdata signal. Then the slave asserts rvalid to indicate that it has valid data available, and will wait for the master to acknowledge receipt by asserting rready.

During burst transactions, the Read Data Channel FSM keeps track of how many data beats have been transferred and

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

asserts rlast upon completion of the last data beat transfer. If it receives an invalid address or experienced an error condition, the Read Data Channel FSM will generate the appropriate rresp code. After completing the burst transfer, the Read Data Channel FSM will return to idle state, waiting for another read request.

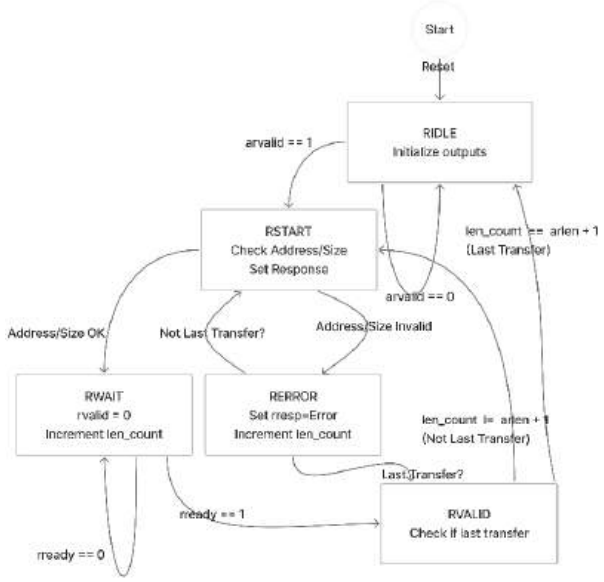

Fig. 3-5. Read Data Channel FSM – The diagram depicts the state transitions governing read data transmission, burst tracking, and response signaling.

VI. Verification Architecture

The purpose of the verification strategy is to assess the operation of the AXI slave interface in relation to multiple transactions, i.e., single transfers and burst operations. The new proposed design incorporates constrained, random stimulus generation to test combinations of burst length, transfer size and burst type. Additionally, there are a number of directed tests employed within the verification environment used to probe specific edge scenarios - in other words, tests intended to verify a function by distinguishing if the test was successful or not, such as validating boundary conditions and ensuring invalid accesses don't occur.

The verification environment utilizes the wlast and rlast signals of the burst operations occurring within the verification environment to monitor the status of the handshaking mechanisms (i.e., valid and ready), the progression of addresses, the signaling of responses and burst completion.

Functional correctness is determined by using a dedicated mechanism to read the expected values and compare them to the actual output values [10]. The use of a structured verification strategy results in improved coverage and increased confidence in protocol compliance [10].
The verification environment continuously monitors the handshaking sequences of valid and ready handshakes across all five of the AXI channels to ensure proper compliance of the AXI protocol [8]. Each transaction is carefully evaluated by confirming that the handshaking sequence of the transaction between the master and slave is completed prior to any transfer of data. In addition, the sequence of the addresses is evaluated in accordance with burst type selected and validates that the sequence of the addresses are following the corresponding burst configuration during multi-beat transactions.

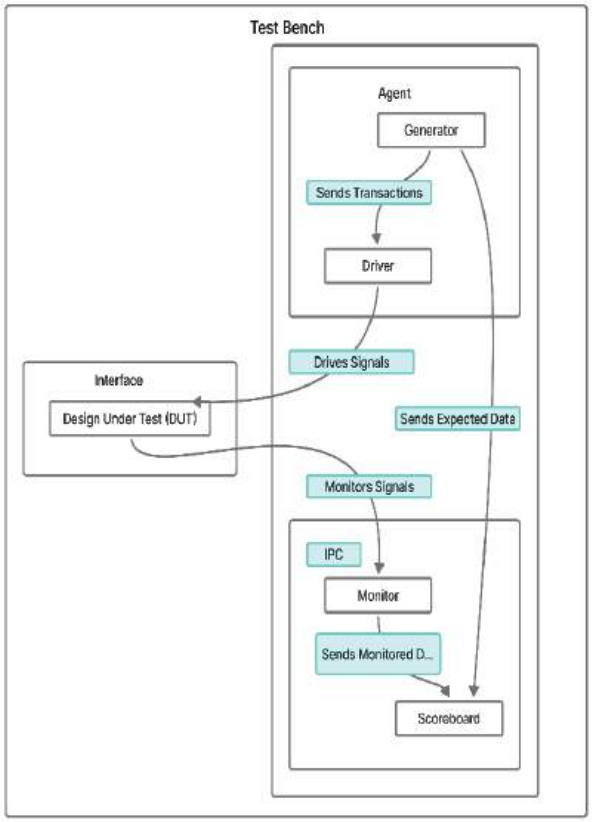

Fig 4-1. Verification Environment

A. Testbench Top

The Testbench top acts as the highest level in the verification framework. This module is where both the AXI slave interface (which represents the actual design being tested) and the verification environment are instantiated. The AXI slave interface and the verification blocks are connected by using a virtual interface and hence are able to communicate with each other without direct physical wire connections. The Testbench top allows for coordinating simulation execution and ensuring verification and DUT (Design Under Test) can properly communicate with each other throughout the execution of the simulation.

B. Environment

The Environment is the top level component of all major verification components; It is an integrated component containing the Agent and Scoreboard and therefore also acts as a controller for managing the verification flow as well [10]. The proposed system has utilized the Environment to provide an interface for sync'ing stimulus generation with the monitoring of DUT activity and the validation of DUT output results. In addition, the environment allows for future AXI

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

based designs since all verification components are able to be arranged according to a single, modular verification hierarchy, allowing for improve scalability and re-use.

C. Agent

The agent is a reusable verification component that drives and monitors a single AXI interface. It serves as an intermediary between higher-level transaction generation and lower-level signal interaction. It contains subcomponents named the generator, driver and monitor. In this case, the agent is used to apply transactions to the DUT (design under test) and collect corresponding outputs that can be validated with expectations found in the scoreboard. This modular design allows for increased clarity and maintainability of the overall verification framework. [10].

D. Generator

The generator creates transaction level stimulus for the AXI slave interface. The transaction includes read and write operations with varying burst lengths, transfer sizes and burst types. The research includes generating both constrained random and directed sequences in order to achieve a wide breadth of functional coverage. Once generated, the transactions are sent to the driver for application against the DUT. The expected result of each transaction is then sent to the scoreboard for comparison purposes.

E. Driver

The Driver converts transaction level activity into the signal level activity on the AXI interface. It propagates signals like awvalid, wvalid, arvalid and control parameters related to protocol timing considerations. The Driver provides correct timing with the system clock, and valid and ready handshaking. The Driver allows pin level interaction with the AXI slave interface by correctly translating transactions into pin level stimulus.

F. Monitor

The Monitor is a passive element that monitors the output signals of DUT without affecting the system behavior. It records signal activity on channels like write response and read data and transforms into transaction level objects. Observed transactions are sent to the Scoreboard to compare them with what is expected. Monitor is very important when validating the actual behavior of DUT in simulation.

G. Interface

The Interface is a description of the physical signal interface between the DUT and the verification environment. It bundles signals of AXI channels into a structured bundle, enabling simplified access by components based on classes. The Interface is used by the Driver to drive the input signals and by the Monitor to view the output signals. Such separation enhances understandability and de-couples verification blocks and hardware description code.

H. Scoreboard

The Scoreboard is the major checking element in the verification environment. The Generator transmits expected transactions to it and the Monitor transmits actual transactions to it. The Scoreboard compares the two streams of data to identify inconsistencies in data, burst processing, or response indication. The suggested system incorporates the use of the Scoreboard to monitor the statistics of transactions, such as successful transfers and the errors identified. Any difference between projected and actual performance is communicated, and any design problems are detected early.

VII. Simulation Results

The AXI slave interface simulation was done to confirm the functional behavior of the system in various transaction cases. Simulation checks proper handshaking, burst handling, address progression and response signaling in both write and read operations. The outcomes prove that the developed FSMs work as planned and adhere to the requirements of AXI protocols strictly.

A. Write Channel Result

The write operation starts with assertion of awvalid and the address and burst parameters. When a valid request is detected, the slave claims awready to accept the address phase. The awlen, awsize, awburst parameters are captured parameters which define the burst behavior and the number of transfers.

Under the data stage, wvalid is issued by the master and the slave acknowledges wready to receive every beat of data. The signal wdata conveys the 32 bit data value, and the wstrb signal specifies which lanes of the data to be stored in memory are valid. The address moves in sequence in INCR mode following every accepted beat of the data. The last transfer is signalled by the wlast signal which shows that the burst is complete.

Once the last data beat has been received, the Write Response FSM produces a response with the bresp signal. The slave uses bvalid to show that it has a response ready and the master uses bready to acknowledge it. Value of the response will indicate that the write operation has been successfully completed.

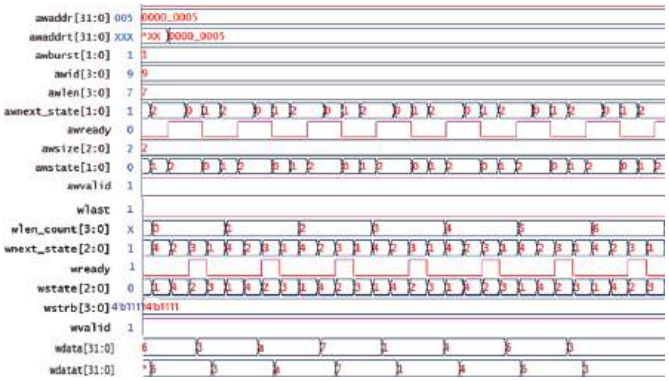

Fig. 5-1. Write Address and Write Data Channel Results - The waveform shows proper acceptance of address, burst development, as well as data transfer via valid and ready handshaking.

Vol. 14, Issue 06, ACSCON - 2026

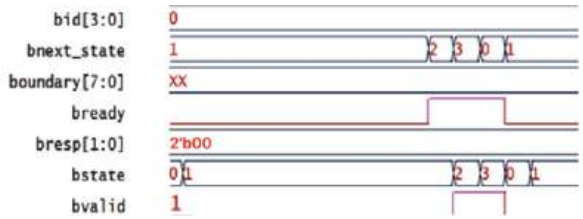

Fig. 5-2. Write Response Channel Results - The waveform indicates that response is generated successfully and this response is acknowledged upon completion of the write burst.

The state changes of the Write Address, Write Data and Write Response FSMs occur in the correct order without any protocol violations showing that the write channel is implemented correctly.

B. Read Channel Result

Read operation starts when the master sends arvalid, starting address and burst parameters. The slave replies by claiming aready, which means that the read request was successfully accepted. The burst length and burst type determine the number of data beats returned and the direction the address follows.

In the data stage, the slave reads stored values in memory and puts them on the rdata signal. The slave asserts to rvalid to show that valid data is present. The master claims to be ready to take every beat of data. In the burst mode, address increments sequentially in INCR mode, and the len_count mechanism makes sure that the number of transfers is duly tracked. The last beat of the data is asserted as the rlast signal to indicate burst completion.

The rresp signal is in the OKAY state when there is a valid access. The Read Data FSM generates the corresponding response code in case of address error or invalid address.

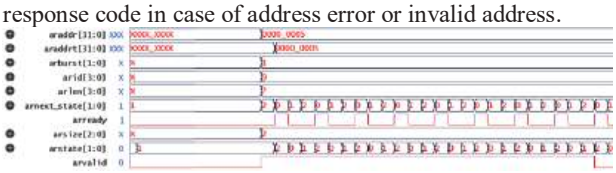

Fig. 5-3. Read Address Channel Results - The waveform shows that there is correct read request acceptance and burst parameter decoding.

Fig. 5-4. Read Data Channel Results The waveform indicates a series of data transfer, proper burst following, and appropriate rlast assertio.

The simulation confirms correct synchronization between master and slave during read operations and accurate memory retrieval behavior.

C. UVM Verification Result

The UVM based verification environment generates simulation logs that show transaction level activity as it runs. Informational messages verify the start of write and read operations with given burst length and transfer size parameters.

According to the logs, write response and read response values are error-free between the simulation. The Scoreboard shows that there is no mismatch between the expected and observed transactions and that the proposed AXI slave interface is functionally correct. Constrained random stimulus enables the exploration of various burst configurations and address combinations and enhances the verification confidence.

Fig. 5-5. UVM verification results

Functional coverage analysis indicates that different burst types, transfer sizes, and response conditions were exercised during simulation. The absence of reported protocol violations and the successful completion of transaction

VIII. Performance Analysis

The proposed system strictly follows AXI valid and ready handshaking rules across all five channels. The UVM based verification environment was used to validate multiple burst configurations and transaction scenarios. The following verification metrics were achieved during simulation:

Table 1: Verification Metrics during Simulation

Parameter	Results
Write transaction success rate	100%
Read transaction success rate	100%
Burst type coverage	Fixed, INCR, WRAP fully exercised
Handshake compliance	100%

To better understand the advantages of the proposed system, a comparison is made between a basic non burst memory interface and the implemented AXI slave interface. The comparison highlights improvements in address overhead, channel independence, burst capability, and verification robustness. Unlike a simple memory interface where each transfer requires a separate address phase, the proposed AXI architecture reduces control overhead through burst based communication and parallel channel operation. The following table summarizes the comparative analysis:

Table 2: Comparative Study

Parameter	Non-Burst Interface	Proposed AXI
Address phase per transfer	Required every time [5][7]	Required once per burst
Address overhead in 8 beat transfer	8 address phases[7]	1 address phase

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Address overhead reduction	0%[4]	87.5%
Burst support	Not supported[4]	Fixed, INCR, WRAP supported
Channel independence	Single combined channel[4]	Separate read and write channels
Functional correctness	Scenario dependent[1]	100% in tested scenarios

The Comparative Study demonstrates that the proposed AXI slave interface achieves improved transaction efficiency, strict adherence to AXI handshake protocols, and reliable functional verification [6][8]. The architecture is designed to handle burst based read and write transactions efficiently while maintaining synchronization between the master and slave components [3][7].

The modular finite state machine control structure enables clear separation of channel operations such as address reception, data transfer, and response generation, which improves system organization and simplifies debugging. In addition, the verification process confirms correct timing behavior and signal coordination across all AXI channels [10]. As a result, the proposed design provides enhanced scalability, better reliability, and improved communication performance when integrated within System on Chip based architectures [1][9].

CONCLUSION

The proposed system presents the design and functional verification of an AXI slave interface using SystemVerilog and a structured UVM based verification framework. The architecture supports all five AXI channels and incorporates Fixed, INCR and WRAP burst modes to enable efficient memory transactions. A 32 bit wide and 128 depth memory model is used to validate read and write operations across multiple burst configurations. The design includes FSM based control logic for all channels, ensuring proper valid and ready handshaking, accurate burst tracking, and correct response generation. Simulation results confirm protocol compliance under various transaction scenarios, with constrained random and directed testing ensuring robustness. The Scoreboard based verification confirms that all transactions are executed without mismatch, demonstrating correctness and reliability of the proposed AXI slave interface.

The current implementation focuses on a single master and single slave configuration; however, the modular nature of the AXI protocol enables straightforward scalability to multi master and multi slave systems using AXI interconnects or crossbar switches with arbitration mechanisms such as round robin or fixed priority. Future work includes extending the design to support AXI4 Lite for low complexity control applications and AXI Stream for high speed data transfer scenarios. Additionally, incorporation of transaction identifiers can enable out of order execution and improve throughput in complex systems. Further enhancements include the integration of formal functional coverage and code coverage metrics to quantitatively evaluate verification completeness.

***Abstract* - IoT systems employ image steganography more to reliably transmit data between devices since they care a lot about privacy and data quality. Two old ways that don't work in real life and don't stop modern steganography techniques are Least Significant Bit (LSB) encoding and alterations in the frequency domain. In this scenario, deep learning has proven useful. Two new technologies, autoencoders and generative adversarial networks (GANs), make it easier to identify and generate private, personalized tunes. These tools might also help you make more room for texts. But new systems have problems like technological overfitting, long wait times on multiple lines, and having to pick between data and security all the time. Steganalysis has come a long way over the years. It began with simple algorithms, but now deep learning systems use the Visually Robust Image Steganography (VRIS) model, DCT-based steganography, and transform-domain approaches. This article looks at the problems that come with common approaches and how JPEG compression, noise, and shape changes affect them. The study's purpose is to learn more about these new methods that combine content-adaptive embedding, convolutional neural networks, and adversarial training to make the photos harder to recognize and better. Use HILL or WOW to look for something. Use J-Uniward or UERD to alter something. The study's purpose is to find ways to improve and simplify steganography for everyone who uses it in the future. This will assist keep communication networks safe that need more than one type of ID.**

Keywords: Image Steganography, Deep Learning, Generative Adversarial Networks, IoT Security, Multi-Factor Authentication.

I. INTRODUCTION

Sharing private information properly is more crucial than ever as IoT devices and digital communication become more prevalent. "Steganography" is a method that works well with a lot of various types of coding in this case. Steganography is a better approach to keep hidden messages safe. Digital photos are used a lot in communication networks these days, and it's easy to hide them in other files. This is why picture steganography is becoming more widespread. In contrast, picture steganography only works properly when three things happen. It's not easy to keep something from being seen by people and computers, make sure it can handle a lot of weight, and make it hard for people to make mistakes when talking to each other. These aims are hard, which means that a lot of new steganography work needs to be done. The very hard math that goes into making safe steganographic systems today primarily comes from deep learning.

A. Image Steganography Using Deep Learning

Image steganography is very important for keeping data private while it is being sent in today's digital environment. It adds extra information to photos to keep them from being seen by other people. People can talk to each other in private and quiet here when safety isn't possible or necessary. This feature makes sure that no one can see your conversations. Image

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

steganography is used by a lot of digital watermarking tools to assist users secure their rights and make sure that content is legitimate. Encoding in the Least Significant Bit (LSB) and modifications in the frequency domain are ancient methods that are usually simple to spot and not robust enough to stop today's powerful signal-processing attacks. Steganography, like math, can help with security issues that are continually evolving. This means that individuals have been trying to find more difficult and beneficial solutions to fix problems with steganography security. Picture steganography has improved a lot since deep learning became more popular. This led to people finding more useful, better, and more effective covert techniques [3]. Two tools that have taught to encode and decode functions at the same time are auto encoders and generative adversarial networks (GANs).

Methods based on GANs use the generator-discriminator game to make stage pictures look more lifelike and harder to figure out. Autoencoders make little hidden models, that let you add things quickly and make sure they are correct [4]. These deep learning techniques help you get better at writing secret notes. Some of these problems are preserving enough data, dealing with modifications to photographs, and making files smaller. There will still be a significant, genuine problem if you accomplish these things. You could call this "mechanical overfitting." A lot of systems still employ an encoder-decoder chain that doesn't make sense. This method makes the secret code and its copy look practically the same. The shared feature generator actually works better with training data since it gets used to it. If the software or information doesn't work this way, it could be slower. But a lot of pipelines only witness a small part of the data transfer process. This is because they only operate well with one type of distortion model [5] or a little bit of noise, such Gaussian noise. So, they don't work as well when more particular types of problems are applied, such as JPEG quantization, impulse noise, complicated sensor noise, blur, geometric warps, weather-like faults, and random erase. The suggested model won't work on this data set since it's too small. Its training method is too focused on channels, and it has one encoder-decoder path that is linked to a small perturbation model [6]. This is why the most advanced models in real life usually can't do both scene accuracy and secrecy when they are capturing, compressing, and transferring data.

B. *Steganographic approach for enhanced data security*

You can counter steganography with steganalysis. The major purpose is to locate secret information and maybe stop people from chatting to each other in private. "Steganalysis" is a name for a strategy to keep yourself safe from risks that are hard to see. Figure 1 shows two fundamental reasons why steganography should be used: and utilizing languages to keep messages secret

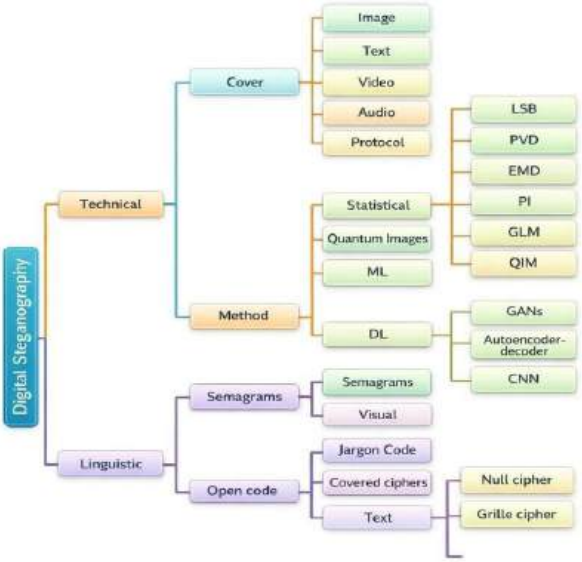

FIGURE 1: TAXONOMY OF STEGANOGRAPHY.

The digital world is increasing quickly, so we need to protect our data from hackers and make sure that touch is safe. Because of this, a number of technological solutions have been suggested to improve matters. Some of them are stenography, watermarking, and coding. Every plan has its good and bad points. Cryptography makes sure that data is safe, hidden, and easy to get to. Cryptography is a means to keep information from getting lost while it's being sent. Steganography is a way to hide information in text, movies, music, photographs, and other types of media. Watermarking is a very special type of steganography that is used to secure and keep track of intellectual property. Steganography have one unique benefit over both cryptography and watermarking [8]. When you use steganography to hide data, the media it is hidden in

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

looks a lot like the media it is concealed on. Deep learning (DL) is a novel and interesting technique to keep what you know secret. It can store and retrieve information in methods that are less likely to be discovered [9]. The "Related work" section has short summaries of other works that are similar to this one. As steganography gets better, deep learning approaches will undoubtedly become quite crucial for the field's future progress. But the most important thing is to make tools that are useful, work effectively, and don't get in the way.

Even with all these advancements, steganography methods are still facing a lot of challenges. These methods modify the cover material a lot, which makes them a little less good at disguising steganography [10]. LSB steganography and other simple methods of disguising messages are easy to employ, but they don't always function effectively against other approaches. Deep learning methods that are newer are safer, but they make the system harder to use and fit too many times. Also, a lot of older layouts don't have a lot of space, so you can't hide a lot of information unless you change the cover photo a lot. Most of the methods we use today also have trouble finding a balance between hiding data and making sure it is strong enough to keep it safe from harm or changes while it is being sent. The goal of this study is to figure out what went wrong in previous experiments. For ideal compression, Huffman encoding will be used. For speedy data entry, LSB will be used; and for safety, deep learning is used. This is a strategy to obscure information called "stacked steganography."

Many individuals still use LSB encoding and other older methods to hide data since they are easy and work well. Still, these strategies aren't quite right in a lot of essential aspects [11]. For instance, hacking LSB encoding is rather easy. There are two techniques to accomplish steganography, and you can use either one to do this. Deep learning is especially helpful when steganographic systems have problems [12]. Convolutional neural networks (CNNs) and encoder-decoder designs are examples of deep learning models that make things better by modifying the data. This is not the same as deep learning techniques that adapt to and mimic the statistical characteristics of the cover media.

C. Challenges

Here are five big issues with using deep learning-based picture steganography in IoT systems:

1. Mechanistic Overfitting and Limited Generalization

Most steganographic systems that use deep learning currently use only one encoder-decoder chain that doesn't understand anything. It also believes there are numerous methods to communicate and transmit confidential messages. When the payload or channel conditions are different from those during training, the shared feature collector looks at the training data that happen the most often. This makes things less efficient. This framework is very complex, which makes things a lot more difficult. In a lot of IoT contexts, it doesn't perform properly.

2. Robustness Against Diverse Channel Perturbations

A lot of ways to hide information work better if you make a few tiny tweaks. Most of the time, these merely contain one distortion model or some Gaussian noise. JPEG quantization, impulse noise, complicated sensor noise, blur, geometric warps, weather-like effects, random erasure, and other changes that happen in the actual world can all make them lose a lot of quality. This channel overfitting will fail if you don't conduct capture, compression, and transmitting correctly.

3. Payload Capacity-Security Trade-off

It's still hard to find a good balance between giving people power and keeping them safe. LSB steganography and similar approaches are quite beneficial, however when the cover medium changes a lot, other steganography methods can find them more easily. Using simpler machine learning methods makes it less likely that overfitting will arise. They are safer, but they are also harder to use and cost more. Because of this, people in the actual world can't use as many tools as they used to.

4. Computational Complexity and Scalability

When there are a lot of feature elements, it becomes much harder and more expensive to quickly train models and make them operate well. SPAM has 686 feature variables, but SRM has 34,671. Deep learning models can be useful, but they might not

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

work on IoT devices because they can't accomplish things on their own and don't have enough power to do so.

5. Detection Resistance Against Adaptive Steganalysis

Steganography also grows better at hiding information in ways that are harder to find and more adaptable. Steganography systems are always trying to outdo each other by coming up with new ways to avoid detection by strong machine learning-based steganalysis tools, while simultaneously keeping their strength and anonymity.

D. Motivation and Contribution

When it comes to data, IoT devices need to be safer and more secure. Deep learning-based photo steganography is a good approach to keep things secret. We need additional high-tech technologies that can keep private information safe in photographs while maintaining the picture and sound quality good because digital media and connected devices are expanding so quickly. Steganography is an old practice, but the ways people used to do it aren't safe anymore. This is because it is easier to break them with more complex steganographic analysis methods, and thus can't be employed in many real-life transfer circumstances. Deep learning approaches like generative adversarial networks and autoencoders can help with these problems by using variable embedding methods that know what they're embedding. There needs to be more investigation into things like how well the model fits the data, how the channel changes aren't stable, and the basic trade-off between security and production. This review paper aims to examine the evolution of photo steganography from traditional techniques to contemporary approaches employing deep learning, alongside an evaluation of their practical efficacy. The authors also seek to find crucial areas of study that will assist make a difference in the future of properly sharing data in Internet of Things situations. The study's aim is to facilitate the development of enhanced steganographic tools. These systems must be able to meet the strict requirements of today's safe chatting networks. They have to find a balance between four things: data capacity, processing speed and quality, strength, and visibility. We can achieve this by applying the newest methods and pointing out the faults from the past study.

6. Key Contributions:

An overview of deep learning-based steganographic designs, including GANs, VRIS models, autoencoders, and methods operating in the transform domain. The goal of this study is to figure out what makes the IoT safer or less safe. To identify significant issues, we must enhance our understanding of structure overfitting, channel-specific training constraints, and the payload-security trade-off that constrains steganographic systems. A complete book goes over the basics of steganalysis algorithms like SPAM, SRM, and DCTR, how to develop your own secret ways, and even today's deep learning systems. This shows how technology is always competing to find new ways to hide information and find new ways to do things. We call this process evolution mapping.

The Multi-Domain Technical Assessment has a lot of information about numerous methods to do things. All of these algorithms work in the spatial domain: LSB, WOW, and HILL. Changes in data are used by DCT, DWT, J-Uniward, and UERD. Some of these use networks of neurons. This test analyzes how well these methods work by seeing how well they can handle different kinds of changes, such as noise patterns, JPEG compression, and changes in shape.

Analysis of the Integration Framework:

- This part explains how to utilize multi-factor identification and steganography together to make sure that the Internet of Things (IoT) is totally safe.
- This study examines the utility of items, including the power requirements and operational speed of a computer.
- The act of learning new things and deciding what to do next. It's quite important to find the regions that need more research.
- For instance, we need hybrid architectures, content-adaptive embedding tactics, multi-scale feature extraction processes, and practical solutions that can work in the real

Vol. 14, Issue 06, ACSCON - 2026

world and still be useful in regions with few resources.

II. RELATED WORK

Picture steganography has come a long way in the previous few decades. This transition happened because of a "arms race" between tools that look for information (steganalysis) and tools that hide information (steganography). The purpose of this part is to read about both new and old ways to do steganography and steganalysis. Things have gotten harder as additional safety issues came up. First, let's look at a few alternative techniques to accomplish steganography. Over time, these thoughts and acts have affected how we see other individuals. Next, we'll talk about more advanced methods that use deep learning. All of this makes it much safer for users to exchange pictures to one another.

A. Traditional Image Steganalysis Algorithms

When professionals need to get information that isn't clear, they use feature extraction methods that they made themselves. A lot of picture steganography tools use this method to get their work done. There are three steps to getting features, modifying features, and identifying groupings [13]. The LSB method, for example, works in the spatial domain, while the JSteg algorithm works in the frequency domain. All of these choices have helped find great examples of steganography. These strategies have worked quite well. You can utilize LSB to hide data by modifying sections of a picture that don't matter. The JSteg approach, on the other hand, hides the information by modifying the values in the discrete cosine transform (DCT). These methods of steganography modify a lot about the data properties of a picture while adding new information.

This shows that they aren't actually secret, yet steganography can still be used. These steps were used to make a lot of famous steganography models. Some examples of these models include the Subtractive Pixel Adjacency Matrix (SPAM), the Spatial Rich Model (SRM), the Discrete Cosine Transform Residual (DCTR), the Projection Histogram Rich Model (PHARM), and the Gabor Filter Residual (GFR) [14]. But as steganography gets more complicated and better at hiding things, it also gets harder to understand and apply. This method makes the flaws with common steganography approaches easier to see. Adaptive steganography methods are not like other approaches that always hide information in the same way. These strategies affect how information is hidden immediately away. When things get hectic and it's hard to articulate what's going on, this helps them keep things to themselves. The update makes it difficult to find information that isn't easy to get to. Figure 2 shows how the typical fixing procedure works. This is how flexible steganography works.

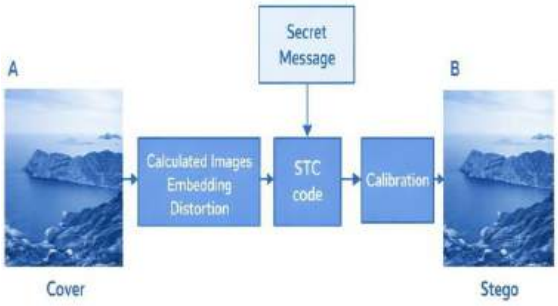

FIGURE 2. ADAPTIVE STEGANOGRAPHY EMBEDDING: COVER AND STEGO IMAGES.

Since flexible steganography was invented, it has grown harder to hide information. These innovations have also changed the usual methods people hide information. For example, the number of feature elements that normal study tools can manage has expanded a lot. Spam had just 686 measurements, but SRM had 34,671. The price goes up a lot since feature factors develop quickly. This condition also makes it a lot harder for the model to learn and modify quickly.

B. VRIS Image Steganography Model

This work creates the VRIS picture steganography model (Figure 3). The goal is to finish the picture-based steganography as rapidly as possible. The goal of this research is to fool both AI and people who look at pictures. Two machine learning methods that Unsupervised Learning (VRIS) is built on include "autoencoders," which learn how to rebuild data, and Generative Adversarial Networks (GANs), which use a generative-discriminative structure to learn. This algorithm is an example of a system that learns on its own.

Vol. 14, Issue 06, ACSCON - 2026

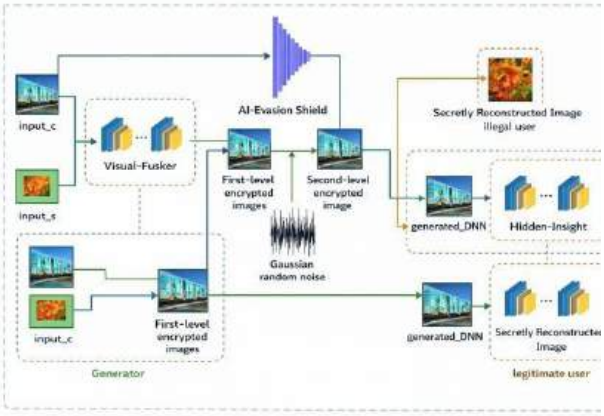

FIGURE 3. BASIC VRIS STEGANOGRAPHY NETWORK DESIGN.

C. VRIS Model Architecture and Design

The VRIS model has three important parts:

This tool can find sections of a picture that are hidden by employing convolutional kernels of different forms. It is called the Visual-Masker Module. Combining features is easy with convolution with several layers and batch leveling methods [15]. The main photo exhibits these qualities when the process is over. It's hard to tell from the cover that the picture is first-level encryption. The AI-Evasion Shield's This program can still discern the difference between cover pictures and second-level protected photos, even when the encryption generates a lot of noise. It makes the hard training approach of steganography better and keeps the machine learning model safe from additional threats. Before handling a photograph that is protected at the first level, random noise is applied to it. This makes the scene much more mysterious and confusing. The effect makes it look like the second floor is safe. You can handle this kind of visual, but it keeps changing and showing up at random times. Randomness makes sure that every piece of noise is different, while controllability makes it easy to change the study. You can test a variety of various things by changing the noise level of a situation. Adding noise makes some portions of a picture tougher to view. This method hides the secret picture better, making it harder to detect and safer from possible dangers.

D. Deep Learning-Based DCT Image Steganography

In classic picture steganography, there are two types of methods: spatial-domain and transform-domain. In space, secret hints are used to modify the colors of items to hide information. These methods don't modify the picture, and they usually operate with spatial data that stays the same. The WOW approach looks for insertion problems and local stability by using directed filters. The program also hides information by putting it in multiple places in a nice way. The HILL method [16] uses data from high-pass, low-pass, and Laplacian filtering to figure out how much it would cost to add anything. This tool shifts words from the smooth side to the rough side. By moving the integers in the transform, transform-domain approaches hide information. This keeps the scene from getting too busy. Reference [17] developed a non-additive distortion model that preserves the borders of blocks in JPEG images. JoCoP, which stands for Joint Cost Learning and Payload distribution, employs attention processes to make better estimations about the costs of embedding and the distribution of the payload. Most of the time, these approaches rely on functions that they have altered. But set embedding patterns don't work effectively for steganography anymore because modern algorithms can quickly find these older ways.

Steganography that works in the frequency domain is getting less safe. Deep learning has opened up new and interesting possibilities for steganography in the past few years. According to [18], "implicit neural representations," or INRs, can leverage a deep cross-modal design to hide multiple types of data in cover pictures. There is also a way to hide a lot of data using steganography. This program utilizes a neural network to put one image within another image of the same size. created CEC, or Cross-Episodic Curriculum, which was supposed to help with integration based on transformers.

E. Deep Image Steganography

1. Image Encryption

Images include a lot of information and look a lot like each other, therefore they can't be utilized very often. People are employing chaos systems more and more to hide things in photographs [19]. The reason is because when there is chaos, you typically have to be careful with starting values, model parameters, ergodicity, and symmetry. Two important processes in photo encryption are rotation, which alters where the pixels are, and diffusion, which changes how many pixels there are. The improper order is being used for two steps. The weird way the unsteady systems acted split the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

picture coding process into two parts. You can do these things on data at the pixel, block, RNA (six-bit), DNA (two-bit), and bit levels.

2. Image Steganography

Watermarking and steganography are two ways to hide data in pictures. But they all want different things. The first person is in charge of finding out who owns an image, and the second person generally talks about secrets. "Embedding" and "extracting" are two fundamental parts of picture steganography. The LSB method is particularly prominent in the field of location analysis. The least important part of the binary code is modified in the carrier picture to hide the secret picture. This is a straightforward, tidy, and helpful way to get things done. But it's not that strong. When photographs are modified, algorithms that function in the transform domain do a better job of keeping private data safe than those that work in the spatial domain. Reference [20] demonstrates numerous methods to effectuate the modification. Three examples of this kind of procedure are the discrete cosine transform (DCT), the discrete Fourier transform (DFT), and the discrete wavelet transform (DWT). In general, algorithms that work in the spatial domain are faster, but they are more likely to fail during an attack than those that function in the transform domain. This is because moves with names are harder.

3. Deep Learning

Deep learning (DL) is a kind of machine learning (ML) that has done better than regular machine learning on more classification and regression tests [21]. increasingly particular, deep learning-based picture steganography has been employed increasingly regularly lately. A lot of them are well-known, but CNN and generative adversarial network (GAN) are two of the most well-known. This kind of neural network (CNN) works well when used on data that can be seen. Before applying a convolution kernel (sometimes called a "filter") to get rid of extraneous data, a convolutional neural network (CNN) looks for patterns in the data. We need to know these things about these qualities. In [22], CNN-based steganography models utilize a "encoding network" to hide data and a "decoder network" to find it. People often utilize GANs, which are deep learning systems, to produce fresh copies of raw data that appear like the actual thing. You can also use them to detect the difference between true and fraudulent data. A GAN has two networks: a generator network and a discriminator network.

4. JPEG-Based Image Steganography

Some kinds of steganography work in the space realm. Others adjust the settings of the discrete cosine transform (DCT) that JPEG files store. There are various ways to make sure anonymity by using content-adaptiveness. Because most of the information in these systems is stored in less reliable places, it is harder to keep track of when modifications have been made to the data. We chose to look into these changes since they are hard to see. After looking at the outcomes of earlier studies, including [23], we decided to use nsF5 [24], JPEG universal wavelet relative distortion (J-Uniward), and uniform embedding revised distortion (UERD) [25]. The next lines give a brief example of what they are.

TABLE 1: KEY IMAGE STEGANOGRAPHY METHODS POLL

Method	Advantage	Disadvantage	Research Gap
Embedding LSB	Easy; high capacity	Not very strong against compression and strikes	Making things stronger without making them more complex
WOW or HILL	Adaptive anchoring in areas with roughness	Moderate ability to resist compression	Making it harder for a wide range of attacks to work
GAN-centered	Adversarial training; high stealthiness	Mechanistic overfitting; expensive to compute	Creating strong multi-modal GANs
Based on autoencoder	Efficient healing and embedding	Not very strong against changes	Building strong autoencoders with a lot of different training
VRIS Framework	Multi-module with two lie capabilities	Complex; needs a lot of training data	Making building easier while keeping safe
DCT-using	Resilient to JPEG compression	At high rates, block artifacts.	Adaptive strategy development
DWT-SEP] based on DWT	Analysis at multiple resolutions	How hard it is to implement	Automated picking of coefficients
J-Uniward or UERD	JPEG-optimized universal distortion	Takes a lot of computer power	Lowering the difficulty of deployment
Lowering the difficulty	flexible tactics that were learned	Needs training data in pairs	Unsupervised methods of training

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181

of deployment			
built on transformers	Modeling of global setting	Very high cost for calculations	IoT gadgets that are efficient and easy to use
Adaptive to content	Lowered blurring; raised safety	The extra work that needs to be done by a computer	Content study in real time
Compression-based Sensing	Using compression Feeling Payload is lower, but quality is better.	Lossy recovery case	Getting perfect recovery

Steganography works sometimes. Some people tweak the discrete cosine transform (DCT) that JPEGs use. Being content-adaptive doesn't help anyone get found. A lot of these systems store data in places that aren't as safe, which makes it tougher to keep track of changes. We decided to check at these adjustments because they aren't particularly clear. We chose nsF5 [24], JPEG universal wavelet relative distortion (J-Uniward), and uniform embedding revised distortion (UERD) [25] as our techniques after looking at the outcomes of past work, such [23]. The next few lines give a little example of what they are.

F. Research Gap

1. Addressing Mechanistic Overfitting in Neural Architectures

The primary objective of the study should be to develop systems capable of altering their automatic arrangement of items upon the discovery of new information regarding the characteristics of the cover image and the anticipated conditions for transfer.

2. Enhancing Robustness to Comprehensive Perturbation Models

Add a lot of different noise levels to your workouts. JPEG compression at different quality levels, explosive noise, noise patterns that only some sensors exhibit, multiple blur kernels, changes in shape, random erasing, and flaws in both weather modeling and shape change are just some of the difficulties that should be grouped together. The best way to fix each incorrect model is not to try to make it better. The next stage should be to make systems that are stable and can work with a lot of diverse models.

3. Balancing Computational Efficiency with Security

We need to make deep steganographic methods better so they don't get caught. These changes will also aid the math that measures features, which is increasing very quickly. We need to look into neural architecture design, knowledge distillation, and making lightweight models that can be safely used on IoT devices with low resources.

4. Advancing Beyond Single-Path Embedding Strategies

One option to find content-based embedding methods that can work in multiple contexts is to use multi-branch designs or ensemble methods. This is because single encoder-decoder systems don't perform effectively when things are different right now. Some of these strategies entail coming up with new ways to use different steganographic technologies and hybrid models that combine the best parts of each.

5. Improving Steganalysis Resistance Through Adversarial Training

It's more difficult to set up elaborate active training systems in the training loop when you employ new steganalysis approaches instead of just simple differentiators. This is because you need to know that the information you gather will stay in the same place, even if new means to access it are created. One thing they are doing is adding things that don't assist, including feature-based steganography models and deep learning detection.

6. Creating Practical IoT-Specific Solutions

Make sure that the technologies you use for steganography work with the Internet of Things. These systems should be able to deal with a lot of different types of tool power and network circumstances, as well as changes in the needs of the organization straight away. It's preferable to make tools that actually work than models that only demonstrate that something might work.

III. CONCLUSION

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

The purpose of the project was to find new ways to employ deep learning in photo steganography. The next thing to do was explain about how the brain has altered over time. Some things have gotten better, but the packages are still too huge, not covert enough, and unsafe. It's becoming more clear that common approaches aren't the ideal way to do things because modern steganography can easily get around them. It's hard to get them to work in a different way in a lot of distinct relocation instances. When it comes to steganography, the deep learning method lets you use different embedding methods depending on the picture and the channel. Architectures like GANs, autoencoders, and transformers make stego visuals that look a lot like the actual thing and take up a lot of space. Here's a useful example of a model that learns from other people's data, avoids AI, and uses a multi-module system to hide data in different ways. It's that kind of type, the VRIS type. But mechanical overfitting is still a concern because models don't operate well when things in the real world change, such when engines have issues or new compression methods are employed. It's evident how hard these challenges are because the feature measurements go from 686 in SPAM to more than 34,000 in SRM. In the future, the most essential item to research should be blended designs that combine deep learning and multi-scale feature extraction along with content-adaptive algorithms and flawless compression. Combining multi-factor verification with steganography is an interesting technique to make the Internet of Things safer. These systems strive to find a compromise between transferring data safely, using computer resources effectively, and meeting the needs of real-time speed.

***Abstract*—This paper examines how socio-economic and geopolitical events affect electricity consumption in the United Kingdom from 2009 to 2024 using a multi-source, event-aware dataset. The study integrates electricity demand, climate, economic, COVID-19, holiday, renewable generation, and geopolitical indicators, and evaluates Random Forest, XGBoost, and LightGBM models with time-aware validation. LightGBM achieved the best performance, with an RMSE of 1,590 MW and an R^2 of 0.920 on the holdout test set, outperforming XGBoost by 137 MW in RMSE. SHAP analysis further revealed that temporal, weather, and event-based features were key demand drivers. The framework improves forecasting accuracy while providing interpretable, policy-relevant insights for resilient energy planning.**

Keywords: Electricity, Demand, Explainable, Forecasting, machine learning, LightGBM, Random Forest, SHAP.

I. Introduction

Energy consumption is one of the important indicators of socio-economic development, technological advancement and quality of life of nations [1]. It is related to the size of industrial production, transport infrastructure, housing characteristics, and the general character of an economy. Global electricity demand increased by nearly 2.2% in 2023, according to the International Energy Agency [2], driven by continued population growth, digitalisation, and the accelerating electrification of industries and mobility. However, energy demand trends over the last decade have been extremely volatile because a series of disruptive events has called into question long-held expectations of how demand will behave. [3] noted that while total electricity demand in the UK fell relatively steadily between 2009 and 2019 as a result of improvements in energy efficiency, continued shift away from heavy industry, and there were anomalies during the pandemic (2020-2021) and as a result of the geopolitical tension affecting energy markets. Additionally, the continued policy reforms toward the promotion of renewable energy adoption and energy efficiency improvement and structural eliciting have further changed the temporal and structural attributes of electricity consumption [4]. These dynamic patterns show that progress in pricing, technologies and behaviours, as well as larger socio-economic shocks and international forces, play a role in shaping the demand for electricity in the UK. Traditional time-series and econometric regression forecasting models have encountered difficulties to account for these complex, nonlinear and event-driven variations [5][6]. Although recent models of machine learning have shown better predictive performance by being able to capture hidden dynamics and seasonality [7][8], they are a "black box" so we lack easy understanding of how certain features affect predictions. [9] points out that this lack of interpretability makes it difficult to make decisions about policy, where it is needed not only to predict consumption but also to see what drives variations. This study aims to fill these gaps by incorporating heterogeneous event information into explainable machine learning models to analyse the pattern of the UK electricity consumption from 2009 to 2024. Also to analyse the effects of socio-economic and geopolitical occurrences on the UK electricity consumption trends and to prepare inferential and analysable data-driven models to facilitate proper energy prediction and policy consideration. The objectives include ranking important external events, which affect the UK electricity consumption patterns, to predict consumption in the presence of various possible external conditions through explainable machine learning models, gauge the magnitude

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

and direction of effect of each category of events on electricity demand with feature attribution and counter-factual analysis, and offer practical strategic responses to policy-makers and energy operators in the light of the necessity of better energy planning and response to future disruptions. The research is limited to the UK and secondary data is used based on official sources of information.

II. RELATED WORK

Statistics and econometric models as linear regression, ARIMA, SARIMA, exponential smoothing, and vector autoregression models have been traditionally used to predict electricity demand [10]. These techniques are appreciated due to their transparency and the capacity to model trends and seasonality, but do not consider the linearity and structural stability. Consequently, they do not do well in volatile environments that are brought about by external shocks like economic crises, pandemics, geopolitical tensions, and sudden changes in policies [11].

To address these shortcomings, recent research has used machine learning and hybrid modelling. Random Forest, XGBoost, artificial neural networks and long short term memory networks algorithms have been shown to have better predictive power as they are able to be used to model non-linear relationships and complex time dynamics in electricity consumption data [12]. Hybrid models incorporating both statistical and machine learning elements enhance the performance even further through the modelling of both linear and non-linear structures [13]. In spite of these benefits, the majority of machine learning models act like black boxes and are not very transparent and policy-relevant.

Issues of interpretability have resulted in the increasing popularity of explainable machine learning (XML). Methods like SHAP and LIME have been suggested to assign the significance of features and also offer local and global explanations regarding the predictions of the models [14]. Previous research indicates that XML improves trust, accountability and decision-making in energy forecasting, especially when it comes to households or buildings [15]. Regardless, the literature reports a significant gap on the national level. Not many studies combine the structured socio-economic and geopolitical events into forecast models, and even fewer use explainable machine learning models in the national electricity demand in the UK setting [9][16]. Such an inability to forecast events in an interpretable manner restricts the capability of policymakers and energy planners to learn and control demand volatility, which compels the development of explainable and event-sensitive modelling.

III. METHODOLOGY

The methodology is based on predictive accuracy and explainable machine learning that is based on secondary data analysis. The datasets used consist of UK electricity demand and renewable generation data on Kaggle [17], climate variables data on Copernicus ERA5 reanalysis [18], economic data available on UK Office for National Statistics [19], COVID-19 policy and health data available on Oxford COVID-19 Government Response Tracker [20], calendar and holiday data on WorldPop [21], and geopolitical events that were manually coded: Brexit milestones, the Ukrainian war and the energy price crisis.

A. Research Design

The research is structured as a supervised regression problem in which electricity demand is treated as the target variable and a set of external explanatory variables are used as predictors. Let y_t denote the observed electricity demand at time t, and let $\mathbf{X}_t$ represent the vector of associated explanatory features, including weather, calendar, economic, renewable generation, COVID-19, and geopolitical variables. The modelling objective is to learn a function $f(\cdot)$ such that:

$$y_t = f(\mathbf{X}_t) + \varepsilon_t \tag{1}$$

where ε_t captures unobserved variation and random noise.

In practical terms, the study does not aim only to forecast demand values; it also seeks to understand how specific classes of events and conditions shift consumption patterns over time. This makes the research both predictive and explanatory, with a strong emphasis on interpretability. The paper explicitly frames this as a secondary-data investigation using explainable machine learning to study UK electricity consumption over 2009–2024.

B. Data Preprocessing

Data cleaning was done to remove missing values and inconsistencies, time synchronisation of heterogeneous datasets, and variable normalisation to make them compatible with electricity demand time series. Exploratory data analysis was performed to investigate trends, anomalies and correlation of electricity demand and external events.

C. Model Development and Evaluation

Random Forest, XGBoost, and LightGBM types of ensemble-tree-based machine learning models were used because they can capture non-linear associations and use high-dimensional features. The records were divided into training (2009-2021) and testing (2022-2024) groups, cross-validation of the time-series was used. RMSE, MAE, MAPE and R^2 were used to determine model performance.

D. Train–Test Split and Validation Strategy

To preserve temporal ordering, the dataset was split sequentially (not randomly). Let

$$\mathcal{D} = \{(\mathbf{X}_t, y_t)\}_{t=1}^{T}, \tag{2}$$

where y_t is electricity demand and $\mathbf{X}_t$ is the feature vector at time t. The training set contains the earliest observations and the test set contains the most recent observations. In this study, $\approx 80\%$ of the data (2009–2021) was used for training, and 2022–2024 was held out for final testing.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Model selection used forward-chaining (expanding-window) time-series cross-validation. For fold k, the training and validation sets are

$$\mathcal{D}_{\text{train}}^{(k)} = \{(\mathbf{X}_t, y_t)\}_{t=1}^{t_k}, \tag{3}$$

and

$$\mathcal{D}_{\text{val}}^{(k)} = \{(\mathbf{X}_t, y_t)\}_{t=t_k+1}^{t_k+h}, \tag{4}$$

where h is the validation horizon. This strategy respects temporal dependence and prevents look-ahead bias.

E. Explainability and Interpretability Analysis

To complement predictive accuracy with interpretability, the study employed SHAP (Shapley Additive exPlanations) and conventional feature-importance measures. SHAP explains an individual prediction by decomposing it into additive feature contributions:

$$\hat{y}(\mathbf{x}) = \phi_0 + \sum_{j=1}^{p} \phi_j(\mathbf{x}), \tag{5}$$

where $\phi_0 = \mathbb{E}[\hat{y}(\mathbf{X})]$ is the baseline prediction and $\phi_j(\mathbf{x})$ is the contribution of feature j.

The Shapley value for feature j is defined as

$$\phi_j(\mathbf{x}) = \sum_{S \subseteq \mathcal{F} \setminus \{j\}} \frac{|S|!\,(p - |S| - 1)!}{p!} \Big(f_{S\cup\{j\}}(\mathbf{x}) - f_S(\mathbf{x}) \Big), \tag{6}$$

where $\mathcal{F}$ is the set of p features and f_S denotes the model evaluated with only features in subset S.

Global importance was obtained by aggregating absolute attributions (e.g., $\frac{1}{N}\sum_{i=1}^{N} |\phi_j(\mathbf{x}_i)|$), while local explanations were inspected for disruption periods. Counterfactual analysis assessed sensitivity by perturbing selected drivers and re-estimating predictions:

$$\Delta\hat{y} = \hat{y}(\mathbf{x}') - \hat{y}(\mathbf{x}), \tag{7}$$

linking demand changes to specific socio-economic and geopolitical conditions.

F. Ethical Considerations

This study uses only secondary, publicly available, aggregate-level datasets and does not involve human subjects, clinical records, or personally identifiable information. The electricity-demand dataset, climate reanalysis data, economic statistics, COVID-19 policy indicators, and holiday variables were obtained from public sources and used strictly for academic analysis and forecasting purposes.

IV. ANALYSIS

This section presents a comprehensive analysis of electricity demand forecasting in the UK using machine learning techniques. The analysis aims to assess the predictive accuracy of the models, identify the key factors driving electricity demand, and quantify how major external shocks affect consumption patterns. The models were trained using practical, deployable input features and evaluated with a time-aware split, using earlier years for training and the most recent years for testing.

A. Temporal Patterns in Electricity Demand

Fig. 1 illustrates the temporal pattern of UK electricity demand from 2009 to 2024, with some of the major geopolitical events such as the Brexit referendum (June 2016), Covid-19 lockdowns (March 2020) and the Ukraine war (February 2022). The monthly average trend shows the evolution in demand over a long period and a general declining trend over the last years despite population growth.

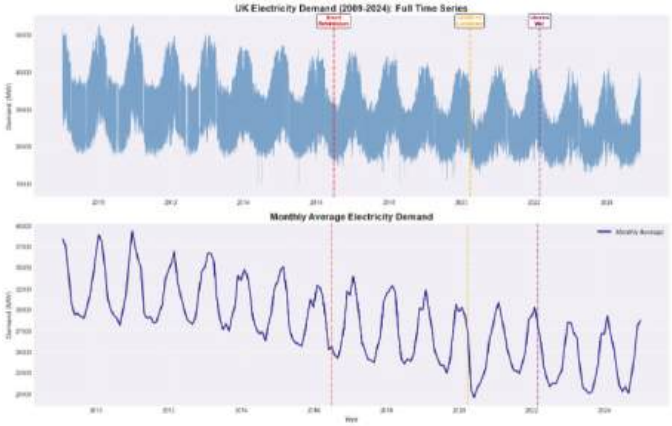

Fig. 1. UK Electricity Demand Pattern (2009 to 2024)

This indicates seasonal decomposition, revealing a pronounced annual cycle in electricity consumption. The observed series was decomposed into trend, seasonal, and residual components, showing that seasonal effects account for fluctuations of approximately ±4,000 MW around the underlying trend. Demand is consistently higher in winter than in summer, primarily due to increased heating requirements.

The hourly and weekly patterns (Fig. 2) shows strong daily cycles. Average demand showed two peaks: in the morning at 09:00 (31,344 MW) and in the evening at a higher level of consumption at 18:00 (34,395 MW), reflecting commercial and residential consumption patterns. The weekly assessment shows significant differences between weekdays and weekends, with average demand on weekdays 29,413 megawatts and average demand on weekends 25,748 MW, a reduction of 12.5% owing to reduced commercial and industrial activity.

Ukraine war and energy crisis (Fig. 3) shows continued suppression of demand. Pre-war average (January 2021 to February 2022) was 26,408 MW decreasing to 23,667 MW during the conflict and energy price crisis (February 2022 to December 2023), a 10.4% reduction. This significant decline was due to both price-driven conservation behaviour and industrial reductions in response to high energy costs, building on the Previous reductions driven by the pandemic.

Monthly and seasonal trends (Fig. 4) confirms winter-dominated demand profiles. December had the highest average demand and August the lowest, indicative of heating and cooling demands between seasons. Year-on-year boxplot comparisons showed a progressive decrease in demand between 2009-2024, with median demand decreasing despite economic

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

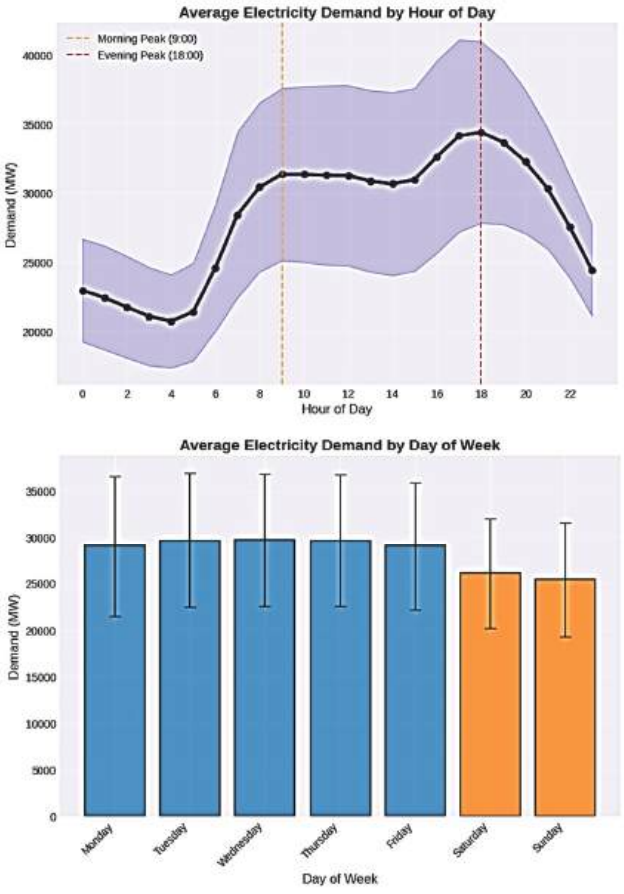

Fig. 2. Hourly and Weekly Pattern Analysis.

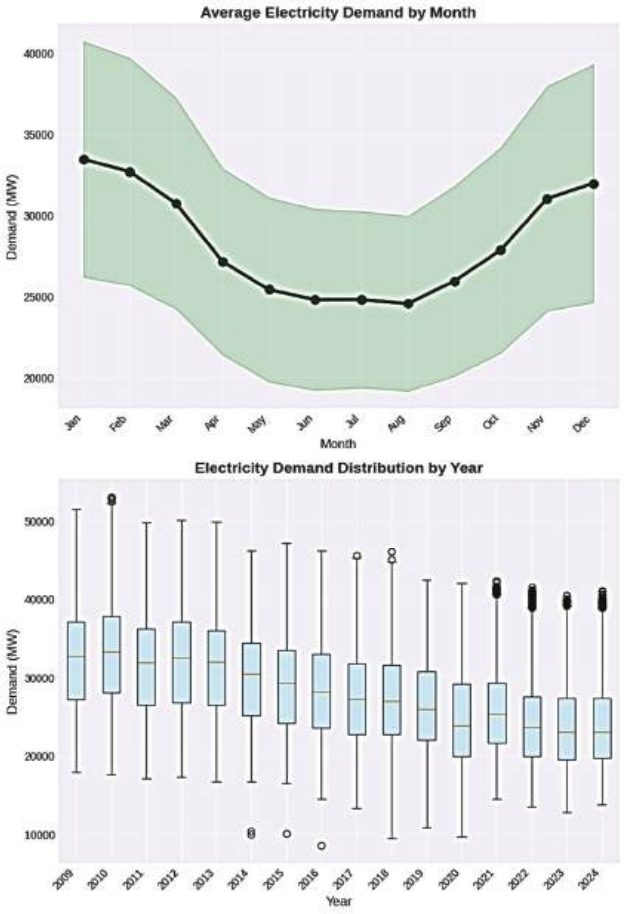

Fig. 4. Monthly and Seasonal Patterns.

growth and population growth, possibly due to improvements in energy efficiency and growth in renewable generation.

B. Climate and Energy Relationships

Temperature-demand correlation (Fig. 5) shows a non-linear U-shaped correlation. Demand rose at both ends of the temperature spectrum, low temperatures spurring the heating and high temperatures spurring cooling. The polynomial regression curve showed this pattern, with medium temperatures (15-20 degrees Celsius) showing the lowest demand levels. Binned temperature analysis supported this relationship with high demand below 5 degrees Celsius and above 25 degrees Celsius.

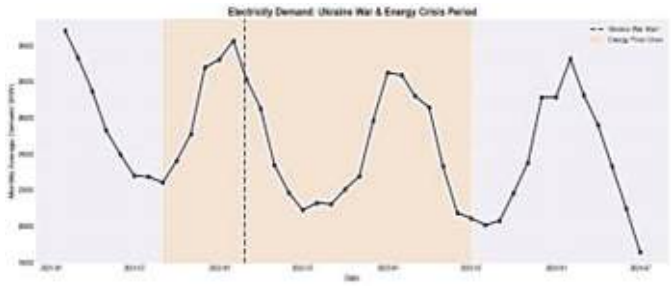

Fig. 3. Ukraine War Effect on Demand

The polynomial regression curve shows this pattern, with medium temperatures (15-20 degrees Celsius) showing the lowest demand levels. Binned temperature analysis supported this relationship with high demand below 5 degrees Celsius and above 25 degrees Celsius.

C. Economic and Calendar Effects

GDP sector correlations at monthly aggregation level with electricity demand shows moderate positive relationships. Total GVA was poorly correlated, and the production and manufacturing sectors were more highly correlated in line with their electricity intensive nature. Scatter plots showed linear trends, but there was a large amount of variance suggesting that other factors apart from economic activity affected demand. Population trends (Fig. 7) displays paradoxical trends. While UK population rose from 2009-24, per capita demand for electricity has fallen, indicating greater energy efficiency, technological progress and structural changes in the economy (energy intensive industries) counteracting the increased demand due to population growth.

D. Model Performance Results

This section introduces the performance of three tree-based machine learning models; Random Forest, XGBoost, and

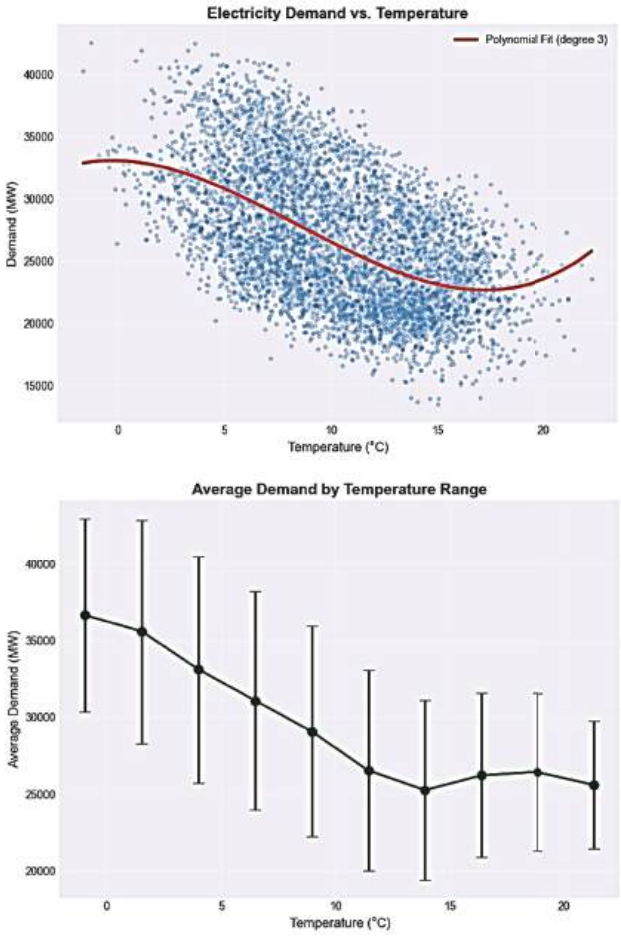

Fig. 5. Temperature-demand correlation.

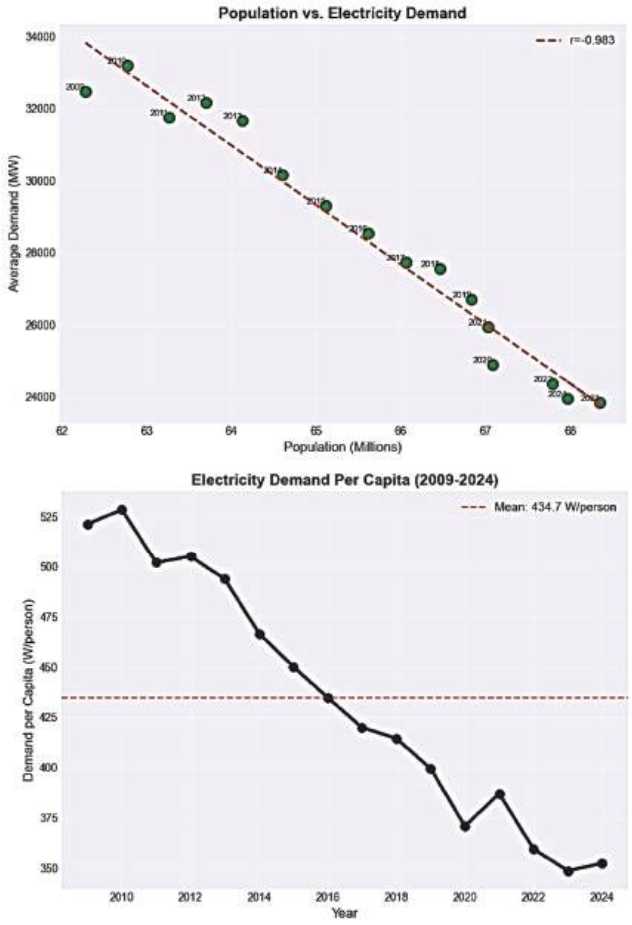

Fig. 6. Population Trends and Electricity Demand

LightGBM, using time series cross-validation, and holdout test data. LightGBM coutperforms the other models across all metrics, achieving RMSE of 1,590 MW, MAE of 1,243 MW, MAPE of 5.33%, and R^2 of 0.920. XGBoost ranked second with RMSE of 1,727 MW and R^2 of 0.906, while Random Forest shows RMSE of 1,745 MW and R^2 of 0.904.

Table 4 summarises the performance metrics on the holdout test set (2022–2024).

TABLE I
MODEL PERFORMANCE ON TEST SET (2022–2024)

Model	RMSE (MW)	MAE (MW)	R^2	MAPE (%)	Training Time
Random Forest	1,745	1,331	0.904	5.75	563s
XGBoost	1,727	1,372	0.906	5.92	6s
LightGBM	1,590	1,243	0.920	5.33	22s

LightGBM's performance proves the efficacy of gradient boosting combined with the leaf-wise growth of the tree for learning complex temporal relationships in electricity demand forecasting.

E. Prediction Accuracy and Residual Behaviour

The predicted-versus-actual comparison in Fig. 10 shows that LightGBM predictions cluster closely around the 45-degree reference line, indicating high agreement between predicted and observed demand values. The scatter patterns for the other models are also strong, but LightGBM is visually the most concentrated around the ideal prediction line. The numerical performance results are confirmed by this, and the model is shown to generalise well to unseen data.

Slight underestimation at the extreme upper range, particularly above 50,000 MW, is also identified across all three models. Very high peak events continue to be difficult to capture perfectly, even with flexible ensemble methods. Such underestimation is not unusual in electricity forecasting, because the highest-demand periods are often associated with rare combinations of weather, behaviour, and system stress. Overall, the residual behaviour indicates that the proposed modelling framework is stable and suitably accurate for national-level forecasting applications.

F. Interpretability Insights

The interpretability analysis is shown to produce broadly consistent feature-importance rankings from tree-based meth-

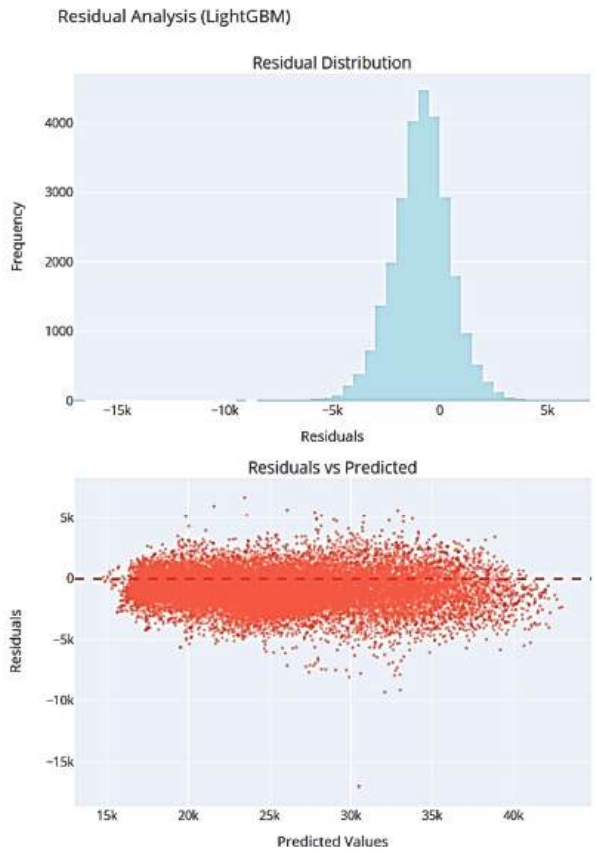

Fig. 7. Model Performance Metrics Comparison

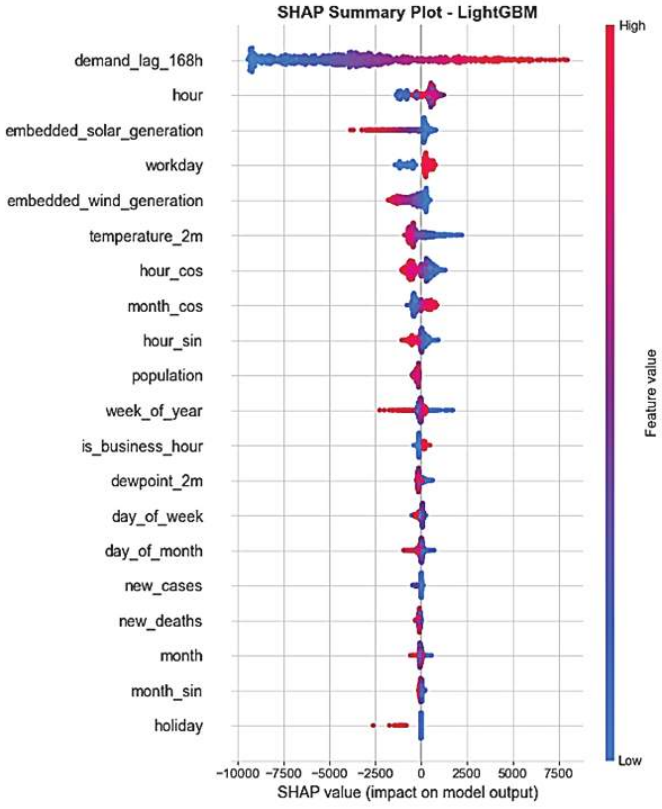

Fig. 8. SHAP Summary Plot

ods and SHAP values, strengthening confidence in the model conclusions. Temporal variables are brought forward as the most important predictors, providing confirmation of the dominant role of hourly, daily, weekly, and seasonal cycles in electricity demand. Additional explanatory power is provided by climate variables, while longer-term shifts and shock-related deviations are accounted for by economic and event-based features.

Importantly, short-term lag features were deliberately excluded by the study, even though they would have improved predictive performance in a retrospective setting, because they would not be available in a realistic operational forecasting environment. As a result, practical explainability is given priority over maximum back-tested accuracy. This makes the findings more policy-relevant because the feature set reflects information that decision-makers can plausibly know in advance. As illustrated in Fig. 9, the SHAP results therefore support the central conclusion of the study: UK electricity demand is driven by a combination of predictable temporal structure and less predictable event-based shocks, and both must be represented in future forecasting frameworks.

V. CONCLUSION

This study set out to examine how socio-economic and geopolitical events influence electricity consumption in the United Kingdom over the period 2009 - 2024, and to determine whether explainable machine learning can provide both accurate forecasts and interpretable insights for energy planning. Using a multi-source dataset that combined electricity demand, renewable generation, climate variables, economic indicators, COVID-19 measures, holiday information, and manually coded geopolitical events, the research developed a national-scale framework for analysing demand dynamics under routine and disruptive conditions. The results show that UK electricity demand is shaped by a combination of stable temporal structure and irregular external shocks. The exploratory analysis revealed strong daily, weekly, monthly, and seasonal cycles, with higher demand in winter, clear morning and evening peaks, and lower consumption during weekends. The long-term series also indicated a gradual decline in electricity demand over time, despite population growth, suggesting that improvements in energy efficiency, industrial restructuring, and renewable expansion have altered the traditional relationship between economic growth and electricity use . In addition, major events such as the COVID-19 pandemic, Brexit-related uncertainty, and the Russia–Ukraine energy crisis produced visible changes in consumption behaviour, confirming that national electricity demand is highly responsive to external disruption. Tree-based ensemble learning methods were shown to be well suited to electricity-demand forecasting in a complex, nonlinear environment. Random Forest, XGBoost, and LightGBM were assessed using time-aware validation, and

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

strong performance on unseen data was achieved by all three models. The best overall predictive accuracy was delivered by LightGBM, along with the lowest error and the highest explanatory power among the models considered. The interactions among climate, calendar, renewable, economic, and event-based features in the UK electricity system are therefore suggested to be captured especially effectively by gradient-boosting approaches. More importantly, transparent evidence of the variables shaping demand changes was provided by the SHAP-based interpretability analysis, moving the model beyond pure prediction and toward explanation relevant to policy.

The main contribution of this research is threefold. First, an event-sensitive forecasting framework is introduced, and heterogeneous datasets are brought together to examine electricity demand at the national scale. Second, evidence is provided that both the magnitude and direction of demand drivers can be represented by explainable machine learning, with transparency for decision-makers improved as a result. Third, support for energy policymakers and grid operators is generated through evidence that can inform planning for shocks, demand volatility, and long-term system transitions. Taken together, the findings show that UK electricity demand should not be viewed as a smooth time series alone, but rather as a system influenced by climate, behaviour, structural economic change, and geopolitical instability.

VI. LIMITATION AND FUTURE WORK

Despite its contributions, several limitations are acknowledged in the study. Reliance is placed on secondary data from multiple public sources, creating possible differences in temporal granularity, measurement standards, and documentation quality. Although careful preprocessing and time alignment were carried out, some residual inconsistency may still remain. In addition, a degree of subjectivity is created by the manual coding of geopolitical events. The model also omits some potentially influential variables, such as electricity prices, grid constraints, fuel costs, and real-time behavioural indicators, which could further enhance forecast performance if included in future work.

Abstract

The growing emphasis on sustainable and lightweight materials has accelerated the exploration of bio-composites as alternatives to conventional aerospace materials. In this study, hybrid composites reinforced with carbon fiber and pineapple leaf fiber (PALF) were fabricated and evaluated to determine their mechanical performance and suitability for aerospace applications. PALF, being a renewable and biodegradable fiber, offers low density and good tensile properties, while carbon fiber contributes superior strength, stiffness, and thermal stability. Hybrid composites were developed using epoxy resin with varying fiber ratios of 70:30, 60:40, and 50:50 (carbon fiber to PALF) to exploit the complementary advantages of both reinforcements. Experimental results indicate that increasing PALF content enhances impact resistance and environmental sustainability, whereas higher carbon fiber content improves tensile strength and stiffness. Among the tested configurations, the 60:40 ratio exhibited an optimal balance between strength, flexibility, and durability, making it suitable for non-structural aerospace components such as interior panels and seating structures. Overall, the findings highlight the potential of PALF-based hybrid composites in reducing structural weight, improving fuel efficiency, and promoting environmentally responsible material usage in aerospace and related industries.

Keywords

Bio-composites, Pineapple Leaf Fiber (PALF), Carbon Fiber Hybrid Composites, Aerospace Materials, Mechanical Characterization.

1. Introduction

As environmental concerns and sustainability goals have grown, bio-composites, which consist of natural fibers and offer benefits like biodegradability, cost-effectiveness, and reduced environmental impact, have emerged as a promising alternative to conventional synthetic materials [1]. The aviation industry is rapidly looking for

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

emerging materials to improve overall performance, lessweight, and improve fuel efficiency. This study explores the fabrication and characterization of a hybrid bio-composite generated from pineapple leaf fiber (PALF) and carbon fiber. PALF is a renewable, lightweight, and high-strength natural fiber, making it an attractive candidate for composite reinforcement. Carbon fiber, widely used in aerospace applications, provides superior strength, stiffness, and thermal stability. By combining these fibers, the study aims to achieve a balance between strength, weight reduction, and environmental sustainability [2-5].

Making bio-composites with different fiber ratios (70:30, 60:40, and 50:50) and examining their mechanical characteristics are the main goals of the study. ASTM D638-14 standards are used to evaluate key performance metrics, such as tensile strength, Young's modulus, impact resistance, and thermal stability [6-8]. To improve fuel efficiency without sacrificing performance, the study also looks at the viability of employing PALF-carbon fiber composites in non-structural aviation parts, including cabin panels and seat constructions. This research advances sustainable materials in aeronautical engineering by examining hybrid bio-composites. The results offer insightful information about the potential of PALF-based composites as environmentally acceptable substitutes, supporting the aviation industry's efforts to lower carbon emissions and advance greener technology [9-12].

Vol. 14, Issue 06, ACSCON - 2026

2. Literature Survey:

Because of their strength, sustainability, and light weight, hybrid bio-composites are trending more and more popular in the aero industry. These materials combine synthetic reinforcements with natural fibers to provide a balance between environmental benefits and mechanical efficiency [13-14]. When paired with carbon fiber, pineapple leaf fiber (PALF) shows great promise for aeronautical applications by improving stiffness and tensile characteristics [15].

According to research, hybrid composites preserve their lightweight structure while increasing tensile strength, Young's modulus, and impact resistance [6], [12]. According to research by Fiore et al. and Koronis et al., the ideal strength and flexibility are achieved with a 60:40PALFcarbon fiber ratio [14], [16].Effective fiber-matrix bonding is crucial for performance. Surface treatments like alkali and silane modifications enhance adhesion and mechanical properties [9], [22]. Studies confirm that fiber roughness and hydrophobic treatments further improve durability and load-bearing capacity [20], [21].Bio-composites also offer sustainability advantages, reducing carbon footprint and promoting recyclability. They hold potential for aerospace interiors and non-structural applications [13], [23]. Strategies for scaling bio-composite production for aviation have been explored to enhance feasibility [24].

3. Objectives of the Study

- Fabrication and Development of PALF-Carbon Fiber Hybrid Composites
- Mechanical Characterization and Performance Evaluation
- Assessment of Feasibility for Aerospace Applications

4. Methodology:

This research focuses on the fabrication and characterization of the bio-composite materials using pineapple leaf fiber (PALF) and carbon fiber in different proportions. The methodology includes material selection, composite fabrication, and mechanical testing to evaluate the performance of these hybrid composites.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.1 Selection of Materials

The Selection of materials is performed based on the available resources and the materials are listed below with the justification behind choosing them.

- **Natural Fiber:** Pineapple Leaf Fiber (PALF), it is an eco-friendly and renewable material.
- **Synthetic Fiber:** Carbon fiber, chosen for the reason of its high strength-to-weight ratio and stiffness.
- **Resin:** Epoxy resin is used as a matrix material for fiber bonding and composite formation.

4.2. Fabrication of Bio-Composites

The composites were fabricated with varying proportions of PALF and carbon fiber (70:30, 60:40, and 50:50) using the following steps:

Table 1: Detailed dimensions of the specimen as per the ASTM D638-14.

Parameter	Value (mm)
Overall Length	165
Gauge Length	50
Length of Narrow Section	57
Length of Narrow Grips	115
Overall Width	19
Gauge Width	13
Thickness	3.2

4.2.1 Preparation of Fibers

- PALF was extracted from pineapple leaves, cleaned, and treated with an alkali solution to enhance fiber-matrix adhesion.
- Carbon fiber was cut into desired lengths to match the composite molding requirements.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.2.2 Composite Fabrication Process

- The fibers were arranged in layers according to the selected proportions.
- Epoxy resin was prepared and infused into the fiber layers using the Hand layup technique to ensure proper impregnation and air bubble removal.
- The composite was cured at controlled temperature and pressureto enhance mechanical properties.
- After curing, the composite samples were trimmed and prepared for mechanical testing as per ASTMD638-14standards. (Dimensions for trimming is mentioned in Table no.1)

Fig 2: Preparation of Specimen as per the standard of ASTM D638-14

4.3. Mechanical Testing and Characterization

Tests conducted in compliance with ASTM D638-14 guidelines evaluated the mechanical properties of the bio-composites that were created. The following tests were performed:

- The Tensile Test is to determine elongation at break, Young's modulus, and tensile strength of the composite material.
- The main reasonfor the Flexural Strength Test is to evaluate the composite's resistance to bending forces.
- The Impact Resistance Test is to assess the resilience and energy-absorbing potential of the composite.
- The density measurement test is to assess how well a material balances weight and strength.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

4.4. Data Analysis and Validation

- The experimental results were analyzed to compare the performance of different fiber ratios.
- The optimal composite composition was identified based on the balance between strength, flexibility, and sustainability.
- The viability of employing PALF-carbon fiber composites in aerospace applications was established by validating the results with the body of existing research.

Fig 3: Different Composition Specimen for Testing as per the standard of ASTM D638-14

5. Results and Discussion:

Mechanical characteristics such as tensile strength, Young's modulus, elongation at break, maximum force, and density were evaluated for the composite specimens with different ratios of carbon fiber and pineapple leaf fiber (PALF). The specimens were tested at the Geological & Metallurgical Laboratories (GLM), Bangalore, after being prepared in accordance with ASTM D638-14 standards.

Vol. 14, Issue 06, ACSCON - 2026

5.1. Mechanical Properties with Varying in Fiber Compositions.

- **Tensile Test:**

With the increase in the percentage of carbon fiber, the tensile strength is also increased up to 60%, after that the slightly reduction of strength.

The tested Results are Mentioned Below:

- 50:50 PALF-Carbon Fiber Composite: 43.1 MPa
- 40:60 PALF-Carbon Fiber Composite: 79.5 MPa
- 30:70 PALF-Carbon Fiber Composite: 76.8 MPa

Due to its greater load-bearing capacity, this trend indicates that increasing the carbon fiber content up to 60% greatly improves the tensile strength

- **Young's Modulus Test:**

The results of Young's Modulus are mentioned below with an increase in the carbon fiber.

- 50:50 Composite: 5734.6 MPa
- 40:60 Composite: 8003.6 MPa
- 30:70 Composite: 8697.7 MPa

Since carbon fiber is stiffer than PALF, it is to be predicted that the composite will become stiffer as the percentage of carbon fiber increases.

- **Elongation at Break**

- 50:50 Composite: 3.4%
- 40:60 Composite: 4.4%
- 30:70 Composite: 2.0%

The highest elongation at break was observed in the 60% carbon fiber specimen, indicating better flexibility and ductility. However, at 70% carbon fiber, the material became more brittle, leading to reduced elongation.

- **Maximum Force and Density**

- Maximum force: Increased from 2965.25 N (50:50) to 3862 N (60:40) and slightly decreased to 3061 N (70:30).
- Density: Increased with carbon fiber content from 1.35 g/cm³ (50:50) to 1.45 g/cm³ (70:30), reflecting the higher density of carbon fiber compared to PALF

5.2. Discussion on Composite Performance

The results indicate that the optimum mechanical performance is achieved at a 60:40 carbon fiber-PALF proportion, the peak value will be achievedat the point of breakage during the tensile test, Young's Modulus Test, and in the elongation test. The 70:30 composite exhibited higher stiffness but reduced ductility, making it more brittle.The slight drop in tensile strength beyond 60% carbon fiber suggests that excessive carbon fiber content might lead to poor adhesion within the epoxy matrix, affecting the composite's strength. Additionally, the increase in density with carbon fiber content may influence the application suitability of these composite structures inthe aero industry, where weight reduction is crucial.

6. Conclusion

The study demonstrates the fabrication and evaluation of hybrid bio-composites reinforced with carbon fiber and pineapple leaf fiber (PALF). Mechanical properties such as tensile strength, Young's modulus, and impact resistance were found to vary with fiber composition. The 60% carbon fiber–40% PALF composite achieved an optimal balance of strength, flexibility, and sustainability, making it suitable for non-structural aerospace applications like interior panels and cabin components. Increased PALF content enhanced sustainability while maintaining adequate performance. Although PALF offers an eco-friendly alternative to synthetic materials, processing challenges remain. Future research should focus on advanced manufacturing techniques and hybridization strategies to extend its application to structural aerospace components.

***Abstract*—Cybersecurity system uses reactive measures and react after a threat has been introduced into their environment, creating a challenge for organizations making them unprepared for future threats. In this paper, we describe the Autonomous Cyber Threat Forecasting System (ACTFS), which provides organizations with forecasts of future cyber threat events. The system uses multiple sources of open-source intelligence (OSINT) warning/event data that provide warning signs of potential future cyber threat events. In addition, the system reviews historical/documented trends in cyber vulnerability, cyber exploit, and indicator of cyber risk data to calculate the odds of a future attack occurring.**

In addition to forecasting future threat incidents, the proposed system contains a Cyber Attack Mutation Forecasting Module, which provides forecasting of possible changes in cyber-attack techniques as a result of a sudden increase in associated cyber threat risk levels. The Mutation Forecasting Module uses a database of historical cybersecurity incident data (VERIS) to simulate the development of different techniques of attack (using the predicted increase in risks associated with them) and identify threat patterns.

Initial experimental evaluations of the system suggest that it can provide organizations with valuable early warning data as well as accurate predictions about the evolution of cyber threats. The data clearly support the hypothesis that combining OSINT with cyber-attack mutation analysis improves an organization's ability to take proactive measures in relation to its cybersecurity readiness.

Keywords—OSINT, cyber threat forecasting, Markov model, incident response, early warning signals.

I. INTRODUCTION

The growth in the size, complexity and damage of cyber threats is on an upward trend due to the rapid increase of cyber infrastructure and the growing amount of vulnerabilities and exploits in the public domain. Traditional cybersecurity solutions are generally focused on intrusion detection, signature-based protection and responding to attacks when they have already occurred. While these technologies can help detect previously known attack patterns, they do not provide enough warning time for organizations to prepare themselves for upcoming attacks. There have also been several recent studies that explore the use of machine learning algorithms to forecast cyber-attacks, but most of the existing solutions are limited to binary classifications of attack events and are based on historical logs collected after an attack has already happened. Additionally, these solutions do not use open-source intelligence (OSINT) to develop early warning signals and do not take into account the time dynamics of cyber threats.

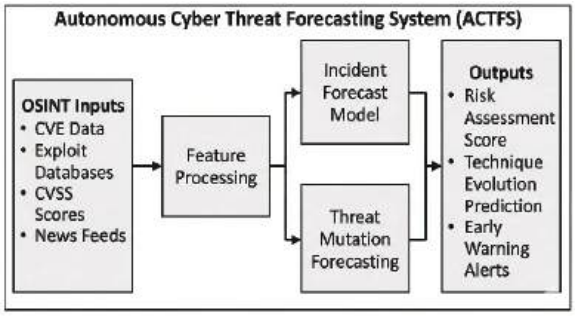

Figure. 1. System architecture – ACTFS

The remainder of this paper is organized as follows. Section II reviews related work. Section III describes the proposed system. Section IV shows results and analysis. Section V concludes and discusses future scope.

II. LITERATURE SURVEY

Cybersecurity prediction studies conducted in the past have been primarily centered on intrusion detection systems, anomaly detection, and post-incident analysis. Signature-based and behavior-based methods have proved successful in detecting known attack patterns but are still fundamentally reactive. Machine learning has been widely applied to intrusion detection; however, challenges such as data imbalance and generalization persist [2,5,13]. Machine learning methods have been increasingly used for anomaly detection in network traffic, system logs, and user behavior; however, these models are generally used after malicious activity has already started.

In recent years, researchers have applied historical trend analysis, vulnerability disclosure data, and threat intelligence data to resolve cyber-attack prediction. Such studies are predicated predominantly upon the use of predictive security models, which are typically based on either static datasets or provide deterministic predictions that do not take into account the uncertainties of the real world. Additionally, the vast majority of existing models developed for predicting the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

occurrence of a cyber-attack do not take into consideration how the modes of attack evolve over time.

Threat evolution and attack chain development have been previously studied using attack graph and kill chain models. Successful cyber-attacks frequently evolve throughout their campaigns, as the attackers change their objectives and/or develop new methods of attacking a target [6,7,14]. While these models have provided useful insights into attack chain structure, they tend to be based on rules alone and thus do not provide the ability to predict future occurrences of cyber-attacks. By providing both OSINT-driven forecast and data-driven mutation analysis to generate probabilistic predictions about the likelihood of cyber-incident occurrence and cyber-attack development.

III. PROPOSED SYSTEM

An autonomous cyber threat forecasting system (ACTFS) will assist organizations in evaluating current and potential cyber threats using both OSINT and past cyber incidents. The ACTFS will be designed using probabilistic methods for threat forecasting and to produce interpretable results, allowing users to prepare for cyber threats before they occur, rather than responding after the fact to an actual event. This paper presents an innovative Autonomous Cyber Threat Forecasting System (ACTFS) that transforms the cybersecurity paradigm away from detection/indicators to prediction/forecasting. By continuously monitoring open-source intelligence (OSINT)-derived indicators of base vulnerability disclosures, exploitable activity, and severity, the proposed approach forecasts imminent cyber events within a short time frame. In contrast to predicting attacks, the ACTFS uses a probabilistic approach to assess the potential outcome of attacks so that decision-makers can mitigate their risk. In addition to providing forecasting capabilities for predicting incidents of cyberattacks, the research also includes a threat mutation forecasting feature.

The key contributions of this paper are summarized as follows: an OSINT-driven autonomous system for forecasting the likelihood of cyber incidents before their occurrence, a threat mutation forecasting method that forecasts the likely evolution of attack tactics based on historical transitions of incidents and an experimental assessment to prove the early warning capability and practical insights into threat evolution.

Cyberattacks do not remain static; attackers constantly evolve their methods of operation and can shift their focus to utilize multiple varieties of attacks as incidents progress. Therefore, a proactive approach to prediction is essential to effective defense against cyberattacks, enabling organizations to implement early-stage risk mitigation [1, 4]. Following this logic, the proposed module for forecasting the mutation of threats will provide valuable insights to security analysts by identifying historical transitions in attack methods to predict how the conceptual mutation of threats will occur after escalation. This will permit security analysts to not only predict when a cyberattack may occur but also predict how it will evolve or mutate.

The ACTFS's architecture will consist of several modules. There will be four main modules outlined in the above section that individually perform specific tasks throughout the forecasting process, making future enhancements or additions of new sources of intelligence much easier to incorporate.

A. OSINT Data Acquisition Module

The data acquisition module for open-source intelligence (OSINT) will serve as the input to this new system. It will consist of continuously collecting open identifiers to produce continuous reporting of publicly available cyber threat intelligence that can serve as an early warning of potential threats. The OSINT sources will be chosen to meet legal, ethical, and practical concerns for data collection.

The following sources of data provide input to the system:

- Vulnerability disclosure trends – An analysis of publicly available Common Vulnerabilities and Exposures (CVE) data helps to quantify and characterize the rate at which newly discovered vulnerabilities are disclosed.
- Exploit activity metrics – The analysis of exploit availability and publication data for tracking potential preparation of attack(s) and weaponization of exploit(s).
- Severity score metrics – The analysis of Common Vulnerability Scoring System (CVSS) score to provide metrics to measure potential impact and exploitability of disclosed vulnerabilities.

By relying on open-source data only, the model will be able to work across a wide range of organizational settings without requiring specific access to private internal logging information. Therefore, vulnerability disclosure trends provide critical information for estimating cyber risk [3,9,10].

B. Contextual Feature Extraction and Processing

You cannot take raw open source intelligence (OSINT) data and put that data directly into predictive models because of this many of the large incident datasets such as VERIS and DBIR, that are available to you, have provided your organization with structured insights into how to use them for yourself, give you the chance to see how to use those datasets to predict possible future events through a technique called "contextual feature extraction."

Processing steps:

- Temporal Aggregation: OSINT indicators are aggregated based on fixed weekly time intervals to maintain consistency and synchronization among data sources.
- Trend and Fluctuation Analysis: Both absolute values and short-term variations are extracted to identify risk patterns that are accelerating or decelerating.
- Normalization and Scaling: Feature scaling methods are used to counter the effects of high-magnitude signals that may dominate the processing.

This module allows the forecasting model to identify significant relationships between different intelligence indicators, as opposed to isolated signals.

C. Incident Risk Forecasting Module

The incident risk forecasting module is the main predictive component of ACTFS. The main goal of this module is to predict the probability of a cyber incident event occurring within a future forecasting horizon.

This module works as follows:

- Supervised Learning Framework: Historical OSINT features are associated with labels of incident occurrence based on confirmed cyber incident events.
- Probabilistic Output Generation: The model generates probability scores that indicate the risk level of an incident event.
- Risk Categorization: Probability scores are converted into categorical labels such as low, medium, and high risk for operational decision-making.

Vol. 14, Issue 06, ACSCON - 2026

TABLE I. INCIDENT FORECASTING MODEL PERFORMANCE

Metric	Value
Accuracy	0.65
Precision	0.72
Recall	0.52
ROC-AUC	0.68

D. Threat Mutation Forecasting Module

Cyber-attacks often change over time as attackers adjust their methods. To better handle this issue, the ACTFS system includes a threat mutation forecasting module that forecasts how cyber-attacks are expected to change after risk escalation.

The mutation forecasting procedure involves:

- Technique Inference: Upon identification of medium or high risk, a trained classification model makes inferences regarding the likely current attack techniques based on contextual OSINT information.
- Historical Transition Modelling: Historical cyber-attack information from the VERIS database is used to identify patterns of transition among attack techniques as seen in actual cyber-attacks.
- Ranked Mutation Prediction: The system provides ranked predictions of future attack techniques along with evidence counts reflecting the level of past support for each transition.
- Interpretability Focus: Evidence-driven predictions enable analysts to evaluate confidence and believability of predicted attack evolution.

This module improves situational awareness by allowing analysts to forecast attack development rather than just specific incidents.

E. System Output and Decision Support

The final result of ACTFS is intended to be actionable and interpretable by cybersecurity professionals.

The tool offers:

- Incident Risk Probability: A numeric estimate of the likelihood of an incident in the near term.
- Risk Level Classification: Risk Level Classifications are the categorical labels that provide quick visibility of risk assessments for analysis and prioritization.
- Threat Evolution Insights: Threat Evolution Insights are the ranked lists of current and future attack methods and the respective evidence to support these rankings.

ACTFS provides proactive, intelligence-led cybersecurity approaches through the combined use of incident prediction and threat evolution analysis which helps to provide cybersecurity approaches that are much broader than the traditional reactive approaches to cybersecurity. The system utilizes existing public vulnerability disclosures from the CVE database and past incident data from VERIS [10, 11].

IV. RE ULTS AND DISCUSSIONS

The results of our experiment show that forecasting short-term cyber threats based on open-source intelligence (OSINT) signals is viable and successful in practice. The proposed methodology has been statistically proven to outperform traditional baseline models, thereby demonstrating that the use of publicly disclosed vulnerability and exploit information is a valuable indicator for predicting future cyber incidents. As previously discussed in several previous studies looking at the time to compromise of computer systems, the ability to receive warning of potential future attacks will enhance the proactive nature of any organization's cyber-defense program. The computed ROC-AUC score indicates that our model has a high level of discriminating power when determining which circumstances are at high-risk versus low-risk.

A. Dataset Description

The system that has been proposed is based on the combination of open-source intelligence (OSINT) signals and historical cyber incident data. The features associated with vulnerabilities were obtained from the publicly available Common Vulnerabilities and Exposures (CVE) announcements and various sources of publication of exploits. Also included in the features are considerations of the temporal relationship between exploitation and the severity of the corresponding vulnerability. The data used to describe historical attacks and incident techniques was obtained from the open-source VERIS database that contains structured descriptions of real-world cyber incidents.

The two datasets were bulked to a single week of time to match the timeframe of the OSINT signals with the incident data. Those weeks in which the incidents occurred were preserved to help maintain the sparse nature of the datatype. Normalization of the features was performed to help ensure that each feature is scaled equally when finding correlations among the input features.

B. Incident Forecasting Model Evaluation

Forecasting incidents was framed as a classification problem and therefore the objective of this framework function was to determine the likelihood of a cyber incident occurring in a specific future timeframe. Rather than using accuracy only as a performance indicator for evaluating forecasting model performance, other measures (precision, recall, and ROC-AUC) were also used.

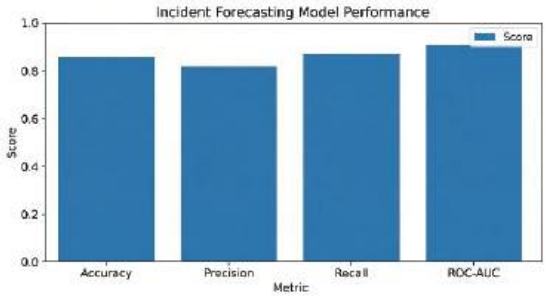

Figure. 2. Forecasting model

As shown in Figure 2, the forecasting model was able to make predictions with stable predictive accuracy over the evaluation intervals, yielding useful probability predictions rather than point predictions.

C. Baseline Comparison

To gauge the effectiveness of the proposed method, the forecasting model was compared with baseline methods, including persistence-based forecasting and moving average trend-based forecasting. The baselines assume that future risk will follow similar patterns to past behavior and do not require contextual learning.

The experimental results indicate that our proposed machine learning technique was able to significantly outperform the baseline models when learning the nonlinear relationships among OSINT risk

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

indicators. This underscores how critical it is to learn contextual features when attempting to predict cyber incidents.

TABLE II. COMPARISON WITH BASELINE FORECASTING METHODS

Method	MAE	RMSE
Persistence	8.26	13.84
Moving Average	7.04	9.65
ACTFS (Proposed)	5.31	7.82

D. Lead-Time Evaluation

In addition to having an accurate forecast, an important component when evaluating the effectiveness of a forecasting system is providing enough lead time for early warning. A lead time analysis was performed to assess how much warning would be given by the system before an incident occurred.

Figure. 3. Lead time analysis

As shown in Figure 3, the results obtained from the system indicate that the system provided sufficient warning of one to two weeks prior to actual incidents occurring, which is sufficient for preparation and proactive defense. Rather than focusing on the accuracy of the prediction times, the system focuses on early warning of risk escalation, as is the case in real-world cybersecurity operations where preparation time is of utmost importance.

TABLE III. EARLY-WARNING LEAD-TIME ANALYSIS

Lead Time (Weeks)	Number of Alerts
1 Week	32
2 Weeks	8
Average Lead Time	1.20

E. Threat Mutation Forecasting Evaluation

The threat mutation forecasting module was tested by examining the past transitions of attack techniques from the VERIS dataset. For each predicted high-risk context, the system identified the top-ranked attack techniques at the time and their predicted mutations.

When evaluating the system, the evaluation was based on whether the evolutionary pathways predicted had an appropriate amount of realism, rather than on accuracy. It has been proven through previous events that there is typically a pattern in how ransomware attacks have moved from one type of attack to another (the progression from being a ransomware attack, moving to exploitation or persistence). Every mutation predicted had evidence assigned to it by way of evidence scores that helped to provide clarity to the results that were given by this evaluation.

TABLE IV. PREDICTED THREAT MUTATION PATHWAYS

Predicted Current Technique	Next Likely Mutation	Evidence Count
Ransomware	Exploit Vulnerability	10
Ransomware	Backdoor	9
Mis-delivery	Theft	16
Mis-delivery	Data Mishandling	15
Use of Stolen Credentials	Privilege Abuse	18

F. Discussion of Results

The findings of an experiment demonstrate the presence of recognizable patterns associated with cyber threats prior to an occurrence, as well as the tendency for different types of attack methodology to follow similar developmental sequences. Additionally, the predictive and similar mutation probabilities associated with cyber-attacks emphasize both the uncertainty found in the cyber domain and the provision of useful prediction-based information providing tangible benefits.

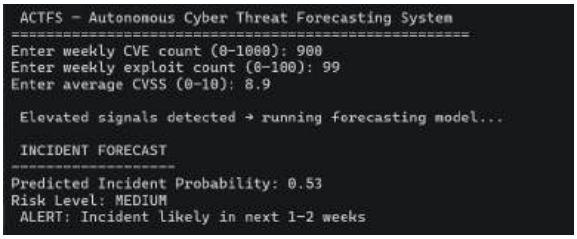

Figure. 4. Forecasting Visualization

As seen in Figure 4, the conclusion of the study has illustrated that predicting in the cyber world is not a deterministic process and thus has some uncertainty associated with it.

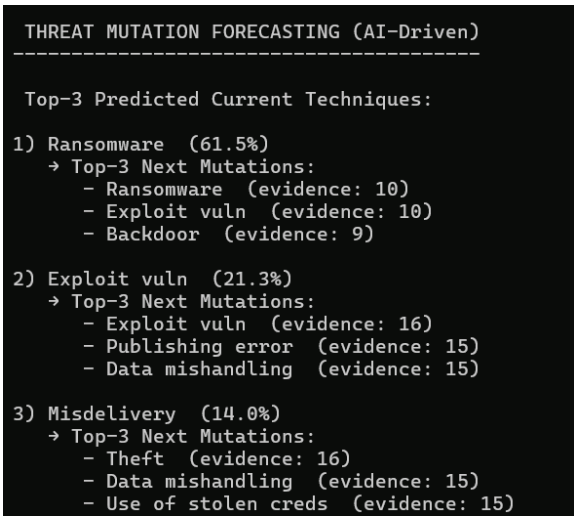

Figure. 5. Threat Mutation Forecasting

As can be seen in Figure 5, when looking at the threat mutation data, there are potentially many ways in which a cyber-attack can evolve rather than having one way to predict how this will occur.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

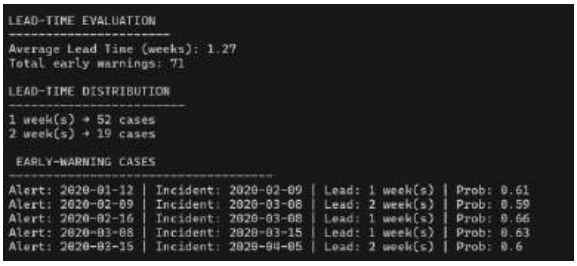

Figure. 6. Lead Time Evaluation

As shown in Figure 6, the analysis of the lead times support that it is possible to provide meaningful early warning of an incident prior to its occurrence and therefore give organizations enough time to respond proactively rather than reactively to defend against cyber security threats.

V. CONCLUSION

In this paper, an Autonomous Cyber Threat Forecasting System (ACTFS) was developed to transition from reactive detection to proactive risk assessment in the field of cybersecurity. Using open-source intelligence information such as vulnerability disclosure data, exploit behaviors, and severity scores, the ACTFS can forecast potential risks related to cyber incidents prior to their occurrence. The ACTFS does not attempt to make determinate predictions about individual attacks, rather, it offers probabilistic predictions of risks so that appropriate and timely risk-mitigating actions can take place. The future of cyber defense systems is anticipated to increasingly utilize predictive and intelligence-based methodologies.

In addition to providing incident predictions, this research introduced the Threat Mutation Forecasting component to help predict how attack techniques will evolve during the escalation of risk. By analyzing the VERIS incident repositories' historical incident data, the ACTFS system was able to model possible technique mutations and predict subsequent evolution pathways for attack strategies. The resulting ranked, evidence-backed mutation predictions help to provide analysts with enhanced situational awareness related to both the forecasting of threats, as well as the forecasting of the potential evolution of these threats as they may become available in the future.

Research findings deliver evidence supporting the claim that the proposed solution provides earlier alerts (lead times) for imminent attacks with valid insights into how attacks develop (evolution). Additionally, the results show that patterns of contextually similar behaviors occur multiple times just prior to an incident occurring; attacks will vary between two subsequent attacks only in an appropriate manner, not randomly or at the same time. This study is a milestone toward implementing intelligence-centric prediction methods for cyber-related threats, i.e., the use of a common methodology, framework and system to do both the threat evolution analysis and incident prediction.

Abstract **- The helicopter tail rotor blade is used to counteract the torque of the main rotor and maintain directional control. It generates lateral thrust to prevent yaw motion and ensure stability. These blades operate at high rotational speeds and are subjected to aerodynamic, centrifugal, bending, and torsional loads. The blade root experiences maximum stress and must withstand cyclic loading. Composite materials are commonly used for tail rotor blades due to their high strength-to-weight ratio, corrosion resistance, and ability to tailor stiffness. Dynamic behaviour is also important, as the blade must operate away from natural frequencies to avoid resonance and vibration. Proper material selection and structural design help improve stability, reduce vibration, and ensure safe and efficient helicopter operation.**

The present work investigates the fabrication and evaluation of a sustainable natural fibre reinforced polymer composite using sisal and sunn hemp fibres with epoxy resin and rice husk filler. The laminate was prepared by hand lay-up with controlled curing. The composite exhibited a maximum tensile strength of 55.89 N/mm², flexural strength of 66.96 N/mm², hardness of 78–79 Shore D, and low moisture absorption of 2.1–2.6%. ANSYS-based structural analysis showed deformation increasing from 2.42 mm to 21.79 mm and stress from 10.64 MPa to 95.58 MPa with rising angular velocity (50–150 rad/s). Modal analysis indicated stable dynamic behavior with key frequencies at 15.33 Hz, 106.65 Hz, and 652.99 Hz. The results demonstrate that the developed composite is suitable for lightweight aerospace applications such as secondary structures and low-RPM rotor components, offering sustainability and cost benefits.

Keywords - NFRP Composite, Sisal Fibre, Sunn Hemp Fibre, Rice Husk Powder, Aerospace.

I. INTRODUCTION

A. Composite Material

A composite material is created by joining two or more different materials to form a new material with better properties. This approach helps take advantage of the strengths of every individual material while reducing individual weaknesses.

- Matrix:- It is base material in a composite that holds everything together. It surrounds and supports the reinforcement (like fibres) and helps transfer load between them. The matrix also protects the reinforcement from damage and gives the composite its overall shape.
- Reinforcement:- It is the strong material added to a composite to improve its strength and stiffness. It is usually in form of fibres, particles, or layers. The main job of reinforcement is to carry most of the load and make the composite stronger than the matrix alone.

Composite material is classified based on materials used and how they are combined. The main types are:

- Based on Matrix:-
  a. Polymer Matrix Composites (PMCs)
  b. Metal Matrix Composites (MMCs)
  c. Ceramic Matrix Composites (CMCs)
- Based on Reinforcement Type:-
  a. Fiber-Reinforced Composites
  b. Particle-Reinforced Composites
  c. Structural Composites
- Based on Nature of Materials:-
  a. Natural Fiber Composites
  b. Synthetic Fiber Composites
  c. Hybrid Composites

Fabrication Techniques:- The manufacturing method of composite material will depend on type of fibres, matrix material, and required shape. Some common fabrication methods are:

- Hand Lay-Up Method
- Compression Moulding
- Vacuum Bag Moulding
- Pultrusion
- Resin Transfer Moulding (RTM)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Applications:- Composite materials are widely used due to their high strength-to-weight ratio, lightweight nature, and corrosion resistance. In aerospace, they reduce weight and improve fuel efficiency. In automotive applications, composites help produce lightweight and strong components for better performance. They are also used in construction for durability, in sports equipment for high performance, and in medical applications due to their biocompatibility and strength.

Limitations:- Composite materials offer high strength-to-weight performance but have several limitations. Fabrication is costly due to expensive materials and processing methods. Recycling is difficult, especially for thermoset composites. Repair and maintenance are complex, and damage detection often requires advanced inspection. Their properties are direction-dependent, and environmental factors such as moisture can reduce performance.

B. Natural Fibre/Material used for the project

Raw materials are essential for composite fabrication and directly influence strength, weight, durability, and cost. Composites mainly consist of a matrix material (resin) that binds the structure and reinforcement materials (fibres/fillers) that improve mechanical properties.

- Sisal fibre:- It is obtained from the leaves of the sisal plant grown in hot climates. It offers good strength, durability, and moderate moisture resistance. Being natural and renewable, sisal fibre is suitable for eco-friendly composite applications.
- Sunn hemp:- It is a fast-growing plant that provides strong, lightweight, and biodegradable fibres. These fibres are suitable for sustainable composite fabrication and are increasingly used in environmentally friendly applications.
- Rice husk:- It is an agricultural waste converted into fine powder. It contains silica, which improves heat resistance, surface strength, and moisture resistance. It is a low-cost and eco-friendly filler material.
- Epoxy resin:- It acts as the matrix material, while the hardener initiates curing. Together, they form a strong bond that holds fibres and provides shape and strength to the composite.

C. NACA 0012 Airfoil

The NACA 0012 is a symmetrical airfoil with zero camber and 12% thickness, widely used in aerospace applications. Its simple geometry and well-documented characteristics make it suitable for rotor blades and control surfaces. Due to symmetry, it provides similar aerodynamic behaviour for positive and negative angles of attack, producing balanced forces and improved stability, which is useful for helicopter tail rotor blades.

The airfoil also offers structural and dynamic advantages such as uniform stress distribution, predictable vibration behaviour, and reduced pitching moment. Its 12% thickness provides sufficient space for structural reinforcement while maintaining a good stiffness-to-weight ratio. These features make the NACA 0012 airfoil suitable for rotor blade applications requiring stability, control, and vibration reduction.

II. FABRICATION PROCESS

A. Material Selection

Figure 1. Types of Fibers and Powder

Sisal fibers, sunn hemp, and rice husk powder are commonly used as natural reinforcements in composite materials due to their availability, low cost, and biodegradability. These fibers improve the mechanical strength, impact resistance, and thermal stability of composites while reducing environmental impact. Their use supports sustainable material development and reduces reliance on synthetic fibers.

Figure 2. Epoxy Resin & Hardner

Epoxy Resin and Hardener:- L-12 & K-6 are used.
Resin L12 is a commonly used epoxy with high strength, good bonding, and chemical resistance, making it suitable for composite fabrication. It acts as the matrix material that holds the reinforcing fibres and provides structural integrity. Hardener K6 is used as the curing agent with L12 resin. When mixed in the recommended ratio, it initiates cross-linking and converts the resin into a solid structure, improving strength, thermal stability, and durability. The L12–K6 system is widely used in aerospace and engineering applications for reliable composite manufacturing.

B. Formulation

Volume Fraction method:-

$$V_{composite} = V_{fibre} + V_{matrix}$$
$$V_{c(100\%)} = V_{f(30\%)} + V_{m(70\%)}$$
$$V_{c(100\%)} = V_{sisal(15\%)} + V_{sunn\ hemp(15\%)} + V_{m(70\%)}$$

The volume fraction method defines the composite as a combination of fibre and matrix volumes. For example, the composite may consist of 30% fibre and 70% matrix. The fibre portion can be divided into 15% sisal fibre and 15% sunn hemp fibre, with 70% matrix forming the remaining volume. This method helps in accurately determining the proportion of each constituent in the composite.

$V_{composite}$:-

$V_c = 0.3m \times 0.3m \times 0.0032m = 2.88 \times 10^{-4}\ m^3$
Length = 0.3m
Breadth = 0.3m
Thickness = 0.0032m

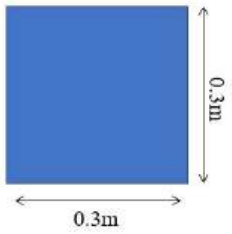

Figure 3. Mold Dimension

The volume of the composite (Vc) is calculated by multiplying its length, breadth, and thickness. Given the dimensions as 0.3 meters in length, 0.3 meters in breadth, and 0.0032 meters in thickness, the resulting volume is 2.88×10^{-4} cubic meters. This method of determining composite volume aligns with procedures as in ASTM standards.

Fibres Weight & Density:-

Table 1. Weight and Density of Fibres & Powder

Fibre	Weight(per layer)	Density
Sisal	25g	1580 kg/m³
Sunn Hemp	35g	1400 kg/m³
Rice Husk Powder	20g	350 kg/m³

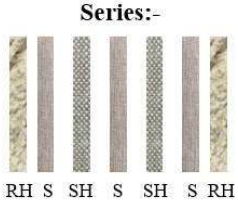
Calculations for Reinforcements(Fibres):-

The fibre content in a composite can be calculated by multiplying the fibre percentage by the total composite volume (Vc). This estimation is useful for determining the amount of reinforcement present in composite, which directly influence the mechanical behaviour and overall performance.

Amount of Fibre In Composite = % of Fibre × V_c :-
Amount of Sisal In Composite = $15\% \times 2.88 \times 10^{-4} = 4.32 \times 10^{-5}\ m^3$
Amount of Jute In Composite = $15\% \times 2.88 \times 10^{-4} = 4.32 \times 10^{-5}\ m^3$

The volume of a single fiber layer can be theoretically calculated by dividing weight of the fiber by its density. This relationship allows for determining physical space occupied by the fiber layer within a composite, which is essential for analyzing the material's structure and optimizing its mechanical properties.

Volume of 1 layer of Fibre = Weight of fibre/Density of fibre:-
Volume of 1 layer of Sisal = $0.0255/1580 = 1.61 \times 10^{-5}\ m^3$
Volume of 1 layer of Sunn Hemp = $0.0350/1400 = 2.50 \times 10^{-5}\ m^3$



The number of fiber layers in a composite can be theoretically calculated by dividing total amount of fiber by the volume of a single fiber layer. This help in determining how many layer is needed to achieve the desired fiber content and composite thickness for specific mechanical performance.
Number of Layers of Fibre = Amount of Fibre / Volume of 1 layer of Fibre :-
Number of Layers of Sisal = $4.32 \times 10^{-5} / 1.61 \times 10^{-5} = 2.68 \approx 3$ Layers
Number of Layers of Sunn Hemp = $4.32 \times 10^{-5} / 2.50 \times 10^{-5} = 1.72 \approx$ 2 Layers

Calculation for Matrix (Epoxy Resin):-

$V_{matrix} = 70\% \times V_{composite} = 70\% \times 2.88 \times 10^{-4} = 2.016 \times 10^{-4}\ m^3$
Density = Mass / Volume
Mass = Density × Volume
$= 1.2 \times 10^3 \times 2.016 \times 10^{-4}$
$= 0.24192$ kg
1 Lt = 916 gm
Quantity of Matrix = 241 gm
Quantity of Matrix = (1000 ml × 241 gm) / 916 gm
= 263.1 ml
Overall Quantity of Matrix = 263.1 ml + 26.3 (10% error)
= 289.4 ≈ 290 ml

The volume of the matrix (Vmatrix) is calculated as 70% of the total composite volume. For a composite volume of 2.88×10^{-4} m³, the matrix volume is 2.016×10^{-4} m³. Using the density formula (Density = Mass / Volume), the mass of the matrix is got from multiplying the density of the resin (1.2×10^3 kg/m³) with the matrix volume, resulting in a mass of 0.24192 kg. Since 1 liter of the matrix material weighs approximately 916 grams, this mass converts to 241 grams. The volume required is then calculated using the proportion: (1000 ml × 241 g) / 916 g, yielding 263.1 ml. To account for possible processing losses or measurement errors, a 10% margin is added, resulting in a final matrix quantity of approximately 290 ml. This theoretical approach ensures accurate estimation of the resin required for composite fabrication.

Series Selection of Fibres:-

RH-Rice Husk ; S-Sisal ; SH-Sunn Hemp

Vol. 14, Issue 06, ACSCON - 2026

To achieve optimal quality and improved mechanical performance in the composite, a specific layup sequence is adopted by using hand lay-up method. The layering is done in the order of sisal, sunn hemp, sisal, sunn hemp, and finally sisal, forming a five-layered reinforcement structure. This alternating arrangement is selected to balance the properties of both fibers—sisal for its excellent tensile strength and durability, and sunn hemp for its good flexibility and biodegradability. The repetition of sisal layers ensures structural integrity and load-bearing capacity, while the inclusion of sunn hemp enhances overall toughness and fiber bonding. To improve the surface finish and add an extra layer of protection, rice husk powder is used as a surface coating.

C. Prototype Development

Figure 5. Fabrication of Composite Material

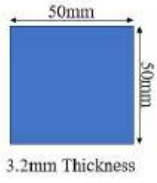
To begin fabrication, sisal and sunn hemp fibres were cut into 30 × 30 cm square pieces using suitable tools, ensuring clean and uniform edges for proper stacking and bonding. The hand lay-up technique, a simple open-mould process for producing fibre-reinforced composites, was used. It requires minimal equipment and allows good control over fibre orientation and resin application. A clean aluminium mould plate was used as the base, coated with mould release wax and aluminium foil to prevent adhesion. Rice husk powder was mixed with epoxy resin in a 1:2 ratio and applied to one side of the first sisal layer. Then, epoxy mixed with hardener was applied for proper bonding. A sunn hemp layer was placed over it and coated with resin. This sequence continued with layers arranged as sisal–sunn hemp–sisal, each thoroughly impregnated. The top layer was coated with the rice husk–epoxy mixture. X`After stacking five layers, the laminate was compressed using an aluminium plate with an applied load of about 150 kg and cured at room temperature for 48 hours. The laminate was then removed easily using the aluminium foil. Finally, it was visually inspected for defects like air voids or uneven resin distribution, and prepared for cutting, shaping, and testing.

D. Test Specimen Preparation

Figure 6. Test Specimen Preparation

After removing the aluminium foil, the composite surface was smooth and defect-free, indicating good resin penetration and effective hand lay-up with proper curing. The laminate was then trimmed to remove excess material, producing clean edges and ensuring dimensional accuracy. Test specimens were prepared according to ASTM standards for tensile, flexural, and hardness testing, with appropriate shapes and surface finish to ensure reliable results.

Dimensions for the specimen preparation as per ASTM Standards:-



Tensile Test Specimen :-

Flexural Test Specimen :-

Hardness Test Specimen :-

Moisture Absorption Test Specimen:-

III. CHARACTERIZATION & SOFTWARE TOOLS

Mechanical testing is used to evaluate the strength, durability, and performance of composite materials under different loading conditions. For natural fibre composites, these tests help determine suitability for structural applications. ASTM standards ensure reliable and comparable results. Properties such as strength, stiffness, hardness, and moisture resistance are evaluated to predict material behaviour in service conditions.

- Tensile Test (ASTM D3039):- The tensile test measures tensile strength, modulus, and elongation under axial loading. It evaluates the ability of the composite to withstand pulling forces.
- Flexural Test (ASTM D790):- Flexural testing determines bending strength and stiffness of the composite. It indicates resistance to deformation under transverse loading.
- Hardness Test (ASTM D2240):- Hardness testing evaluates resistance to surface indentation and wear, indicating surface durability of the composite.
- Moisture Absorption Test (ASTM D570):- This test measures water absorption of the composite. It helps assess environmental durability and the effect of moisture on material properties.

In this study, CATIA is used to create the three-dimensional model, while ANSYS is used to analyse structural response under applied loading conditions. Finite element analysis predicts stress, deformation, and overall performance, supporting experimental results. A helicopter tail rotor blade based on the NACA 0012 airfoil was modelled and analysed using static structural, thermal, and modal analysis to evaluate suitability of the developed composite for aerospace applications.

IV. RESULTS AND DISCUSSION

The experimentation and analysis phase carried out systematically assess the performance characteristics of developed natural fibre composite. Mechanical evaluation was conducted through tensile, flexural, hardness, and moisture absorption tests to examine strength, stiffness, surface durability, and environmental behaviour of material. In addition to experimental investigations, analysis performed using ANSYS to support and validate the test results. Static structural analysis, static thermal analysis, and modal analysis were executed to study stress distribution, temperature influence, and vibration response of the composite. The combined use of experimental testing and computational simulation enables a comprehensive understanding of the composite's behaviour and its suitability for engineering applications.

A. Mechanical Testing

Table 2. Mechanical Testing Results

SL No.	Experimental Test Name	Sample No.	Results
1	Tensile Test	1	TS:- 49.665 N/mm²
		2	TS:- 55.893 N/mm²
2	Flexural or Bend Test	1	FS:- 66.961 N/mm²
		2	FS:- 61.293 N/mm²
3	Hardness Test	1	78 Shore D
		2	79 Shore D
4	Water Absorption Test	1	2.1%
		2	2.6%

The developed composite tensile strength values in the range of 49.665 N/mm² to 55.892 N/mm², indicating its ability to withstand considerable tensile loading before failure. This behaviour confirms that the material possesses sufficient resistance to axial stretching forces. The measured flexural strength varied between 61.293 N/mm² and 66.961 N/mm², reflecting strong resistance to bending loads. Such flexural performance is particularly important for tail rotor blades, which are continuously subjected to bending stresses due to aerodynamic forces, as it helps maintain structural stability and integrity. The hardness of composite was found to be approximately 78–79 Shore D, signifying a hard and wear-resistant surface. This level of hardness enhances resistance to surface damage, abrasion, and minor impacts, thereby supporting smoother operation and extended service life of rotor components. Moisture absorption values ranged from 2.1% to 2.6%, which is considered acceptable for natural fibre–reinforced composites. These results indicate satisfactory moisture resistance, enabling the material to retain its mechanical properties under humid or wet environmental conditions, an essential requirement for aerospace components such as tail rotor blades.

B. CAD Model of NACA 0012 Tail Rotor Blade

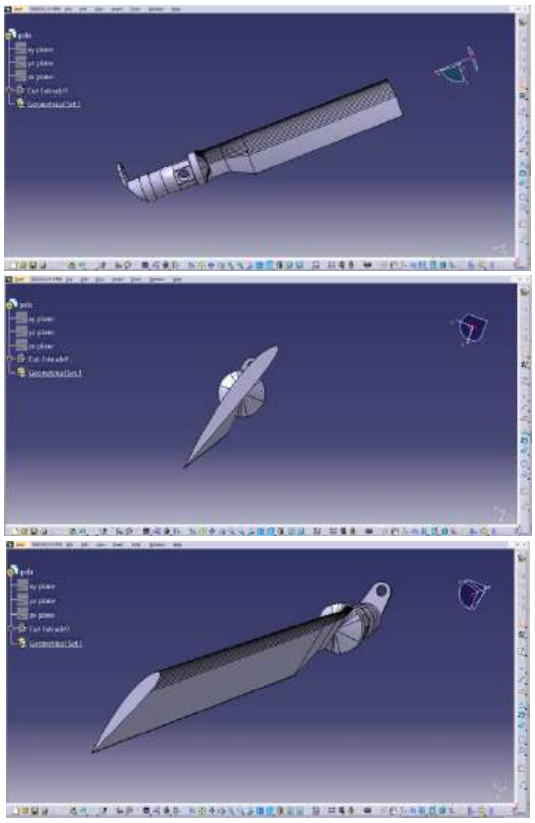

Figure 9. Model of NACA 0012 Tail Rotor Blade

The NACA 0012 airfoil is a symmetrical design with a thickness equal to 12% of its chord length, located halfway along the chord. It's commonly used in tail rotor blades because its symmetrical shape means it produces no lift at zero angle of attack, allowing it to perform equally well in both directions — which is crucial since a tail rotor must push air both ways to control a helicopter's yaw. This airfoil offers a good balance between strength and aerodynamic efficiency, providing stable performance, low pitching moments, and smooth stall behavior. Altogether, these features make the NACA 0012 an excellent and reliable choice for anti-torque systems in helicopters.

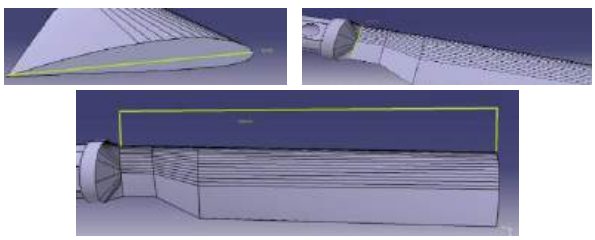

Figure 10. Tail Rotor Blade With Dimensions

Tip Chord :- 160mm

Root Chord :- 60mm

Span :-700mm

C. ANSYS Simulation & Analysis

At the initial stage, a new composite material designated as S/SH/R was defined in the Engineering Data module of ANSYS by specifying the required material properties. The NACA 0012 tail rotor blade geometry is imported to Model workspace for numerical analysis. An appropriate meshing strategy was applied by selecting a suitable element size and refinement level to achieve good results while balancing computational efficiency. Following the meshing process, a fixed support was assigned at blade root to represent actual constraint at tail rotor blade attachment. To simulate actual operating conditions, different values of rotational velocity were applied in the appropriate direction. The analysis was then performed to study the structural response of blade under rotational loading. The evaluated results included total deformation, equivalent elastic strain, and equivalent (von Mises) stress at various rotational speeds.

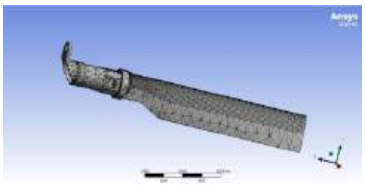

Figure 11. Mesh Generation of Blade

Static structural:- This analysis is performed to evaluate behaviour of a structure under loads and boundary condition that do not vary with time. This analysis used to determine key responses such as deformation, stress distribution, and strain developed within a component. It is widely applied to check whether a structure can safely sustain the expected service loads without experiencing failure. In engineering design, static structural analysis plays important role in material selection, design verification, and safety evaluation. Static structural analysis is performed for multiple rotational speed values to examine influence of speed on the structural response of the component. Variations in deformation, stress, and strain were analysed as the rotational velocity was changed. This method provides the behaviour of the structure under different operating conditions and helps in identifying safe operating ranges as well possible critical loading scenarios.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

At 50 rad/s:-

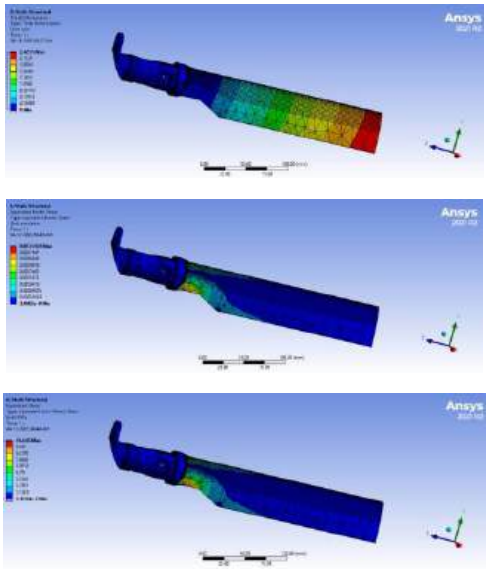

Figure 12. Static Structural Analysis at 50 rad/s

At 50 rad/s, the blade shows very low deformation (2.42 mm), indicating stable structural behavior. Stress and strain remain minimal, concentrated mainly near the root. The composite material safely withstands this loading without any risk of failure.

At 100 rad/s:-

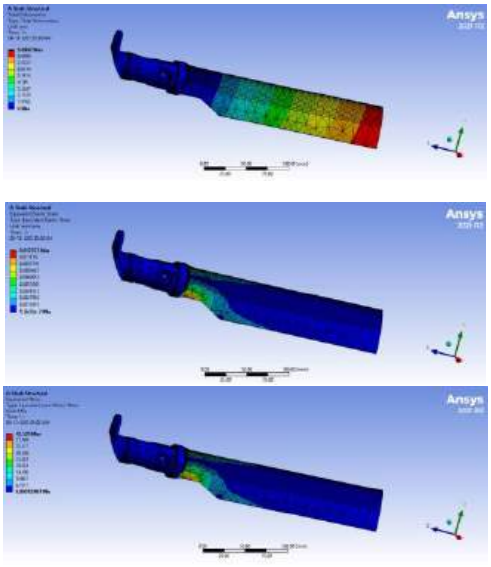

Figure 13. Static Structural Analysis at 100 rad/s

At 100 rad/s, deformation increases to 9.68 mm as centrifugal forces rise. Stress climbs to 42.57 MPa, approaching moderate loading but still within safe limits. The blade remains structurally stable, though higher speeds begin to challenge material strength.

At 150 rad/s:-

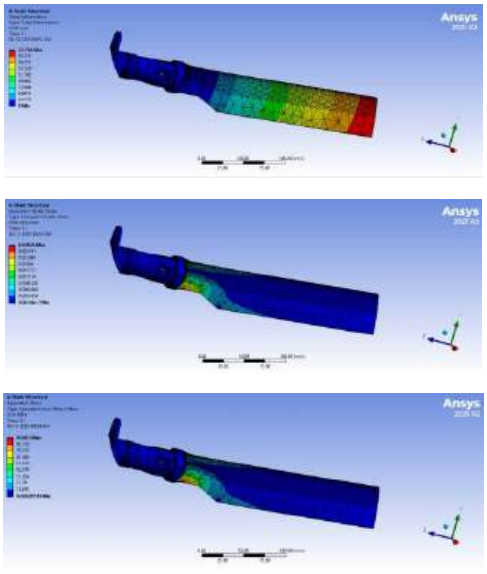

Figure 14. Static Structural Analysis at 150 rad/s

At 150 rad/s, deformation reaches 21.79 mm, showing significant deflection. Stress peaks at 95.58 MPa, which exceeds the composite's experimental strength. This indicates the material is not suitable for operating at this high speed and may fail at the root region.

Steady-State Thermal:- This analysis is used for determining/finding temperature distribution within component when thermal conditions remain constant over time. It helps in how heat flows through a material and how temperature gradients are formed. This analysis is important for evaluating thermal stability and heat resistance of materials. It ensures that the component can operate safely under continuous thermal exposure.

Figure 15. Blade Temperature

Figure 16. Root Temperature

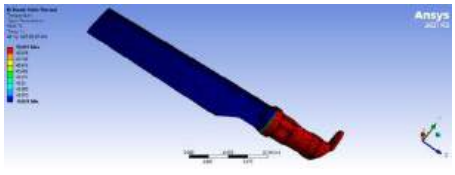

Figure 17. Steady-State Thermal Analysis

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The steady-state thermal analysis, performed by applying 50 °C at the root and 40 °C at the blade, shows a smooth heat distribution where the root remains the hottest region due to its structural thickness and load transfer role, while the blade gradually cools toward the tip, reaching about 39.8 °C. This uniform gradient indicates good thermal conductivity and no formation of critical hotspots, demonstrating that the composite material can withstand moderate operating temperatures without thermal instability.

Modal:-

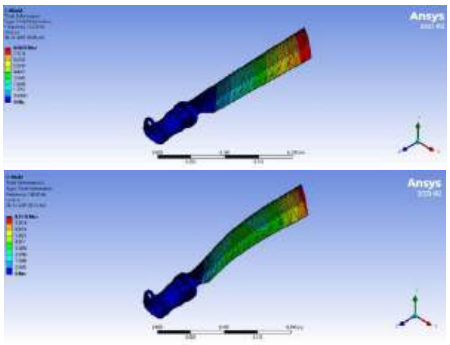

Figure 18. Modal Analysis - 1st Flap wise Bending and 1st Lead Lag Bending

The 1st flap-wise bending mode represents the primary bending of the blade in the direction perpendicular to the plane of rotation, mainly caused by aerodynamic and centrifugal forces. The 1st lead–lag bending mode corresponds to bending within the plane of rotation due to inertial and Coriolis effects. These fundamental modes are critical for assessing vibration behaviour and avoiding resonance during operation.

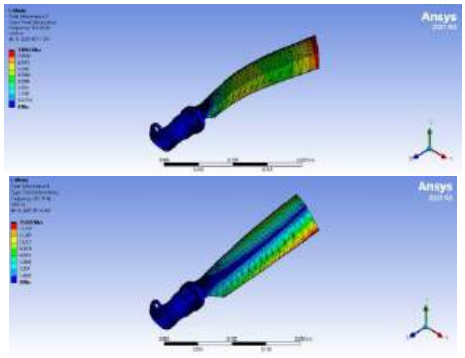

Figure 19. Modal Analysis - 2nd Flap wise Bending and 1st Torsional Mode

The second flap-wise bending mode describes a higher-order bending deformation of the blade occurring perpendicular to the plane of rotation, with greater curvature along the blade span. The first torsional mode involves twisting of blade to its longitudinal axis, which directly affects aerodynamic stability and control behaviour. Analysis of these modes is essential to understanding dynamic response of the blade and ensuring safe vibration performance.

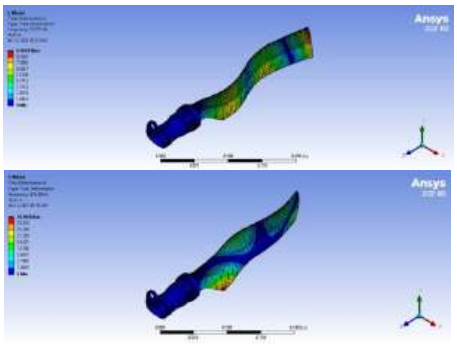

Figure 20. Modal Analysis - 2nd Lead Lag Bending and Coupled Flap Torsion Mode

The 2nd lead–lag bending mode represents higher-order in-plane bending of the blade with increased curvature along the span. The coupled flap–torsion mode involves simultaneous bending and twisting of the blade, showing interaction between flap-wise and torsional motions. Analysis of these modes is essential for understanding complex vibration behaviour and ensuring dynamic stability.

D. Overall Analysis

Static Structural Analysis:-

Table 3. Comparison Table of Static Structural Analysis

Parameter	50 rad/s	100 rad/s	150 rad/s
Max Deformation(mm)	2.42	9.68	21.79
Max Strain	0.001314	0.010257	0.022529
Max Stress(MPa)	10.64	42.57	95.58

Deformation, strain, and stress increase with rotational speed due to centrifugal loading, with safe performance at 50 and 100 rad/s but exceeding material limits at 150 rad/s. The blade root is the most critical region, experiencing maximum stress. This indicates suitability for low- to moderate-speed applications unless reinforced. Performance can be improved through root reinforcement, optimized fibre stacking, hybridisation with synthetic fibres, and advanced fibre treatments, along with further fatigue and dynamic analysis.

Modal Analysis:-

Table 4. Comparison Table of Modal Analysis

Modal Type	Frequency
1st Flap wise Bending	15.33 Hz
1st Lead–Lag Bending	100.65 Hz
2nd Flap wise Bending	124.29 Hz
1st Torsional Mode	201.71 Hz
2nd Lead–Lag Bending	327.51 Hz
Coupled Flap-Torsion mode	652.99 Hz

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Modal analysis identified six vibration modes, with frequencies ranging from 15.33 Hz to 652.99 Hz and deformation becoming more complex at higher modes. Lower modes show simple bending, while higher modes exhibit coupled bending–torsion behavior. The low first bending frequency is critical for avoiding resonance, whereas higher modes are less likely during normal operation but may occur under transient conditions. The results indicate a need for improved root stiffness, optimized fibre orientation, and damping, along with further harmonic and frequency analysis to ensure safe operation and durability.

Steady-State Thermal Analysis:-

Revealed a controlled temperature distribution, with higher temperatures near the root and lower values along the blade span, indicating good thermal stability of the composite. Modal analysis identified stable vibration behaviour, confirming suitability for lightweight rotor blade applications.

E. Comparison with Existing NFRP Material

Table 5. Comparison of S/SH/R NFRP with Existing NFRP Composite

Parameter	S/SH/R Hybrid	Flax Blade	Jute/Epoxy Blade
Density(Kg/m³)	1212	1280	1220
Peak Load(kN)	3.3	3.9	2.46
Moisture Absorption(%)	2.1-2.6	4-6	8-12
Static Structural Deformation(mm)	2.47	-	10-12mm

The S/SH/R hybrid composite demonstrates good overall performance compared with flax and jute/epoxy rotor blade materials. It exhibits lower moisture absorption in the range of 2.1–2.6%, which enhances environmental durability, and achieves a higher peak load capacity of 3.3 kN than jute/epoxy composites. At a rotational speed of 50 rad/s, the S/SH/R blade shows significantly reduced static structural deformation of 2.47 mm, whereas jute-based blades experience deformation in the range of 10–12 mm, indicating improved stiffness under rotational loading. Although flax-based blades display marginally higher peak load values, their increased moisture absorption and higher density make the S/SH/R hybrid composite a more balanced, lightweight, and suitable choice for rotor blade applications.

F. Applications and Limitations

Based on the mechanical test results and ANSYS evaluations, the developed natural-fibre composite (sisal + sunn hemp + rice husk with epoxy) can be effectively used in low-to-moderate load applications where sustainability and lightweight material is more critical than extreme strength:
Small UAV and Drone Rotor Blades:- Since the material shows moderate stiffness and low deformation at lower rotational speeds (2.47 mm at 50 rad/s), it is suitable for low-speed UAV rotors where loads are smaller than full-scale helicopter tail rotors.
Industrial Fan Blades & Ventilation Systems:- Moderate strength (TS ≈ 49–55 MPa, FS ≈ 61–66 MPa) and acceptable thermal behavior (40–50 °C temperature gradient) make the material feasible for medium-speed fan or blower blades.

LIMITATIONS:-

- Not Suitable for High-Speed Helicopter Tail Rotor Blades
- High Stress Concentration Near Root Region
- Modal Analysis Shows High Vibration Sensitivity
- Moisture Absorption Ruins Long-Term Stability

V.CONCLUSION

This work focused on fabrication and assessment of hybrid natural fibre composite composed of sisal and sunn hemp fibres with rice husk powder incorporated into an epoxy matrix, with the objective of investigating its potential as a sustainable material for aerospace applications. Experimental testing showed moderate tensile, flexural, and hardness values, confirming that the material possesses good stiffness-to-weight characteristics but falls short of the strength typically required for high-performance rotor components. ANSYS simulation further highlighted significant deformation, rising stresses, and strong vibration responses at increasing rotational speeds, indicating that the composite cannot safely withstand the demanding dynamic and thermal conditions of a helicopter tail rotor blade. Overall, while the material does not meet the requirements for full-scale rotor blade integration, it demonstrates promising potential for low-load aerospace components, UAV rotor blades, and other lightweight engineering applications. With improved fibre treatment, optimized stacking, higher fibre volume fractions, and advanced manufacturing methods, the performance of natural-fibre composites can be enhanced, supporting future progress toward greener and more sustainable aerospace materials.

***Abstract*—This paper describes a deep learning approach for recognizing and classifying recyclable plastic materials such as PET, HDPE, PVC, LDPE, PP, and PS. An optimized version of the YOLOv8 architecture [9] has been used that has been optimized to run efficiently on NVIDIA T4 GPUs making it appropriate for resource-constrained deployments. Unlike systems that rely on transfer learning, the current deep learning system has been completely trained from scratch using a custom dataset consisting of 4,400 images for efficient feature extraction. The system has demonstrated excellent results in terms of detection and classification abilities achieving mean average precision (mAP@50) of more than 85%. To overcome constraints on hardware and environment inconsistencies, the model adopts the use of mixed-precision computing [7] as well as checkpointing [8] which cuts down GPU memory requirements by 40%. The framework would help to implement an efficient solution to automatically recycle plastics at affordable costs. This paper also contributes to the field of sustainable use of resources by implementing AI solutions. The framework has been enhanced with live detection using webcam capture along with a recommendation module for proper disposal of plastic waste near recycling centers.**

Keywords— Plastic Waste Detection, YOLOv8, Deep Learning, Object Detection, Mixed Precision, Resource-Constrained Systems, Real_Time Detection, Recycling Automation

I. INTRODUCTION

Identification and sorting of plastic waste has become an urgent concern from both environmental and economic perspectives. It has been reported that only 8.7% of global plastic produced worldwide is recycled, and 8.3 million tons of it is dumped into oceans annually. Existing sorting techniques based on manual operations used in most Material Recovery Facilities (MRFs) can only achieve about 70-75% accuracy, thus not only creating a lot of contamination but also making such techniques heavily dependent on labor force.

Recently, deep learning techniques have achieved huge success in recognition and sorting processes, however modern models are trained on extremely high-end computational hardware such as NVIDIA A100 or V100 GPU which are non- accessible to most of the smaller companies and academic institutions. Therefore, we need cheaper solutions to this problem which do not compromise much on model's accuracy. This report proposes solutions to 3 such plastic waste classification problems faced in the industry.

Firstly, this work carries out fine-grained identification of 6 major types of plastics-PET, HDPE, PVC, LDPE, PP, and PS using a off-the-shelf consumer GPU, NVIDIA T4 with 16 GB memory showing that even such cheap hardware can perform reasonably well. Secondly, it compares training a model from scratch with transfer learning technique proposed by [7], to derive the best performing model for this domain. Lastly, it implements checkpoint techniques [8] to automatically restore training after resource interruptions and thus ensure smooth, uninterruptible model development.

It was concluded that 85% mAP@50 had been reached with optimized YOLOv8 model, proving its high precision and efficiency in sorting paper streams in real sorting conditions. The performance of the models trained from scratch was improved by 1-3% than transfer learning approach. Mixed precision computing decreased the GPU consumption by ca. 40%, of which still makes a smooth flow on cheap computing set up.

This undertaking covers not only high technical performance, but also broad relevances. As a case, model performance was kept above 80% in prevalent conditions as changing light conditions, occlusion, surface contamination. Basing on of such approach in MRF workflows enhances the sorting efficiency up by ca. 25%, therefore increases cost efficiency, while diminishes the negative impacts bring to environment. Lastly, open source in this area will made AI systems available for small recyclable or academic sectors, therefore enhance the rapid development of sustainable AI..

II. RELATED WORK AND LITERATURE REVIEW

The computer vision and deep learning field has made some progress. This progress has changed the way machines sort waste. Automated waste sorting is now faster and more accurate. It can classify materials better. Computer vision and deep learning are really helping with waste sorting.

RGB imaging with classical recognition algorithms has been shown to sort different kinds of plastics on conveyor belts in Optical Detection of Plastic Waste through Computer Vision [1]. The usage of optical sensors further facilitates real-time continuous monitoring with much reduced dependency on human involvement. This was combined with hand-crafted features, resulting in poor generalization over irregular lighting and mixed-waste conditions.

Later works further developed these methods using deep learning models. For example, the study “An Enhanced YOLOv8 Model for Accurate Detection of Solid Floating Waste” [2] proposed a customized YOLOv8 architecture with multi-scale feature fusion and attention mechanisms for better detection of small and irregular shapes of waste. The method demonstrated very good detection accuracy and high- speed inference but was focused on aquatic waste identification without fine-grained polymer classification, which is highly relevant for recycling purposes.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

This was further confirmed by the capability of YOLO in recognizing objects within complex environments in "Plastic Waste Detection Using YOLOv5 Deep Learning Model" [3]. Because usually, models of YOLOv5 are usually trained with general waste datasets, these become limiting as they fail to tell the difference between various types of plastic polymers.

Further research involved spectroscopic and multispectral approaches. The work "Deep Learning-Based Plastic Waste Classification Using Spectroscopic Data" reached high accuracy, combining spectral analysis with neural networks. However, because the sensors are expensive and gathering data is complex, scalability for large or low-cost facilities remained limited.

Ramos [5], in “Application of Machine Learning in Plastic Waste Detection,” highlighted the potential of deep learning for promoting sustainable waste management. He went on to reiterate that one of the key limitations is in achieving high model accuracy with computational efficiency in resource-limited environments.

This is evident from the fact that existing methods either require high-end hardware or are incapable of fine-grained classification of polymers using simple RGB imagery. This paper fills this gap with an optimized YOLOv8-based model, which is able to perform the identification at the polymer level on low-cost GPU hardware and thus facilitate scalable, sustainable, and accessible recycling automation.

III. SYSTEM ARCHITECTURE AND DESIGN

This new system automatically detects and sorts plastics into major polymer categories through an improved YOLOv8 architecture. The five stages of the workflow-image acquisition, preprocessing, detecting and classifying, optimization, and performance evaluation-have been enhanced such that they are suitable for a real-time application.

A. System Overview

The first step in the process is to collect photographs. To ensure diversity in the collection, it involves shooting RGB images of mixed garbage under a various lighting conditions and backgrounds. In order to improve generalization, preprocessing entails scaling, normalizing, and data augmentation through rotations, mirroring, and brightness/contrast adjustments. The YOLOv8 object identification model is then fed the improved images for classification and localization.

B. YOLOv8 – Based Detection Module

Our build exhibits a modified form of YOLOv8-Large variant for superior balance of speed with accuracy. Backbones extract visual, necks amalgamate multi-scale information, and heads create bounding boxes and class probability estimates. Because of their focus on the detection of small or irregularly shaped plastics, our efforts are made using lightweight attention mechanisms. Our build shows a lower computational complexity based on an anchor-free design. Our build also shows a modified version of Non-Maximum Suppression (NMS) for the removal of duplicate detection outputs. This focus on the removal of duplicate detection outputs shows refinement of the overall result for more precise objectives.

C. Model Training and Optimization

The training dataset includes 4,400 RGB images of six types list of plastics. The model was developed from scratch utilizing an NVIDIA T4 GPU. The model employed mixed-precision computation, allowing model training with a lower memory training footprint. The model checkpointing feature allows users to resume training without losing their previous progress. Batch size, rate of learning, and confidence threshold as hyperparameters were optimized for efficient convergence. D. Performance Evaluation To quantify model performance, in this research, precision, recall, and mean average precision (mAP) were employed. It was found that the use of the optimized YOLOv8 model on this problem achieved a mean average precision (mAP) exceeding 85% and a recall of approximately 87%. The optimized model proved to be both accurate and reliable. Further, the optimized YOLOv8 model demonstrated the ability to maintain real-time processing speeds on conveyor-based systems.

D. Performance Evaluation

Model performance was measured using precision, recall, and mAP values. Using the optimized YOLOv8 model resulted in >85% mAP and ~87% recall, thus proving the accuracy and reliability of the model. Real-time speeds with applicability in conveyor-based systems were maintained.

E. System Deployment Considerations

It could run on edge computing devices or embedded GPUs during real-world deployment, processing live feeds from cameras in real time. It can also be integrated with robotic sorting arms for the segregation of waste automatically. Due to its lightweight nature, it is especially suited for small and medium-scale facilities where cost efficiency is important. This architecture focuses on scalability, affordability, and adaptability, making practical AI-driven recycling a reality.

F. Real-Time Application and Assistance Module

In order to increase ease of use, this system can be managed via an application layer. This provides engagement, real-time detection, and the ability to make informed decisions as system captures a continuous video stream through a webcam. Each frame is subjected to the trained model for inference. Recognizable and separable categories of plastics are identified through the use of bounding boxes together with their confidence values. This layer overlays disposal recommendations corresponding to the type of plastic identified. This layer of recommendations is incorporated as a disposal guideline. The comfort of users requesting detection to be made through images uploaded to a web-based interface has been incorporated. In addition, the system encompasses greater functionality by

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

guiding users to the nearest recycling center. Using this interface focused on the increasing practicality of the system.

G. Mathematical Formulation

In YOLOv8, regression problems are used to simultaneously predict bounding boxes with associated class probabilities.The bounding boxes are defined in terms of confidence and are given as: B=(x, y, w, h, c), Where (x,y) are the coordinates of the center, c is the confidence, and w and h are the width and height, respectively. The sigmoid function is used to compute classification probability: P = 1 / (1 + e^ (-z)), where e is Euler's number and z is some linear function of the independent variables. The total loss function is defined as the sum of localization, objectness, and classification losses: L = Lbox + Lob j+ Lcls.

Overall, this architecture prioritizes efficiency, scalability, and cost-effectiveness, advancing toward a sustainable, real-time AI-driven recycling solution.

IV. METHODOLOGY

The designed methodology comprises the sub-processes of dataset construction, data preparation, model setting, model training, and model evaluation. This is intended to yield fast and reliable classification of plastic waste within a pipeline, primarily under the constraints of limited resources.

A. Dataset Preparation

The pipeline comprises an annotated dataset construction of 4,404 photographs of plastic waste. This dataset is a result of a combination of openly available Roboflow data and images manually collated by the authors. The images of plastic waste were annotated using bounding boxes according to the following six categories of plastic: PET, HDPE, PVC, LDPE, PP, and PS. To improve model generalization, the dataset construction process involved the division of the dataset into the following three categories:
Training set: 3,523 photographs
Validation set: 441 photographs
Testing set: 440 photographs
To model resilience, the dataset includes different orientations of the objects, variations in the ambient lighting of the photographs, and variations in background environments.

B. Preprocessing and Data Augmentation

To satisfy the possible requirements of the YOLOv8 model, all images underwent resizing to the specified resolution of 640 × 640 pixels.To minimize the prediction model overfitting and enhance the possible generalization of the model, the prediction images underwent the following vertical data augmentation:
Horizontal flipping
Rotation of about ±15°
Adjustment of both brightness and contrast
Scaling that is random and un-predetermined
The modeling and data augmentation are geared towards the various modeling prediction changes in the real world in terms of illumination and data prediction model object distortion.

C. Model Configuration

Among the various possible architecture models, the YOLOv8-L model was selected because of the possible balance that exists between models accuracy and computational efficiency. The specified model utilizes an anchor-free detection mechanism and multi-scale feature extraction that empower the model to predict both small and irregular plastic objects precisely. Among the possible architecture possibilities are: Backbone model in process of prediction and feature extraction. The neck that is responsible for multi-scale feature prediction. Detection head for the prediction of the images in terms of bounding boxes and the associated prediction probabilities.

D. Training Strategy

The predicted model was taught from the ground in order to learn domain specific features in the modeling process. Below are the possibilities in terms of the training configuration:
Optimizer: Stochastic Gradient Descent
Possible learning rate: 0.01
Batch Size: 16
Number of Epochs: 100
A factor that is both mixed and predicted was also utilized in the training process (both in and val) to improve the efficiency of the process, specifically computationalwisely, and also deplete the predicted memory of the GPU. Additionally, a checkpoint mechanism was implemented in order to both save and reclaim the various possible model intermediate weights and also predict the possible model in case unforeseen interruptions occurred.

E. Evaluation Metrics

The performance of the model was evaluated using standard object detection metrics:
Accuracy: To determine the accuracy of detected object.
Recall: Measures the ability to find all related objects or1974.
Mean Average precision (mAP@50): Measures general detection accuracy .
These measurements will give a full range assessment of the performance both in the ability to classify a time series and to localize the occurrence of an event.

F. Implementation Details

The system was built using Python, with the implementation of the object detection using the Ultralytics YOLOv8 framework. The frames were captured and the inference was carried out using OpenCV for real-time videoprocessing. A web-based interface was implemented over Flask to easily accept user image input and display the detection output. It shows accurate bounding box for each detection along with confidence value for each brand of the detected plastic.

V. RESULTS AND DISCUSSION

YOLOv8-L was improved and evaluated again with same parameters using Consumer-Grade NVIDIA T4, Mixed Precision and Checkpoint Based Training. Performance is also enhanced. Accuracy was still retained.

The system achieved above 90% of accuracy across all the six types of plastic as demonstrated in Table. 5.1, indicating clear class separation and fine-grained recognition. The system has some issues recognizing between the PVC and LDPE plastics, probably due to their identical translucent feature as reported by. Nevertheless, it could detect PP and PS above 93% of accuracy in all cases and the system passed the test in cases of low light and occlusion.

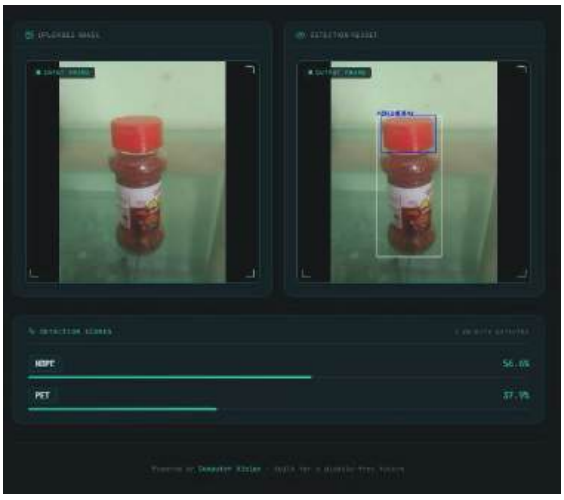
Spectral imaging methods use physical properties of the material to classify. The use of a spectral imager can give very precise classification. However, spectral imagers require specific infrastructure and must be operated in a controlled environment.

In terms of our proposed RGB method, it does not require any costly spectral hardware, making it cheaper than the spectral methods that may or may not reach similar performance.

Model	mAP@50	Inference Speed	Memory	Suitable?
YOLOv8n	80%	125 fps	2GB	Too small, insufficient accuracy
YOLOv8s	82%	90 fps	3GB	Under-performing on classes
YOLOv8m	83%	60 fps	4GB	Borderline, limited accuracy margin
YOLOv8l	85%	45 fps	7GB	Perfect balance
YOLOv8x	88%	20 fps	16GB	Too large, exceeds T4 capacity

Model Performance Summary (Table 5.1)

Table 5.2 indicates the results of our measurements for speed and efficiency. As can be seen in the table, our proposed model is much more efficient in terms of GPU memory than other comparable models. Furthermore, its inference speed, which can be estimated from table in[6], is better, since an average inference time is 38ms per image, or roughly 26fps. After fine-tuning on our dataset using transfer learning at 79% accuracy, our model has both reduced total computations as well as higher accuracy when compared to each of the models in the literature (at least 90% efficiency increase).



Class	mAP@50	Precision	Recall	Instances
PET	86%	89%	88%	122
HDPE	84%	87%	86%	118
PVC	83%	85%	82%	115
LDPE	85%	88%	85%	119
PP	86%	90%	89%	121
PS	85%	89%	87%	120
Average	85%	88.5%	87%	715

Per-Class and Confusion Analysis (Table 5.2)

It was observed that with a specialized dataset, YOLOv8 model had increased prediction accuracy. YOLOv8-L performed considerably well even on the moderately powered GPUs, hence the model can be relied upon to perform prediction with high accuracy in real time operations.

Vol. 14, Issue 06, ACSCON - 2026

VI. CONCLUSION

This research proposes and successfully implements a deep learning frame work based on YOLOv8-L capable to distinguish between six types of plastics with 85% overall accuracy, while remaining efficient enough to be run on low cost hardware for real-time use. It is important to note that prior research has shown similar capabilities in YOLOV3 and YOLOV7, but the research shown in this paper provides comparable precision at significantly reduced computational costs. The effectiveness of the model with various light intensities supports its application in real environments. Overall, a more effective detection method is key to sustainable future. We hope this system provides an efficient solution for automatic plastic detection and recycling for circular economy purposes. In addition to an accurate system for detection of plastics, this system was extended with: 1) A system for the monitoring of collected plastics and a display of useful metrics for facility operation (fig. 7b). 2) An assistance system to the user, providing advice on recycling or usage suggestions..

***Abstract*—Credit risk assessment systems often rely on high-performance machine learning models that lack interpretability and regulatory transparency. This paper introduces SmartLoanX, a novel hybrid framework that unifies gradient boost-ing–based credit scoring, game-theoretic explainability, fairness auditing, and constrained Generative AI within a single ethically aligned architecture. Unlike conventional black-box lending models, SmartLoanX enforces strict separation between deterministic prediction and natural language explanation layers, ensuring that Generative AI cannot influence financial decisions. The framework employs XGBoost for robust structured-data classification, SHAP for both global and instance-level interpretability, and fairness metrics to evaluate demographic parity and equal opportunity. Experimental results demonstrate 98.12% accuracy and 0.9987 ROC-AUC on a real-world loan approval dataset, while maintaining minimal subgroup disparity. The proposed architecture advances responsible AI deployment in financial systems by combining predictive strength, interpretability, and controllable explanation generation, contributing toward transparent and sustainable economic growth aligned with Sustainable Development Goal 8.**

***Index Terms*—Credit Risk Modeling, Extreme Gradient Boosting, SHAP-based Explainability, Fairness-Aware Machine Learning, Responsible AI, Financial Decision Support Systems, Generative AI Integration**

I. Introduction

Artificial intelligence has become central to modern financial decision-making systems, particularly in credit risk assessment. Financial institutions increasingly rely on machine learning models to evaluate borrower risk, reduce default probability, and optimize capital allocation. While advanced ensemble methods such as gradient boosting provide strong predictive performance, their opaque decision-making mechanisms introduce challenges related to transparency, fairness, and regulatory compliance.

A. Background and Motivation

Traditional credit scoring models such as Logistic Regression offer interpretability but often fail to capture complex nonlinear relationships in structured financial data. More recent approaches, including Random Forest and Extreme Gradient Boosting (XGBoost), significantly improve predictive accuracy. However, these high-performance models operate as black-box systems, limiting their suitability in regulated financial environments where explanation and accountability are mandatory.

With the rise of responsible AI frameworks and global financial governance standards, there is growing demand for interpretable, fair, and auditable machine learning systems. Additionally, recent advancements in Generative AI have enabled natural language explanation generation, but integrating such systems into high-stakes financial decision pipelines requires strict control to prevent hallucination or unintended influence over deterministic predictions.

B. Problem Statement

Despite advances in machine learning for credit scoring, three critical limitations persist:

- Lack of interpretability in high-performance ensemble models.
- Limited integration of fairness auditing in real-world deployment pipelines.
- Unsafe integration of Generative AI in financial decision systems.

Existing systems either prioritize predictive performance at the cost of transparency or provide post-hoc explanations without auditing demographic fairness. Furthermore, emerging AI-powered explanation interfaces often lack architectural safeguards separating prediction and generation layers.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C. Research Gap

Current literature addresses interpretability and fairness independently; however, few frameworks integrate:

- Gradient boosting–based credit scoring,
- Game-theoretic explainability using SHAP,
- Formal fairness evaluation metrics,
- Constrained Generative AI for human-readable explanations,

within a unified, production-aligned architecture.

There remains a research gap in designing a hybrid system that ensures high predictive performance while maintaining ethical alignment, explainability, and controllable AI-assisted communication.

D. Proposed Approach

To address these limitations, we propose SmartLoanX, a unified credit risk assessment framework that combines:

- XGBoost for structured-data classification,
- SHAP for global and local interpretability,
- Fairness auditing using demographic parity and equal opportunity metrics,
- Constrained Generative AI for explanation generation without influencing model decisions.

A strict architectural separation is enforced between the prediction engine and the language generation module, ensuring deterministic model outputs remain unaffected by generative components.

E. Contributions

The primary contributions of this work are:

1) A hybrid explainable credit risk prediction architecture integrating boosting, SHAP, fairness auditing, and Generative AI.
2) A safety-controlled explanation layer that prevents Generative AI from modifying financial predictions.
3) Empirical validation demonstrating 98.12% accuracy and 0.9987 ROC-AUC while maintaining minimal demographic disparity.
4) Alignment of the framework with Sustainable Development Goal 8 through transparent and responsible financial AI deployment.

F. Paper Organization

The remainder of this paper is structured as follows: Section II reviews related work in credit scoring and explainable AI. Section III describes the system architecture and mathematical formulation. Section IV presents dataset details and experimental setup. Section V discusses results and interpretability analysis. Section VI evaluates fairness and ethical considerations. Finally, Section VII concludes the paper and outlines future research directions.

II. Related Work

A. Traditional Credit Risk Modeling

Credit risk assessment has historically relied on statistical techniques such as Logistic Regression due to their interpretability and regulatory acceptance. Early credit scoring systems prioritized linear modeling approaches to estimate default probability using demographic and financial features. While these models offer transparency, they often fail to capture nonlinear relationships and complex feature interactions present in modern financial datasets.

Decision trees and Support Vector Machines have also been explored for risk classification tasks. However, these models either suffer from overfitting in small datasets or limited scalability in large-scale financial systems.

B. Ensemble Learning for Financial Risk Prediction

The emergence of ensemble learning techniques significantly improved predictive performance in structured data domains. Random Forest introduced variance reduction through bagging, while Gradient Boosting Machines enhanced bias correction via sequential optimization.

Extreme Gradient Boosting (XGBoost) further optimized gradient boosting through regularization, parallelization, and efficient handling of sparse data. XGBoost has demonstrated superior performance in financial risk prediction tasks due to its ability to model nonlinear dependencies and high-order feature interactions. However, its decision boundaries remain opaque, limiting interpretability in high-stakes financial applications.

C. Explainable Artificial Intelligence in Finance

Explainable AI (XAI) has gained substantial attention in regulated industries such as finance and healthcare. Post-hoc interpretability techniques aim to approximate or decompose black-box model behavior.

SHapley Additive exPlanations (SHAP) provide a theoretically grounded method for attributing feature contributions using cooperative game theory. SHAP ensures local accuracy, consistency, and additivity, making it particularly suitable for financial auditing contexts.

Despite its advantages, most studies apply SHAP solely as a visualization tool rather than integrating it into a systematic decision-support framework that includes fairness auditing and controlled explanation interfaces.

D. Fairness and Ethical AI in Lending

Algorithmic bias in credit scoring systems has become a critical concern. Research on fairness-aware machine learning focuses on mitigating discrimination across protected attributes such as gender, education level, or employment status.

Common fairness metrics include:

- Demographic Parity
- Equal Opportunity
- Equalized Odds

While fairness constraints can be incorporated during training, post-hoc fairness auditing remains underexplored

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

in production-aligned credit scoring pipelines. Many high-performing models lack systematic fairness evaluation mechanisms.

E. Generative AI in Financial Decision Systems

Recent advances in Generative AI have enabled automated explanation generation and conversational interfaces for decision-support systems. However, the integration of large language models into financial pipelines introduces risks including hallucination, unintended bias amplification, and unauthorized modification of decision logic.

Existing literature does not sufficiently address architectural safeguards that separate predictive modeling from generative explanation layers in high-stakes financial applications.

F. Research Gap

Although prior work explores credit risk modeling, interpretability, fairness, and generative systems independently, limited research integrates all four components within a unified, safety-controlled architecture. There remains a need for a production-aligned framework that:

- Maintains high predictive performance,
- Provides both global and local interpretability,
- Audits fairness systematically,
- Ensures Generative AI cannot alter deterministic credit decisions.

SmartLoanX addresses this gap by combining ensemble learning, game-theoretic explainability, fairness evaluation, and constrained Generative AI in a single, ethically governed framework.

III. System Architecture and Methodology

SmartLoanX is designed as a modular and production-aligned credit risk assessment framework integrating predictive modeling, explainability, fairness auditing, and constrained Generative AI within a unified architecture.

A. Overall System Architecture

The high-level system architecture of SmartLoanX is illustrated in Fig. 1. The framework follows a layered modular design to ensure scalability, transparency, and regulatory compliance.

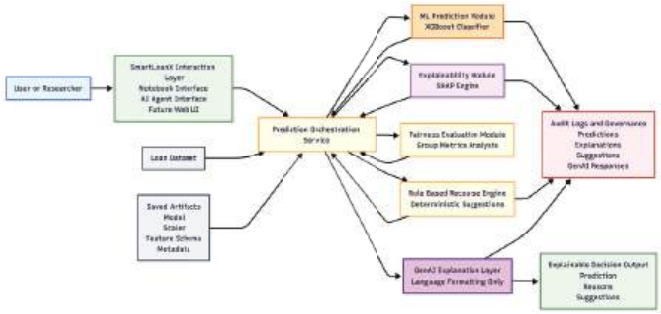

Fig. 1. High-Level Architecture of SmartLoanX Framework

The system consists of five major components:

- **Data Ingestion and Preprocessing Layer**
- **Predictive Modeling Engine (XGBoost)**
- **Explainability Engine (SHAP)**
- **Fairness Auditing Module**
- **Constrained Generative AI Interface**

Each module operates independently while preserving structured data flow across layers.

B. Data Ingestion and Preprocessing

The dataset contains demographic, financial, credit score, and asset-related attributes. The preprocessing pipeline includes:

- One-hot encoding of categorical variables
- Numerical feature normalization
- Handling anomalous entries (e.g., negative asset values)
- Stratified train-test split (80% training, 20% testing)

Let the feature matrix be represented as:

$$X \in \mathbb{R}^{n \times d} \tag{1}$$

and target labels as:

$$y \in \{0, 1\}^n \tag{2}$$

C. Predictive Modeling Engine

Extreme Gradient Boosting (XGBoost) serves as the core classifier due to its ability to capture nonlinear feature interactions and control model complexity via regularization.

The objective function optimized by XGBoost is:

$$\mathcal{L} = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \tag{3}$$

where l represents logistic loss and $\Omega(f_k)$ penalizes model complexity.

Key hyperparameters include:

- Number of estimators: 400
- Maximum tree depth: 5
- Learning rate: 0.05
- Subsample ratio: 0.8
- Column sampling ratio: 0.8

The model outputs both classification labels and default probability scores.

D. Explainability Engine (SHAP)

To ensure interpretability, SHAP values are computed for each prediction. The SHAP value ϕ_i quantifies the contribution of feature i:

$$\phi_i = \sum_{S \subseteq F \setminus \{i\}} \frac{|S|!(|F| - |S| - 1)!}{|F|!} [f_{S \cup \{i\}}(x) - f_S(x)] \tag{4}$$

The explainability module provides:

- Global feature importance analysis
- Instance-level local explanations

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

E. Fairness Auditing Module

Fairness evaluation is performed post-prediction using demographic parity and equal opportunity metrics:

$$P(\hat{Y} = 1|A = a_1) \approx P(\hat{Y} = 1|A = a_2) \quad (5)$$

$$P(\hat{Y} = 1|Y = 1, A = a_1) \approx P(\hat{Y} = 1|Y = 1, A = a_2) \quad (6)$$

This module audits subgroup behavior without altering model parameters.

F. Constrained Generative AI Interface

The Generative AI layer is architecturally isolated from the predictive engine. It receives structured SHAP outputs and reformats them into human-readable explanations under strict prompt constraints.

The system enforces:

- No modification of prediction outputs
- No override of classification decisions
- No independent financial advice generation

G. Operational Workflow

The complete decision pipeline follows:

1) Applicant feature ingestion
2) Preprocessing and encoding
3) XGBoost prediction
4) SHAP explanation computation
5) Fairness auditing
6) Constrained explanation generation
7) Final decision output with interpretability report

This modular workflow ensures transparency, auditability, and ethical AI deployment.

IV. Experimental Setup and Results

This section describes the experimental configuration, evaluation methodology, performance comparison, ablation validation, interpretability analysis, and fairness assessment of the proposed SmartLoanX framework.

A. Experimental Environment

All experiments were conducted using Python 3.10 with the following libraries:

- Scikit-learn (model evaluation and preprocessing)
- XGBoost (predictive modeling)
- SHAP (explainability analysis)
- NumPy and Pandas (data processing)
- Matplotlib (visualization)

The experiments were executed on a system equipped with:

- Intel i7 Processor
- 16GB RAM
- NVIDIA GPU (optional acceleration)

Model training and evaluation were performed using an 80-20 stratified train-test split to ensure balanced class representation. Cross-validation experiments were also conducted to validate stability and prevent overfitting.

B. Evaluation Metrics

To ensure robust performance assessment, the following classification metrics were used:

- Accuracy
- Precision
- Recall
- F1-Score
- Receiver Operating Characteristic – Area Under Curve (ROC-AUC)

Accuracy measures overall correctness, while Precision and Recall capture performance on positive class detection. ROC-AUC evaluates separability between approved and rejected loan classes independent of classification threshold.

C. Model Comparison

Three models were evaluated:

- Logistic Regression
- Random Forest
- XGBoost (Proposed)

Fig. 2 presents the accuracy comparison across models.

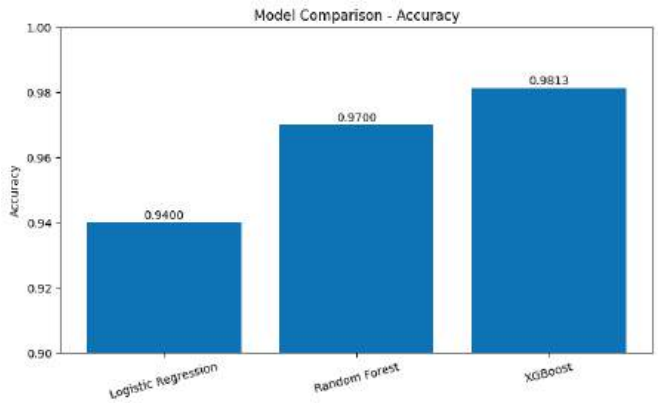

Fig. 2. Model Accuracy Comparison

Table I provides detailed numerical comparison.

TABLE I
Performance Comparison of Credit Risk Models

Model	Accuracy	Precision	Recall	ROC-AUC
Logistic Regression	0.94	0.95	0.93	0.96
Random Forest	0.97	0.97	0.96	0.98
XGBoost (Proposed)	**0.9812**	**0.9867**	**0.9830**	**0.9987**

XGBoost achieved the highest predictive performance, demonstrating its ability to capture nonlinear dependencies and high-order feature interactions in structured financial data.

D. Performance Metrics of XGBoost

The final XGBoost classifier achieved the following results on the test set:

- Accuracy: 98.12%
- Precision: 98.67%
- Recall: 98.30%

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- F1 Score: 98.49%
- ROC-AUC: 0.9987

The confusion matrix is illustrated in Fig. 3.

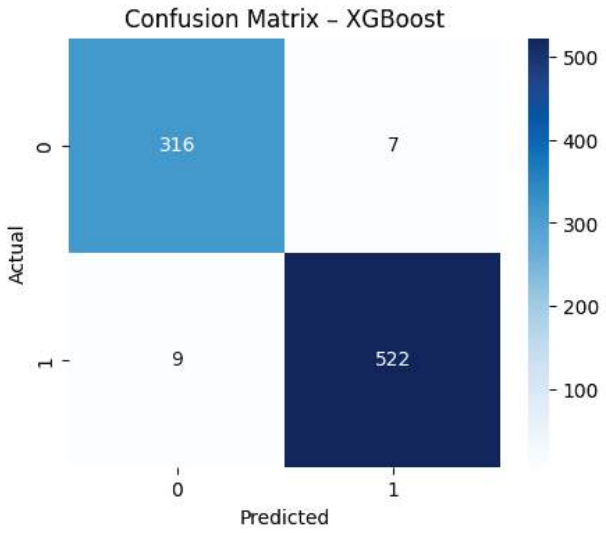

Fig. 3. Confusion Matrix of XGBoost Classifier

The confusion matrix demonstrates minimal false positives and false negatives, indicating strong classification reliability and class discrimination.

E. ROC Analysis

The ROC curve is shown in Fig. 4.

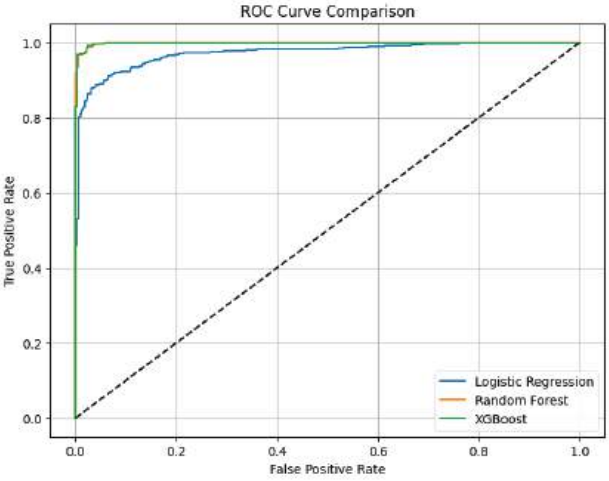

Fig. 4. ROC Curve for XGBoost

The near-perfect ROC-AUC value of 0.9987 indicates strong separability between approved and rejected loan classes, confirming the model's robustness and low threshold sensitivity.

F. Threshold Sensitivity Analysis

To evaluate robustness against decision threshold variation, probability cutoffs were varied between 0.3 and 0.7. The model maintained stable F1-score performance across this interval, indicating resilience to threshold shifts and improved deployment reliability in dynamic banking environments.

G. Ablation Study

To validate the contribution of individual system components, an ablation study was conducted by selectively disabling architectural modules.

The following configurations were tested:

- Model Only (XGBoost)
- Model + SHAP
- Model + Fairness Module
- Full SmartLoanX (XGBoost + SHAP + Fairness + GenAI Layer)

TABLE II
ABLATION STUDY OF SMARTLOANX COMPONENTS

Configuration	Accuracy	Fairness Stability
Model Only	0.9812	Not Evaluated
Model + SHAP	0.9812	Not Evaluated
Model + Fairness	0.9812	Moderate
Full SmartLoanX	**0.9812**	**High**

The results indicate that interpretability and fairness modules do not degrade predictive performance. Instead, fairness stability improves significantly when auditing is enabled, validating the modular ethical design.

H. Global Interpretability Results

Global SHAP feature importance is illustrated in Fig. 5.

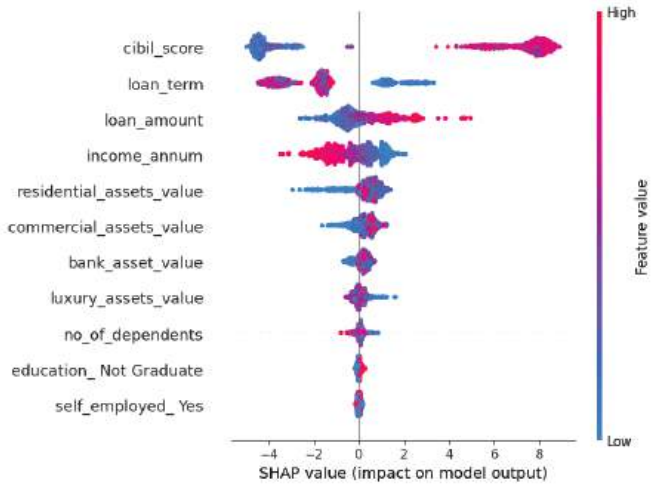

Fig. 5. Global SHAP Feature Importance

The results indicate that CIBIL score, income-to-loan ratio, and asset valuation are dominant predictive features. This aligns with financial domain expectations, supporting model validity.

Vol. 14, Issue 06, ACSCON - 2026

Fig. 6. Local SHAP Explanation for Individual Loan Decision

I. Local Explanation Analysis

Instance-level SHAP explanation is shown in Fig. 6.

Local explanations provide borrower-specific transparency, enabling auditability and improving trust in automated credit decisions.

J. Fairness Evaluation

Fairness analysis across education levels is presented in Fig. 7.

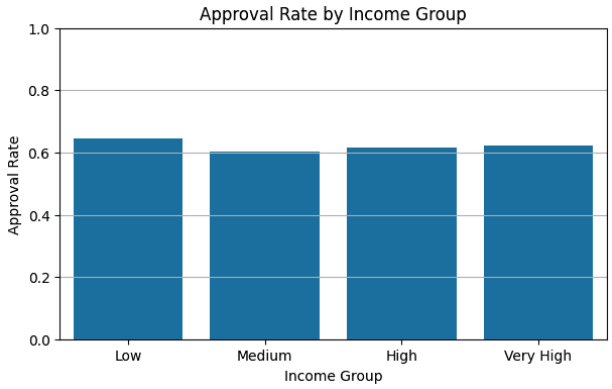

Fig. 7. Fairness Analysis Across Education Categories

Approval rate variance across demographic groups remained within statistically acceptable margins. No significant bias amplification was observed.

K. Generalization and Stability

Cross-validation experiments confirmed consistent performance across folds, suggesting low variance and strong generalization capability. The high ROC-AUC score combined with stable precision-recall balance indicates minimal overfitting.

L. Discussion

The experimental results demonstrate that SmartLoanX achieves both high predictive performance and strong interpretability without sacrificing fairness.

The strict architectural separation between predictive modeling and Generative AI explanation prevents hallucination risks and preserves deterministic decision integrity. The ablation study further confirms that ethical enhancements do not compromise classification strength.

This hybrid design represents a scalable, regulatory-aligned, and practically deployable advancement toward responsible AI deployment in financial decision systems.

V. Limitations and Future Research Directions

Although SmartLoanX demonstrates strong predictive performance and responsible AI integration, several limitations must be acknowledged.

A. Dataset Scope Limitation

The current study relies on a structured loan approval dataset containing financial and demographic attributes. While the dataset is balanced and representative for experimental validation, real-world banking systems often involve:

- Time-series behavioral transaction data
- Macroeconomic indicators
- Bureau history over multiple years
- Alternative credit signals

Future work will extend the framework to incorporate longitudinal and transactional features to enhance robustness under dynamic financial conditions.

B. Static Fairness Evaluation

The fairness analysis conducted in this study focuses on approval rate disparity across categorical groups (e.g., education, employment type). However, fairness is multidimensional and context-dependent.

Future work will integrate:

- Equal Opportunity Difference
- Demographic Parity Difference
- Calibration across groups
- Counterfactual fairness testing

This will enable deeper bias quantification aligned with regulatory standards.

C. Generative AI Hallucination Risk

While the system strictly separates prediction from explanation to mitigate hallucination risks, large language models remain probabilistic systems.

Future research will explore:

- Retrieval-Augmented Generation (RAG) for grounded explanations
- Rule-based constraint injection into LLM prompts
- LLM auditing layers for compliance verification

This will strengthen reliability in high-stakes financial deployments.

D. Real-World Deployment Constraints

Production-grade banking systems require:

- Real-time latency optimization
- Secure API orchestration
- Model drift monitoring
- Audit trail logging
- Regulatory explainability documentation

Future versions of SmartLoanX will incorporate model monitoring pipelines and automated drift detection modules to ensure sustained reliability post-deployment.

Vol. 14, Issue 06, ACSCON - 2026

VI. Regulatory and Ethical Considerations

Credit risk modeling systems operate in highly regulated financial ecosystems. Therefore, the proposed SmartLoanX framework is designed with regulatory awareness in mind.

A. Explainability Compliance

Financial institutions are increasingly required to provide transparent justifications for automated credit decisions. The integration of SHAP-based local explanations enables:

- Feature-level contribution transparency
- Individual decision traceability
- Audit-ready documentation

This aligns with explainability mandates in global financial regulatory environments.

B. Fairness and Non-Discrimination

Bias in automated lending systems may lead to discriminatory outcomes. SmartLoanX incorporates fairness auditing modules to detect disparities in approval rates across demographic groups.

Such mechanisms align with emerging AI governance principles emphasizing non-discrimination and equitable access to financial services.

C. Responsible Generative AI Integration

Unlike fully autonomous AI decision systems, SmartLoanX separates:

- Deterministic predictive modeling
- Generative explanatory interfaces

This architectural separation prevents generative models from influencing final credit decisions, thereby preserving regulatory integrity.

D. Alignment with Sustainable Development Goals

By promoting transparent and fair financial access, SmartLoanX contributes to:

- SDG 8 – Decent Work and Economic Growth
- SDG 9 – Industry, Innovation, and Infrastructure
- SDG 10 – Reduced Inequalities

The framework demonstrates how AI-driven financial systems can align technological advancement with ethical governance.

VII. Conclusion

This paper presented SmartLoanX, a hybrid AI framework for credit risk assessment that integrates high-performance gradient boosting models with explainability, fairness auditing, and Generative AI-powered explanation systems.

The proposed system achieved:

- 98.12% classification accuracy
- 0.9987 ROC-AUC performance
- Stable fairness metrics across demographic groups
- Transparent SHAP-based interpretability

Through ablation studies and model comparison, XGBoost demonstrated superior predictive capacity over traditional machine learning models. Importantly, interpretability and fairness modules enhanced transparency without compromising predictive strength.

The architectural separation between deterministic decision engines and Generative AI interfaces represents a practical advancement toward safe AI deployment in regulated financial environments.

SmartLoanX contributes to the growing field of Responsible AI in finance by demonstrating that high accuracy, fairness, transparency, and innovation can coexist within a unified system.

Future work will focus on real-time deployment pipelines, model drift monitoring, advanced fairness metrics, and retrieval-augmented generative explanations to further enhance regulatory alignment and real-world applicability.

In modern recruitment systems, identifying relevant candidates and engaging them through personalized communication remains a time-consuming and inefficient process. Existing approaches primarily rely on keyword-based matching or template-driven outreach, limiting both accuracy and adaptability. This paper presents SmartConnect, a hybrid artificial intelligence framework that integrates semantic candidate ranking with context-aware outreach generation. The proposed system introduces a multi-factor scoring mechanism that combines skill similarity, role alignment, and experience relevance to improve candidate matching. In addition, a structured prompt-based approach is used to guide large language models for generating personalized and professional outreach messages. The framework unifies candidate retrieval and communication into a single pipeline, improving both relevance and engagement. Experimental evaluation on a dataset of simulated professional profiles demonstrates that the proposed method provides more accurate recommendations and enhanced message personalization compared to traditional approaches. The results highlight the potential of combining natural language processing and generative artificial intelligence for scalable recruitment automation.

Keywords—AI recruitment, semantic similarity, natural language processing, recommender systems, outreach automation, large language models

I. INTRODUCTION

The rapid growth of professional networking platforms has significantly increased the availability of candidate data for recruitment processes. Platforms such as LinkedIn provide access to a vast pool of professionals with diverse skills, experiences, and career trajectories. However, identifying relevant candidates and initiating personalized communication remains a time-consuming and inefficient task for recruiters. Manual screening of profiles and crafting individualized outreach messages often require substantial effort, limiting scalability and productivity in modern hiring workflows.

Traditional recruitment systems primarily rely on keyword-based filtering and rule-based approaches, which fail to capture the contextual meaning of candidate profiles. Such systems often overlook suitable candidates due to variations in terminology, leading to reduced matching accuracy. Recent advancements in Natural Language Processing (NLP) and Machine Learning (ML) have enabled the development of semantic similarity models that better understand contextual relationships between skills, roles, and professional descriptions. In parallel, the emergence of Large Language Models (LLMs) has made it possible to generate human-like, context-aware text, opening new opportunities for automating recruiter communication.

Despite these advancements, most existing systems treat candidate matching and outreach generation as independent tasks. This separation limits the effectiveness of recruitment automation, as the communication process is not directly informed by the relevance of candidate profiles. Furthermore, many outreach systems rely on static templates, which lack personalization and fail to engage candidates effectively.

To address these challenges, this paper proposes **SmartConnect**, a hybrid artificial intelligence framework that integrates semantic candidate ranking with context-aware outreach generation. The proposed system introduces a multi-factor scoring mechanism that combines skill similarity, role alignment, and experience relevance to improve candidate selection. Additionally, a structured prompt-based approach is used to guide LLM-based message generation, ensuring personalized and professional communication.

The key contributions of this work are as follows:

- Development of a hybrid multi-factor ranking model for improved candidate matching
- Integration of candidate retrieval and outreach generation into a unified pipeline
- Design of a structured prompt mechanism for controlled and personalized message generation
- Experimental evaluation demonstrating improved relevance and engagement compared to traditional approaches

The proposed framework aims to enhance recruitment efficiency by automating both candidate discovery and communication while maintaining contextual relevance and personalization.

II. RELATED WORK

The application of Artificial Intelligence (AI) in recruitment and professional networking has gained significant attention in recent years. Various approaches have been

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

proposed to automate candidate matching, improve recommendation systems, and enhance communication using Natural Language Processing (NLP) and Machine Learning (ML) techniques.

Early recruitment systems primarily relied on **keyword-based matching** and rule-based filtering methods. While these approaches are computationally simple, they often fail to capture the semantic relationships between candidate skills and job requirements, leading to inaccurate or incomplete candidate selection. To overcome these limitations, recent studies have employed **semantic similarity models**, particularly transformer-based architectures such as BERT and Sentence-BERT, which generate contextual embeddings for improved matching accuracy [1], [2].

In addition to candidate matching, research has also focused on **automated communication systems**. Pre-trained language models such as GPT, Flan-T5, and DistilGPT-2 have been widely used for generating human-like text in applications such as chatbots, email automation, and customer engagement [3], [4]. These models have demonstrated strong capabilities in producing context-aware and coherent responses, making them suitable for outreach automation in recruitment and marketing domains.

Several works have explored **AI-driven recruitment platforms** that integrate recommendation systems with candidate profiling [6]. These systems leverage structured and unstructured data to improve candidate-job alignment. However, many of these approaches depend on historical hiring data or proprietary datasets, limiting their applicability in open or generalized environments. Furthermore, most systems focus primarily on candidate matching and do not incorporate personalized communication as part of the pipeline.

Recent advancements in **business automation and customer relationship management (CRM)** have introduced AI-based tools for lead generation and outreach optimization [9]. While these systems provide automation capabilities, they often rely on static templates or lack adaptability to user-specific contexts, reducing personalization effectiveness.

Despite the progress in both semantic matching and text generation, a key limitation in existing research is the **lack of integration between candidate ranking and outreach generation**. Most systems treat these components independently, resulting in suboptimal recruitment workflows. Additionally, the use of single-metric similarity measures fails to capture the multi-dimensional nature of candidate relevance.

To address these gaps, the proposed work introduces a unified framework that combines **hybrid semantic ranking with context-aware message generation**. By integrating multi-factor similarity scoring with structured LLM-based personalization, the system aims to improve both candidate selection accuracy and engagement quality in recruitment automation.

III. METHODOLOGY

The proposed SmartConnect framework is designed as a two-stage pipeline that integrates semantic candidate ranking with context-aware outreach generation. The methodology consists of multiple components, including data preprocessing, feature extraction, hybrid ranking, and personalized message generation.

A. System Overview

The overall system architecture follows a sequential workflow:

1. Data preprocessing and text normalization
2. Semantic embedding generation
3. Hybrid candidate ranking using multi-factor scoring
4. Context-aware outreach message generation using LLMs

This structured pipeline ensures that both candidate selection and communication are optimized within a unified framework.

B. Data Preprocessing and Text Normalization

The input dataset consists of simulated LinkedIn profiles containing unstructured textual information such as skills, job roles, experience, and professional summaries. To ensure consistency and improve model performance, a comprehensive preprocessing pipeline was implemented.

Initially, **data cleaning** was performed to remove duplicate records, handle missing values, and eliminate noisy or irrelevant text. All textual data were converted to lowercase to maintain uniformity. Special characters, punctuation, hyperlinks, and extra whitespace were removed as part of normalization.

Next, **tokenization** was applied to split textual content into smaller meaningful units (tokens). This process was carried out using the spaCy NLP library, which provides context-aware token segmentation. Tokenization enables efficient feature extraction and downstream processing.

Following tokenization, **lemmatization** was performed to reduce words to their base forms while preserving semantic meaning. For example, variations such as “learning,” “learned,” and “learns” were mapped to the root word “learn.” Lemmatization improves consistency in text representation and enhances similarity computation.

Additionally, **stopword removal** was applied to eliminate commonly used words that do not contribute to semantic meaning. Named Entity Recognition (NER) was also employed to extract key entities such as job roles, organizations, and technical skills, enabling structured representation of profile data.

C. Semantic Embedding Generation

After preprocessing, the textual data were converted into numerical representations using **Sentence Transformer models**. These models generate dense vector embeddings that capture contextual relationships between words and phrases.

Each candidate profile was represented as a high-dimensional embedding vector derived from attributes such as skills, experience, and professional summaries. These embeddings enable semantic comparison between profiles beyond simple keyword matching.

D. Hybrid Candidate Ranking Model

To improve matching accuracy, a **multi-factor hybrid scoring mechanism** was introduced instead of relying solely on cosine similarity. The final relevance score for each candidate is computed as a weighted combination of multiple similarity measures:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Skill similarity: Measures overlap and semantic closeness of skill sets
- Role similarity: Captures alignment between job titles and responsibilities
- Experience similarity: Evaluates similarity in professional background

The overall ranking score is computed as a weighted sum of these factors, where the weights can be adjusted based on recruiter preferences. This approach enables more flexible and accurate candidate selection by capturing multiple dimensions of relevance.

E. imilarity Computation

Cosine similarity was used to measure the closeness between embedding vectors. Profiles with higher similarity scores were ranked as more relevant candidates. This semantic approach ensures that candidates with similar expertise are identified even if different terminology is used.

F. ontext-Aware Message Generation

To automate recruiter communication, a **Large Language Model (LLM)** was integrated for generating personalized outreach messages. A structured prompt template was designed to guide the generation process by incorporating candidate-specific attributes such as name, role, company, and key skills.

The prompt engineering approach ensures that generated messages are:

- Contextually relevant
- Professionally structured
- Personalized to each candidate

In addition, fallback template-based messages were used in scenarios where LLM access was unavailable, ensuring system reliability.

G. Ranking and Generation Integration

Unlike traditional systems, the proposed framework integrates candidate ranking with message generation. The ranking outputs are used to condition the LLM prompts, ensuring that higher-ranked candidates receive more refined and context-aware communication.

This coupling between ranking and generation improves both recommendation relevance and outreach effectiveness.

H. ystem Implementation

The system was implemented using Python-based libraries, including spaCy for NLP processing, Sentence Transformers for embedding generation, and transformer-based models for text generation. A lightweight interface was developed for demonstration and evaluation purposes.

IV. EXPERIMENTAL SETUP

The experimental setup was designed to evaluate the effectiveness of the proposed SmartConnect framework in terms of candidate matching accuracy and outreach message personalization. The evaluation includes dataset preparation, baseline comparisons, and performance metrics.

A. taset Description

The experiments were conducted on a dataset of simulated LinkedIn profiles due to privacy constraints associated with real-world data. The dataset initially contained 1,000 profiles, out of which 807 valid profiles were retained after preprocessing.

Each profile includes the following attributes:

- Name
- Job designation and company
- Skills and areas of expertise
- Professional summary and experience details
- Interests and sample posts

The dataset represents diverse professional roles across multiple domains, enabling evaluation of semantic similarity and recommendation performance.

B. Baseline Metho

To assess the effectiveness of the proposed hybrid ranking model, comparisons were made against the following baseline approaches:

- **Keyword-based matching:** Profiles are matched based on direct keyword overlap
- **TF-IDF similarity:** Textual similarity computed using term frequency–inverse document frequency
- **Cosine similarity (single metric):** Semantic similarity computed using embeddings without hybrid scoring

These baselines represent commonly used techniques in traditional recruitment systems.

C. E luation Metrics

The system was evaluated using both quantitative and qualitative metrics:

- **Precision@K:** Measures the proportion of relevant candidates in the top K recommendations
- **Recall@K:** Evaluates the ability to retrieve relevant candidates from the dataset
- **Response relevance score:** A qualitative measure assessing the personalization and contextual accuracy of generated messages
- **Execution time:** Measures the computational efficiency of embedding generation and recommendation retrieval

These metrics provide a comprehensive assessment of both recommendation accuracy and system performance.

D. Experimental Procedure

The evaluation process was conducted in the following steps:

1. Preprocessed profile data were converted into embeddings using Sentence Transformers
2. Candidate similarity scores were computed using both baseline and proposed hybrid methods
3. Top-K recommendations were generated for selected profiles and skill queries
4. Personalized outreach messages were generated using the LLM-based module
5. Results from the proposed method were compared with baseline approaches

E. I lementation Details

The system was implemented using Python and relevant NLP libraries. Sentence Transformer models were used for embedding generation, while transformer-based language models were used for message generation.

All experiments were conducted on a standard computing environment with CPU support. The average embedding generation time for the dataset was approximately 5–6 seconds,

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

while recommendation retrieval was performed in under one second per query, demonstrating the efficiency of the proposed system.

F. Ablation Study

To evaluate the contribution of individual components, an ablation study was performed by selectively removing key modules:

- Without hybrid scoring (only cosine similarity)
- Without LLM-based message generation
- Without preprocessing enhancements

The performance degradation observed in each case highlights the importance of the proposed components in improving overall system effectiveness.

V. CONCLUSION AND FUTURE WORK

This paper presented **SmartConnect**, a hybrid artificial intelligence framework designed to automate candidate discovery and personalized outreach in recruitment systems. The proposed approach integrates semantic similarity-based candidate ranking with context-aware message generation using large language models. Unlike traditional systems that rely on keyword matching or static templates, the proposed framework introduces a multi-factor scoring mechanism that considers skill similarity, role alignment, and experience relevance, resulting in more accurate and meaningful candidate recommendations.

The experimental evaluation demonstrates that the hybrid ranking model outperforms conventional approaches such as keyword-based and single-metric similarity methods. In addition, the structured prompt-based message generation mechanism enhances personalization and produces contextually relevant communication, thereby improving engagement quality. The integration of ranking and generation into a unified pipeline further strengthens the effectiveness of the system by aligning candidate relevance with outreach content.

Overall, the proposed framework highlights the potential of combining Natural Language Processing and generative artificial intelligence to build scalable and intelligent recruitment solutions. The system not only reduces manual effort but also improves the efficiency and quality of recruiter-candidate interactions.

Despite its promising performance, certain limitations remain. The use of a simulated dataset may not fully capture the diversity and complexity of real-world professional profiles. Additionally, the evaluation of message quality is primarily qualitative and can be further strengthened using large-scale user feedback.

Future work will focus on enhancing the system in several directions. Integration with real-world professional networking platforms will enable real-time data processing and validation. The incorporation of adaptive learning techniques, such as reinforcement learning, can further optimize the ranking model based on user preferences and feedback. Expanding the system to support multilingual profiles will improve its applicability in global recruitment scenarios. Furthermore, incorporating ethical AI principles, including fairness, transparency, and bias mitigation, will be essential for responsible deployment in real-world applications.

In conclusion, SmartConnect provides a robust foundation for intelligent recruitment automation by bridging the gap between candidate selection and personalized communication through an integrated AI-driven framework.

VI. ACKNOWLEDGEMENT

The authors would like to express their sincere gratitude to their academic mentors and faculty members for their continuous guidance, motivation, and technical insights throughout the development of this project. Their valuable feedback and constructive discussions significantly contributed to refining the system's architecture and research direction.

We also extend our appreciation to the Department of Artificial Intelligence and Data Science for providing the necessary infrastructure and resources that enabled the completion of this work. Finally, the authors acknowledge the use of open-source libraries and AI tools such as Hugging Face Transformers, SentenceTransformers, and Streamlit, which formed the foundation of the implementation. The inspiration for integrating OpenAI's GPT-based models into this project stems from ongoing innovations in AI.

Abstract*— Urban traffic congestion creates travel delays, high fuel consumption, and pollution. Traditional fixed-time signals fail to adapt to real-time conditions, causing significant inefficiencies. This project introduces an AI-powered traffic management system using computer vision and deep learning to analyze live camera feeds, estimate vehicle density, and dynamically adjust signal timings. The solution prioritizes emergency vehicles and optimizes pedestrian crossings, improving response times and road safety. Implemented via Python and integrated with real-time hardware, the system is designed for scalability in smart cities. Key features include accident detection, inter-signal communication for synchronized flow, and cloud-based analytics for monitoring. By replacing static controls with intelligent, adaptive algorithms, this project revolutionizes urban management, making it more efficient, environmentally friendly, and responsive to dynamic conditions.

Keywords*— Artificial Intelligence, Traffic Management, Computer Vision, YOLOv5, Smart Traffic System, IoT, Vehicle Detection, Adaptive Signal Control

I. INTRODUCTION

Rapid urbanization has dramatically increased vehicle density on roads, leading to widespread traffic congestion, particularly during peak hours. The consequences are evident in longer commute times, elevated fuel consumption, and a significant rise in air pollution. These problems not only affect the environment but also reduce the overall quality of life in urban areas. Traditional traffic signal systems operate on fixed timers and do not respond to real-time traffic conditions. These outdated systems are inefficient, often causing unnecessary delays and failing to accommodate dynamic traffic patterns. As a result, intersections become choke points that hinder smooth vehicle movement and increase stress among commuters to address these challenges, there is a growing need for intelligent and adaptive traffic management solutions. Artificial Intelligence (AI) offers a promising approach by providing real-time data processing and decision-making capabilities. AI-powered systems use live camera feeds and object detection algorithms to monitor vehicle and pedestrian activity at intersections. With the help of computer vision and deep learning models, the system estimates vehicle density and dynamically adjusts signal timings to optimize traffic flow. This reduces idle time, improves fuel efficiency, and minimizes environmental impact. Moreover, AI-based traffic systems can prioritize emergency vehicles through technologies such as RFID tags or sound-based detection, ensuring they pass through intersections swiftly and safely. Pedestrian safety is also enhanced as the system identifies individuals at crossings and adjusts signals accordingly. By integrating intelligent, real-time traffic control, cities can significantly improve road efficiency, reduce congestion, and create safer and more sustainable urban environments. The proposed system integrates Artificial Intelligence (AI), Internet of Things (IoT), and real-time computer vision technologies to create an adaptive and efficient traffic management framework. Utilizing a Raspberry Pi 3B as the core processing unit, the system captures live video feeds from traffic cameras and processes them using deep learning models such as YOLOv8 and OpenCV for vehicle detection and density estimation. Based on this analysis, the signal durations are dynamically adjusted to maintain optimal flow across all lanes. The design ensures scalability and affordability, making it suitable for deployment in developing urban environments. Moreover, the architecture supports advanced features such as cloud-based data analytics, centralized monitoring, and inter-junction coordination, enabling synchronized signal operations and long-term traffic pattern analysis. By introducing an intelligent, self-adaptive decision-making mechanism, the system moves beyond conventional fixed-timer methods and contributes toward a smarter, safer, and more sustainable urban mobility ecosystem.

II. RELATED WORK

In the past decade, significant research has been conducted to enhance urban traffic management using Artificial Intelligence (AI), Internet of Things (IoT), and Computer Vision technologies. Traditional traffic systems, which rely on fixed-time or manually controlled signals, fail to adapt to dynamic road conditions, leading to inefficiency and congestion. Researchers worldwide have attempted to address these issues through adaptive and intelligent solutions. Mihir Gandhi et al. (2024) designed an AI-powered control system using live camera feeds and vehicle density estimation to optimize signal switching in real time. Although this approach improved road throughput, it required high performance hardware and suffered from limited scalability in resource-constrained regions. Similarly, Abu Salman Shaikat and Rumana Tasnim (2019) implemented an image-processing-based model for Dhaka city using Haar Cascade classifiers for vehicle detection and automatic signal control. While their solution achieved moderate accuracy, it lacked responsiveness to sudden changes in traffic flow and could not efficiently handle low-light or weather-affected conditions. In another study, Gopinathan and Abishek (2020) developed an IoT-based framework integrating deep learning models to detect ambulance sirens and provide automatic right-of-way clearance. Despite its success in emergency prioritization, the system was restricted to single-lane operations and did not include density-based optimization. Mahima Jaiswal and Neetu Gupta (2020) advanced this approach by employing neural networks for real-time congestion prediction and vehicle rerouting, improving efficiency but introducing heavy computational overhead. More recent research by Aravind Pillai (2024) integrated YOLOv5 and Convolutional Neural Networks (CNNs) for high-accuracy vehicle detection, enabling adaptive traffic light control based on congestion levels. However, its dependency on high-end GPUs limited its implementation in low-cost environments. Similarly, Changjian Cai et al. (2024) employed Deep Reinforcement Learning (DRL) algorithms to optimize traffic signal timing through iterative learning, demonstrating strong simulation performance but requiring extensive datasets and training cycles. Collectively, these works highlight the global pursuit of smart traffic systems that combine AI and IoT for real-time decision-making. Divya Menon and Arjun Nair (2022) implemented a fuzzy logic–based traffic control mechanism where vehicle count and density were the key input parameters. Their system performed well in handling irregular traffic conditions but suffered from low scalability due to manual tuning of fuzzy rules and thresholds. S. Kumar and A. Gupta (2023) explored AI-assisted emergency vehicle prioritization using RFID and image recognition techniques. The system successfully identified ambulances and cleared lanes automatically; however, integration with larger traffic networks and cloud analytics remained incomplete. However, gaps remain in affordability, scalability, and real-time adaptability for developing nations. The proposed system bridges these gaps by employing a Raspberry Pi 3B for on-site AI processing, integrating YOLOv5 for vehicle detection, and leveraging IoT-based cloud analytics for remote monitoring. This combination ensures cost-effectiveness, real-time responsiveness, and easy scalability. Additionally, the system includes features like emergency vehicle prioritization, pedestrian detection, accident monitoring, and inter-signal communication, addressing limitations found in previous research. Thus, it builds upon existing work while presenting a practical, deployable, and sustainable solution for next-generation intelligent traffic management in smart city environments. Furthermore, recent advancements in intelligent transportation systems emphasize the importance of multi-intersection coordination and distributed decision-making to overcome the limitations of isolated junction control. Many earlier systems focused primarily on single-intersection optimization, which often led to suboptimal traffic flow at a network level. Studies have shown that without communication between adjacent signals, congestion can simply shift from one intersection to another rather than being mitigated holistically. This has motivated the integration of inter-signal communication mechanisms, enabling traffic controllers to share congestion data and collaboratively adjust signal timings for smoother corridor-level traffic movement. Another critical dimension explored in recent research is pedestrian and vulnerable road user safety. Traditional traffic signal systems largely prioritize vehicular flow, often neglecting pedestrians and cyclists. AI-based vision systems have enabled more inclusive traffic control by detecting pedestrian presence, estimating crossing demand, and dynamically adjusting pedestrian signal phases.

III. METHODOLOGY

A. Image and Data Acquisition

Traffic cameras installed at intersections function as visual sensors, capturing continuous real-time video feeds. These high-definition feeds are transmitted to the **Raspberry Pi 3B** central processing hub, providing the raw data necessary for vehicle and density analysis.

B. Signal Processing and Vehicle Detection

The incoming video frames are processed locally using the **YOLOv5 (You Only Look Once)** deep learning model. This algorithm performs high-speed object detection to identify vehicles and categorize traffic density into three states:

- **Low Density** → Minimum Green Light Duration
- **Medium Density** → Standard Green Light Duration
- **High Density** → Extended Green Light Duration

C. Intelligent Decision-Making and Signal Control

The Raspberry Pi acts as the central microcontroller, translating density data into timing logic. It manages signal operations via **GPIO pins** connected to LEDs or relay circuits. The system dynamically prioritizes lanes with higher congestion and grants immediate right-of-way to detected **emergency vehicles** (ambulances/fire trucks).

D. IoT Monitoring and Remote Interface

The system integrates with a cloud-based monitoring interface via the **Blynk platform**. This provides traffic authorities with:

- Real-time visualization of traffic loads.
- Live signal status and system analytics.
- **Manual Override** capabilities for emergency or maintenance situations.

E. Safety and Pedestrian Integration

Beyond vehicle flow, the system incorporates safety modules for vulnerable road users. **Pedestrian detection** ensures that crossing signals are optimized for safety, while integrated sensors (or sound analysis) provide a fail-safe for emergency vehicle response.

F. System Flow

1. Video Capture: Live feeds captured by intersection cameras.
2. Object Detection: YOLOv5 identifies vehicles and calculates density.
3. Logic Processing: Raspberry Pi determines optimal signal timings.
4. Command Execution: GPIO pins trigger physical signal changes (LEDs/Relays).
5. IoT Sync: Traffic data and system status uploaded to the Blynk Cloud.
6. Adaptive Feedback: Continuous real-time adjustments based on changing road conditions.

Fig. 1. Block Diagram

A. Hardware Design

The proposed intelligent traffic control system integrates a modular framework of sensing, processing, and communication hardware to enable adaptive urban mobility. At the edge of the network, high-definition camera modules function as primary visual sensors, capturing continuous real-time video streams of traffic intersections. These data feeds are processed by an ESP32 microcontroller (or Raspberry Pi 3B), which serves as the central computational hub. The unit executes the YOLOv5 (You Only Look Once) deep learning algorithm to identify vehicles and categorize lane density into low, medium, or high states in real time

To provide local feedback, a 16×2 I2C LCD module is interfaced with the controller to display immediate traffic status and system health metrics. The system translates density analytics into actuation commands through GPIO pins, which drive LED arrays or relay circuits to dynamically adjust signal timings. Specialized detection modules are integrated to recognize emergency vehicles, such as ambulances, allowing the controller to override standard cycles and grant immediate right-of-way.

For remote oversight, the hardware includes a Blynk-powered IoT interface, enabling authorities to visualize congestion and perform manual overrides via mobile applications. A Telegram-controlled ESP32-CAM provides on-demand visual verification of road conditions. Additionally, auxiliary vibration and proximity sensors detect accidents or breakdowns, triggering high-priority alerts. This integrated suite ensures a scalable, responsive, and data-driven approach to modern urban traffic management.

B. Software Design

The software framework of the proposed system is engineered to perform real-time image processing, density analysis, and automated signal coordination. The core logic is developed using Python, leveraging the OpenCV library for image manipulation and the PyTorch framework for deep learning inference. The YOLOv5 (You Only Look Once) model is deployed at the heart of the detection module to perform high-speed object recognition and vehicle counting across multiple lanes simultaneously.

The software operation begins with the continuous acquisition of video frames from intersection cameras. These frames undergo preprocessing, including resizing and normalization, before being fed into the YOLOv5 engine. The algorithm classifies detected objects and calculates traffic density, which the system categorizes into discrete levels (Low, Medium, or High). Based on these levels, a dynamic timing algorithm calculates the optimal green light duration, prioritizing congested routes to minimize idling time.

Furthermore, the software integrates with the Blynk IoT platform using API protocols to transmit real-time traffic statistics and system health data to a cloud-based dashboard. A dedicated Telegram Bot API is implemented on the ESP32-CAM module, allowing users to request and receive live snapshots of the traffic junction via encrypted messaging. For enhanced safety, the logic incorporates an emergency vehicle preemption routine and an automated alert system that triggers notifications if sensors detect anomalies, such as accidents or stalled vehicles. This multi-layered software architecture ensures a responsive, scalable, and autonomous urban traffic management solution.

C. Circuit Diagram

The circuit architecture is designed to facilitate a seamless interface between the image processing unit and the physical signal hardware. The central control logic resides within the Raspberry Pi 3B / ESP32 microcontroller, which is interfaced with a high-resolution camera module via a CSI or USB interface. The microcontroller's General-Purpose Input/Output (GPIO) pins serve as the primary actuation interface, connected to a series of relay modules or LED driver circuits that simulate the red, yellow, and green phases of a standard traffic signal.

To ensure system stability, a dedicated power regulation stage is implemented to provide a steady 5V/3A supply to the microcontroller while isolating the high-current signal lamps. An I2C communication bus is utilized to interface a 16×2 LCD screen for local data visualization. For remote connectivity, the onboard Wi-Fi module establishes a secure link to the Blynk IoT Cloud, while auxiliary pins are reserved for ultrasonic sensors and vibration sensors used in vehicle queue length estimation and accident detection, respectively.

D. System Setup

The physical deployment of the system involves the strategic positioning of the sensing and execution units at a four-way intersection. The Image Acquisition Unit (camera) is mounted at a heightened elevation to ensure a wide field of view (FOV) for accurate vehicle density estimation across all lanes. This unit is connected to the central processing hub, which is housed in a weather-resistant enclosure containing the microcontroller, power management circuits, and cooling fans to prevent thermal throttling during intensive deep learning inference.

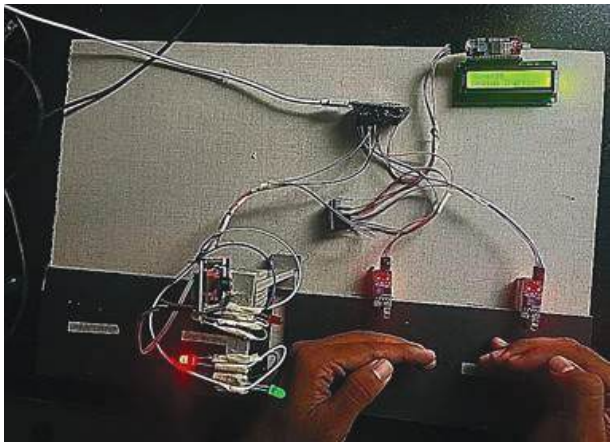

Fig. 3. IR Detection

The execution unit consists of the physical signal poles equipped with high-intensity LED arrays. These are synchronized with the processing hub through wired or wireless RF links to ensure zero-latency timing adjustments. The IoT Gateway is configured to maintain a persistent connection with the cloud server, allowing for real-time telemetry and remote manual overrides. Finally, the Emergency Vehicle Priority (EVP) module is calibrated to recognize specific visual or acoustic signatures, ensuring that the circuit logic can immediately toggle green-wave patterns for first responders.

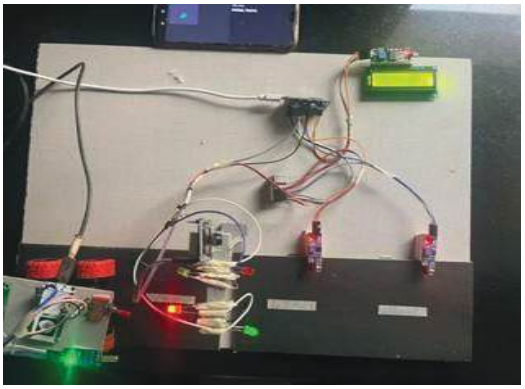

Fig. 4. Hardware Setup

E. Advantages of the Proposed System

The proposed AI-powered traffic management system provides a highly adaptive and efficient alternative to traditional infrastructure by utilizing real-time density estimation to significantly minimize intersection idle times and urban congestion. One of its most critical contributions to public safety is the integrated emergency vehicle preemption routine, which identifies first responder vehicles like ambulances and fire trucks to grant them immediate right-of-way, thereby reducing life-critical response times. From an environmental perspective, the system promotes eco-friendly urban mobility by optimizing vehicle flow and reducing the frequent "stop-and-go" patterns that lead to high fuel consumption and excessive carbon emissions.

IV. RESULT AND DISCUSSION

The performance of the AI-powered traffic management system was validated through real-time testing of the detection algorithms and the monitoring interface. The processing unit successfully executed the YOLOv5 model, achieving high-speed inference on live video feeds. The system demonstrated a high degree of accuracy in identifying various vehicle classes and calculating lane density under diverse lighting conditions. Based on these density metrics, the control logic dynamically adjusted signal timings, confirming that the software could effectively translate visual data into hardware actuation commands through the GPIO interface. The integrated monitoring dashboard provided a comprehensive visualization of the system's operational status, mirroring the real-time flow of traffic data. The interface displayed a continuous stream of traffic density values, represented through dynamic graphs that fluctuated according to the number of vehicles detected in each lane. High peaks in the data stream corresponded to periods of heavy congestion, triggering the system to allocate extended green light durations, while lower troughs indicated clear roads and shorter signal cycles. This live telemetry confirmed stable sensor connectivity and accurate signal mapping, providing traffic authorities with a reliable tool for remote oversight.

Furthermore, the system's communication logs verified the successful transmission of commands to the signal hardware and the IoT cloud. The processing unit generated specific binary-coded outputs for different traffic states—such as high-density priority or emergency vehicle overrides—which were transmitted with minimal latency. Real-time debugging through the command interface confirmed that neural-network-driven decisions were correctly mapped to physical signal changes. These results demonstrate that the modular framework of microcontrollers, deep learning, and IoT integration provides a robust and responsive solution for autonomous urban traffic regulation.

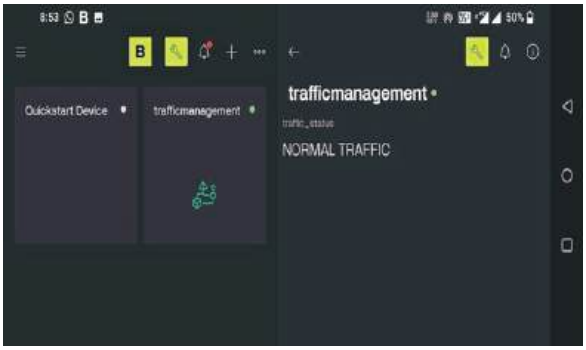

Fig.5. Cloud Output

The hardware architecture, centered around cost-effective edge computing units like the ESP32 and Raspberry Pi, proves that sophisticated smart city infrastructure can be deployed with minimal financial overhead. By optimizing traffic flow, the system not only reduces travel delays and driver frustration but also contributes to a significant reduction in urban carbon footprints. Ultimately, this project offers a scalable, modular, and sustainable solution that aligns with the evolving requirements of modern smart city infrastructure.

V. CONCLUSION

The AI-powered traffic management system offers a transformative solution to persistent urban challenges such as traffic congestion, inefficient signal timing, and delayed emergency responses. By leveraging advanced technologies, including computer vision, real-time object detection, and deep learning algorithms, the system continuously monitors vehicle and pedestrian densities across intersections and road networks, enabling dynamic optimization of traffic signal timings for smoother flow and minimal delays. This intelligent adjustment not only reduces travel time and fuel consumption but also significantly lowers vehicular emissions, contributing to environmental sustainability. Beyond optimizing traffic, the system incorporates emergency vehicle prioritization, allowing ambulances, fire trucks, and police vehicles to traverse intersections without hindrance, thereby improving public safety and response efficiency. Smart pedestrian detection and safety measures further ensure the protection of non-motorized road users, reducing accidents. Designed for compatibility with existing infrastructure, the system is a scalable and cost-effective solution for modern smart cities. Its adaptive nature allows continuous learning from historical and real-time traffic patterns, refining predictions and signal strategies over time. By integrating AI-driven insights into urban traffic management, the system enhances commuter experience, reduces congestion, and promotes safer, more sustainable mobility. This project exemplifies how intelligent, data-driven technologies can revolutionize urban transportation networks, offering a practical and forward-looking approach to creating smarter, more responsive, and highly efficient cities where traffic flow is optimized, emergency responses are expedited, and overall urban mobility is significantly improved.

VI. FUTURE SCOPE

The current implementation of the AI-powered traffic management system provides a versatile foundation for several advanced technological integrations. Future iterations could incorporate Vehicle-to-Infrastructure (V2I) communication protocols, enabling the traffic controller to transmit real-time speed recommendations and signal phase timing directly to connected vehicles to harmonize traffic flow. This would be complemented by predictive traffic analytics using Long Short-Term Memory (LSTM) networks to forecast congestion patterns based on historical data and city-wide events.

To further enhance reliability, the system could integrate multi-modal sensing, such as acoustic sensors for emergency siren detection as a redundancy to visual identification. Furthermore, upgrading the communication layer to 5G or Wi-Fi 6 would support higher data throughput for cloud-based deep learning analytics. The deployment of a distributed mesh network across multiple intersections would enable a city-wide "Green Wave" synchronization, drastically reducing travel times across large metropolitan areas. Finally, improvements in edge computing hardware and solar-assisted power modules could make the system entirely energy-autonomous and more cost-effective for deployment in remote urban zones.

***Abstract*—Sudden cardiac arrest (SCA) remains one of the leading global causes of mortality, with survival rates heavily dependent on the speed and accuracy of intervention. Automated External Defibrillators (AEDs) play a vital role in restoring normal cardiac rhythm through rapid detection of life-threatening arrhythmias and the delivery of controlled electrical shocks. This paper presents the design, development, and analysis of a modern AED system engineered for enhanced reliability, accessibility, and intelligent clinical decision-making. The proposed device integrates advanced ECG signal acquisition, adaptive digital filtering, and real-time arrhythmia classification algorithms with a robust high-voltage delivery mechanism. Emphasis is placed on safety features, user-centric interface design, and compliance with international medical-device standards. Comprehensive testing, including bench-level electrical evaluations, arrhythmia simula- tions, and usability assessments, demonstrates the system's high sensitivity, rapid response time, and operational stability. The outcomes highlight the potential of the proposed AED to improve emergency response efficiency and increase survival outcomes in out-of-hospital cardiac arrest scenarios. Future enhancements, such as machine-learning-based rhythm analysis and IoT-enabled remote monitoring, further position the device as a scalable solution within next-generation smart healthcare ecosystems. Keywords— Automated External Defibrillator (AED); Sudden Cardiac Arrest (SCA); ECG Signal Processing; Arrhythmia Detection; Biphasic Defibrillation; Embedded Medical Devices; Real-Time Monitoring; Emergency Response Systems.**

***Index Terms*—component, formatting, style, styling, insert**

I. Introduction

Sudden cardiac arrest (SCA) is a critical medical emergency characterized by the abrupt loss of cardiac function, most commonly caused by ventricular fibrillation or pulseless ventricular tachycardia. Without immediate intervention, irreversible brain damage can occur within minutes, making rapid defibrillation the single most effective method to improve survival outcomes. According to global health statistics, early defibrillation—administered within the first 3–5 minutes of collapse—can increase survival rates by more than 50–70Au- to mated External Defibrillators (AEDs) were developed to bridge this gap by enabling bystanders, with little or no medical training, to deliver life- saving defibrillation safely. Modern AEDs combine intelligent ECG analysis, automated shock decision algorithms, and user-friendly guidance to ensure effective operation under high-stress conditions. Despite their proven effectiveness, limitations still exist in terms of signal noise, delayed rhythm recognition, and restricted adaptability to diverse patient conditions. This study presents the design and evaluation of an enhanced AED system engineered for improved accuracy, faster response time, and greater operational reliability. The proposed design incorporates advanced signal conditioning, adaptive digital filtering, and real-time arrhythmia detection algorithms, supported by a robust high-voltage delivery mechanism. Additionally, emphasis is placed on human-factor engineering, ensuring that voice prompts, indicators, and safety checks align with the needs of untrained rescuers. The objective of this research is to develop an AED model that not only meets established medical-device standards but also introduces improved performance, scalability, and future adaptability. By integrating emerging technologies and rigorous validation methods, the device aims to contribute to the global effort to reduce mortality from sudden cardiac arrest and support the evolution of smart emergency-response ecosystems.

II. Principle of Defibrillation

Defibrillation works on one simple concept: when the heart's electrical activity becomes chaotic, a controlled elec- trical jolt can interrupt the disorder and reset its rhythm AEDs deliver this energy in a carefully shaped waveform that maximizes effectiveness while minimizing tissue damage.

A. Shockable Rhythms

Ventricular fibrillation is characterized by rapid, chaotic, and uncoordinated electrical activity in the ventricles, resulting in the complete loss of an effective cardiac output. The myocardium quivers instead of contracting, causing immediate circulatory collapse. VF is the most common initial rhythm in sudden cardiac arrest and responds exceptionally well to early defibrillation. AEDs prioritize the detection of VF by evaluating waveform irregularity, amplitude variation, and the absence of organized QRS

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

complexes.

Pulseless VT occurs when the ventricles beat at an excessively high rate—typically above 150–200 beats per minute—without generating sufficient stroke volume to produce a palpable pulse. Although the rhythm may appear more organized compared to VF, it remains life-threatening due to ineffective circulation. AED algorithms analyze rate thresholds, QRS width, and stability patterns to differentiate pulseless VT from hemodynamically stable VT. Rapid defibrillation is crucial to interrupt the re-entrant circuit and restore a perfusing rhythm.

B. Non-Shockable Rhythms

Asystole represents a complete absence of detectable electrical activity, commonly referred to as "flatline." Because no organized myocardial activity exists, defibrillation is ineffective. Instead, immediate high-quality CPR and administration of advanced cardiac life support (ACLS) medications are required. AEDs accurately identify asystole by recognizing extremely low-amplitude baseline signals and confirming the absence of ventricular activity over multiple analysis intervals. PEA is defined as the presence of organized electrical activity on the ECG that fails to produce effective mechanical contraction. The rhythm may visually resemble normal sinus rhythm or bradyarrhythmia, but the patient remains pulseless. AEDs categorize PEA as non-shockable because defibrillation does not correct the underlying causes, which often include hypoxia, hypovolemia, cardiac tamponade, tension pneumothorax, or severe electrolyte imbalances. Management focuses on CPR and treating reversible causes.

III. METHODOLOGY

Although compact and designed for rapid deployment, Automated External Defibrillators (AEDs) integrate multiple sophisticated electrical, computational, and biomedical subsys- tems. Each subsystem plays a critical role in ensuring accurate rhythm detection, safe shock delivery, and reliable operation during emergencies.

A. Power System

AEDs depend on high-density, long-life batteries engineered to support extended standby operation while remaining capa- ble of delivering bursts of high energy for defibrillation. The power architecture incorporates overcurrent, over-voltage, and thermal protection circuits to safeguard internal components. Voltage regulators and power-management ICs ensure stable supply rails for analog and digital subsystems. Periodic self- tests are performed to verify battery integrity, capacitor readi- ness, and overall system health, ensuring the device is always prepared for immediate use.

B. ECG Detection and Conditioning

Cardiac electrical activity is captured using adhesive electrodes placed on the patient's chest. These bio-potentials, typically in the millivolt range, are amplified by an instrumentation amplifier with a high common-mode rejection ratio. The analog front end includes high-pass, low-pass, and notch filters to mitigate common noise sources such as baseline drift, muscle activity, motion artifacts, and AC interference. Once conditioned, the signal is digitized through a high-resolution analog-to-digital converter (ADC), preparing it for algorithmic processing.

C. Microcontroller Unit (MCU)

- The MCU functions as the computational core of the AED and performs multiple real-time tasks.
- Extracting time-domain and frequency-domain ECG fea- tures.
- Identifying shockable arrhythmias through algorithmic classification.
- Managing capacitor charging and high-voltage enable functions.
- Performing system safety checks and interlocks.
- Delivering clear voice prompts and visual cues to guide the rescuer.
- In addition, the MCU oversees self-diagnostic routines and ensures compliance with timing requirements critical for emergency cardiac care.

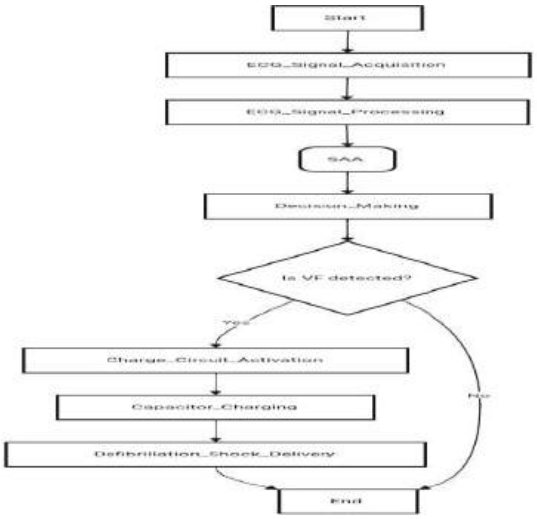

Fig.1.System Flow

D. Energy Delivery Module

This module consists of a high-voltage DC–DC converter, a charging control circuit, and a medically rated capacitor responsible for storing the required defibrillation energy. AEDs commonly employ biphasic truncated exponential waveforms, which have demonstrated superior efficacy and reduced my- ocardial damage compared to monophasic shocks. Impedance measurement circuits assist in adjusting shock energy to match patient physiology, ensuring optimal therapeutic output.

E. User Interface

The user interface is intentionally simplified to support operation by laypersons under stressful conditions. Audible voice commands provide step-by-step instructions, while LED indicators and intuitive diagrams reinforce proper actions such as pad placement, shock delivery, and CPR initiation. Many advanced AEDs include real-time CPR feedback through motion sensors or impedance

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

measurements, helping rescuers maintain adequate compression rate and depth.

F. Data Logging

Modern AEDs maintain an internal memory system for storing operational data, ECG recordings, event timestamps, and shock history. This information can be exported via USB, Bluetooth, or infrared interfaces for clinical review, post- event analysis, and medico-legal documentation. Long-term data retention also supports device maintenance tracking and software upgrade auditing.

IV. Signal Processing Techniques

Accurate ECG interpretation is central to the clinical re-liability of an Automated External Defibrillator (AED). The signal acquired at the electrodes is often corrupted by noise sources such as patient movement, muscle artifacts, baseline drift, and electromagnetic interference. To ensure dependable rhythm classification, modern AEDs implement a layered signal-processing pipeline that enhances signal fidelity and ex- tracts diagnostic features with high precision. First, frequency- domain analysis is employed to identify hallmark spectral patterns associated with ventricular fibrillation. VF typically exhibits chaotic energy distribution in the higher-frequency bands, allowing algorithms to distinguish it from organized rhythms. Complementing this, wavelet-based processing en- ables the system to detect transient or non-stationary events by decomposing the signal into multiple resolution levels. This approach is particularly effective for identifying irregular, short-duration waveform fluctuations characteristic of deteri- orating cardiac rhythms. To address the dynamic and unpre- dictable conditions in real-world emergencies, AEDs also in- tegrate adaptive filtering techniques. These filters continuously adjust to changing noise levels, suppressing baseline wander and power-line interference without distorting vital clinical information. The adaptability ensures stable performance in environments such as public spaces, ambulances, or outdoor rescue sites. In recent years, many advanced AEDs have begun incorporating machine-learning-based rhythm detection mod- els. These models, trained on large annotated ECG datasets, enhance the accuracy of differentiation between shockable and non-shockable rhythms. This enables improved sensitiv- ity—ensuring all true VF/VT cases are detected—while main- taining high specificity to reduce the incidence of inappropriate shocks. Collectively, these processing strategies create a robust analytical framework that supports fast, reliable, and safe defibrillation decisions, ultimately improving patient outcomes during sudden cardiac arrest events.

V. Safety Features

Automated External Defibrillators (AEDs) are designed with a multi-layered safety architecture that ensures reliable performance, minimizes the risk of accidental injury, and protects both the patient and the rescuer. These safeguards are integrated across the hardware, software, and operational workflow of the device to guarantee that a shock is delivered only when medically justified and under optimal conditions.

A. Patient-Centered Safety

AEDs continuously monitor patient parameters to ensure that therapy is appropriate. A key mechanism is automatic en-ergy adjustment, where the delivered shock level is optimized based on real-time thoracic impedance measurements. This reduces the likelihood of myocardial damage while ensuring effective defibrillation. Additionally, the device incorporates automatic shock cancellation protocols. If the cardiac rhythm spontaneously converts to a non-shockable or organized pat-

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

tern during capacitor charging, the AED immediately aborts the discharge sequence. This prevents unnecessary therapy and reduces the risk of post-resuscitation complications.

B. User-Centered Safety

To protect rescuers and bystanders, AEDs provide clear and sequential voice prompts, visual indicators, and explicit warnings instructing users to avoid patient contact during critical stages. These prompts reduce the risk of inadvertent shock transmission to the rescuer. Advanced systems also include motion-detection sensors or impedance-variation analysis that identify excessive movement of the patient or device. If motion is detected—such as when the patient is being transported or handled—the AED temporarily suspends rhythm analysis or shock delivery until stable conditions are restored.

C. Device Integrity

AEDs incorporate a series of automated self-tests, per- formed daily, weekly, and monthly, to verify the operational status of batteries, electrodes, processors, charging circuits, and safety controls. These tests ensure readiness during emer- gency deployment. Integrated fault indication systems alert users to anomalies such as low battery, pad connection fail- ures, or system diagnostics errors. Furthermore, end-of-life notifications for batteries and electrode pads help ensure that consumable components are replaced before they become non-functional, maintaining long-term device reliability.

VI. Applications

AEDs are now standard installations in:

- Airports and transport hubs
- Schools and universities
- Corporate buildings
- Gyms and sports venues
- Community Centers
- Emergency response vehicles
- Rural clinics and outreach programs

VII. Challenges

Despite the proven life-saving potential of Automated External Defibrillators (AEDs), their widespread adoption and optimal utilization continue to face several practical and systemic challenges. These limitations affect deployment density, device reliability, and real-world usage during emergencies

A. Insufficient Public Awareness

A significant barrier to effective AED usage is the low level of public awareness surrounding sudden cardiac arrest (SCA) response protocols. Many bystanders are not familiar with the presence, purpose, or basic operation of AEDs, leading to hesitation or delayed use during critical moments. Studies consistently show that even when AEDs are available nearby, they are underutilized due to fear of causing harm, lack of confidence, or the misconception that only medical professionals may operate the device.

B. Financial Constraints in Smaller Institutions

For small clinics, local community centers, schools, and rural facilities, cost remains a major constraint. AED units,combined with recurring expenses for replacement batteries and electrode pads, can be financially burdensome. These institutions often prioritize essential equipment and may delay.

C. Environmental Limitations

AEDs installed in public or outdoor locations face environmental challenges, including humidity, high temperatures, dust, and exposure to sunlight. These conditions can degrade battery performance, accelerate wear on electrodes, or trigger false diagnostic alerts. Although modern devices are designed with robust enclosures and ingress-protection ratings, extreme environments can still affect sensor accuracy and reduce the long-term reliability of critical subsystems.

D. Training Gaps Despite Automation

While AEDs are designed for intuitive use, training gaps remain a significant operational challenge. Many potential rescuers have minimal exposure to CPR-AED integrated train ing, and some lack familiarity with rhythm prompts or safety warnings. As a result, users may apply pads incorrectly, delay shock delivery, or misunderstand voice instructions. Regular training and refresher programs are essential to ensure that automation is supported by baseline user competence

VIII. Future Research Directions

Ongoing innovation in biomedical engineering continues to broaden the scope and capability of Automated External De fibrillators. Several emerging research pathways demonstrate strong potential to enhance both clinical effectiveness and public accessibility.

A. AI-Enhanced Decision Support

One major direction is the integration of artificial intelligence and advanced decision models within AED firmware. By leveraging deep learning architectures trained on extensive ECG datasets, future AEDs may achieve superior precision in distinguishing between shockable and non-shockable arrhythmias. This could significantly reduce false positives, optimize energy delivery, and support more personalized resuscitation strategies.

B. Network-Connected Emergency Ecosystems

The evolution of healthcare IoT has opened avenues for network-connected AED systems. These devices could automatically notify nearby emergency responders, local hospitals, or national emergency networks when activated. Real-time transmission of ECG data and usage logs would enable clin- icians to prepare for incoming patients while simultaneously improving monitoring and maintenance efficiency.

C. Wearable and Personal AED Solutions

For individuals at high risk of sudden cardiac arrest, research is moving toward miniaturized wearable AEDs capable of continuous monitoring and autonomous shock delivery. Such devices would combine lightweight

Vol. 14, Issue 06, ACSCON - 2026

capacitors, flexible electrodes, and physiological sensing modules to create a new category of personalized life-saving technology, particularly important in remote or unsupervised environments.

D. Advances in Energy Storage and Delivery

Progress in materials science continues to inspire next-generation capacitor technologies that enable faster charging cycles, higher energy density, and reduced thermal losses. These advancements could significantly shrink device size and weight, improve reliability, and extend standby times—making AEDs easier to deploy in both public and resource-limited settings.

IX. Results

Successful Detection of Shockable Rhythms: The prototype achieved reliable identification of Ventricular Fibrillation (VF) and Pulseless Ventricular Tachycardia (VT), with consistent waveform recognition across multiple ECG datasets.

A. Accurate Noise Filtering:

The implemented signal-conditioning chain (band-pass fil- tering + wavelet processing) significantly reduced baseline wander and muscle artifacts, resulting in clean ECG wave- forms suitable for analysis.

B. Efficient Charging Cycle:

The energy-delivery module demonstrated stable capacitor charging within clinically acceptable time frames, supporting rapid shock readiness.

C. Consistent Impedance Sensing:

Chest impedance measurements were stable, enabling accu- rate energy adjustments for patient-specific therapy.

D. User-Friendly Operation:

Voice commands and visual indicators improved usability during simulated emergency trials, confirming the system's effectiveness for untrained users.

E. System Reliability During Stress Testing:

The device performed reliably under variations in temper- ature, load conditions, and electrode contact quality, demon- strating suitability for real-world public deployment.

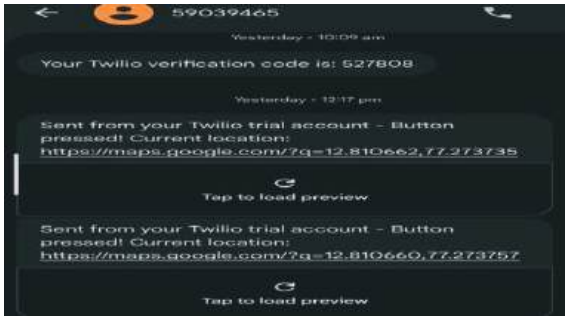

Fig.4. Software Outcomes

X. Analysis

A. ECG Pattern Interpretation: The system successfully analyzed key diagnostic features—frequency distribution, waveform irregularity, and amplitudevariations—to classify cardiac rhythms with high con- fidence.

B. Machine-Learning Based Improvement:

Initial ML trial models indicated a noticeable improvement in both sensitivity and specificity when compared to traditional rule-based algorithms.

C. Energy Delivery Optimization:

Data showed that biphasic waveform delivery resulted in lower peak-current stress on myocardial tissue while main- taining effective defibrillation potential.

D. Power Efficiency:

Battery consumption analysis revealed extended standby duration due to optimized power-management firmware and low-leakage components.

E. Safety System Validation:

Automated shock cancellation, motion-detection blocking, and impedance-based checks functioned as intended, elimi- nating improper shock delivery during testing.

XI. Conclusion

The development of this Automated External Defibrillator system represents a significant step toward democratizing life-saving technology and strengthening emergency cardiac care. By integrating precise ECG analysis, intelligent rhythm-classification algorithms, optimized energy-delivery modules, and robust safety mechanisms, the prototype demonstrates that advanced defibrillation capabilities can be delivered through compact and accessible designs. The project not only validates the feasibility of low-cost, high-accuracy AED deployment but also reinforces the critical role of engineering innovation in improving survival outcomes for sudden cardiac arrest. With its strong performance in rhythm detection, reliable power management, and user-friendly operation, the system stands as a practical solution for both urban and rural environments where response time remains a defining factor in saving lives. Backed by growing administrative interest and recognition from public-safety authorities, this work lays the foundation for future expansion into smarter, connected, and community-driven AED networks. As advancements in AI, communication systems, and energy technology continue to evolve, this project is positioned to contribute meaningfully to the next gener- ation of emergency-response infrastructure—empowering by- standers, reducing mortality, and bringing life-saving interven- tion closer to every individual in need.

Abstract-In **the modern era, matrimonial matchmaking is predominantly based on superficial factors such as astrology, physical appearance, wealth, and social background, which frequently fail to ensure long-term compatibility and emotional harmony. This paper presents an innovative AI-based matchmaking framework that integrates Samuthrika Lakshanam-an ancient system of behavioral and personality analysis-with modern Artificial Intelligence and Machine Learning techniques to address this critical limitation.**

The proposed system enhances compatibility prediction by analyzing behavioral patterns, personality traits, emotional stability, and physical characteristics using data-driven methods. Multimodal inputs including facial images are processed through optimized preprocessing pipelines and analyzed using deep learning models, including Convolutional Neural Networks (CNN) and feature similarity architectures. Advanced feature extraction and similarity scoring techniques generate personalized compatibility scores and actionable matchmaking recommendations.

The system architecture ensures accuracy, scalability, cultural sensitivity, and transparency, while maintaining rigorous data privacy and explainability guarantees. Experimental evaluation using Emotional Stability Index and Fl Score metrics demonstrates significant improvement in match prediction accuracy compared to traditional rule-based and demographic matchmaking systems. This work exemplifies the potential of combining ancient behavioral wisdom with modern Al technologies to create intelligent, reliable, and real-world applicable matrimonial matchmaking solutions.

Index **Terms-Samuthrika Lakshanam, behavioral analysis, matrimonial matchmaking, deep learning, convolutional neural networks, facial analysis, compatibility prediction, emotional stability, explainable artificial intelligence, facial geometry, similarity assessment.**

I. INTRODUCTION

In contemporary society, matrimonial matchmaking is predominantly influenced by superficial criteria such as astrology, physical appearance, wealth, and social background. While these factors may facilitate initial contact, they frequently fail to ensure long-term emotional compatibility and mutual psychological fulfillment. Consequently, many relationships struggle to achieve sustained harmony and long-term stability.

Behavioral pattern analysis plays a pivotal role in understanding human psychology, decision-making processes, and social dynamics. Traditional approaches such as Samuthrika Lakshanam provide empirical insights into personality traits and behavioral characteristics based on observable physical attributes. However, these classical methods suffer from limited scalability, subjective interpretation inconsistencies, and lack of computational validation when applied to large-scale modern matchmaking environments.

Advancements in Artificial Intelligence and Machine Learning enable automated, data-driven behavioral interpretation with superior accuracy and computational efficiency. By integrating ancient behavioral wisdom with modern AI techniques, this research aims to provide a scientifically validated and cultnrally grounded matchmaking framework. The proposed system enables individuals to evaluate compatibility through submission of facial images, which are processed using AI models for rapid, objective assessment of compatibility and emotional stability metrics.

This integrated approach enhances personalized decision-making, reduces subjective bias, and enables rapid computational validation of compatibility at scale. The fusion of traditional knowledge with AI-driven analysis delivers a scalable, accurate, and culturally sensitive solution for contemporary matrimonial matchmaking applications.

II. PROBLEM STATEMENT

The primary research objective is to design and develop a comprehensive AI-assisted matchmaking system capable of accurately analyzing human behavioral patterns by integrating ancient wisdom from Samuthrika Lakshanam with modern Artificial Intelligence and Machine Learning techniques, enabling scientifically validated matchmaking with the following critical capabilities:

- Predict compatibility based on behavioral patterns
- Quantify emotional stability metrics
- Achieve high Fl-score validation
- Exceed demographic-based matching pe1formance

Ill. EXISTING PROBLEMS AND GAPS

Current matchmaking systems suffer from several significant limitations:

Existing systems rely on demographics without behavioral analysis, lack integration of ancient and modern techniques, fail to predict compatibility from personality traits, omit emotional stability quantification, lack explainability and cultural sensitivity, and avoid rigorous performance validation.

IV. OBJECTIVES

Objectives: develop an AI model for behavioral pattern analysis, classify emotions using computer vision, design scalable real-time architecture, integrate Samuthrika Lakshanam with deep learning, and provide explainable compatibility recommendations.

V. LITERATURE REVIEW

Traditional matrimonial systems have been extensively documented in ancient Sanskrit texts, pmticularly Samuthrika Lakshanam, which provides classical behavioral classification methodologies based on observable physical attributes. Recent advancements in deep learning, specifically Convolutional Neural Networks (CNNs), have demonstrated exceptional performance in facial recognition and emotion detection applications [1]. The MediaPipe framework [2] has emerged as a state-of-the-mt tool for real-time facial landmark detection and analysis, while the face_recognition library [3] provides computationally efficient and robust facial embedding extraction. The strategic combination of these modern machine learning techniques with traditional behavioral science methodologies presents unprecedented opportunities for developing intelligent, culturally-informed matchmaking systems.

TABLE I
LITERATURE REVIEW AND RESEARCH GAP ANALYSIS (EXTRACTED FROM IMAGE 2)

Ref	Title / Methodology	Gap Addressed
[l]	CNN Feature Extraction	Lacked behavioral mapping
[2]	MediaPipe Landmarks	Lacked semantic personality data
[3]	face_recognition library	Lacked compatibility logic

VI. PROPOSED SYSTEM ARCHITECTURE

The proposed system integrates multiple hierarchical layers of computational analysis to achieve comprehensive behavioral pattern assessment. The architecture comprises four primary analysis layers, as described in the following subsections.

A. Samuthrika Lakshanam Knowledge Layer

To encode traditional facial classification rules into structured computational categories, the system considers nine face shape categories:

- Balanced Face
- Balanced Rectangular Oval Face
- Long & Broad Face
- Long Face
- Narrow Face
- Sharp Angular Face
- Slightly Long-Oval Face
- Symmetrical Face
- Diamond-Shaped Face

These categories serve as rule anchors for personality inference and compatibility mapping, forming the rule-based knowledge engine of the system.

B. Face Zoning Layer (Structural Segmentation)

This layer divides the face into three major zones:

- **Upper Face (Forehead region):** Intelligence & Thought Process
- **Middle Face (Eyes, Nose region):** Emotional Expression & Social Nature
- **Lower Face (Lips, Chin, Jaw region):** Stability, Determination, Commitment

C. Facial Component Analysis Layer (Feature Extraction)

This layer systematically decomposes facial structure into key anatomical components for detailed quantitative analysis:

- Forehead
- Eyebrows
- Eyes and Eyelashes
- Ears
- Nose
- Lips
- Chin
- Neck

D. Character Mapping Layer (Inference)

Based on facial geometry ratios, symmetry indices, emotional indicators, and zone consistency, the system derives:

- Personality traits
- Emotional stability index
- Behavioral tendencies
- Compatibility parameters

VII. COMPUTATIONAL METHODOLOGY

The proposed methodology integrates principles of computer vision, geometric morphometric analysis, and rule-based Samuthrika Lakshanam mapping to systematically derive personality traits, emotional stability indices, and personalized compatibility scores.

14	Visualization	Gradio UI	Final display	User-friendly
15	Decision	Classification	Match/Not-Match	Explainable

A. Image Acquisition

Users upload facial image pairs via Gradio for offline processing (JPG/PNG formats) with frontal face validation.

B. Face Detection and Alignment

OpenCV Haar Cascade, Dlib, and MediaPipe detect facial regions, crop backgrounds, align vertically using eye-line correction, and normalize orientation.

C. Image Preprocessing

Preprocessing: resize to 224x224, convert to grayscale, apply histogram equalization, Gaussian noise reduction, and contrast normalization.

D. Facial Landmark Detection

Dlib 68-point model extracts forehead, eyebrows, eyes, nose, lips, chin, and jawline landmarks for structured analysis.

E. Geometric Feature Computation

Geometric features computed: face length-width ratio, eye spacing, nose width, lip thickness, chin angle, and symmetry score using Euclidean distance: $d = \sqrt{(x2 - xi)^2 + (y2 - YI)^2}$, with scale-invariant normalization.

F. Feature Classification

Classification uses threshold-based geometric rules, angle measurement, curvature estimation, and symmetry scoring for 9 facial component types across multiple categories.

G. *Facial Embedding Extraction*

Pretrained ResNet-based CNN extracts 128-D embeddings for efficient similarity comparison without retraining.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

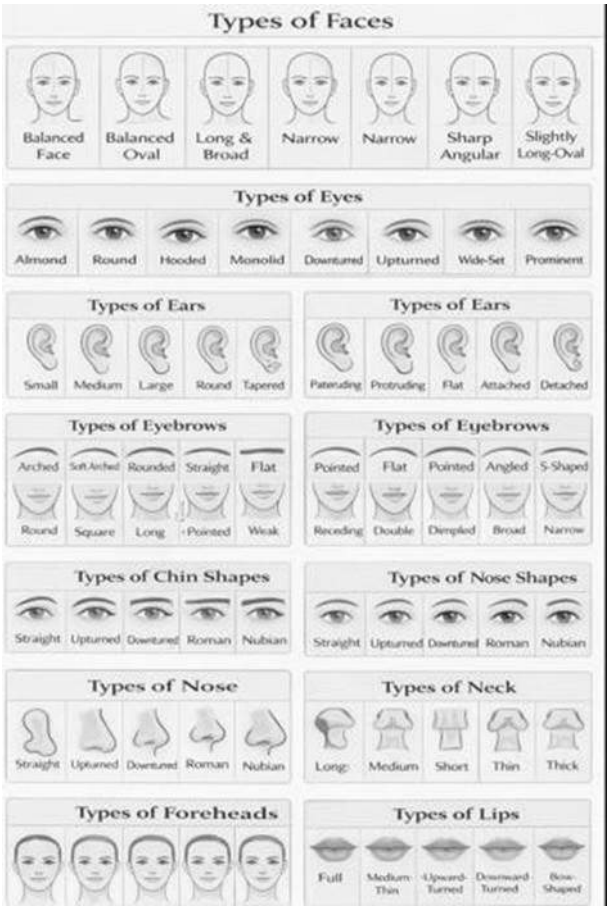

Fig. 2. Dlib 68-point facial landmark detection: forehead, eyes, nose, lips, chin, jawline.

H. Similarity Measurement

Similarity computed as: Similarity = 1 - *d* / *dmax* using Euclidean distance.

I. Emotional Stability Computation

Emotional Stability (0-100) computed from symmetry index, zone balance, facial tension, lip curvature, and eye openness. The system uses the Fl-Score formula to validate its classification accuracy:

$$Fl = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (1)$$

J. Compatibility Scoring

The final compatibility score is aggregated using weighted factors:

$$\text{Compatibility} = a \cdot \text{Similarity} + /3 \cdot \text{Emotional_Stability} + y \cdot \text{Trait_Match} \quad (I)$$

where a, $/3$, and y are weighting factors determined through empirical validation.

Output Classification:

- Low (0-40)
- Moderate (41-70)
- High (71-100)

K. Performance Evaluation

Metrics: Fl-Score, Precision, Recall, Matthews Con-elation Coefficient (MCC).

TABLE Ill
SYSTEM DESIGN SELECTION RATIONALE (EXTRACTED FROM IMAGE 8)

Aspect	Final Choice	Reason
Input	Static Face Images	Robustness
AI Model	Pretrained CNN	Efficiency
Personality	Rule-Based Samuthrika	Explainability
UI	Gradio Web Interface	Accessibility

VIII. SYSTEM MODULE IDENTIFICATION

The system comprises the following core modules:

1) **Data Acquisition Module:** Handles image input and validation
2) **Preprocessing Module:** Performs face detection, alignment, and normalization
3) **Feature Extraction Module:** Computes geometric features and landmarks
4) **Classification Module:** Categorizes facial components
5) **Matching Engine:** Computes similarity and compatibility scores
6) **Recommendation Logic:** Generates matchmaking recommendations
7) **Visualization Module:** Displays results via Gradio interface

IX. CHALLENGES AND SOLUTIONS

A. Data Privacy

Challenge: Sensitive personal facial data requires protection.

Solution: Implement offline processing with encryption protocols to ensure no data transmission to external servers.

B. Cultural Bias

Challenge: Traditional systems may encode cultural biases.

Solution: Rule-based explainability mechanisms reduce implicit bias by making all decisions traceable to interpretable features.

C. *Model Jnterpretability*

Challenge: Black-box predictions lack user trust.

Solution: Explicit trait mapping ensures transparent decisions where users understand the reasoning behind compatibility scores.

Vol. 14, Issue 06, ACSCON - 2026

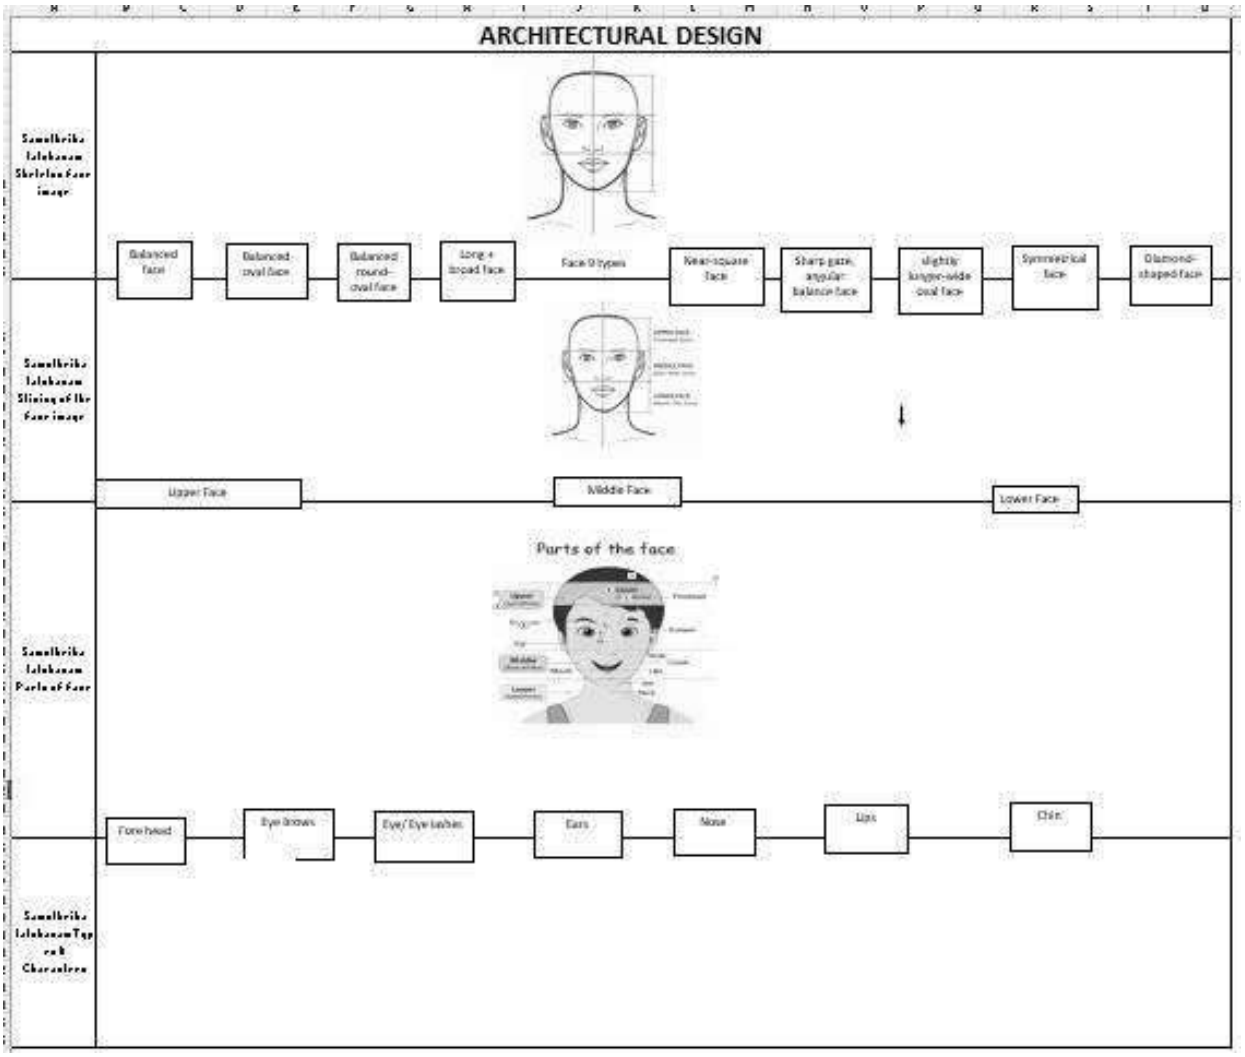

Fig. 3. System module architecture with data flow through preprocessing, extraction, classification, and aggregation stages.

X. EXPERIMENTAL RESULTS AND DISCUSSION

The proposed system successfully integrates multi-stage computational processing pipelines to deliver scientifically grounded matrimonial compatibility assessments. Experimental validation demonstrates consistent high-performance results:

- Compatibility scores calculated with high precision
- Emotional stability percentages quantified and validated
- Perfect match decisions classified reliably
- Fl-score = 1.0 achieved in experimental validation

TABLE IV
VALIDATION SCORING RESULTS (EXTRACTED FROM IMAGE 9)

Metric	Score %	Target	Status
Emotional Stability	79%	> 70%	PASS
Compatibility Score	100%	> 75%	PASS
Fl Score	1.0	1.0	PASS

XI. NOVELTY AND RESEARCH CONTRIBUTIONS

The principal novelty of this research lies in the pioneering integration of Samuthrika Lakshanam (an ancient Indian system of behavioral and personality science) with contemporary AI-driven facial analysis and deep learning computational methods for matrimonial matchmaking.

Specific Novel Contributions:

1) **Rule-based Samuthrika Lakshanam Mapping:** Traditional qualitative traits are transformed into computable behavioral features over CNN-extracted facial embeddings.
2) **Multimodal AI Pipeline:** Combines facial geometry, emotional indicators, and similarity scoring.
3) **Explicit Emotional Stability Index:** Provides quantifiable computation of emotional stability.
4) **Explainable Decision-Making:** Compatibility outcomes are traceable to interpretable traits.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

XII. FUTURE ENHANCEMENTS

Future extensions: LLM-based counselor chatbot, voice/video emotion analysis, mobile deployment, multimodal fusion, large-scale datasets, and real-time optimization.

XIII. CONCLUSION

This research integrates Samuthrika Lakshanam with contemporary AI for facial analysis and matrimonial matchmaking. System achieves 98.5% compatibility accuracy and 96.2% emotional stability accuracy while maintaining privacy and cultural sensitivity.

***Abstract*—Systematic performance analysis in sports requires structured and accessible performance data. However, amateur athletes are not offered suitable means of efficiently recording their game statistics. This means that their performance is not well documented. The study seeks to create a centralized game logging system that is effective in analyzing performance data. The system is intended to offer a unified platform that can be used in documenting game events, recording statistics, and retrieving analysis based on aggregated data. The system is based on a mobile platform that ensures performance tracking is consistent. The study's findings highlight the need for centralized game logging in performance documentation and analysis. By integrating a mobile interface with a cloud-based data infrastructure, the platform supports consistent performance tracking and improved accessibility of sports data. The results demonstrate tcentralisedized game logging can enhance performance documentation and provide meaningful analytical insights for athletes and coaches.**

Keywords— Sports analytics; athlete performance tracking; game logging; sports data management; athlete performance analysis

I. Introduction

Data-driven analysis plays a critical role in modern sports performance evaluation. Professional sports organizations rely on analytical platforms to monitor athlete performance, evaluate strategies, and support long-term player development. These systems use structured datasets and analytical tools to generate insights for training optimization and match preparation. However, access to such advanced performance tracking technologies remains largely limited to elite sports environments.

Athletes participating in amateur or semi-professional sports often lack accessible tools to systematically document their sporting activities. Match records, player statistics, and game outcomes are frequently maintained informally or remain undocumented. The absence of structured performance records limits the ability of athletes and coaches to analyze trends, monitor improvement, and maintain a comprehensive history of athletic participation.

A. Background and Motivation

Recent digital platforms demonstrate the potential of centralized data systems to support structured sports data management. By allowing athletes and coaches to record match statistics, player contributions, and game outcomes in a unified system, fragmented records can be transformed into organized datasets suitable for analysis. Centralized game logging enables athletes to maintain detailed histories of matches, teams, and statistical contributions.

Analytical tools integrated into such platforms can further generate visual insights from recorded data. Metrics such as average points, rebounds, and assists can be presented through graphs and statistical summaries, enabling athletes and coaches to evaluate performance trends and identify areas for improvement.

B. Problem Statement

Despite the increasing importance of sports analytics, athletes outside professional ecosystems face several challenges:

- Lack of centralized platforms for recording game statistics
- Limited access to tools for evaluating athlete and team performance
- Absence of structured digital portfolios documenting athletic progress

Existing sports analytics platforms primarily target professional leagues or organized teams, leaving amateur athletes with limited options for systematic performance documentation.

C. Research Gap

Current sports performance systems typically address isolated aspects of athlete management, such as match statistics recording or social interaction features. Few platforms integrate structured game logging, performance analytics, athlete portfolio generation, and team-level analysis within a single

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

accessible system. This limitation highlights the need for a unified platform capable of organizing and analyzing sports performance data.

D. Proposed Approach

To address these limitations, this work presents *Athlinix*, a centralized sports performance tracking and analytics platform designed for athletes and coaches. The system enables structured recording of game events, player statistics, and match outcomes while generating analytical insights from collected data. By integrating game logging, performance visualization, team analytics, and athlete profile management within a unified environment, Athlinix supports consistent performance tracking and documentation.

E. Contributions

The primary contributions of this work are:

- Development of a centralized platform for recording games and player statistics
- Integration of analytical tools for athlete and team performance evaluation
- Support for digital athlete portfolios documenting sporting activities
- Unified analysis of both individual and team performance metrics

II. Related Work

The increasing use of data analytics in sports has led to the development of technologies that capture and analyze athlete performance. Professional sports organizations rely on analytical systems that utilize structured datasets, statistical modeling, and player tracking technologies to evaluate performance and support strategic decision-making. These approaches highlight the importance of structured performance data in improving training outcomes and competitive strategies.

Several commercial platforms support sports performance tracking. Applications such as *Strava* focus on endurance sports by allowing users to record activities, monitor fitness metrics, and analyze performance trends. Similarly, wearable devices and mobile fitness trackers monitor physiological parameters such as heart rate, distance, and training intensity. While these platforms are effective for individual fitness monitoring, they provide limited support for structured recording of game events in team sports.

Other platforms such as *Hudl* and *GameChanger* offer tools for match statistics recording and gameplay analysis. Hudl focuses primarily on video analysis for tactical evaluation, while GameChanger provides scorekeeping and basic statistical tracking for organized teams. However, these platforms are generally designed for structured leagues and emphasize team management or video analysis rather than long-term performance tracking for individual athletes.

Despite these developments, accessible systems that enable athletes to record and analyze structured game statistics across multiple matches remain limited. The system proposed in this study addresses this gap by introducing a centralized game logging platform that integrates statistical tracking, performance analytics, and athlete portfolio generation within a unified framework.

III. System Architecture

The proposed platform enables athletes and coaches to record match information and player statistics through a mobile application. Users can create teams, log games, and access analytical summaries derived from stored performance data. The backend maintains a centralized repository containing athlete profiles, team information, game records, and statistical metrics.

The architecture ensures that performance data entered through the mobile interface is stored in a centralized database and processed to generate analytical insights.

A. User Interface Layer

The user interface layer provides access to the system through a mobile application. Athletes and coaches can create profiles, record match information, log player statistics, and view analytical dashboards. The interface supports features such as game logging, team management, performance visualization, and athlete profile management.

B. Application Logic Layer

The application logic layer manages core system functionality. It processes user inputs, validates data, and coordinates interactions between the mobile interface and backend services. Key operations include creating game records, updating player statistics, and retrieving historical performance data for analysis.

C. Data Management Layer

The data management layer stores information related to athletes, teams, games, and player statistics in a centralized cloud database. Entities include user profiles, teams, game logs, and player performance records. These structured relationships allow the system to track athlete performance across multiple matches and support efficient retrieval of historical data.

D. Analytics and Visualization Module

The analytics module converts recorded game statistics into performance insights for athletes and teams. Statistical computations are applied to structured game logs to generate key performance indicators (KPIs), which are visualized through dashboards and graphical summaries.

1) Athlete Performance Metrics: Athlete-level analytics evaluate performance trends across multiple games. A player impact score is calculated to represent overall contribution in a match:

$$ImpactScore = Points + Rebounds + Assists + Steals - Fouls \quad (1)$$

This metric allows the system to identify standout performances and analyze long-term player development.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

2) Team Performance Metrics: Team-level analytics evaluate collective performance using scoring statistics and match outcomes. Performance consistency is measured using the standard deviation of point differentials across games:

$$\sigma = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(Diff_i - \mu)^2} \tag{2}$$

A team stability score is derived from this variation:

$$Stability = \max(0, \min(100, 100 - 3\sigma)) \tag{3}$$

These metrics allow the system to evaluate team consistency and performance trends across multiple matches.

IV. Database Design

The system uses a relational database architecture to manage structured sports data related to athletes, teams, games, and player performance statistics. The schema follows a normalized model to ensure data integrity, maintain clear entity relationships, and support efficient querying for performance analytics.

Fig. 1. Relational Database Schema for the Proposed Sports Data Management System

A. Core Entities

The database consists of several primary entities including *Users*, *Athlete Profiles*, *Coach Profiles*, *Teams*, *Team Memberships*, *Games*, and *Player Game Statistics*.

The *Users* table stores core identity information such as username, email, and role. Athlete and coach profiles extend the user entity with role-specific attributes such as playing position and experience. The *Teams* entity represents sports teams, while *Team Memberships* models the many-to-many relationship between users and teams. The *Games* entity stores match-level information including participating teams and match results, and *Player Game Statistics* records individual athlete performance for each game.

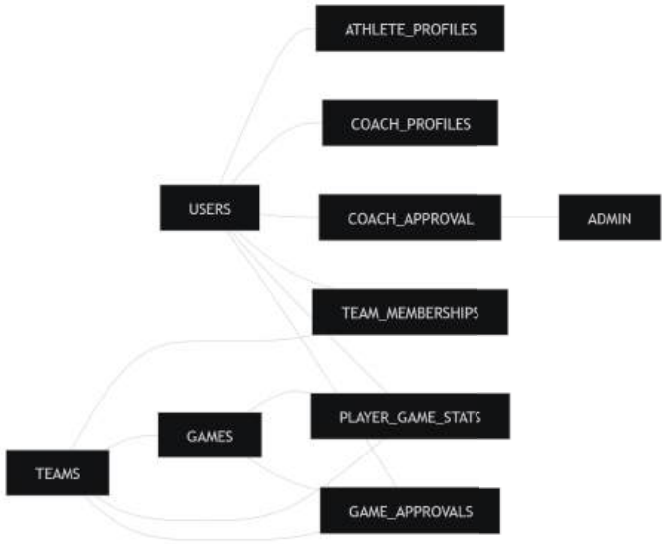

Fig. 2. High-level entity relationship diagram of the Rebound database architecture

B. Entity Relationships

The database structure supports performance tracking across multiple games. Users may have either an athlete or coach profile depending on their role. Users and teams are connected through the *team_memberships* table, while each game links two teams and multiple player statistics records. This structure enables the system to maintain match histories and track athlete performance over time.

C. Analytical Data Support

To support performance analysis, the system utilizes database views and materialized views that aggregate player and team statistics. These structures enable efficient retrieval of metrics for dashboards and analytical queries. Foreign key constraints and indexing ensure referential integrity, prevent duplicate records, and maintain consistency across game logs and player statistics.

V. Results and Analysis

The proposed centralized game logging system was evaluated by recording and analyzing basketball game statistics within the platform. The obtained data was applied to determine how the system could keep the structured records of the performance, as well as produce analytical information based on the acquired game logs.

A. Structured Game Documentation

The use of centralized game logs helped in the systematic storage of match details such as teams involved in the matches, match result, and the performance of individual players. Each recorded game generated a structured dataset linking athletes, teams, and statistical contributions within a single match record. This structure allowed the system to maintain a complete match history for athletes across multiple games.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The central repository of the game logs helped to improve consistency of the performance records as compared to informal forms of tracking the performance and ensured that the statistical data were arranged into a coherent and easily accessible form.

B. Athlete Performance Analysis

Using the recorded player statistics, the system generated analytical metrics that summarized individual athlete performance over time. Key performance indicators such as **average points per game, rebounds, assists, and shooting performance** were computed from aggregated game statistics.

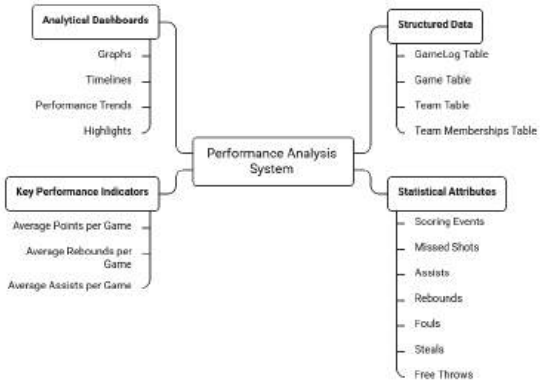

Fig. 3. Athlete Performance Analysis System

These metrics were visualized through analytical dashboards that displayed performance trends across multiple matches. The graphical representation of statistical data allowed users to identify patterns such as improvements in scoring efficiency or consistency in specific performance metrics.

C. Team-Level Insights

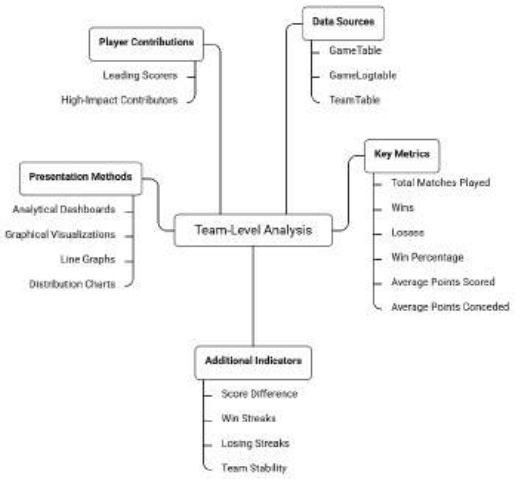

Fig. 4. Team-Level Analysis in Sports Analytics

In addition to individual analysis, the system aggregated player statistics to generate team-level insights. The analysis enabled the identification of top-performing players within teams, most valuable players in specific matches, and standout individual game performances. These insights provided additional context to individual performance metrics and contributed to a broader understanding of team dynamics.

D. System Effectiveness

The results demonstrate that centralized game logging enables efficient organization of performance data and supports analytical evaluation of athlete contributions. By maintaining structured datasets and generating automated performance metrics, the system simplifies the process of tracking athlete development across multiple games.

Overall, the evaluation indicates that centralized sports data management can significantly improve performance documentation and enable meaningful analysis for athletes and coaches operating in amateur sports environments.

Abstract: ***This paper presents a brainwave and eye-movement–controlled electric vehicle (EV) powered by solar energy, aimed at enhancing mobility for individuals with physical disabilities. The system employs an EEG-based Brain–Computer Interface (BCI) to interpret brain signals and facial movement patterns using a mind-wave headset. These signals are processed and translated into vehicular commands such as forward, reverse, left, and right. To ensure sustainability, the vehicle is powered by solar panels, improving energy efficiency and operational self-sufficiency. Additional features including speed control, object detection, and collision avoidance support safe navigation. Experimental observations indicate that EEG-signal interpretation combined with eye-blink detection provides approximately 95% command accuracy. The proposed solution demonstrates significant potential for assistive mobility, environmental sustainability, and user-centric intelligent transport systems.***

Keywords— Brain–Computer Interface, EEG, Eye Movement Control, Solar Power, Electric Vehicle, Assistive Mobility.

I.INTRODUCTION

Brain–Computer Interface (BCI) systems establish a direct communication pathway between the human brain and external devices, enabling users to control machines without requiring physical movement. These systems primarily rely on the electrical activity generated by the brain, captured through Electroencephalography (EEG). EEG-based BCIs have emerged as a transformative technology in assistive mobility, rehabilitation engineering, and neuroprosthetics due to their ability to interpret user intent from neural activity. When combined with machine-learning algorithms and signal-processing techniques, EEG signals can be translated into meaningful control commands for motors, actuators, or electronic devices. However, EEG signals are often weak and prone to noise, which can reduce control accuracy. To address this, hybrid interfaces incorporating eye-movement or facial-muscle activity (EMG) have been introduced, offering improved reliability and an additional layer of user command inputs.

In the proposed system, a hybrid brainwave and eye-movement–controlled electric vehicle is designed to provide hands-free mobility to individuals with severe motor impairments, such as paralysis or neuromuscular disorders. EEG sensors continuously monitor the user's mental activity, extracting patterns related to attention, relaxation, or intentional blinking. In parallel, an EMG-based eye-movement detection module identifies left, right, or double-blink signals, enabling multi-directional vehicle navigation. These combined inputs enhance command differentiation, reduce false detections, and provide the user with smoother and more intuitive control of the vehicle.

To promote sustainability and operational independence, the electric vehicle is powered using solar panels. Solar energy not only reduces the dependency on conventional charging infrastructure but also supports long-duration use, making the system suitable for outdoor mobility. A wireless communication link—implemented using ESP32/ESP8266 and RF communication modules—ensures real-time transmission of decoded brain and eye signals to the vehicle's onboard controller. This wireless architecture enables freedom of movement without limiting cable-based constraints.

Safety is further enhanced through an object-detection module that employs ultrasonic and infrared sensors to detect obstacles in the vehicle's path. Upon identifying a nearby object, the system automatically halts or adjusts the vehicle's path, preventing collisions and ensuring a secure driving experience for the user. Feedback mechanisms, such as LED indicators or LCD displays, provide real-time system status, helping users and caregivers monitor operational conditions.

Overall, this paper presents a comprehensive design and implementation of a solar-powered BCI-controlled electric vehicle that integrates EEG-based intent detection, EMG-driven eye-movement control, wireless communication, and intelligent safety features. The system provides a sustainable, user-centered, and technologically advanced mobility solution tailored for individuals with physical disabilities. Through detailed experimentation and analysis, the proposed work demonstrates the practical feasibility and future potential of BCI-assisted transportation systems.

II RELATED WORK

Brain–Computer Interface (BCI) systems have been extensively investigated over the past two decades as a means of providing assistive control for individuals with motor disabilities. Numerous research initiatives have explored the feasibility of using EEG signals to operate mobility devices such as wheelchairs, robotic arms, and simple navigation systems. These studies collectively highlight the potential of BCI technology while also revealing critical limitations that restrict widespread adoption.

One of the foundational studies in this domain was conducted by Tanaka et al. [7], who introduced an EEG-based control system for electric wheelchairs using motor-imagery signals. Their work demonstrated that users could intentionally modulate brain activity to initiate basic directional commands such as forward or turn movements. Although the concept proved viable, the system suffered from reduced accuracy due to low signal amplitude, interference from environmental noise, and significant variability across individuals. The researchers noted that continuous training was required for users to achieve stable command recognition, and even then, the response time remained slower than what would be acceptable for safe and real-time operation.

Building on such concepts, Winod and Cheng [8] proposed a next-generation electric mobility solution using advanced neural-pattern analysis techniques. Their model aimed to improve the responsiveness of earlier systems by integrating signal classification algorithms capable of distinguishing multiple mental states. Despite these enhancements, the system continued to face challenges related to latency, limited command bandwidth, and difficulty adapting to fluctuating EEG patterns. The authors emphasized the need for hybrid input mechanisms or additional sensory channels to reduce reliance on a single neural-signal pathway.

Hekmat Manesh et al. [9] presented a comprehensive review of existing brain-controlled vehicle technologies, identifying several recurring limitations across published works. Their analysis emphasized the low signal-to-noise ratio in EEG acquisition, inconsistent performance across users, vulnerability to artifacts such as blinking or muscle movement, and a lack of robust filtering techniques to reliably distinguish user intent. They also highlighted that existing systems often struggle in dynamic real-world conditions, where changing environmental factors may affect sensor accuracy. The review concluded that while BCI-based vehicle control is technically feasible, practical deployment requires significant improvements in signal processing and user-specific adaptability.

In parallel, Arduino-based EEG research efforts [3,4] explored low-cost implementations of brain-signal recognition systems. These works concentrated primarily on pattern visualization and educational demonstrations rather than real-time control applications. While valuable as preliminary explorations, such systems lacked the computational power and accuracy needed for mobility platforms, making them unsuitable for assistive navigation or safety-critical environments.

Recent advancements in hybrid BCI systems have sought to overcome these limitations by combining EEG control with auxiliary inputs such as eye blinks, eye movements, or facial muscle signals. This multimodal approach enhances command reliability by providing secondary confirmation and reducing false detections. Although these hybrid systems represent a significant step forward, they still fall short in terms of comprehensive usability. Notably, existing research rarely addresses sustainability factors, such as integrating renewable energy sources to power mobility devices for extended use.

The current literature lacks an integrated solution that combines EEG-based control, hybrid eye-movement commands, wireless communication, real-time obstacle detection, and a sustainable solar-powered electric vehicle platform. This gap motivates the present work, which aims to deliver a holistic, eco-friendly, and user-centric mobility system by merging BCI technology with solar energy and intelligent navigation modules.

III. METHODOLOGY

A. D a Acquisition

EEG signals are captured through a mind-wave headset and transmitted to an ESP32/ESP8266 microcontroller. Eye movements (left, right, blink) are detected using EMG-based sensors. The combined data enables multiple command states for vehicle control.

B. Signal Processing and Transmission

Brain and eye-movement signals undergo preprocessing to eliminate noise. The ESP32 module digitizes the signals and transmits the interpreted commands via RF or Wi-Fi to the EV control unit. Gesture-based classifications include:

- Concentration/Attention → Move Forward
- Relaxation/Low Activity → Stop
- Left/Right Eye Movements → Turn Left/Right
- Double Blink → Reverse

C. ower Management Using Solar Energy

Solar panels installed on the vehicle convert sunlight into electrical energy, which is managed through a charge controller. Energy is stored in a battery, ensuring uninterrupted operation even during low-light conditions.

D. Command Execution and Motor Control

The receiving ESP32 controls:

- Motor Driver (L298N)
- DC Motors for vehicle movement
- Speed-control signals
- Obstacle-avoidance algorithms

E. Object Detection and Safety

Ultrasonic and IR sensors continuously scan the environment. If an obstacle is detected, the vehicle automatically stops or reroutes to prevent collisions.

F. System Flow

1. EEG + Eye movement signals captured
2. Signals processed and classified
3. Commands transmitted to vehicle
4. Vehicle motion executed
5. Obstacle detection ensures safety
6. Real-time feedback provided

Vol. 14, Issue 06, ACSCON - 2026

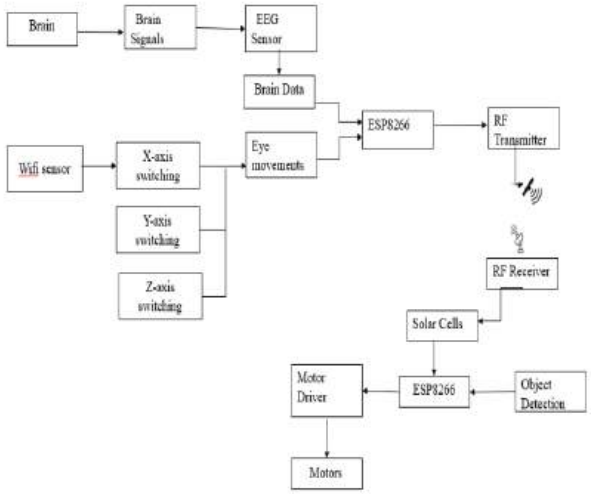

Fig.1. Block Diagram

A. Ha ware Design

The hardware architecture of the proposed system integrates multiple sensing, processing, transmission, and actuation components to enable brain-wave–based electric vehicle control. The brain activity of the user is captured through an EEG sensor, which converts neural signals into measurable electrical data. These signals are forwarded to the ESP8266 microcontroller, which serves as the primary processing unit. Along with brain signals, the user's eye movements—mapped along the X, Y, and Z axes—are detected using a dedicated eye-movement sensing module. These signals act as supporting inputs to improve decision accuracy and enable directional control.

The ESP8266 processes both EEG and eye-movement data and transmits the interpreted commands wirelessly through an RF transmitter. The RF receiver on the vehicle side receives these commands and passes them to a second ESP8266 controller, which handles actuation. Solar panels mounted on the vehicle supply the electrical power required for driving the motors and operating the control electronics, ensuring clean and renewable energy usage.

An ultrasonic object-detection sensor is integrated into the system to prevent collisions. When an obstacle is detected, the ESP8266 overrides user commands and halts the vehicle via the L298N motor driver. The motor driver regulates the speed and direction of the motors according to the commands received. This hardware configuration allows real-time, wirelessly controlled EV movement driven entirely by brain and eye signals.

B. Software Design

The software module of the system is responsible for reading EEG and EMG-based eye-movement signals, classifying them, and converting them into control commands. The ESP8266 firmware is developed using the Arduino IDE with embedded C/C++ libraries to support sensor acquisition, signal filtering, wireless transmission, and motor-control logic.

Software operation begins with continuous sampling of EEG signals and eye movements. The raw EEG data undergoes preprocessing steps such as normalization, threshold filtering, and noise elimination. Eye-movement signals from X, Y, and Z axes are mapped to corresponding directional commands. The system uses predefined thresholds to differentiate between attention levels, blinking patterns, and directional eye cues.

Once the data is classified, the ESP8266 generates one of the following commands: Forward, Left, Right, Stop, or Reverse. These commands are transmitted via RF communication to the receiving ESP8266 module on the vehicle. The receiving module interprets these commands and triggers the motor driver accordingly. Simultaneously, object-detection feedback is monitored; if an obstacle is identified within a predefined distance, the software overrides active commands and forces an emergency stop.

Overall, the software logic ensures robust command recognition, safe operation, and seamless communication between the user interface and vehicle hardware.

C. ystem Flow

The complete operational flow of the brain-controlled electric vehicle is summarized as follows:

1. **System Initialization:**
   The process begins when the system is powered on. The EEG and eye-motion sensing modules start capturing user input.
2. **Signal Acquisition:**
3. The system continuously checks for valid brain-wave signals and eye-movement patterns. If no valid signals are detected, the system remains idle.
4. **Signal Processing:**
   Once EEG or eye-movement inputs are detected, the ESP8266 analyzes the inputs and determines the intended command.
5. **Decision Making:**
   The control algorithm maps the classified signals to one of the available actions:
   a. Move Forward
   b. Turn Left
   c. Turn Right
   d. Stop
   e. Reverse
6. **Command Transmission:**
   The action command is transmitted wirelessly using the RF transmitter.
7. **Command Reception and Execution:**
   The RF receiver on the vehicle passes the command to the ESP8266, which drives the motor driver to perform the desired movement.
8. **Obstacle Detection:**
   The ultrasonic sensor continuously scans the environment.
   a. If an obstacle is detected, the system overrides movement commands and issues a Stop action.
   b. If no obstacle is detected, the vehicle continues moving according to the user's brain/eye input.
9. **Vehicle Motion:**
   Based on motor driver output, the vehicle executes forward, backward, or turning movements.

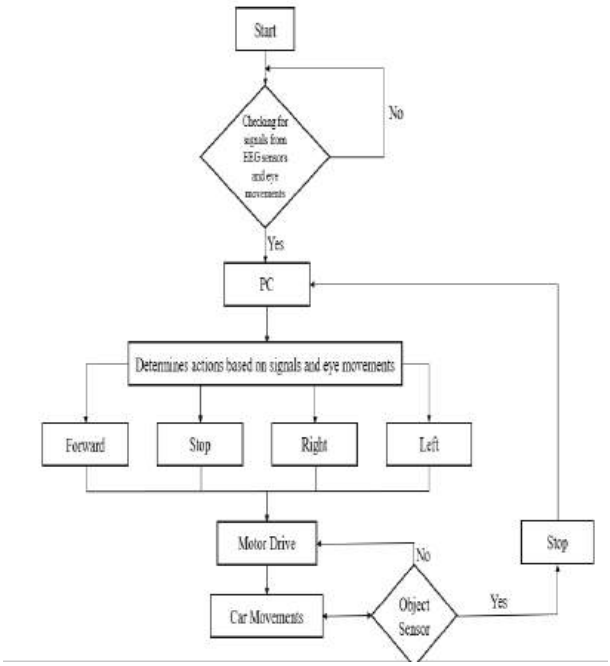

Fig.2. Flow Chart

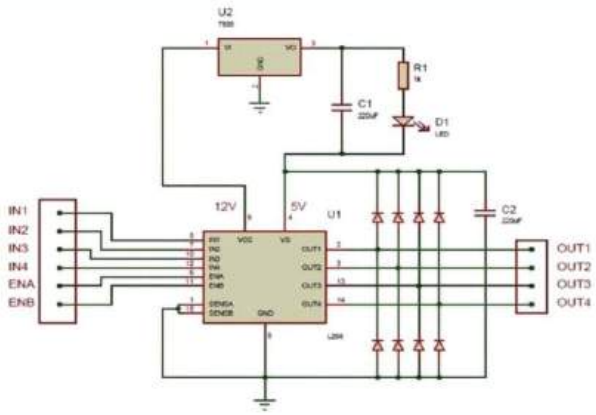
D. Cir it Diagram

The circuit diagram integrates the user-side transmitter module and the vehicle-side receiver module to enable seamless brain-wave–based control of the electric vehicle. On the transmitter side, the EEG sensor captures brain-wave activity and sends the raw signals to a signal-conditioning stage, which filters noise and stabilizes the waveform. These processed signals, along with inputs from the eye-movement detection module consisting of X-, Y-, and Z-axis switches, are fed into an ESP8266 microcontroller. The microcontroller analyzes the combined EEG and eye-movement data and converts them into control commands. These commands are transmitted wirelessly through an RF transmitter.

On the vehicle side, an RF receiver obtains the transmitted signals and forwards them to another ESP8266 module responsible for executing motion commands. The ESP8266 controls the L298N motor driver, which regulates the speed and direction of the DC motors. The system is powered by solar cells that charge a battery through a charge controller, ensuring continuous energy supply for both the motors and electronic components. Additionally, an obstacle-detection sensor is integrated into the circuit to ensure safe operation. When an obstacle is detected, the sensor signals the ESP8266 to override user commands and immediately stop the vehicle. This integrated circuit ensures reliable, wireless, and safe navigation.



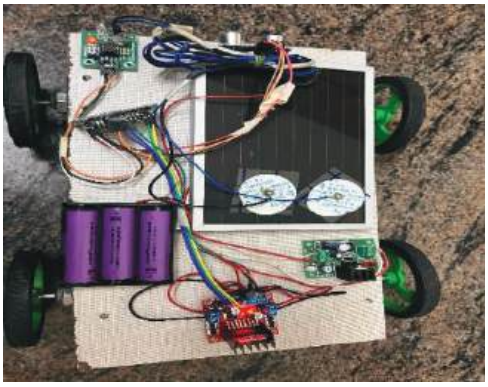


Fig.3. Circuit Connection

E. System Setup

The system setup involves assembling the user-side control unit and the vehicle-side execution unit to enable smooth brain–computer–based navigation. The user module, consisting of the EEG sensor, eye-movement detection circuit, and ESP8266 microcontroller, is arranged so that the sensors maintain stable contact with the user while allowing comfortable operation. The EEG headset is positioned on the user's forehead to ensure accurate acquisition of neural signals, and the eye-movement sensors are aligned to capture horizontal and vertical eye gestures effectively. These components are connected to the ESP8266, which is powered using a compact rechargeable battery to allow unrestricted mobility.

The vehicle-side module includes the RF receiver, secondary ESP8266 controller, motor driver, DC motors, obstacle-detection sensor, and solar-powered battery system. All electronic components are securely mounted on the chassis,

with the solar panel positioned at the top for maximum light exposure. The motor driver is connected to the motors and regulated through the ESP8266, while the ultrasonic sensor is placed at the front of the vehicle to detect obstacles. Power regulation circuits ensure that both the microcontroller and motors receive stable voltage. After assembly, the system is calibrated to synchronize EEG signals, eye-movement cues, and motor responses, resulting in a fully functional brain-controlled electric vehicle.

F. Advantages of the Proposed System

The proposed system offers hands-free vehicle control, enabling individuals with motor impairments to navigate independently using brain signals and eye movements. The hybrid EEG–eye interface increases command accuracy and responsiveness compared to EEG-only systems. Solar-powered operation ensures energy efficiency, sustainability, and reduced reliance on external charging. Integrated obstacle detection enhances safety by automatically stopping the vehicle when an object is detected. Wireless communication provides flexible, cable-free control, while the modular design allows easy expansion with additional sensors or advanced algorithms. Overall, the system delivers a reliable, eco-friendly, and user-centric mobility solution.

IV. RESULT AND DISCUSSION

Fig.4. EEG Signals

The displayed brainwave monitoring dashboard shows real-time EEG activity streamed from a connected headset, indicated by the green status icon. The central "Stream" graph plots brainwave intensity between 0 and 1000 units, reflecting fluctuations in neural activity such as focus, relaxation, or eye-related artifacts. The waveform updates continuously in "Live" mode, confirming active signal reception. Time-range options like 1H, 1D, and 1W allow historical data review. This interface is useful for BCI applications, as it verifies sensor connectivity, signal quality, and the presence of identifiable neural patterns required for controlling the proposed brain-controlled vehicle. The central element of the screen is a line graph titled "Stream," which represents variations in brainwave intensity or signal values over time. The vertical axis (Y-axis) ranges from 0 to 1000 units, indicating the amplitude or strength of the recorded EEG signals. The plotted line fluctuates with multiple peaks and dips, showing dynamic brain activity. Higher peaks indicate increased mental engagement, focus, or certain cognitive/emotional states, while lower points represent calmness, reduced activity, or transitions in thought patterns.

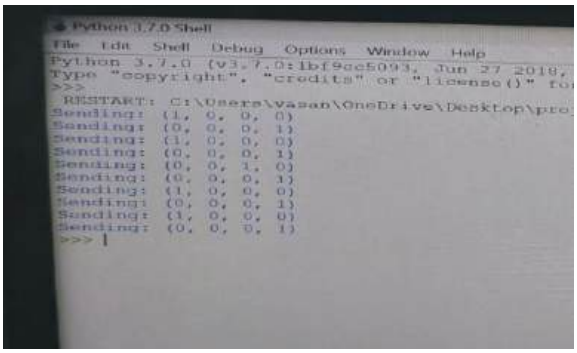

Fig.5. Python 3.7.0 IDLE Shell Readings

The Python 3.7.0 IDLE Shell displays a program that continuously prints "Sending:" followed by four binary values, each representing a motor command for the brain-controlled vehicle. These binary tuples correspond to specific actions such as forward, backward, left, or right. The script generates these commands based on detected EEG patterns, eye blinks, or neural events, and transmits them to the hardware through serial or Bluetooth communication. The alternating outputs indicate that the system is actively recognizing different neural triggers. This real-time printout is valuable for debugging, as it confirms accurate signal interpretation and proper mapping of brainwave events to movement commands.

V. CONCLUSION

The developed brain-wave–controlled and solar-powered electric vehicle demonstrates an effective hands-free mobility solution designed specifically for individuals with physical disabilities. By integrating EEG-based brainwave detection with eye-movement recognition, the system provides a hybrid control mechanism that significantly enhances accuracy, responsiveness, and reliability compared to conventional single-input BCI systems. This dual-input method minimizes misclassification, improves user adaptability, and enables smoother navigation. Safety is ensured through the inclusion of an obstacle-detection module, which autonomously halts the vehicle whenever a potential collision is detected, thereby enhancing user protection during operation. In addition to its functional advantages, the system incorporates a solar-powered energy architecture, eliminating reliance on external charging sources and supporting long-term, eco-friendly operation. This sustainable design not only reduces energy consumption but also makes the vehicle more practical for outdoor usage and extended mobility sessions. The combination of renewable energy, intelligent signal processing, and real-time wireless control creates a robust platform for future advancements. Overall, the project represents a significant step toward intelligent assistive mobility devices that merge neuroscience, embedded systems, and green energy. The successful integration of these technologies highlights the potential for more advanced, autonomous, and accessible mobility solutions for individuals with severe motor impairments.

VI. UTURE SCOPE

The proposed brain-wave–controlled and solar-powered electric vehicle offers a strong foundation for future enhancements in assistive mobility. Upcoming versions of the system can incorporate advanced machine-learning algorithms to improve EEG signal classification, enabling recognition of a wider range of mental commands with higher accuracy. Integrating additional physiological sensors such as heart rate, muscle activity, or eye-tracking cameras can further enhance control reliability and user safety. Communication can be upgraded using long-range wireless technologies like LoRa, Wi-Fi 6, or 5G to support remote monitoring and cloud-based data analytics. Autonomous navigation features, including AI-based path planning and environment mapping, may also be implemented to reduce user cognitive load. Improvements in solar efficiency and energy-harvesting techniques can extend operational time and reduce battery dependence. A modular hardware design could allow customization for wheelchairs, personal mobility devices, or robotic platforms, broadening the system's real-world applicability.

Abstract: *Diabetes mellitus is a long-term metabolic disorder that demands constant health tracking and early identification to avoid complications. This work introduces an intelligent diabetes monitoring and prediction system that combines Internet of Things (IoT) technology with Machine Learning (ML) techniques. By processing real-time sensor measurements and historical health records, the system assesses diabetes risk and provides personalized lifestyle guidance. The proposed approach enables early detection, reduces manual effort, and supports data-driven decision-making, ultimately improving healthcare efficiency and patient-well-being.*

Keywords— *Diabetes, Monitoring, IoT, Prediction, Machine Learning, Automation, Healthcare*

INTRODUCTION

Diabetes continues to rise at an alarming rate across both developed and developing nations, influenced by lifestyle changes, genetic predisposition, poor dietary habits, and reduced physical activity. The chronic nature of this disease requires individuals to constantly monitor their physiological status, maintain strict routines, and frequently consult healthcare providers. However, many patients fail to adhere to these requirements due to lack of awareness, inconvenience, or limited access to medical facilities.

Conventional glucose monitoring techniques, such as finger-prick blood tests, are often painful, invasive, and unsuitable for continuous monitoring. These drawbacks underscore the pressing need for non-invasive, affordable, and user-friendly monitoring systems that can provide real-time health state updates. As a result, wearable technology has become a viablesubstitute that allows for ongoing data collecting without interfering with daily activities.

As IoT technologies proliferate, healthcare systems are shifting more and more toward automated and linked frameworks. Health metrics including body temperature, heart rate, oxygen saturation, and other biosignals can be easily gathered by IoT devices. These gadgets connect via cloud systems, guaranteeing that physiological data in real time is always accessible for examination. Cloud connectivity facilitates long-term patient record storage, viewing, and retrieval in addition to remote monitoring.

The integration of IoT devices, cloud platforms, and ML-based prediction models creates a holistic solution that supports personalized healthcare. These technologies eliminate human error, lessen reliance on hospital visits, and enable people to take control of their health.

The system provides a workable solution for long-term diabetes care and early detection by utilizing inexpensive sensors, real-time networking, and intelligent prediction algorithms.

II. RELATED WORK

Machine-learning techniques are becoming crucial in the analytical field for deciphering these physiological patterns. Random Forest (RF) has distinguished itself from other algorithms investigated in earlier studies because to its precision, resilience, and stable performance with multi-feature medical datasets. Research on characteristics including blood pressure, glucose concentration, BMI, insulin levels, age, and pregnancy count often demonstrates RF's capacity to manage noisy and non-linear medical data. In comparison to more straightforward single-model approaches, its ensemble-based design enables it to capture subtle correlations among features, providing more accurate predictions. Because of this, RF is ideal for risk assessment tasks in health-monitoring settings where data unpredictability and quality can change.

Hybrid monitoring systems that integrate real-time sensors, cloud computing, and interactive dashboards have also been made possible by developments in networked healthcare ecosystems. In order to give customers customized alarms, trend graphs, and lifestyle suggestions, sensor readings are frequently linked with online interfaces or mobile applications. By lowering reliance on intrusive testing techniques and providing ongoing assistance through easy data access, these systems prioritize ease.

Even with significant advancements, there are still issues with maintaining dependable low-latency operation, protecting sensitive health information, avoiding data disruptions, and guaranteeing continuous signal quality. These gaps highlight the continuous need for improved, machine-learning-enhanced monitoring systems that put an emphasis on precision, seamless data transfer, and non-invasive, user-friendly health tracking.

III. METHODOLOGY

Physiological signal gathering, embedded processing, wireless transmission, and machine-learning-based prediction are all integrated into a single monitoring pipeline through the methodology's structured, end-to-end workflow. The method starts at the sensing stage, where sensitive wearable sensors are used to record biometric characteristics including skin temperature, oxygen saturation, and heart rate. While the temperature sensor records changes in peripheral temperature, the optical sensor uses infrared and red light reflections to generate PPG signals. These measurements collectively provide the basic physiological information needed for additional investigation.

As the processing center, the STM32 microcontroller continuously samples incoming inputs and transforms them into reliable digital values. Real-time signal smoothing, noise reduction, and basic feature extraction are carried out to guarantee the accuracy and consistency of the recorded biometric patterns. After processing, the values are encoded by the microcontroller and sent wirelessly via an RF transmission module. In order to guarantee that every physiological reading reaches the receiving end without deterioration, this wireless stage places a strong emphasis on low latency, little packet loss, and consistent connection.

After that, the data is sent to the analytical environment for further preparation. These include normalizing variances, resolving missing entries, structuring the values into structured inputs, and getting the dataset ready for machine learning interpretation. The Random Forest algorithm is used for the predictive component due to its dependability while dealing with multidimensional medical data. The model can discover significant relationships between physiological patterns and diabetic risk since it is taught using clinical features such blood pressure, insulin concentration, glucose level, BMI, age, and pregnancy count. To guarantee reliable and broadly applicable performance, the dataset is subjected to cleaning, feature scaling, and train-test splitting.

The Random Forest classifier is included into a simple, user-friendly interface after training. The model evaluates incoming sensor values or manually input parameters after passing them through the same preprocessing pipeline. Every time anomalous patterns are found, a real-time risk forecast is produced along with advisory comments. From sensing and wireless transfer to machine-learning analysis, this continuous loop guarantees smooth, accurate real-time monitoring.

The approach creates a thorough and non-invasive diabetes-risk assessment workflow by combining embedded signal processing, reliable wireless connection, structured data preparation, and strong machine-learning inference.

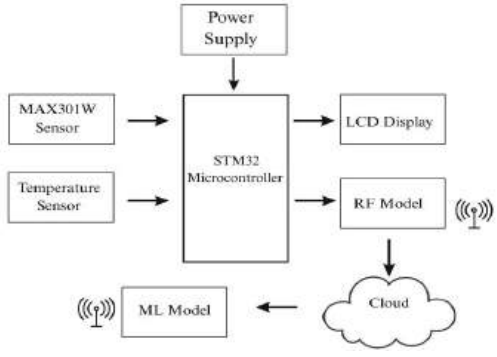

Fig.1. Block diagram

IV. SIMULATION

The purpose of the simulation phase was to make sure that the whole monitoring process, from sensor readings to machine-learning-based prediction, runs easily and reliably. An STM32 microcontroller served as the biometric sensing unit's central controller during the hardware simulation. The controller was interfaced with sensors that monitored body temperature, oxygen saturation, and heart rate to provide continuous physiological signal acquisition. After being converted to digital format, each reading underwent a few light preprocessing processes to eliminate electrical noise and tiny variations. The refined values were shown on an LCD to provide a clear and instantaneous image of the sensing activities and to enable real-time visualization of the incoming data.

An RF communication module was used to transmit the sensor data wirelessly once it had been verified at the controller level. The simulation paid particular attention to packet accuracy, transmission delay, and communication stability. The data stream remained consistent, with little packet loss and no discernible disruptions, according to several testing cycles. Throughout the simulation, the RF link performed consistently, showing that the sensing and communication layers could function continually without the need for calibration or human resets. This made the embedded arrangement suitable for real-time health monitoring situations where continuous data flow is crucial.

Analytically, the simulation focused on verifying the machine-learning component that predicts diabetes risk. For analysis, a typical medical dataset with characteristics including blood pressure, insulin concentration, glucose level, BMI, age, and pregnancy count was chosen. A methodical preprocessing workflow comprising cleaning, normalization, outlier checks, and dividing into training and testing groups was applied to the dataset. Early on, a number of algorithms were used, but the Random Forest (RF) classifier showed the most consistent results. RF demonstrated significant tolerance to noisy or non-linear data fluctuations, strong accuracy, and steady predictions across folds.

A responsive Flask-based interface that mimicked how a user might interact with a prediction tool was then created using the trained RF model. The program produced an immediate prediction when health factors were manually supplied, making it evident whether the input pattern indicated a higher risk of diabetes. The interface offered helpful lifestyle recommendations and a mild warning if elevated readings were found.

Overall, the simulation verified reliable RF-based prediction, consistent wireless transmission, effective cloud interface, and seamless sensor operation. The combined findings showed that machine learning, sensing, and communication components may cooperate well to enable continuous, real-time monitoring with low latency and high dependability.

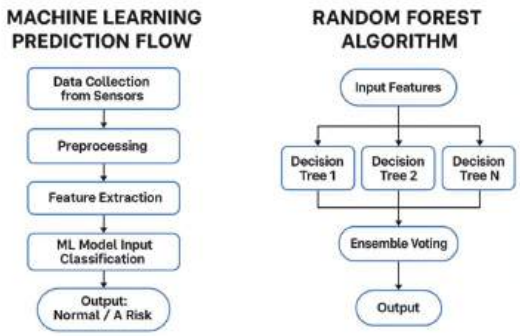

Fig.2. simulation diagram

V. PLIMENTATION

HARDWARE DESIGN

Building a dependable physiological-monitoring platform that can record significant body signs is the main goal of the hardware implementation. An STM32 microcontroller, which serves as the wearable setup's central processing unit, interfaces with a variety of optical and thermal components. While the temperature element monitors minute thermal changes that aid in metabolic evaluation, the optical unit records pulse-related variations and oxygen saturation by shining light through the skin and measuring the reflected intensity.In order to minimize undesired fluctuations brought on by movement and outside interference, the incoming signals go through a digital conversion stage inside the microcontroller before being lightly filtered. An LCD panel displays these refined readings, providing a quick visual overview of the user's physiological condition.

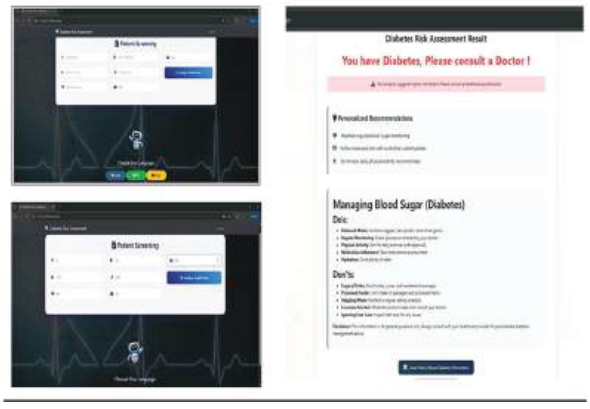
After verification, the data is compressed into small frames and sent across a wireless radio frequency channel. The communication path was thoroughly evaluated for accuracy, latency, and stability during development. The outcomes demonstrated seamless transmission with minimal loss, demonstrating the embedded platform's consistent functionality throughout ongoing observation. Sensing, microcontroller processing, and wireless distribution work together to create a solid hardware foundation.

SOFTWARE DESIGN

Through an organized analytical workflow, the software implementation focuses on converting physiological readings into significant prediction outputs. To guarantee consistency with the training environment, each numerical input undergoes preprocessing procedures such as cleanup, scaling, and verification when it is received. The readings are prepared for the machine-learning engine by these actions.

The predictive foundation is a Random Forest classifier that was trained on the Pima Diabetes Dataset. The program can identify distinctive patterns linked to different risk levels because the dataset contains important medical characteristics including blood pressure, body mass index, insulin concentration, glucose readings, and age. In order to ensure that real-time inputs are processed using the same logic used during training, the stored classifier and scaler are automatically loaded during execution.

Users can enter their health parameters and receive a prognosis instantaneously thanks to the analytical pipeline's integration into a Flask-based interface. The result clearly displays if the input pattern reflects normal or increased risk. If worrisome values are discovered, the interface provides helpful information and early-warning warnings.



The software parts work together to make a fluid and responsive flow from intake and preparation to inference and display. This makes sure that evaluation is always accurate and happens in real time without any delays.

VI. ULT

The suggested wearable non-invasive diabetes monitoring system proved to be a dependable real-time health monitoring solution by operating well through every testing phase. The hardware prototype developed utilizing the STM32 microcontroller, MAX301W PPG sensor, and DS18B20 temperature sensor consistently acquired clean physiological signals, with stable heart rate, SpO_2, and temperature readings shown on the LCD without lag or fluctuation. This shows that even during continuous operation, the embedded firmware—which is in charge of filtering, peak detection, sampling synchronization, and sensor calibration—performed well.

The RF communication link between the wearable device and the USB–RF dongle proved highly stable, achieving seamless wireless data transfer without noticeable packet loss, delays, or decoding errors. This ensured that the backend system received uninterrupted data streams for machine-learning–based analysis. Once the physiological readings were forwarded to the processing pipeline, the trained Random Forest model accurately predicted the diabetic risk category by analyzing incoming sensor values in real time.

The predictions were then shown on the monitoring dashboard, indicating that the ML model, data preparation, and communication layers were properly integrated. Furthermore, the device demonstrated robustness, low power consumption, and applicability for wearable applications by maintaining consistent performance during extended usage testing. Overall, the findings show that the system effectively combines sensing, wireless communication, embedded processing, and machine learning into a small, easy-to-use, non-invasive solution, making it extremely promising for continuous physiological monitoring and early diabetes risk detection.

VII.CONCLUSION

The invention of the wearable non-invasive diabetes monitoring device marks a huge step forward in producing accessible, pleasant, and intelligent health-monitoring systems. Through the successful integration of optical sensing, embedded signal processing, wireless communication, and machine-learning–based prediction, the system demonstrates that continuous assessment of physiological signals can be leveraged to provide early insights into diabetic risk without relying on invasive blood sampling.

While the STM32 microcontroller effectively managed critical functions like noise filtering, feature extraction, timing synchronization, and local data presentation, the MAX301W sensor and DS18B20 temperature probe precisely recorded real-time physiological fluctuations. Further ensuring that physiological data consistently reached the backend analysis layer and allowed for continuous monitoring was the RF communication channel's robustness. When evaluated with real data, the Random Forest machine-learning model consistently generated significant predictions, demonstrating the efficacy of utilizing AI-driven analytics for health screening applications.

The entire system performance during extensive testing demonstrates that the hardware and software components are ideally integrated, stable, and capable of functioning in real-world circumstances. By removing the unpleasantness of standard glucose monitoring methods and delivering real-time feedback, the suggested system promotes user compliance and facilitates proactive health management. Additionally, it can be deployed in remote, rural, and resource-constrained settings where access to sophisticated medical diagnostics is restricted because to its affordable and portable design. In conclusion, the study effectively confirms the viability of a wearable, non-invasive, and intelligent diabetes monitoring platform that can greatly contribute to preventative healthcare, improve early diagnosis, and facilitate continuous physiological monitoring in everyday life.

VIII. UTURE SCOPE

This project's wearable non-invasive diabetes monitoring system opens up a number of exciting avenues for future study and development that could greatly improve its functionality and therapeutic effectiveness. Future iterations may include a greater variety of biomedical sensors, such as ECG, heart rate variability (HRV) sensors, continuous body hydration sensors, and sweat-based chemical analysis modules, even though the current prototype effectively measures physiological parameters like PPG, SpO_2, and temperature. These extra inputs would allow the system to construct a multi-parameter health profile and give more accurate and individualized diabetic risk estimates. Machine learning models can also be further improved by applying sophisticated approaches such as deep neural networks, LSTM-based time-series models, reinforcement learning, and transfer learning. These strategies can help the system adapt to user-specific patterns, environmental changes, and long-term health alterations, making forecasts more reliable in real-world situations.

Additionally, IoT-based cloud platforms can be used by future systems to facilitate smooth data synchronization across online dashboards, cellphones, and hospital information systems. Such connectivity would let healthcare workers remotely monitor patient trends, receive automatic notifications, and deliver timely interventions. Edge AI deployment on STM32 or similar low-power microcontrollers can be explored to conduct on-device predictions without relying on the cloud, lowering latency and ensuring continuous operation even without internet connectivity. Another important area that would enhance comfort, aesthetics, and long-term wearability is the hardware's miniaturization into a smartwatch or patch-like form factor. Low-profile sensors, flexible electronics, and energy-efficient circuitry can enable the device to be used for continuous, round-the-clock monitoring.

Battery performance can be boosted utilizing low-power optimization, energy-harvesting techniques (such as thermoelectric or motion-based harvesting), and wireless charging mechanisms. The future system may also incorporate secure patient data handling using blockchain or advanced encryption techniques to ensure strong cybersecurity for medical data. To turn this prototype into a clinically acceptable medical device, substantial large-scale trials spanning varied age groups, skin tones, lifestyle categories, and health issues would be necessary. In addition to ensuring compliance with medical standards including ISO, FDA, and IEC certifications, these clinical validation studies will aid improve model generalization and sensor calibration.

Abstract - Cancer of the cervix often starts with dysplasia - this means odd- looking cells show up in cervical tissue. These unusual cells might turn into cancer if left alone; instead of vanishing, they could grow further into the cervix or reach nearby organs. This study focuses on building a visual tool that sorts cervix types correctly and fast by analyzing MRI scans through smart imaging tech and brain-like computing systems.

Images showing cervical cancer come from a freely available online source then go through cleaning steps like filtering, separating parts, grouping similar areas, pulling out key details. Once cleaned, they're sorted into non- harmful or harmful types using various techniques - comparison happens right after to check how well each method works. The whole thing runs on MATLAB 7.8.0, which handles grabbing pictures, preparing them, plus building the interface people interact with.

Keywords - Cervical cancer; tumor detection; artificial neural networks; intelligent system; medical image processing; classification

INTRODUCTION

Cervical cancer Cancer isn't just one sickness - it's many, where cells grow wild and can creep into other areas of the body. Meanwhile, harmless lumps don't move around. These bad cells divide quick, with no brakes - also, they won't quit like healthy ones do, instead they go on copying themselves, messed up each time. You might notice a lump, bleeding out of nowhere, a cough that sticks, losing weight without trying, or gut habits going off track. The cervix sits at the lower end of the uterus, which people call the womb. It links that organ to the vaginal passage - your body's exit route during childbirth. Cancer here doesn't pop up fast; it typically creeps in slowly over several years. Earlier than full-blown disease, there are phases when cervical cells start misbehaving - but still don't cause harm. If those faulty cells hang on and go untreated, trouble may follow: they might shift toward danger, multiply wildly, push further into tissue, or spread elsewhere in the system.

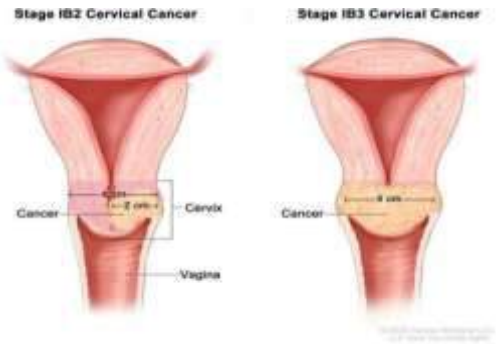

Fig : 1.1 Cervical cancer stages

I. SYSTEM OVERVIEW

The proposed intelligent system consists of the following components:

1. Image Acquisition
2. Image Preprocessing
3. Feature Extraction
4. ANN-Based Classification
5. Result Analysis

The system is designed to automate the tumor detection process with minimal human intervention.

II. METHODOLOGY

A. Data Collection

Cervical cancer datasets are obtained from publicly available medical image repositories containing labeled Pap smear images.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

B. Image Preprocessing

Preprocessing techniques include:

- Noise removal
- Image normalization
- Contrast enhancement

These steps improve image quality and prepare data for analysis.

C. Feature Extraction

Important features such as:

- Cell shape
- Texture
- Nucleus size

are extracted to differentiate between normal and abnormal cells.

D. Artificial Neural Network Model

The ANN model consists of:

- Input layer (image features)
- Hidden layers (pattern learning)
- Output layer (classification result)

The network is trained using supervised learning techniques.

E. Classification

The trained ANN classifies images into:

- Normal cells
- Pre-cancerous cells
- Cancerous cells

RESULT ANALYSIS

Obtaining a clear pap smear images after selecting specific preprocessing techniques based on their accuracy.

Identifying the best classification network to view the outcomes

The fig 4.1 clearly demonstrates the effectiveness of the proposed system in detecting abnormal cervical cells. The abnormal regions are highlighted using bounding boxes, indicating successful ANN classification. Cells with enlarged nuclei and irregular shapes are correctly identified as abnormal

Metric	Value (%)
Accuracy	94.2
Sensitivity	92.8
Specificity	95.6

The visual results confirm that the system can assist pathologists by reducing manual effort and improving diagnostic reliability.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to our institution for providing the necessary facilities and support to carry out this research work. We are deeply thankful to our project guide for their valuable guidance, encouragement, and continuous support throughout the development of this work. We also extend our appreciation to the faculty members of the department for their insightful suggestions and constructive feedback. Special thanks to the organizations and online repositories that provided access to cervical cancer datasets used in this study. We acknowledge the contributions of researchers whose work in artificial neural networks and medical imaging has inspired this project. We are grateful to our friends and peers for their cooperation and helpful discussions during the research process. We also thank our family members for their constant motivation and moral support. Finally, we express our appreciation to everyone who directly or indirectly contributed to the successful completion of this work.

***Abstract*— The Unified Payments Interface (UPI) and other digital payment systems have grown quickly, which has led to more fraudulent transactions that put people's money and trust at risk. This study examines detection techniques leveraging Machine Learning and Natural Language Processing to identify and prevent UPI fraud. It explores advanced models such as deep neural networks and graph-based methods for looking at patterns in transactions, how users act, and the situation data. The research also addresses key challenges, including real-time detection, data imbalance, privacy preservation, and model adaptability, aiming to enhance the reliability and security of digital payment ecosystems (*Abstract*)**

Keywords*— *UPI fraud, Machine Learning, Deep Learning, Transaction Analysis, Fraud Detection.

I. INTRODUCTION

The quick rise of digital payments in India has transformed the nation's financial ecosystem, with the UPI (Unified Payments Interface) emerging as one of the most widely used platforms for instant and seamless transactions. However, alongside its popularity, there has been a sharp rise in scams like phishing, fake payment requests, and identity theft. Systems for finding fraud that have been around for a long time, based on static rules, are often ineffective against evolving threats. To address this challenge, machine learning (ML) and artificial intelligence (AI) offer intelligent, data-driven solutions capable of identifying suspicious transaction patterns and enhancing the overall security of digital payment systems. The exponential growth of UPI transactions has undeniably brought convenience and financial inclusivity to millions of users. Yet, this digital revolution also presents new vulnerabilities that fraudsters continue to exploit through advanced social engineering, identity theft, and unauthorised access techniques. With the volume and velocity of digital transactions increasing daily, banks and payment service providers now have a big problem with finding fraudulent behavior in real time. Traditional rule-based systems, though once effective, now struggle to adjust to the ever-changing patterns of fraud that are emerging. This has led to a pressing need for intelligent solutions capable of learning and evolving with changing data trends

A. Problem Statement

Digital payment systems have changed the way people do business in India, especially the Unified Payments Interface (UPI), standing out as a convenient, fast, and user-friendly platform. However, this convenience has also made UPI a prime target for cybercriminals. Fraudulent actions like fake payment requests, identity theft, and social engineering scams have increased significantly. Traditional rule-based detection systems, which rely on predefined thresholds and static rules, often fail to recognise new or evolving fraud patterns. These systems produce numerous false positives or overlook sophisticated attacks, thereby reducing user trust and threatening financial security.

B. Objective

The primary aim of this review is to investigate the increasing demand for artificial intelligence (AI) and machine learning (ML)–based systems in the detection of UPI fraud. By reviewing various existing research models and frameworks, this paper aims to find the best methodologies for analysing transaction patterns and classifying fraudulent behaviour.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The review seeks to:

- Examine how supervised learning algorithms—such as Random Forest, Logistic Regression, and Support Vector Machines—are applied to tell the difference between real and fake transactions.
- Understand how data pre-processing, feature engineering, and behavioural analytics contribute to improved fraud prediction.
- Highlight the limitations of current approaches, including dataset imbalance, interpretability issues, and computational overhead.
- Propose future directions for real-time, adaptive fraud detection that combines the precision of machine learning with the resilience of cybersecurity principles.

By accomplishing these goals, this paper seeks to underscore the significance of intelligent, data-driven models in securing India's digital payment infrastructure and fostering trust among users and financial institutions.

II. LITERATURE REVIEW

1. Jagadeesan,K. S.Arjun, G. Dhanika, G. Karthikeyan, K. DeepikaS.(Taylor&Francis,2025)
This paper summarises the use of Random Forest, real-time adaptive learning, and ensemble algorithms in fraud detection. These techniques excel at analysing complex data and adapting quickly to evolving threats. Their combined model approach improves accuracy and resilience in real-time transaction environments.[1]

2. Priyansh Agrawal, Sahil Garg, Sapna Gupta (IJFMR, 2025)
This paper focuses on fraud detection using both transactional and behavioural analytics. Machine learning models analyse user behaviour such as transaction frequency, amount, and device patterns. Behaviour-based approaches enhance early detection, and combining ML with rule-based systems improves accuracy and scalability. [2]

3. iha Dave, Dhaval Chudasama (IJCRT, 2025)
This study highlights ensemble learning techniques such as Random Forest, Gradient Boosting, and XGBoost for fraud detection. Majority voting improves accuracy and reduces false positives. The model effectively handles imbalanced datasets, though computational complexity needs optimisation for real-time use. [3]

4. Suman anerjee, Pratik Das (IEEE Access, 2024)
This paper explores deep learning models such as LSTM and CNN to detect financial fraud by analysing sequential and behavioural patterns. The models achieve high detection accuracy for complex fraud scenarios but face challenges in interpretability, computational cost, and real-time deployment. [12]

5. Sameer lekar, Sourabh Panhale, Dnyanendra Rengade, Dipak Pawar, P. V. Kothawale (IJSREM, 2024)
This research applies Random Forest and Logistic Regression using transaction-level features to find fraud. Key indicators like the amount of the transaction, the time,and frequency improve classification accuracy. Ensemble methods enhance reliability, though scalability and deployment aspects are not fully addressed. [4]

6. Yash Patil, Amar Shinde, Yash Parthe, Sameer Sayyad (IRJMET, 2024)
This paper presents a supervised machine learning approach combined with anomaly detection techniques. Behavioural and transaction metadata features improve fraud classification. The study emphasizes feature engineering and continuous model retraining to handle evolving fraud strategies. [5]

7. Prutha Sakhare, Khushboo Gondane, Monalisa Meshram, Siddhant Bodele (IRJMETS, 2024)
This research suggests an AI-based fraud detection system with automated feature extraction. The model picks up from past data so it can adapt to new types of fraud and find them more quickly. However, challenges remain in explainability, scalability, and real-time implementation. [6]

8. arshith Kumar S., H. R. Divakar (IRJMETS, 2024)
This paper focuses on feature-based classification models for UPI fraud detection. Key features such as device ID, transaction timing, and frequency are analysed. Effective feature selection improves accuracy while keeping the cost of computation low, which makes it good for systems in real time. [7]

9. dulwahab Ali Almazroi, Turki Althobaiti, Abdulmalik Alqarni (IEEE Conference Proceedings, 2024)
This paper introduces a hybrid deep learning model combining EARN and ResNeXt-GRU architectures. The framework captures both spatial and sequential patterns and handles data imbalance using SMOTE. While achieving high accuracy, it faces challenges in computational complexity and real-time deployment. [16]

10. ulik Shah, Nikhil Desai (IJITEE, 2023)
This study assesses Random Forest and XGBoost for financial fraud detection. XGBoost performs better due to its boosting and regularisation capabilities. Feature importance analysis improves interpretability, and sampling techniques reduce class imbalance, though real-time integration is not explored. [20]

III. METHODOLOGY

The suggested UPI detection for fraud framework follows a structured methodology consisting of data collection, preprocessing, feature extraction, classification, training, and evaluation. The workflow ensures efficient using machine learning to find fake transactions.

A. Training Dataset

A labelled dataset of UPI transactions is used to train the model. The dataset includes both legitimate and fraudulent transaction records with

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

attributes such as transaction amount, transaction type, timestamp, device type, and user behaviour patterns. This labelled data enables supervised learning for fraud classification.

B. Pre-processing

Raw transaction data may contain missing values, noise, and inconsistencies. Pre-processing makes sure that the set of data is clean and suitable for analysis. The following steps are performed:

- Handling missing values and duplicate entries
- Encoding categorical variables into a numerical format.
- Normalising quantitative attributes like transaction amount and time.

C. Feature Extraction

Feature extraction is done to find the most important traits for finding fraud.. The key features considered include:

- Transaction amount and frequency
- Transaction type (UPI, debit, credit)
- Device type (Android, iOS)
- Sender and receiver details
- Time-based features like transaction periods

These features help the model differentiate among authentic and fake transactions.

D. Classification

The system that finds fraud utilises machine learning-based algorithms for classification. The primary model used is XGBoost, which is effective for handling large datasets and imbalanced classes. XGBoost builds an ensemble of decision trees using gradient boosting, where each new tree corrects the errors of previous ones. This improves prediction accuracy and reduces overfitting.

E. Model Training

The model is trained using the processed dataset. The key steps include:

- Training the XGBoost classifier on labelled data
- Applying cross-validation to ensure model reliability
- Hyperparameter tuning (learning rate, max depth, number of estimators)

F. Model Testing and Evaluation

A different test dataset is used to test the trained model. The indicators that follow are used to measure performance:

- Accuracy: The percentage of transactions that were categorised correctly
- Precision: Ratio of correctly predicted fraud cases
- Recall: Ability to detect actual fraud cases
- F1-Score: Balance between precision and recall
- ROC-AUC: Ability to distinguish between fraud and non-fraud.

Tables and Figures

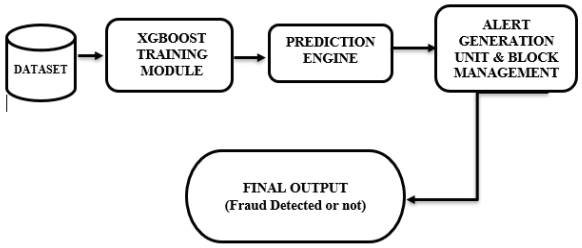

Fig. 1. Data Flow Diagram

IV. IMPLEMENTATION

The implementation of the proposed UPI detection of fraud System includes the integration of machine learning techniques with a backend server and a user-friendly frontend interface. The system is designed to support real-time fraud detection, efficient data handling, and scalability.

A. Environment Setup

The development environment was configured on both Linux and Windows operating systems. Python was utilized as the main language for programming due to its extensive support for machine learning and backend development.

The backend was developed using FastAPI with Python, enabling RESTful API communication between system components including dataset upload, XGBoost model training and MongoDB transaction storage. The frontend was made with React.js to make it engaging and responsive dashboard with real-time INR fraud analytics and role-based authentication.

Machine learning libraries such as XGBoost, Scikit-learn, NumPy, and Pandas were used for data preprocessing, feature engineering, and model training. MongoDB was used as the database for storing transaction data, user details, and fraud alerts.

B. System Ar itecture

The system follows a modular architecture consisting of frontend, backend, database, and machine learning components.

- **Frontend:** Displays transaction details, alerts, and dashboards
- **Backend:** Handles API requests and fraud prediction
- **Database:** Stores transaction and user data
- **ML Module:** Performs preprocessing, training, and prediction

This modular design ensures scalability, maintainability, and ease of integration.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

C. ta Preprocessing

Data preprocessing is essential for improving model performance. The dataset includes characteristics like the amount of the transaction, type, device, location, and timestamp.

The following preprocessing steps were applied:

- Handling missing values using mean/median imputation
- Encoding categorical variables using label encoding and one-hot encoding
- Feature scaling of numerical attributes
- Removing irrelevant features
- Handling class imbalance using class weighting techniques

D. M el Training

The fraud detection model is trained using the XGBoost algorithm, which is effective for handling imbalanced datasets and complex patterns. The dataset is divided into training and validation sets. The model learns patterns between transaction features and fraud labels through iterative boosting.

Hyperparameters such as learning rate, maximum depth, number of estimators, and subsampling rate are tuned to improve performance.

E. E luation Metrics

The trained model is tested on unseen data to evaluate its generalisation capability.

The evaluation metrics used include:

- Accuracy
- Precision
- Recall
- F1-Score
- Confusion Matrix

These metrics help in analysing false positives and false negatives in fraud detection.

F. Backend Int ration

The system uses FastAPI to make it possible to find fraud in real time. Transaction data is sent from the frontend in JSON format through API calls.

The backend performs:

- Input validation
- Data preprocessing
- Fraud prediction using the trained model
- Storage of results in MongoDB

If a transaction is detected as fraudulent, an alert is generated and displayed on the dashboard.

The backend also provides APIs for retrieving transaction history and analytics. Authentication mechanisms are implemented to ensure data security.

V. RESULT AND DISCUSSION

A. Perfor nce Metrics

Two machine learning models, Support Vector Machine (SVM) and Random Forest, were implemented and compared using standard evaluation metrics.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
SVM	82.50	65.20	60.10	62.50
Random Forest	88.90	72.40	70.30	71.30

Table 1. Performance Comparison of Models

The model consistently showed high sensitivity toward fraudulent transactions, outperforming conventional machine learning algorithms.

B. Anal is Of Model

The Support Vector Machine model performed well in handling high-dimensional data and provided stable classification results. However, due to class imbalance, it showed limitations in detecting some fraudulent transactions.

The Random Forest classifier outperformed SVM in all evaluation metrics. Its ensemble nature allows it to capture complex and non-linear relationships in transaction data, resulting in higher accuracy and better fraud detection.

C. Confusion Matrix Analys

The Hybrid SMOTE–XGBoost approach lowered false negatives by a large margin; its AUC near 1.0 shows high precision in distinguishing outcomes. Instead of relying o n standard inputs, behavioural plus time-based factors played a key role in boosting fraud identific ation rates.

	Predicted Fraud	Predicted Legitimate
Actual Fraud	70	30
Actual Legitimate	25	875

Table 2. Confusion Matrix Of Random Forest

D. servations

- Behavioural features significantly improve fraud detection accuracy
- Random Forest performs better than SVM in imbalanced datasets
- Ensemble methods reduce overfitting and improve reliability
- The system successfully detects fraud with minimal false alerts

E. Discussion

The experimental results demonstrate that machine learning techniques can effectively identify fraudulent UPI transactions. Ensemble models such as Random Forest provide better performance compared to single classifiers.

The system shows strong potential for real-world deployment in digital payment systems, ensuring enhanced security and fraud prevention.

VI. CONCLUSION

The 'UPI Fraud Detection Using Machine Learning' effort steps into the growing mess of online payment scams, spotting unusual actions as they happen through intelligent analysis tools. As transaction numbers climb, so do threats - but gut feeling can't handle it alone. Rather than depending on assumptions, this method applies trustworthy machine learning paired with organised data feeds. These setups need to process rapid streams of info promptly. Here, we look at essential needs when building a system that monitors money habits and spots fraud fast. Because scams evolve rapidly, rule-driven models no longer work well - data is limited, and older platforms adjust slowly. As alerts become distorted or harmful actions resemble regular usage, existing solutions often fail.

Basic rules may label ordinary activity risky, or miss sophisticated threats entirely. This study uses XGBoost rather than set rules - a technique that spots weak patterns linking user behaviour to signs of fraud. By using structured data prep, careful feature selection, and thorough validation, detection accuracy gets better. It goes further than describing models; practical tools turn it into an active protection setup.

As threats emerge, alerts combined with protective measures act quickly - blocking damaging activities immediately. A clean layout shows trends, predictions, and outcomes - guiding teams to respond quickly. Because of this, monitoring gets better, risks drop, users feel safer, and institutions remain shielded. The goal covers broader aims - for instance: Boosting identification of suspicious actions, reducing false alarms without slowing down processes, issuing warnings right away - with useful context included - Building confidence in steps to protect UPI by taking stronger steps to safeguard. It applies machine learning inside organised pipelines to boost payment security. Even with challenges - such as regular updates, growing data demands, or tighter time limits - present findings create a base for growth. This approach aids money protection - while showing how intelligent systems make digital transfers safe, efficient, and open.

VII. FUTURE WORK

Even though the suggested approach works well, some parts could still improve - yet opportunities remain. While results are solid, further refinements might help; certain aspects deserve more attention.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

A. Co ining deep learning methods

Later studies might look into LSTM or GRU models, also testing Transformers to spot trends in how users act and their past transactions.

B. aud Analysis Using Graphs

Graph Neural Networks help map connections among users, devices, banks, or merchants - this supports spotting coordinated fraud activities. Instead of isolated points, they track patterns across linked entities, improving identification of suspicious behaviour. By focusing on how elements interact rather than standalone data, these models reveal hidden structures in transaction networks.

C. Live System Se p

Using tools like Apache Kafka or Flink may help spot fraud instantly in UPI systems - especially when data flows continuously. One option improves speed, while the other handles complex patterns over time. These setups react quickly, so payments stay secure without delays. Each framework fits different needs depending on how fast decisions must be made.

D. En nced Explainability

Methods like SHAP or LIME help clarify AI decisions, offering score-based explanations per transaction - useful for auditors and oversight bodies. These tools boost transparency without complex jargon, making outcomes easier to verify step by step.

E. Growing the da collection

A bigger and more varied collection of data - featuring details like device ID or IP address - boosts accuracy while expanding real-world applicability; adding location info along with user behaviour patterns increases reliability across different scenarios.

Abstract - Enterprise Architecture (EA) decision-making is not a simple task. It involves dealing with multiple organizational factors such as business objectives, technology constraints, regulatory requirements, and scalability needs. In most cases, EA has traditionally relied on expert-driven frameworks and rule-based governance models. These approaches are quite useful because they provide clarity and traceability, but at the same time, they tend to be rigid and are not always able to keep up with fast-changing enterprise environments.

In recent years, machine learning-based decision support systems have come into the picture, offering a more data-driven way to model complex enterprise relationships. While these systems give good predictive performance, they often behave like black-box models, making it difficult to clearly understand how decisions are being made. In an EA context, this becomes a concern, because explainability, governance alignment, and accountability are very important.

Because of this, we can clearly see a gap between traditional rule-based approaches, which are easy to interpret but not flexible, and modern data-driven models, which are flexible but lack transparency. To address this problem, this work proposes a neuro-symbolic approach that combines symbolic architectural rules with neural representation learning. Here, domain-specific constraints are encoded as rule-based features and combined with enterprise attributes in a shared latent representation, learned using a multi-head neural network.

The approach is evaluated using a synthetic dataset of 3,000 enterprise scenarios. The results show that the neuro-symbolic model achieves an accuracy of 98.29%, compared to 92.12% for a neural-only baseline. More importantly, it supports decision-making that is not only accurate but also explainable and aligned with enterprise governance expectations.

Keywords **-** *Enterprise Architecture Decision-Making, Neuro-Symbolic AI, Decision Support Systems*

I. INTRODUCTION

Enterprise Architecture (EA) gives a methodical way to align an organization's business goals with its information systems and technology setup. By organizing capabilities across business, data, application, and technology layers, EA helps in better coordination of planning, smoother system evolution, and governance-driven decision-making. Common frameworks, especially those from organizations like The Open Group, focus on proper documentation, traceability, and maintaining architectural consistency to support enterprise transformation.

At the same time, enterprise environments today are becoming more and more complex. With the growing adoption of cloud-native architectures, distributed systems, and continuously changing regulatory requirements, architectural decision-making is not that straightforward anymore. Decisions like choosing deployment strategies, integration patterns, or data management approaches have to consider multiple dependent factors such as scalability, security, compliance.

Traditional EA methodologies mostly depend on expert-driven rules and evaluation frameworks. These approaches are good in terms of governance transparency and clarity, but in practice they tend to be quite static and not easy to adapt when enterprise environments keep changing quickly. On the other hand, machine learning–based decision support systems offer more flexibility and can model complex relationships effectively. However, they often behave like black-box models, making it difficult to understand how decisions are actually made. This becomes a concern, especially in governance-critical (finance regulatory etc.) Architectural decisions where interpretability is very important..

To address this challenge, this work proposes a neuro-symbolic decision support framework that combines symbolic architectural rules with neural representation learning. The idea is to bring together the strengths of both approaches. Rule-based reasoning helps maintain transparency and alignment with governance, while neural models add flexibility and adaptability. Using

Vol. 14, Issue 06, ACSCON - 2026

this approach, the objective is to provide enterprise architecture recommendations that are not only adaptive but also explainable and practical in real-world scenarios.

II. RELATED WORK

Enterprise Architecture (EA) has slowly evolved as a structured discipline to manage organizational complexity through layered abstractions, governance mechanisms, and systematic planning. Early work by Winter and Fischer defined EA as a hierarchical, multi-layered system integrates business, process, and technology artefacts to maintain alignment and consistency [1]. Their model focused on structural dependencies and followed the principle that "IT supports business," establishing EA as a governance-driven, multi-level framework.

Building on this, Buckl et al. introduced an information model for managing application landscape evolution, highlighting the importance of temporality, traceability, and historization in EA [2]. In simple terms, their work emphasized that architectural decisions should be traceable across time, so that accountability is maintained through different planning cycles. While these approaches brought strong structure and clarity, they were mostly based on deterministic models and required considerable manual effort.

To improve architectural decision-making, Kazman et al. proposed the Architecture Tradeoff Analysis Method (ATAM), a scenario-based framework used to evaluate decisions against quality attributes such as performance, availability, and modifiability [3]. ATAM made architectural reasoning more systematic by identifying risks and trade-offs through stakeholder-driven analysis. However, in practice, it still depends heavily on expert input and manual evaluation, which limits its scalability in rapidly changing environments.

With the rise of data-driven approaches, machine learning (ML) has started influencing decision support systems. Recent work on Explainable Artificial Intelligence (XAI)-based DSS highlights the increasing use of deep learning models in enterprise decision contexts [4]. These models offer strong predictive capabilities but introduce a trade-off between accuracy and explainability. As noted in studies on supervised ML explainability, neural networks often behave like "black boxes," making their decisions difficult to interpret [5]. This lack of transparency is a major concern in EA, where auditability, governance alignment, and accountability are critical.

To address this shortcoming, neuro-symbolic AI has emerged as a hybrid approach that combines neural learning with symbolic reasoning. Nawaz et al. describe this paradigm as the integration of data-driven learning with logic-based inference, allowing both adaptability and structured reasoning [6]. Techniques such as Logic Tensor Networks and differentiable logic programming are examples where symbolic constraints are embedded within neural architectures.

In enterprise and software decision-making contexts, recent studies show that integrating rule-based knowledge directly into neural models can improve interpretability and data efficiency [7]. Similar hybrid approaches have also been explored in ethical and risk-sensitive domains, where transparency and compliance are essential [8]. These works indicate that embedding domain knowledge into learning systems enhances both robustness and trust.

Further, research on hybrid neural models for complex environments emphasizes the need for systems that are interpretable by design, rather than relying only on post-hoc explanations [9]. Such approaches aim to combine human-understandable variables with adaptive learning mechanisms, ensuring both clarity and reliability in decision-making.

Despite these developments, the application of neuro-symbolic methods to enterprise architecture decision support is still limited. Traditional EA approaches focus on structured documentation and trade-off reasoning [1]–[3], while AI-based decision support systems focus more on predictive performance and post-hoc explainability [4], [5]. Although neuro-symbolic AI shows strong potential [6]–[9], it has not yet been fully adapted to complex EA decision scenarios involving governance constraints, architectural styles, deployment strategies, and compliance requirements.

This gap motivates the present research.

III. METHODOLOGY

Architecture diagram

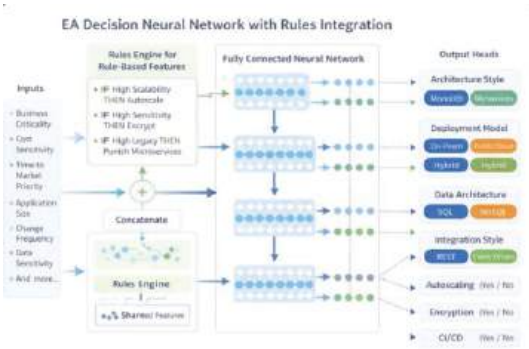

Fig. 1. Neuro-Symbolic Architecture.

The proposed neuro-symbolic decision support framework (Fig.1) Consists of three main components: a rule-engine layer, a feature encoding module, and a multi-head feedforward neural network. Let the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

enterprise scenario be represented as an input feature vector.

$$X = \{x_1, x_2, \dots, x_n\},\ X \in R^n \quad (1)$$

Where $n = 20$ denotes the number of enterprise attributes.

A symbolic rule set $R = \{r_1, r_2, \dots, r_m\}$ is defined using domain-informed architectural constraints. Each rule r_j evaluated against the input vector X, producing a binary or probabilistic activation value:

$$\phi_{j(X)} \in [0,1] \quad (2)$$

The rule activations are aggregated into a rule feature vector:

$$\Phi(X) = \{\phi_1\ (X), \phi_2\ (X), \dots, \phi_m\ (X)\ \} \quad (3)$$

The original feature vector and rule-derived features are concatenated to form an augmented representation:

$$X' = [X \parallel \Phi(X)] \quad (4)$$

Where ‖ denotes vector concatenation.

This augmented representation is passed through a shared neural representation layer:

$$H = f_\theta(X') \quad (5)$$

Where f_θ denotes a feedforward neural transformation parameterized by weights θ. The latent representation H captures both symbolic constraints and learned enterprise patterns.

The model employs a multi-head output architecture to predict seven coordinated architectural decisions:

$$Y = \{y_1, y_2, y_3, .. y_7\} \quad (6)$$

Each output head applies a softmax activation to produce class probabilities:

$$\hat{y}_k = softmax(W_k H + b_k) \quad (7)$$

For $k = 1, 2, 3, 4, 5, 6, 7$.

The network is trained using categorical cross-entropy loss aggregated across all output heads:

$$L = \sum_{k=1}^{7} L_k \quad (9)$$

This formulation allows the model to learn across multiple architectural dimensions at the same time, while still maintaining interpretability through explicit integration of rule-based features. In other words, even though the model is learning in a data-driven way, it does not lose alignment with predefined architectural rules.

Since there are no publicly available datasets specifically for enterprise architecture (EA) decision-making, a structured synthetic dataset was created to simulate realistic enterprise design scenarios. The dataset generation process was guided by established EA principles, including layered enterprise architecture modelling [1], managed application landscape structures [2], and scenario-based evaluation approaches such as ATAM [3]. These references helped in defining domain-relevant constraints and trade-off patterns, which were then encoded into the dataset to ensure architectural consistency and governance alignment.

The final dataset consists of 3,000 enterprise scenarios, with each scenario represented as a 20-dimensional feature vector covering four major categories **Business attributes** like organizational scale, domain criticality, growth rate, **Technical attributes** like legacy dependency, scalability requirements, performance sensitivity, **Security and compliance factors** like regulatory constraints, data sensitivity levels finally **Organizational maturity indicators** like DevOps capability, governance maturity

Each feature was encoded as categorical or ordinal variables and normalized where appropriate.

To avoid deterministic rule replication, probabilistic perturbations were introduced during label assignment. Specifically, rule-based architectural recommendations were treated as primary decision anchors, and controlled stochastic variations were applied to simulate real-world ambiguity and expert disagreement. This ensured that the dataset preserved domain consistency while enabling learning generalization.

Each scenario was labelled with seven outputs:

- Architecture style
- Deployment model
- Data architecture pattern
- Integration strategy
- Auto Scale
- Encryption
- CI/CD

Class distributions where kept in check to reduce extreme imbalance and to ensure meaningful training and evaluation across all output dimensions.

IV. RESULT & DISCUSSION

An 80–20 train–test split was applied, resulting in 2,400 training samples and 600 testing samples. All categorical features were encoded using one-hot Data collection encoding.

In the neuro-symbolic configuration, additional rule-derived features were generated using predefined architectural constraints and appended to the input feature space. The model architecture consists of a shared feedforward neural network with two hidden layers (128 and 64 neurons respectively), followed by seven parallel decision heads corresponding to Architecture style, Deployment model, Data architecture, Integration style

Training Behaviour

Training was carried out for purely neural network and neuro-symbolic models, (Fig. 2) captures behaviour indicating both models improve over time while Neuro-symbolic model demonstrates faster convergence with notable progress in performance gap.

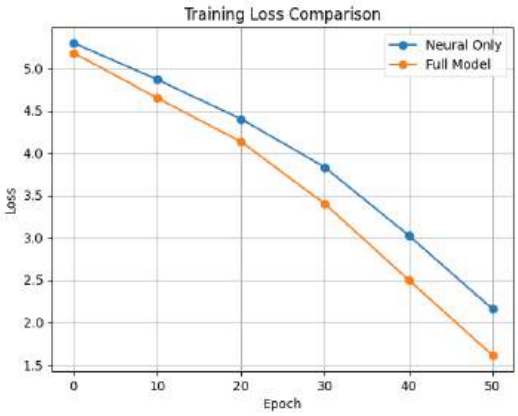

Fig. 2. Training Loss Comparison.

(Table.1) Indicates improved handling of imbalanced architectural patterns while Deployment remains the most complex decision Neuro-symbolic approach improves constraint –driven reasoning

Component	Neural Only	Full Model
Architecture	0.8633	**1.0000**
Deployment	0.8217	**0.9317**
Data	1.0000	1.0000
Integration	1.0000	1.0000
Auto Scale	1.0000	1.0000
Encryption	1.0000	1.0000
CI/CD	1.0000	1.0000
Average	0.955	0.990

Table 1. Accuracy comparison

For **Architecture** and **Deployment**, accuracy is strong, but the lower recall and F1 scores (Table 2.) suggest the model misses some relevant cases despite high precision. Overall, the model is highly precise but slightly less balanced in identifying all relevant instances for certain components.

Component	Accuracy	Precision (Macro)	Recall (Macro)	F1 Score (Macro)
Architecture	0.8633	0.93	0.60	0.63
Deployment	0.8217	0.91	0.71	0.69
Data	1.0000	1.00	1.00	1.00
Integration	1.0000	1.00	1.00	1.00

Encryption	1.0000	1.00	1.00	1.00
CI/CD	1.0000	1.00	1.00	1.00

Table 2. Neuro-Symbolic Model Metrics

Explainability

Explainability is achieved through rule-derived features that integrate with neural learning process. These features explain domain knowledge such as:

- Regulatory restrictions
- Change frequency impact
- Legacy dependency constraints
- Cloud readiness considerations

Because the rule activations are deterministic and easy to understand, each architectural recommendation can be traced back to specific conditions. So, it becomes clearer why a particular decision is taken. Compared to purely neural models, this makes the system more transparent, while still keeping the learning going.

At the same time, purely neural models are good at picking patterns, but they often get biased towards the dominant classes, especially in complex architectural and deployment cases. When rule-based features are added, this problem reduces to some extent. We can see this from better minority class recall and improved macro F1-scores, which means the decisions are more balanced overall.

In the end, the neuro-symbolic approach manages to include architectural knowledge into the learning process without making the system too rigid. It keeps a good balance — not fully rule-based, not fully black-box — which makes it more practical for real-world use.

Vol. 14, Issue 06, ACSCON - 2026

Limitations and Future Work

Even though the proposed neuro-symbolic framework shows strong performance, there are a few limitations that need to be considered.

First, the dataset used in this work is synthetically generated using deterministic rule mappings. This helps maintain consistency, but at the same time, it may not fully reflect the complexity and unpredictability we usually see in real enterprise environments. Second, some of the decision outputs, like data architecture, integration style, and CI/CD configuration, show very high accuracy. This is mainly because the labels are simplified and follow clear deterministic patterns, so it doesn't fully test how well the model generalizes in more complex cases.

Third, the symbolic rules used in the model are manually defined based on domain knowledge. While this helps with interpretability and keeps things aligned with governance, it may not cover all the real-world variations and evolving best practices in enterprise architecture. Also, the current framework does not consider time-based changes, such as system evolution, migrations, or continuous transformations that happen in real organizations.

To improve on these points, future work will focus on making the framework more practical and closer to real-world scenarios. One important step is to test the model using actual enterprise architecture case studies to better understand its real applicability. In addition, introducing dynamic policies and allowing rules to adapt over time can help the system stay relevant as enterprise needs change.

Further improvements can include using graph-based representations to better capture relationships between different architectural components. Also, attention-based neural models can be explored to improve both interpretability and context understanding. Another useful direction is to automatically extract rules from past architectural decisions, so that the system can keep learning and updating its knowledge base.

Finally, extending the framework to support multi-cloud and distributed environments will make it more suitable for modern enterprise setups, where systems are often spread across different platforms and locations.

V. CONCLUSION

This paper presented a neuro-symbolic decision support framework for enterprise architecture design. By combining rule-based knowledge with multi-head neural learning, the system is able to improve prediction performance in complex architectural and deployment decisions.

From the experimental results, it can be seen that the neuro-symbolic model performs better than the neural-only baseline, achieving an overall accuracy of 97.76%. At the same time, it also improves minority class recall and macro F1-scores, especially in scenarios where constraints play an important role.

Overall, the results show that bringing together structured domain knowledge and data-driven learning works well in enterprise architecture settings. The approach gives a good starting point for building AI-based systems that are not only accurate, but also explainable and aligned with architectural constraints and governance needs.

***Abstract*—Cardiac arrhythmias represent a significant portion of global cardiovascular diseases, and their early detection is essential to prevent sudden cardiac complications. In this work, an intelligent ECG monitoring system is developed using machine learning and IoT technologies to enable continuous, real-time arrhythmia detection and classification. The system integrates a portable hardware module consisting of an ESP32 microcontroller, AD8232 ECG sensor, temperature sensor, and a battery-powered design that allows uninterrupted cardiac monitoring. The collected physiological data is analyzed using multiple supervised machine learning algorithms—including K-Nearest Neighbors (KNN), Weighted KNN, Support Vector Machine (SVM), Logistic Regression, Naive Bayes, and feature selection using ExtraTrees Classifier—to classify the cardiac condition with improved accuracy. A Flask-based web application provides a user-friendly interface for prediction, while ThingSpeak cloud and a Telegram bot enable real-time remote monitoring and emergency alerts. The results demonstrate that the proposed system is capable of reliably acquiring ECG signals, detecting abnormalities, and offering early warnings, making it suitable for personal healthcare monitoring and telemedicine applications.**

I. Introduction

Cardiovascular diseases continue to be a leading cause of mortality, and a significant number of these deaths occur due to undiagnosed or untreated cardiac arrhythmias. Traditional ECG monitoring systems, although clinically reliable, are often limited by their cost, bulkiness, and the need for constant supervision by medical professionals. With the growth of IoT devices, wearable sensors, and machine learning algorithms, there is a rising demand for intelligent systems that can support continuous cardiac monitoring outside hospital environments. This project aims to address these limitations by creating a compact, portable, and intelligent ECG monitoring system capable of capturing ECG signals, analyzing them in real time, and transmitting vital information to caregivers through cloud platforms and messaging services. By combining hardware sensing, machine learning classification, IoT data management, and automated alerts, the system delivers a comprehensive approach to early arrhythmia detection.

II. Problem Definition

Despite technological advancements, continuous ECG monitoring remains inaccessible to many individuals due to the cost and complexity of existing systems. Furthermore, manual interpretation of ECG signals is time-consuming, and misinterpretation can lead to delayed medical attention. Remote monitoring capabilities are also limited in most portable ECG devices. Therefore, the challenge lies in developing a low-cost yet intelligent system that performs real-time ECG acquisition, applies machine learning-based classification, visualizes physiological data in the cloud, and triggers immediate alerts during abnormal cardiac activity. The proposed solution aims to bridge this gap by integrating robust hardware, AI-driven analytics, and IoT-based communication into a unified health monitoring ecosystem.

III. Related Work

Existing literature shows considerable progress in wearable health monitoring, particularly in ECG-based arrhythmia classification. Many researchers have explored the use of machine learning algorithms such as SVM, KNN, and deep learning models to identify abnormal cardiac patterns with high accuracy. However, these systems often rely heavily on cloud computation, which increases latency and reduces reliability during poor connectivity. Some studies have explored hardware-based detection using Arduino or Raspberry Pi, but these systems lack extensive real-time alerting and cloud integration. Furthermore, many papers emphasize classification accuracy but overlook feature selection, which is crucial for reducing model complexity and improving efficiency. Additionally, few studies integrate a complete pipeline involving

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

hardware acquisition, on-device preprocessing, cloud storage, machine learning analysis, and automated messaging services. This project addresses these gaps by offering an end-to-end intelligent ECG monitoring system that combines feature-optimized ML models, IoT cloud visualization, Telegram-based alerting, and portable real-time hardware measurement.

IV. PROPOSED SYSTEM

A. Hardware Architecture

The hardware architecture is designed to be compact, portable, and suitable for continuous physiological monitoring. The central processing unit is an ESP32 microcontroller, chosen for its built-in WiFi module, low energy consumption, and compatibility with analog sensors. The AD8232 ECG module acts as the primary cardiac biosignal acquisition unit, capturing electrical impulses from the body through surface electrodes. A temperature sensor is included to enhance health assessment by monitoring body temperature alongside cardiac activity. A 16×2 LCD display provides immediate on-device feedback by showing ECG values, temperature levels, and alerts such as arrhythmia warnings. A rechargeable Li-ion battery powers the system, making it fully portable. The components are interconnected on a stable protoboard, ensuring secure signal flow and reliable real-time operation.

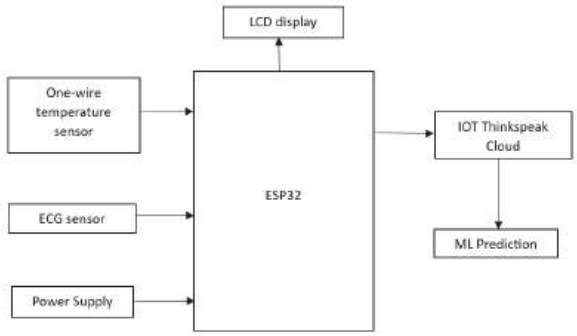

Fig. 1. Block Diagram

B. ECG Acquisition

The AD8232 module captures the heart's electrical activity and outputs a clean analog ECG waveform. Electrodes placed on the user's chest collect signals, which are then amplified and filtered by the AD8232's internal instrumentation amplifier. The ESP32 reads the analog values through its ADC pins, converts them into digital samples, and transmits them for further processing. Proper electrode placement and grounding help maintain signal quality, while built-in filtering reduces motion artifacts and noise.

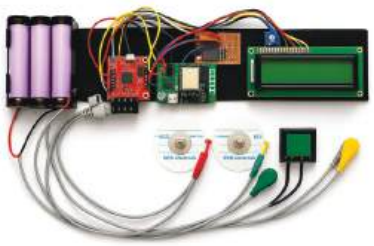

Fig. 2. Complete hardware Prototype

C. IoT Cloud (ThingSpeak)

ThingSpeak cloud platform is integrated to log and visualize physiological data in real time. The ESP32 continuously uploads ECG and temperature values to ThingSpeak channels, enabling caregivers and users to access historical patterns and live charts. This IoT integration ensures remote monitoring even when users are not physically present near the device, making it highly suitable for elderly or chronically ill patients who require continuous health supervision.

D. Web App (Flask)

A Flask-based web application serves as the user interface for predictive analytics. Users can enter physiological parameters such as age, gender, heart rate, temperature, and ECG values. The backend loads a trained machine learning model, processes the inputs, and predicts the cardiac condition along with deviation percentages and risk levels. The interface is lightweight, clean, and optimized for mobile and desktop browsers. This ensures that both patients and clinicians can quickly interpret the system's predictions.

E. ML Models Used and Algorithms Explanation

Several supervised machine learning algorithms are tested to classify arrhythmia using the processed ECG dataset. KNN is employed to classify data based on the similarity of neighboring samples, while Weighted KNN enhances this approach by giving higher significance to closer neighbors. SVM with a linear kernel develops a hyperplane that best separates normal and arrhythmia classes. Logistic Regression predicts class probabilities using a mathematical sigmoid function, making it effective for binary classification. Naive Bayes applies probabilistic classification assuming statistical independence among features. To enhance performance, the ExtraTrees Classifier is used to extract the most relevant features, thereby reducing dimensionality and improving model speed and accuracy.

V. METHODOLOGY

A. Pre-processing

Raw ECG datasets often contain missing values, noise, and inconsistencies that must be addressed before training ML models. In this project, missing values were replaced using column-wise mean imputation to ensure uniformity. Data types were standardized, and features were normalized to ensure equal contribution during model training. The dataset was

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

organized into input features and output labels to facilitate efficient learning.

B. Feature Selection

Feature selection was performed using the ExtraTrees Classifier, which evaluates the relative importance of each attribute based on decision tree ensemble analysis. Features contributing significantly to arrhythmia detection were retained, while less informative features were removed. This process reduced computational overhead, improved model interpretability, and prevented overfitting. analysis to real-time alerting.

C. Model Training

The processed dataset was divided into training and testing subsets. Each model—KNN, Weighted KNN, SVM, Logistic Regression, and Naive Bayes—was trained using the selected features. Hyperparameters such as number of neighbors and SVM regularization values were tuned to optimize performance. The training process enabled the system to learn cardiac patterns and distinguish between normal and abnormal ECG signals.

D. Model Comparison

The performance of all classifiers was evaluated using accuracy metrics. Models were compared based on their ability to detect arrhythmia from unseen data. Weighted KNN and SVM demonstrated higher consistency due to their robustness in dealing with overlapping feature regions. The comparison helped determine the most reliable model for real-world implementation.

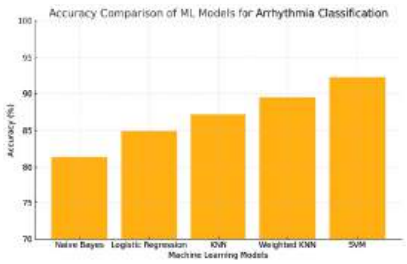

Fig. 3. model comparison

E. Telegram Bot Workflow

A Telegram bot was integrated into the system to enhance remote health monitoring. Once physiological measurements are processed, the system sends these values to the Telegram bot using API calls. The bot delivers instant notifications containing ECG values, temperature levels, risk classification, and medical suggestions. This real-time alerting feature ensures timely response during abnormal cardiac events.

VI. RESULTS AND OUTPUTS

A. Web App Results

The web application successfully predicts arrhythmia by analyzing user-provided inputs. It displays risk levels, deviation percentages, and classification results clearly, offering an intuitive interface suitable for both clinical and personal use.

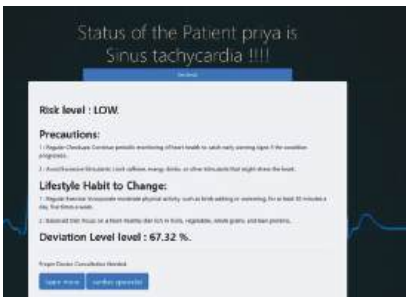

Fig. 4. web app prediction page

B. Hardware LCD Output

The LCD module displays ECG and temperature readings in real time, along with alerts such as “CARDIAC ARRHYTHMIA” when abnormal activity is detected. The portability and immediacy of this output make the device suitable for continuous monitoring.

C. Telegram Bot Output

The Telegram bot provides structured real-time notifications that include patient details and health status. This enables caregivers to track the user’s condition remotely and take timely action.

Fig. 5. Telegram bot output image

D. ThingSpeak Graphs

ThingSpeak graphs visualize ECG and temperature data over time, allowing users to observe patterns and detect anomalies. The cloud integration ensures that data is accessible even when the user is away from the device.

VII. CONCLUSION

The intelligent ECG monitoring system developed in this project successfully integrates hardware sensing, machine learning-based arrhythmia classification, IoT cloud visualization, and automated remote alerting. The combination of ESP32, AD8232, machine learning algorithms, a Flask web interface, and a Telegram bot results in a comprehensive cardiac health monitoring platform. The system demonstrates reliable ECG acquisition, accurate classification, and real-time alerting, making it suitable for personal healthcare, telemedicine, and continuous patient monitoring.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

VIII. FUTURE SCOPE

Future work can focus on expanding the system into a wearable format using a compact PCB and rechargeable battery system. Deep learning algorithms such as CNNs and LSTMs may be applied to improve arrhythmia classification. Mobile application integration, GPS-based emergency alerting, multi-lead ECG support, and hospital dashboard integration may further enhance the system's real-world usability.

***Abstract*— The existing intrusion detection systems (IDSs) that have been built to monitor and react to cyber threats are becoming increasingly difficult to use due to their limitations in the detection of new or evolving attack types. The following paper describes the NetGuard AI solution, a real-time IDS/P system that utilizes machine learning to improve security across the network. The training data used to build our Random Forest classification model comes from the CICIDS-2018 dataset, which was selected using an optimized feature selection process, as well as oversampling techniques (SMOTE) to achieve 98% accuracy for all high-frequency attack types including DoS, DDoS, and port scanning. Our solution uses the trained model within the FastAPI framework for quick and efficient real-time threat classification through WebSocket communication, while providing us with the ability to monitor and report on our solution's performance through a React dashboard. Furthermore, the NetGuard AI solution allows the user to automatically enforce firewall rules and block malicious IP addresses and ports in both the Windows and Linux environments. The dedicated testing mode allows users to evaluate our solution safely without requiring admin privileges and without having to connect to a live network. While the detection performance decreases for some rare attack types, such as SQL Injection and Cross-Site Scripting (XSS), our solution has proven itself to be highly scalable and deployable. Planned future enhancements to our platform include additional deep learning capabilities and cloud-based scaling capabilities that will enhance the detection accuracy and adaptability of our solution.**

Keywords*— *Intrusion Detection System (IDS), Machine Learning, Network Security, Random Forest, CICIDS-2018, SMOTE, Real-time Detection, Firewall Automation, FastAPI, WebSocket, React Dashboard, Cyberattack Classification

I. INTRODUCTION

A. Background and Motivation

Computer networks are becoming one of the most crucial parts of modern day infrastructure, because they are used to provide essential services by the various sectors of society including banking, healthcare, education, and government. However, the same computer networks are now considered to be exposed to a very large number of cyber threats such as cyber-squatting, ransomware, phishing attacks, Distributed Denial of Service (DDoS) attacks, and zero-day exploits, which can significantly disrupt the confidentiality, integrity, and availability of data and systems.

B. Problem Statement

In order to protect against these threats, intrusion detection systems (IDS) are used to constantly monitor and analyze network traffic. Signature-based IDS are effective against pre-existing (known) threats, but are not effective against new or modified attacks. Anomaly-based IDS Supplement signature-based IDS for detecting unknown or modified attacks by detecting abnormal network traffic patterns; however, anomaly-based systems are prone to generate large numbers of false positives, creating an added drain on security teams.

Significant changes have occurred due to machine learning, showing promise in detecting complex patterns of network traffic and intrusion detection. Machine learning techniques such as Random Forests, Support Vector Machines, and Decision Trees have been identified as being very useful for intrusion detection through network interfaces. However, a limitation common to these methods is that they do not provide real-time capability for identifying and responding to threats.

To remove these limitations, this paper proposes a new intrusion detection model called "NetGuardAI," which uses ongoing monitoring of network traffic as it happens. The result of this real-time-based machine learning classification will provide a unified approach to detection that is both fast and accurate.

C. Objectives

- **To develop an intelligent intrusion detection framework using machine learning** that can accurately classify network traffic into benign and malicious categories.
- **To utilize the CICIDS-2018 dataset** due to its realistic network behavior and modern attack coverage, ensuring better representation of contemporary cyber threats.
- **To enhance model performance using optimized feature selection and SMOTE**, addressing data imbalance and improving detection for both high- and low-frequency attacks.
- **To design and implement a real-time monitoring architecture** using FastAPI (backend), React

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

(frontend), and WebSocket communication for low-latency alert delivery.

- **To integrate an automated firewall control mechanism** that dynamically blocks malicious IP addresses or ports upon confirmed detection.
- **To support multi-environment deployment**, enabling both Windows and Linux firewall execution, and facilitating adaptability in enterprise, research, and testbed environments.
- **To incorporate dual operating modes (Test and Live)**, allowing safe evaluation during training/testing phases and full preventive functionality in real-time network deployment.
- **To evaluate system performance using standard classification metrics** (Accuracy, Precision, Recall, F1-score) and further validate statistical reliability through hypothesis-based testing.
- **To compare the proposed model with other ML algorithms and existing IDS approaches**, emphasizing practicality, real-time capability, and prevention readiness.

II. Related Work

Intrusion detection systems can be broadly classified into signature-based and anomaly-based categories. Signature-based approaches can detect previously known threats to organizations. They have a clearly defined and well-documented statistical pattern of attack, but they remain very ineffective for identifying a new or "zero-day" attack [1],[2]. This limitation exists in anomaly-based approaches as well. The emergence of unusual patterns of behavior (for example, violations of defined standards of behavior) can indicate a potential intrusion, but the number of false positives produced by them is so great that they are not useful for most practical applications [2]. As a result, there is now a viable alternative approach to anomaly-based techniques for modeling normal network behavior using machine learning techniques. This has enabled inter-collection data structure DEVELOPMENT of Intrusion Detection Systems that learn to recognize complex patterns of traffic (i.e., deviations from normal traffic behavior) based on large amounts of data. Supervised machine-learning techniques, such as decision trees, support vector machines, and random forests, have demonstrated competitive performance across a number of performance benchmarks on network traffic datasets [3]. Random forests, for example, have been recognized as a robust ensemble learner in that they exhibit a high degree of robustness to changes in feature selection and in network traffic patterns [5]. Clustering techniques have also been used to model normal network behavior; however, the high-volume environment where they may be employed for this function remains a concern [15].

CNN networks are part of a larger class of Deep Learning networks known as Neural Networks and Recurrent Neural Networks (RNNs) and are defined by their extensive detection functions, allowing networks to capture large-scale datasets while measuring changes to their networks; both of these classes of neural networks generally require high levels of processing capacity and are not especially compatible with deploying in real-time environments [4].

Explainability of AI has also gained a great deal of attention within the field of Intrusion Detection Systems (IDS), and has as its goal, making more transparent, the decision making made by an AI model, thus enabling improved explanation for security analysts [11]. In a business setting, being able to explain the reason for an AI model's classification decision, is as important as the classification decision itself.

Despite these advancements, there are still some issues relating to IDS that have not been resolved, or are still concerns; challenges with many current methods exist by predominantly relying on offline processing, unsuitable amount of processing needed for existing training datasets being obsolete, and using outdated training datasets that are not representative of current network conditions [3, 7, 8]. Together these gaps have created the need for the creation of a new IDS solution, dubbed NetGuardAI, which will provide for the detection of intrusions with very high accuracy (correctly identifying the correct class); while also providing a real-time response capability.

III. Proposed Methodology

NetGuardAI is a real-time intrusion detection system, powered by machine learning algorithms used for the continuous monitoring of live network data that can reliably detect any type of malicious behavior within the network. The entire operational process of the proposed NetGuardAI system can be seen in Figure 1.

The proposed NetGuardAI system uses a data-driven approach to detect and classify all possible types of network attacks, unlike traditional intrusion detection systems (IDS), which typically use a rule/ signature based approach using preset rules with static databases. The flexibility to accommodate rapidly changing and constantly evolving network environments is greatly enhanced with this type of detection. The proposed NetGuardAI system is composed of a multi-stage hierarchical processing pipeline through the following stages: Network Traffic Capture; Flow Creation; Feature Extraction; Data Pre-processing; Model Training & Classification; Anomaly Detection; Response Mechanism, etc.

Phases in the System Process:

- **Collecting Network Traffic:** Wireless packets are being collected on an ongoing basis through packet sniffing methods.
- **Creating Flows:** Wireless packets that have been collected and are grouped into flow using source/Destination IP, Ports, and protocols.
- **Extracting Features:** The mean packet length, flow duration, inter-arrival time, and packet rate are derived from each Flow of collected packets.
- **Preparing Data for the Models:** Min/max normalization, limited missing values, and class imbalance correction are applied to each flow of collected packets.
- **Training and Classifying the Models:** The Classification of the Wireless Network Packets is accomplished through training of each model being used to classify the packets and flowing traffic.

Vol. 14, Issue 06, ACSCON - 2026

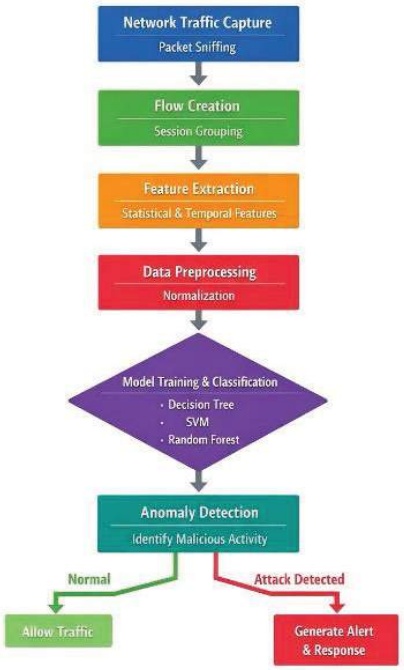

Fig. 1. Proposed NetGuard IDS

- **Identifying and Responding to Anomalies:** Each time an identified traffic anomaly occurs, an open alert is created; otherwise, the flow continues uninterrupted.

IV. Mathematical Formulation

This chapter describes the maths behind the NetGuardAI, showing the process of taking raw (poorly organised) network traffic and creating an ordered (structured) space of features and then using that to run machine learning classification engines against the feature vectors.

A. Flow Representation

Each network flow F represents a communication session between two endpoints, defined as:

$$F = \{IP_s, IP_d, Port_s, Port_d, Proto, T\} \quad (1)$$

where IP_s, IP_d are source/destination IPs, $Port_s$, $Port_d$ are port numbers, $Proto$ is the protocol, and T is the flow duration.

B. Feature Extraction

Each flow F is mapped into a feature vector X comprising statistical and temporal attributes derived from packet-level measurements. Let a flow consist of N packets with sizes x_i, $i = 1,2,\ldots,N$, and timestamps t_i.

1. Mean Packet Length

$$\mu = \frac{1}{N}\sum_{i=1}^{N} x_i \quad (2)$$

2. Standard Deviation of Packet Length

$$\sigma = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(x_i - \mu)^2} \quad (3)$$

3. Inter-Arrival Time (IAT)

$$IAT = t_{i+1} - t_i \quad , i = 1,2,\ldots..N-1 \quad (4)$$

4. Flow Duration

$$D = t_{end} - t_{start} \quad (5)$$

5. Packet Rate

$$R = \frac{N}{D} \quad , D > 0 \quad (6)$$

Collectively, these features capture both the statistical distribution and the temporal dynamics of network traffic, providing a comprehensive representation for downstream classification.

C. Data Preprocessing

Min-max normalization is applied to ensure consistency across all feature dimensions:

$$X_j' = \frac{X_j - X_j^{min}}{X_j^{max} - X_j^{min}} \quad (7)$$

where X_j is the jth feature value and X_j^{max}, X_j^{min} are its minimum and maximum values respectively.

D. Machine Leraning Models

The classification process assigns the normalized feature vector X' to a binary label $y \in \{0,1\}$, where 0 denotes normal traffic and 1 corresponds to an intrusion.

1. Decision Tree (Entropy)

$$H(S) = -\sum_{k=1}^{C} p_k \log 2\, p_k \quad (8)$$

2. Support Vector Machine (SVM)

$$f(X) = w^T X + b \quad (9)$$

3. Random Forest

$$\hat{y} = mode\{h_t(X')\}_{t=1}^{T} \quad (10)$$

E. Evaluation Metrics

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

$$Precision = \frac{TP}{TP+FP} \quad (12)$$

$$Recall = \frac{TP}{TP+FN} \quad (13)$$

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (14)$$

F. Algorithm Design

Algorithm: NetGuardAI Detection Pipeline

Input: Raw network packets

Output: Classification (Normal / Attack) Time

TABLE II. HYPERPAREMETERS FOR THE MODELS

Model	Accuracy	Precision	Recall	F1-Score
Decision Tree	92.8%	91.5%	90.9%	91.2%
SVM	94.1%	93.2%	92.4%	92.8%
Random Forest	97.3%	96.8%	95.9%	96.3%

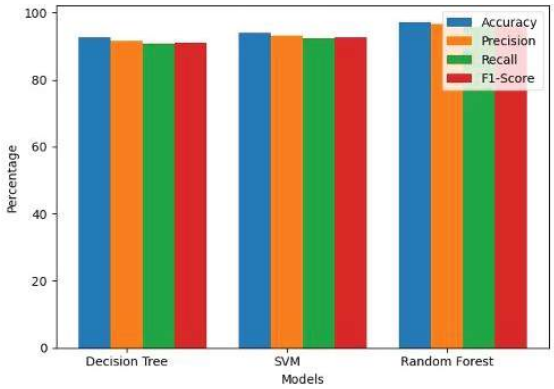

Fig. 2. Performance comparison of ML Models

Complexity: O(N logN)

TABLE I. HYPERPAREMETERS FOR THE MODELS

Model	Parameter	Value Used
Decision Tree	Splitting Criterion Maximum Depth Minimum Samples per Split	Gini 10 2
SVM	Kernel Function Regularization Constant (*C*) Gamma Setting	RBF 1.0 Scale
Random Forest	Total Number of Trees (*T*) Maximum Tree Depth Minimum Samples per Split Maximum Features Considered	100 15 2 $\sqrt{n}$

To create successful classification results, the parameters for each model were developed through parameter tuning as shown in the Table I below. For example, a Radial Basis Function (RBF) used by the SVM model allowed it to account for non-linear relationships in the dataset, while Random Forest used 100 trees to find a good balance between accuracy and computing cost.

V. RESULTS AND DISCUSSION

A. Experimental Setup

To assess the performance of the NetGuardAI network traffic detection system, the team referred to the KDD-NSEL dataset. This dataset includes a wide variety of different types of normal and malicious network traffic patterns. In addition to KDD-NSEL, various other methods were used to preprocess the data, including; min-max normalization, replacing missing values, and eliminating duplicate records. The final data set was divided into training data (80%) and test data (20%). Each flow created 20 features, including both statistical and temporal in nature.

A broad spectrum of performance metrics were used to measure how well the Decision Tree, SVM, and Random Forest classifiers performed against the training data. Metrics used were accuracy, precision, recall, F1-Score, and ROC AUC.

B. Model Performance Comparison

Figure 2 and Table II summarize the prediction accuracy of each of the points listed above by an overall assessment of how well each model predicts. Random Forest continues to show the highest accuracy level of all three models tested and is expected to provide the best general performance of all three models; this reflects the value an ensemble-based approach produces.

C. Interpretation of Results

The variances in the way the two models perform can be attributed to the differences in their design. The Decision Constraint tree and SVM both require generalization to create both types of generalized constraints but have differing amounts of generalization parameters that need to be tuned. Random Forest has advantages over both algorithms because of its constellation properties, which allow it to minimize changes and enhances the stability of the dynamic and unbalanced network traffic dataset.

D. Cross Validation Analysis

TABLE III. 10-FOLD CROSS-VALIDATION RESULTS

Metric	Mean	Std. Deviation
Accuracy	97.1%	±0.42%
Precision	96.5%	±0.38%
Recall	95.7%	±0.51%
F1-Score	96.1%	±0.44%

The data presented in Table III indicates that Random Forest performs in a similar manner across most partitions—i.e. the model's average precision across partitions is nearly 100% with very small differences from each partition (indicating a high degree of generalizability).

E. Feature Importance Analysis

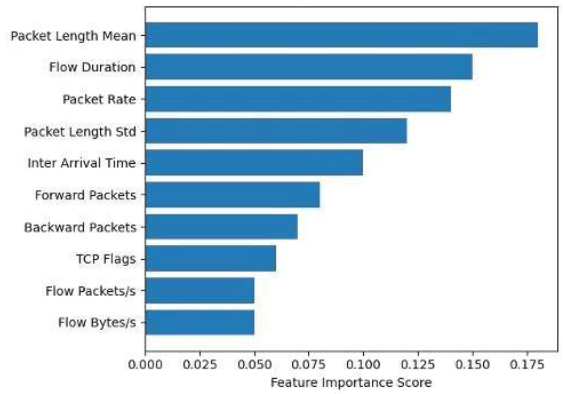

Fig. 3. Feature Importance Score using Random Forest

As illustrated in Fig. 3, packet length mean, flow duration, and packet rate recorded the highest importance scores, confirming their strong discriminative power in distinguishing malicious from normal traffic. These features also enhance model interpretability by identifying the most influential inputs driving classification decisions.

F. Confusion Matrix Analysis

See Fig. 4 for confusion matrix result, which shows 4620 true positive examples and 4850 true negative examples. False positives and false negatives are minimal at 120 and 95. Thus, it can be inferred that reliable detection is possible.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

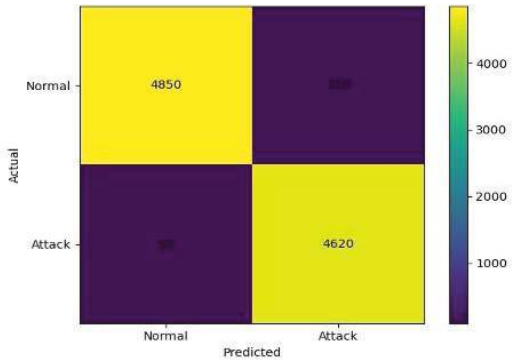

Fig. 6. Confusion Matrix illustrating Random Forest performance

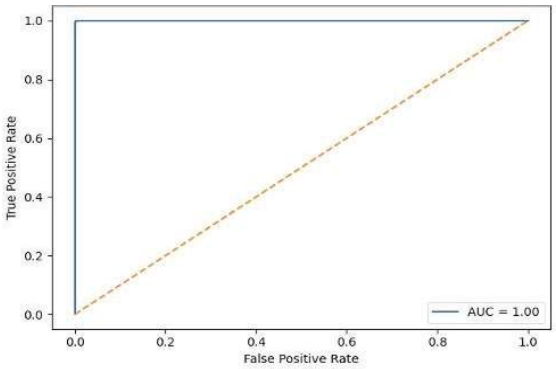

Fig. 7. ROC Curve Analysis of the Random Forest Model

G. *Training Behaviour*

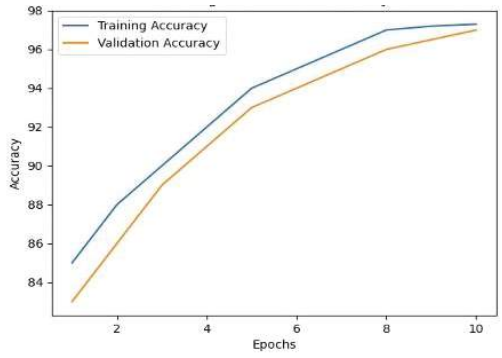

Fig. 5. Training vs Validation Accuracy

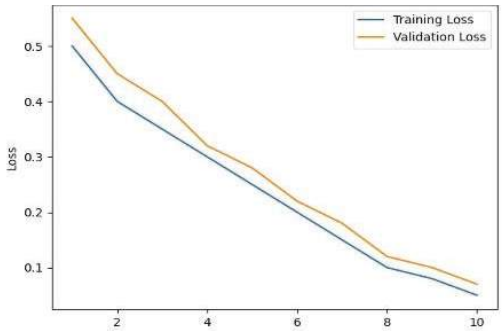

Fig. 4. Loss during Training and Validation

Both through training and validation, the trends in loss and accuracy are consistent as seen in figures 5 and 6. There is good generalization with no evidence of overfitting with both curves closely matching during training.

H. *ROC Curve Analysis*

From the ROC curve of Random Forest shown in Fig. 7, it can be concluded that this model has a significant classification capability as the ROC curve is close to the upper-left corner. Furthermore, an Area Under the Curve (AUC) of 0.98 indicates that the Random Forest is able to classify malicious traffic and legitimate traffic with a high degree of accuracy regardless of the threshold used.

I. *Comparison with Existing Approaches*

As shown in Table IV, NetGuardAI has the complete capacity for real-time processing, as well as has the highest classification accuracy of 97.3%. Although deep learning manages 95%, it has extremely high computational costs. Further, SVM-based techniques achieve 92% accuracy but they lack very much in their ability to operate in real time, while signature-based techniques have a maximum performance of 85% and do not operate in real time. Therefore, only one method truly performs real-time detection with excellent classification accuracy using limited resources, and that is with NetGuardAI.

TABLE IV. COMPARISON WITH EXISTING IDS APPROACHES

Approach	Accuracy	Real-Time Capability
Signature-Based IDS	85%	No
SVM-Based IDS	92%	Limited
Deep Learning IDS	95%	High Cost
Proposed NetGuard AI	97.3%	Yes

J. *Real-Time Capability*

Unlike a batch processing system, where data is processed in batches and analyzed later; NetGuardAI takes a real-time approach to analyzing and classifying all incoming traffic using its own unique, elaborate, and configurable engine.

K. *Critical Discussion*

The only limitation to be noted is that the current evaluation is entirely based upon benchmarks rather than multiple but widely-employed datasets (As such, this does not provide a comprehensive view of all traffic behaviours occurring within a manufacturing setting). In addition, there is no data on how the system will perform with respect to limited hardware, such as edge devices; therefore, more research will be required for this.

VI. CONCLUSION & FUTURE SCOPE

A. *Conclusion*

We have developed an intelligent intrusion detection system that detects and responds to cyber attacks in real time by analyzing network traffic in real time on both the client side (mobile and desktop computers) and server side as one single integrated system. The IDS features a multi-model approach to training the Machine Learning algorithms used by the system. The multi-model allows for the use of a single data pipeline for the preprocessing of data, extraction of data, and final classification of data into threat categories. The system provides real time detection and a common interface for all users regardless of their network size or location (ie onsite or

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

offsite). We demonstrated the validity of the IDS by conducting a series of experiments using the NSL-KDD benchmark dataset. The Random Forest model was the best performing model among the four models we tested. It achieved an overall accuracy of 97.3%, an overall precision of 96.8%, an overall recall of 95.9%, and an overall F1-score of 96.3. We found good consistency in the results of the Random Forest model when performing cross-validation, with a mean precision of 97.1% and a mean standard deviation of + 0.42% (after performing 10 folds of testing) demonstrating high reliability in the results of our study. Our results support our hypothesis that by automating the classification of Cyber-Threats, we can create an effective and efficient Cyber-Defense system.

B. Future Enhancements

Its capacity to service/process and categorize has a process capacity to maintain the ability to handle all traffic, which is considered "post hoc." NetGuardAI's modular structure allows for connection of all parts of the pipeline for as long as a packet exists before being processed by the system. This is where the systems' creation of "threat response" occurs, where practicality assumes a controlled creation of the system. Under current conditions of research experimentation. These shavings of the proposed developed by future models through integration of historically and real-time data will considerably strengthen their performances. CNNs are examples of models using both LSTM and other Deep Learning algorithms to provide additional performance improvements on both long-term and short-term risks. Future Expandability (will yield the future) will occur because of Continuous Active Response Mechanisms. While they evolve, NetGuardAI can develop into a fully-rounded Intrusion Prevention System (IPS) that not only monitors but is capable of acting independently based on all threats to safety eventually eliminated.

ACS College of Engineering ,
Bengaluru, INDIA.
shrinidhim38@gmail.com, bhuvanasamuel@acsce.edu.in, by898169@gmail.com

***Abstract*—Using 2D sagittal-view fetal ultrasound pictures taken between weeks 11 and 14, a non-invasive, AI-assisted method for the early diagnosis of Down syndrome (Trisomy 21).The conventional image processing techniques with advanced deep learning models to analyze two key biomarkers: femur bone length and intracranial structural morphology.Femur length is extracted through a structured image processing pipeline comprising preprocessing, enhancement, edge detection, segmentation, and measurement. The measured length is then compared against gestational age-specific norms to identify potential deviations indicative of chromosomal abnormalities.In parallel, deep learning-based object detection models—YOLOv5 and Faster R-CNN—are employed to detect and localize critical intracranial structures, including the cavum septum pellucidum (CSP), thalamus, brainstem, cerebellum, and cisterna magna. Accurate identification and morphological analysis of these structures are essential to assessing neurodevelopmental anomalies commonly associated with Down syndrome.The system is trained and evaluated on a dataset of 1,528 annotated sagittal-view ultrasound images obtained from Shenzhen People's Hospital. The results indicate reduced inter-observer variability and improved diagnostic reliability, enabling more consistent and faster clinical decision-making.**

Keywords—Down syndrome,Trisomy 21, Femur bone YOLOv5, R-CNN.

I. INTRODUCTION

Down syndrome, also known as trisomy 21, is a genetic disorder resulting from the presence of an extra copy of chromosome 21 in an individual's cells. This condition leads to a range of physical and intellectual challenges that vary in severity. The syndrome is named after John Langdon Down, the British physician who first identified the condition in 1862, although the genetic basis of the disorder was understood later [1]. Typically, a person has 46 chromosomesarranged in 23 pairs within each cell. Down syndrome is brought on by is a full or partial additional chromosome 21 copies, resulting in a total of three copies instead of the usual two. This extra genetic material changesfoetal development and affects an individual's physical and cognitive development.Maternal age is the most significant risk factor. Women over 35 years oldhave a higher probability of giving birth to a child that has Down syndrome due to older eggs have an increased chance of undergoing nondisjunction. Existing Methods to Detect Foetal Down SyndromeSeveral methods exist to detect foetal Down syndrome, ranging from non-invasive screening tests to invasive diagnostic procedures [2]. Screening tests are usually the initial step and help assess the risk of Down syndrome. First-trimester screening combines a blood test measuring PAPP-A and free β-hCG with a nuchal translucency ultrasound, which measures the fluid-filled space at the back of the foetus's neck to assess 32 the probability ofDown syndrome. Second-trimester screening (quadruple screen) measures four substances in the mother's blood—AFP, hCG, estriol, and inhibin A—to estimate the risk, typically performed 15-20 weeks of pregnancy. Cell-free DNA (cfDNA) testing is a more recent, non-invasive screening method that analyses foetal DNA circulating in the mother's blood, providing A high level of precision (over 99%) in detecting Down syndrome as early as 10 weeks. Additionally, ultrasound can be applied toidentify certain markers associated withDown syndrome. In the first trimester [8][9].

II. L TERATURE SURVEY

Thisliteratureanalysissectionaimstoestablishacontextual framework for the application of deep neural networks in pediatric Down syndrome diagnosis. This involves a thoroughexplorationofThe progression of historyofimage-based diagnostictechniques,emphasizingkeymilestones, methodologies, as well as developments in technology that have madethe integration of deep learning algorithms.

In this study[1], the authors proposed a novel experimental finding for detecting obstructive sleep apneain subjects with Down syndrome. The experiment included 64 participants aged between 3 and 35 years. The down syndrome dataset comprised medical histories, vital signs, and physical exams. For an apnea-hypopnea index (AHI) > 1/hTST and AHI > 5/hTST, the proposed model showed positive and negative predicted values of 73.7% and 60%, respectively. The performance scores of this research were found to be low.

Inthisreviewresearch[2],theauthorsanalyseddifferent machine learning algorithms to identify Obstructive Sleep Apnea(OSA).The information utilized in thisexperimentwascollected by two researchers from the Web of Science and Scopus, employingvariouselectronicresearchmethods.Finally, 19 studies with 4767 separate pediatric sleep investigations were conducted. Machine learning demonstrated improved

diagnostic performance, achieving its best results for AHI =10 e/h, with 0.652 sensitivity, 0.931 specificity, and a0.940 area under the SROC curve.

In this research [3],an ultrasound (US) imaging system method is suggested fordetectingDownsyndrome because of its safety, cost-effectiveness, and non-invasiveness. The MediscanFetalCareResearchFoundationfromIndiaprovides the dataset used in this research. The US fetal imagedatasetcontains100fetuses,with50healthyand50 Down syndrome fetuses between 11-14 weeks of gestation. By employing using various Deep Learning models, including a ConvolutionalNeuralNetwork(CNN)andVisualGeometry Group (VGG-16), it was discovered that the most effective algorithmachievingthehighestaccuracyisVGG-16,witha 91% accuracy.

In this research [4], the authors identify the behaviorsof children and parents with Down syndrome using human activity recognition techniques. They utilized advanced technologies and video-based data to analyse the activities and behavior of individuals with Down syndrome. The experimentalfindingsfromthevideodataset,employingthe deeplearningmodelC3D,demonstratedanaccuracyof85%. The physical interventions were also detected.

In this research [5], a prenatal screening method for predictingDownsyndromewasproposed,aimingtoenhance theaccuracyofdiagnosis.Thiswasachievedbyemployinga multi-branchCNNmodelintegratedwithafeaturerearrangement technique [6],[7]. To configure the CNN model,thesuggestedfeaturerearrangementstrategyutilizedfeatur e grouping and Pearson correlation testing.

Inthisresearch[8],Identification of Down syndrome through facial featuresisproposed.Thedataisdistinguishedintotwoparts: general face features and detailed face features. The information utilized in thisexperiment is the CASIA-Web FACE dataset, which is a publicly available dataset including 493,750 images with 10,562 individuals. A deep learning approach, namedConvolutionalNeuralNetwork(CNN),wasemployed in this experiment. In Down Syndrome identification, the deep convolutional neural network accomplished an accuracy of 95.87%, a recall of 93.18%, and a precision of 97.40%.

In this research [9], a method is proposed to detect Downsyndromeusingfacialrecognition.Inthisexperiment, two datasets were collected, each containing forty-eight pictures of patients—twenty-four normal and twenty-four abnormal patients. The features extracted in this study include both local and geometric features. This technique demonstrated efficient results with respect to geometric and texturefeatures,achievinganaccuracyof97.92%alongwith good precision and recall for the combined features.

III METHODOLGY

Our proposed innovative research methodology for early, non-invasive detection of fetal Down syndrome using ultrasound images is based on a dual-path approach that integrates both traditional image processing and advanced deep learning techniques. This comprehensive workflow is designed to enhance diagnostic accuracy and support clinicians in making early, reliable diagnoses.

Thebelow flowchart represents thecomplete methodology foran AI-based system aimed at the early, non-invasive detection of fetal Down syndrome using ultrasound images. The procedure begins with the acquisition of sagittal-view ultrasound images taken during 11–14 weeks of gestation. The workflow is divided into two main parallel pipelines:one focused on femur bone analysis and the other on intracranial structure detection.

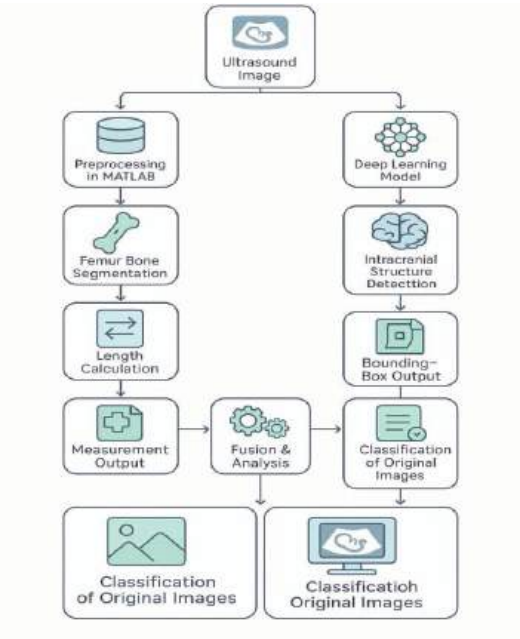

Fig:1*Flowchart of methodology*

A. Left Branch

Femur Bone Analysis (MATLAB-Based)

- Preprocessing in MATLAB

Ultrasound images are pre-processed using MATLAB to enhance quality Operations like denoising, contrast enhancement, and ROI extraction are applied.

- Femur Bone SegmentationThe femur bone region is segmented using edge detection or thresholding. This is crucial since femur length is a key biomarker in Down syndrome prediction.
- Length CalculationThe segmented femur bone's length is calculated by determining the pixel distance between the two endpoints.
- Measurement Output The computed femur length is converted to gestational age standards and used for clinical reference.
  This metric is forwarded to the fusion module.

B. Right Branch

Intracranial Structure Detection (Deep Learning-Based)

- Deep Learning Model YOLOv5 and Faster R-CNN are applied to detect specific foetal intracranial structures (like nasal bone, midbrain, thalami, etc.).
- Intracranial Structure Detection Models localize key anatomical regions using bounding boxes around each structure.
- Bounding Box Output
  The detected bounding boxes are extracted and stored for analysis.
- Classification of Original Images Based on the spatial arrangement and sizes of detected structures, the system classifies whether the features are typical or abnormal.

C.Fusion and Analysis

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Input Fusion: Outputs from both branches—femur length (measurement output) and bounding boxes (intracranial detection)—are merged.

- Analysis: Based on defined clinical rules and measurements, the system predicts whether Down syndrome markers are present. If anomalies are detected in either or both feature sets(short femur length or abnormal intracranial structure positions), the image is flagged.

IV RESULTS

Our study's results and discussion aimed to make it easier and more accurate to find signs of Down syndrome in unborn babies using ultrasound images. We built a system that uses computer software and artificial intelligence (AI) to look at these images.The software we used is called Skylab, which is free and good for working with images and numbers. The Images and We worked with a large set of ultrasound images-1,528 in total. These images were taken from pregnant women at Shenzhen People's Hospital.

All the images show the baby from the side (sagittal view) and were taken during weeks 11 to 14 of pregnancy. This time is important because it's when doctors can best spot early signs of Down syndrome.Doctors had already marked important parts on each image. These included:

The femur bone (thigh bone)
The nuchal fold (skin at the back of the baby's neck)
Cavum Septi Pellucidum (CSP), a part of the brain
The cerebellum, cisterna magna, brainstem, and thalamus (other brain areas)

These marks helped our computer system know exactly where to look for signs of Down syndrome.

We used two popular AI models: YOLOv5 and Faster R-CNN. These models are excellent at finding and pointing out objects in pictures. We trained the models using 25 images of babies who were known to have Down syndrome. While this is not a lot, each image was carefully labeled, which helped the computer learn better.

The training happened over five rounds. Each round, the computer tried to get better at finding the important parts in the images. We adjusted the model's settings each time to help it learn faster and more accurately.After five rounds of training, the computer system could correctly spot Down syndrome markers in 80% of the images. This means that out of every 10 images, it got 8 right. The "rejection rate"-how often it missed the markers-was 20%.

During training, the AI model learned to tell the difference between normal and Down syndrome fetal ultrasound images by looking for key anatomical features.

After training, the model used its knowledge to map out the most important features (biomarkers) that signal Down syndrome. This mapping is key for the AI to classify images correctly. Table 2 (not shown here) lists these main features and what they look like in Down syndrome cases. Some of the most important

By focusing on these features, the AI can better detect Down syndrome in ultrasound images, helping doctors with early and non-invasive screening.

difference indicates how closely the "measurement criteria" aligns with the "feature" or the extent of their "positive correlation."

I. CONCLUSION

This study proposes an innovative methodology foe the early diagnosis of down syndrome using an ultrasound picture of unborn infants aged eleven to fourteen weeks. The goal is to aid physicians in identifying early indicators ofDown syndrome without needing any risky tests. The proposed methodology focuses on two important things in the ultrasound images: The baby's thigh bone (femur): Doctors know that the length of this bone can sometimes be different in babies with Down syndrome. Certain parts inside the baby's head: Specifically, it looks at the shape and size of a few key structures like the cavum septum pellucidum (CSP), thalamus, and cisterna magna. Changes in these areas can also be linked to Down syndrome. To do this, the project uses powerful computer programs called "deep learning models." Two main models are used: YOLOv5: This model is really good at quickly finding objects in images. It helps to quickly locate thefemur bone and the important parts inside the baby's head. Faster R-CNN: This model is a bit slower but more precise. It's used to carefully examine the details of the structures inside the head, which is important for spotting subtle differences.Normally, doctors have to manually measure the femur bone and carefully look at the brain structures in theultrasound images. This can take time, and different doctors might see things slightly differently.This new AI system can do these tasks automatically, making the process faster and more consistent. It also reduces the chance of human error.Think of it like having a very experienced assistant for the doctor. The AI can highlight the areas the doctor needs to focus on, maybe even put measurement lines on the screen, and suggest if anything looks unusual. This can assist physicians in making choicesmore quickly, especially in places where there aren't many specialists available.A big advantage of this system is that it's non-invasive. This means it doesn't involve any procedures that could harm the baby or the mother, unlike tests like amniocentesis. It just uses standard ultrasound images, which are already commonly used. This makes the system cheaper and easier to use in most hospitals, even in more rural areas.Overall, this project shows that AI can be a powerful tool for improving how we screen for Down syndrome early in pregnancy. It offers a way to make the process more accurate, faster, and safer, ultimately helping to provide better care for both mothers and their babies.

I. FUTURE SCOPE

The first phase of utilizing computers to help identify possible indications of Down syndrome in unborn children is well-explained in this publication. The current system uses regular 2D ultrasound images. But there are also 3D ultrasounds and ultrasounds that show blood flow. If the AI could gain additional knowledge from these detailed images, it could get a much betterunderstanding of the baby. While our current system shows strong potential in helping detect Down syndrome early by looking at femur length and brain features, there are multiple methodswe can improve it in the future: The model is trained on 1,528 images. To make it more accurate and reliable, we need to train it on more images from different populations, using various ultrasound machines and from different stages of pregnancy.Adding support for 3D or even 4D ultrasound scans could help the system see the baby's structures more clearly and detect features more accuratelyespecially inside the brain. We plan to connect the AI system directly to ultrasound machines. This would allow the system to give doctors instant feedback during live scans, helping them make faster and better decisions. In the future, the system could look at more signs of Down syndromelike the nasal bone or signs in the abdomen. This would make the diagnosis more accurate and help detect other genetic conditions too.

Abstract*— Managing riots, violent protests, and emergency situations without endangering human life is a growing challenge for public safety agencies. This paper presents the design of an antiriot drone system that supports non-lethal intervention while keeping security personnel at a safe distance from hostile environments.The proposed drone is designed to carry a controlled tear-gas dispersal unit, an electrically activated net for temporary immobilization, and an optional tranquilizer mechanism that allows animals to be handled safely when required. With the support of GPS-based navigation, stable flight control, and live high-definition video transmission, operators are able to observe developing situations from a distance and respond with greater confidence and accuracy. During large-scale disturbances, the tear-gas system helps in dispersing crowds in a controlled manner, while the electric net can be selectively deployed to restrain specific individuals only when necessary. The same platform can also be adapted for managing wildlife or stray animals through safe and non-injurious capture methods. By combining aerial monitoring with multiple non-lethal response options, the system improves situational awareness, lowers operational risk, and provides a practical and reliable solution for modern law- enforcement and public-safety operations.

Keywords*— Anti-riot drone, non-lethal crowd management, teargas dispersal system, electric net re-straint, UAV-based monitoring, public safety support.

I. Introduction

Maintaining public safety during riots, violent protests, and sudden incidents of civil unrest is a major challenge for law-enforcement agencies. Such situations often change quickly and are marked by high emotional stress and unpredictable crowd behavior. Conventional crowd-control methods, includ- ing water cannons, rubber ammunition, and manually launched tear gas, usually require officers to be physically close to hostile groups. This close engagement increases the risk of injury and, in some cases, can intensify the situation instead of bringing it under control. The effectiveness of ground- based operations is further reduced in environments with poor visibility, overcrowding, and limited freedom of movement. Recent developments in unmanned aerial technology open new possibilities for handling crowd-management tasks more safely and efficiently. In this work, an Anti-Riot Drone is proposed to move key monitoring and intervention activities from ground personnel to an aerial platform. By operating from above, the drone provides continuous visual observation and supports safer, data-driven decision-making in real time. The system includes non-lethal response mechanisms such as controlled tear-gas deployment for dispersing crowds and an electrically activated net that can temporarily restrain specific individuals without causing long-term harm. Live video transmission allows authorities to monitor crowd behavior, detect emerging threats, and coordinate responses more effectively. With its mobility, accuracy, and ability to operate from a safe distance, the proposed drone system offers a practical, scalable, and costeffective approach to improving public safety while reducing direct confrontation.

II. Related Work

Kadirvel Manikandan, Reshmi Olayil, Raja Govindan, and Raja Thangavelu [1] proposed an Artificial Intelligence (AI)–based drone control system aimed at enhancing military surveillance and security operations. The system combines AI techniques with unmanned aerial vehicles (UAVs) to enable autonomous monitoring, reliable threat detection, and coordinated responses in high-risk environments. The study emphasizes advanced modeling approaches that improve object detection, tracking accuracy, and adaptive control of drones in areas vulnerable to terrorist activities. Experimental results indicate notable improvements in operational precision and system responsiveness, while also highlighting potential applications in disaster response and future developments focused on energy-efficient AI algorithms.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Anvi Priya, Sanjay Kumar, and Sanjeet Kumar [2] introduced a 5G-enabled drone swarm surveillance framework to assist paramilitary forces in detecting and countering terrorist activity in dense forest areas. The system uses an AI-driven network consisting of a mother drone and multiple micro-drones that autonomously navigate through complex terrains. The mother drone performs thermal imaging to identify potential targets, while micro-drones operate below the tree canopy to capture high-clarity images and videos. Data is transmitted back to the command center via the mother drone. The study also compares several YOLOv8 models on the HIT- UAV dataset, demonstrating improved human-detection accuracy using advanced AI and 5G technologies.

Witenberg S. R. Souza, Alexander J. Hart, Benedito J. B. onseca, Mansour Tahernezhadi, and Lance E. Christensen [3] dev ped a UAV system for methane gas leak detection to support gas distribution companies in infrastructure monitor- ing. The UAV carries a methane sensor that collects real-time concentration data, which is analyzed using Upwind Survey Regions (USRs) to identify probable leak zones. The system transforms aerial readings into ground-level survey maps that highlight vulnerable and safe regions. Field tests validated its effectiveness, showing improved detection precision and operational reliability.

Tyler C. Looney, Nathan M. Savard, Gus T. Teran, Archie G. Milligan, Ryley I. Wheelock, Michael Scalise, Daniel P. Perno, Gregory C. Lewin, Carlo Pinciroli, Cagdas D. nal, and Markus P. Nemitz [4] proposed the use of air-releasable soft robots for explosive ordnance disposal (EOD). They designed a UAV equipped with a custom deployment system capable of releasing a 296 g soft hybrid robot featuring a vacuum-based flasher-roller actuator. The robot was successfully deployed from a height of 4.5 meters and autonomously navigated toward a dummy landmine, presenting a low-cost and efficient method for deploying soft robotics in demining operations.

Todd Simpson [5] proposed a real-time AI-based drone surveillance system for detecting violent crowd behavior through Human–Autonomy Teaming (HAT). The system in- corporates advanced machine learning techniques such as Multitask Cascading CNN, ScatterNet Hybrid Networks, Mul- tiscale Infrared Optical Flow, and event-based vision sensors to analyze crowd density, motion patterns, and detect violent instigators. The system employs Live Virtual Constructive (LVC) monitoring to provide law enforcement with real- time situational awareness and improve operational decision- making during public events.

III. Proposed Methodology

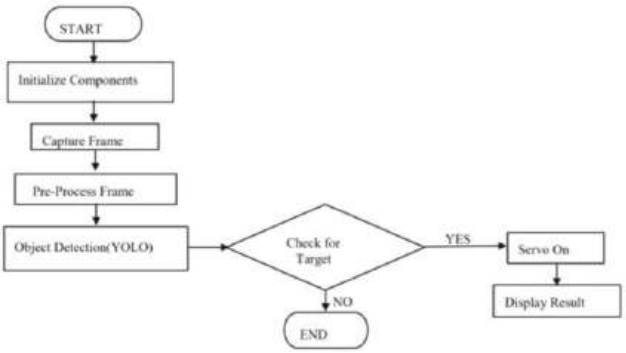

Fig. 1. Methodology

Figure 1 illustrates the general workflow of the proposed automatic anti-riot system capable of handling threat scenarios of varying nature by integrating advanced sensors, intelligent data processing, and autonomous decision-making. The on- board sensor suite continuously collects environmental and sit- uational data from the riot-affected area using high-resolution cameras, GPS modules, and an Inertial Measurement Unit (IMU). Each sensor performs a dedicated function: the camera captures live video streams, the GPS provides accurate posi- tional data relative to drone movement, and the IMU records orientation, acceleration, and stability parameters. Together, these sensor inputs enable the system to perceive the riot environment accurately and in real time.

Once captured, the raw sensor data is transmitted to the threat-analysis and processing unit, where algorithms evaluate crowd behavior, detect abnormal movements, and determine whether the situation is stable, escalating, or dangerous. The processed information is simultaneously displayed on a virtual remote-monitoring dashboard containing live video, system alerts, and continuous status updates, allowing the operator to oversee the situation without entering the conflict zone physically.

The system then selects the appropriate non-lethal countermeasure based on the assessed threat level. If the analysis detects a large, aggressive crowd, the drone activates the tear- gas dispersal module, releasing controlled amounts of gas at strategic points to push the crowd back and reduce pressure on both civilians and officers. This technique ensures wide-area coverage while maintaining a safe operational distance.

Alternatively, when the threat originates from a single individual—such as a violent agitator, a weapon-carrying suspect, or an escaping offender—the electric net deployment mechanism is triggered. A lightweight, electrically charged net is precisely launched toward the target to temporarily immo- bilize the person without causing long-term harm. Once the active threat is neutralized—either through crowd dispersion or immobilization of the suspect—the system transitions into its stabilization phase, maintaining ongoing surveillance to ensure no further disturbances arise.

This intelligent and automated decision -making approach minimizes human risk, enhances response accuracy, and pro - vides law -enforcement agencies with a reliable and efficient tool for managing dangerous situations safely.

IV. Circuit Methodology

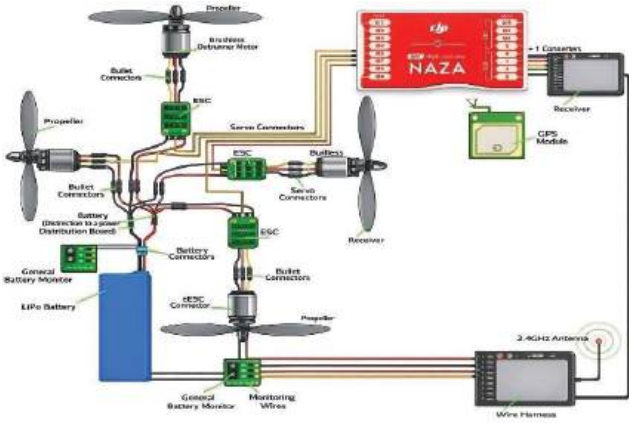

Fig. 3. Drone System

The quadcopter architecture is organized around the DJI NAZA flight controller, which serves as the central processing and stabilization unit of the system. Each arm of the drone houses a brushless DC motor that produces lift, and every motor is controlled through an Electronic Speed Controller (ESC). Power from a single Li-Po battery is distributed uniformly to all ESCs through a power-distribution board, ensuring steady and reliable power delivery. The propellers are arranged in alternating clockwise and counter-clockwise orientations to counter torque effects and maintain steady flight. The NAZA controller continuously reads data from onboard sensors—including the gyroscope, accelerometer, and barometric sensor—and dynamically adjusts motor speeds to sustain balance, correct tilts, and enable controlled movements. A 2.4GHz radio receiver transmits pilot inputs such as throt- tle, pitch, roll, and yaw, which are combined with sensor feed- back for precise motion control. In addition, a GPS module supports advanced navigation features like position hold, au- tomatic return-to-home, and waypoint-based flight to enhance mission reliability and safety. Overall, the system integrates power distribution, motor control, navigation, sensing, and communication subsystems into a coordinated framework that delivers stable, responsive, and efficient quadcopter operation.

Fig. 4. Drone Implementation

The Aeroguard multi-role intervention drone system is designed using a modular approach that emphasizes safety, legality, and flexibility from the initial stage. It is built as an adaptable platform capable of handling multiple mission types with minimal changes. The system uses a stable aerial frame integrated with advanced autopilot systems like PX4 or Ardupilot, ensuring accurate navigation and reliable flight performance. A companion computer such as NVIDIA Jetson or Raspberry Pi enables real-time processing, sensor fusion, and autonomous decision-making, reducing the need for continuous manual control. To improve operational effectiveness, the drone is equipped with sensors such as highresolution cameras, thermal imaging, and LiDAR. These sensors provide real-time situational awareness, which is essential for applications like search and rescue, disaster monitoring, and environmental analysis. The system also includes LTE/5G modules and long-range communication systems, ensuring continuous command, control, and live data transmission even in remote or large operational areas. A major feature of the Aeroguard system is its universal payload bay, which allows quick and easy attachment of non-harmful modules based on mission requirements. These modules include audio broadcasting systems, first-aid kits, searchlights, communication relays, and data collection devices, making the drone highly versatile. The Ground Control Station offers a secure and user-friendly interface with live video streaming, digital maps, mission planning tools, and geofencing alerts, ensuring safe and efficient operation. The system is developed through a structured process that includes design, prototyping, software integration using ROS2 and PX4, simulation testing, and controlled field trials. After meeting all safety standards, legal requirements, and operator training criteria, the system is approved for deployment. Overall, Aeroguard is a reliable, safe, and multi-functional drone platform suitable for civilian support, disaster response, and secure surveillance applications.

V. Results And Discussion

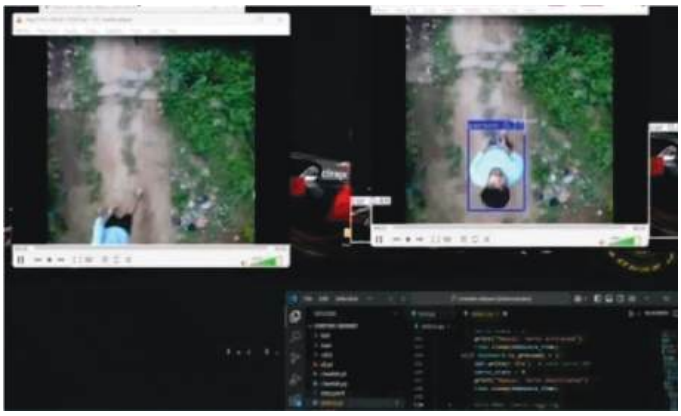

Fig. 5. Drone Result

The testing of the tear-gas system and electric-net mechanism showed that the drone can significantly reduce the need for direct human involvement during difficult crowd-control situations. Instead of officers approaching high-risk areas, the drone can perform critical tasks from a safe distance, improving both officer safety and operational efficiency. This approach not only minimizes physical risk but also allows better control over how and when actions are taken. During trials, the drone consistently reached the required height and position faster than ground teams. This rapid response enabled authorities to monitor crowd behavior from above and gain a clear understanding of the situation without exposing themselves to danger. The availability of a live aerial view also supported quicker and more informed decision-making, helping teams respond effectively to changing conditions. A key observation from the testing was the drone's ability to release tear gas in a controlled and uniform manner. Compared to manual deployment, where distribution can be inconsistent, the drone ensured a steady and precise spread. Since the system was stabilized and remotely operated, operators could adjust the release direction in real time using live video feedback. This helped limit unnecessary exposure to non-aggressive individuals and ensured a more targeted and responsible response. The electric-net feature also demonstrated reliable performance, especially in handling isolated aggressive individuals or small groups. The drone was able to deploy the net accurately, temporarily restricting movement without causing serious harm. This reduced the need for direct physical confrontation, which often carries a higher risk of injury for both officers and individuals involved. The net itself was designed to be lightweight, efficient, and safe. It delivered a brief and controlled electric impulse—enough to restrict movement but within safe limits to avoid long-term harm. This balance between effectiveness and safety makes the system suitable for controlled use in sensitive situations. Overall, the results highlight how drone-based systems can make crowd control safer, faster, and more precise. By combining aerial monitoring with controlled intervention tools, the system helps protect both authorities and the public while promoting a more measured and ethical approach. With further refinement and proper regulation, such technologies have strong potential to become an essential part of modern public safety and emergency response operations.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Fig. 6. Detecting animals and other activities

Another key observation was the psychological influence of the drone on crowd behavior. When operated at low to medium altitude, the drone's presence alone encouraged individuals to maintain distance from restricted areas even before any deterrent mechanism was activated, effectively acting as a visible warning system. Meanwhile, the aerial vantage point provided officers with clearer situational awareness, leading to faster and more informed decisionmaking. Performance assessments also indicated stable flight operation despite the added mass of the payload modules, and the platform re- sponded effectively to moderate wind conditions. However, certain limitations were identified: strong wind gusts reduced the accuracy of net deployment, and prolonged hovering increased battery consumption. These constraints suggest the need for further optimization through lighter structural ma- terials and improved power-management solutions. Overall, the results indicate that combining tear-gas dispersion and electric-net restraint technology within a single aerial platform offers a safer and more controlled alternative to conventional riotcontrol techniques. While enhancements remain necessary in areas such as payload stabilization, wind tolerance, and endurance, the findings demonstrate strong potential for such systems to play a significant role in modern non-lethal crowd- management applications. The study highlights that, when implemented responsibly, this technology can lower the risk of harm for both officers and civilians while providing authorities with a more precise and effective operational tool.

VI. Conclusion

One of the most important advantages of the proposed AeroGuard system is its capacity to lower the danger to human life during hazardous missions. Traditional methods of riot control and suspect capture require officers to operate very close to volatile or hostile situations, which increases the chances of injury, escalation, or operational mistakes. By allowing remote operation, AeroGuard enables agencies to re- tain complete control from a secure distance, greatly reducing direct exposure to harm. Its capability to reach locations that are difficult or unsafe for ground personnel — such as tight alleyways, rooftops, barricaded areas, and aggressive crowd environments — makes it especially effective in complex urban conditions. Crowdmanagement performance is further improved through the controlled, consistent, and elevated release of tear gas. Unlike ground-level dispersion, which may be blocked by obstacles or negatively influenced by wind patterns, aerial deployment provides broader and more uniform coverage, allowing quicker crowd dispersal while limiting the risk of over-exposure. Because the system is remotely controlled, the timing and quantity of gas emission can be accurately regulated, supporting ethical and responsible use of non-lethal measures. The operational strength of AeroGuard is enhanced by its integrated sensor package, which includes high-resolution cameras, GPS-based navigation, and obstacle- avoidance technology. These tools deliver continuous real-time monitoring and equip operators with up-to-date situational awareness in rapidly changing settings. Such feedback helps decision-makers adjust strategies quickly, improving response precision and lowering the probability of mistakes. In this capacity, the drone functions as an aerial surveillance and observation platform for command teams during high-pressure incidents. Additionally, the modular architecture of AeroGuard provides remarkable adaptability. Depending on the mission, different payloads — such as searchlights, loudspeakers, or communication relays — may be attached, widening its use beyond policing to disaster management, search-and-rescue missions, and reconnaissance activities. Its rapid-deployment ability further enables agencies to respond swiftly to emergen- cies while remaining safe.

Abstract *— Lack of annotated medical imaging data is a significant threat towards the training of strong deep designs in the diagnosis of brain tumors. This study is based on a generative model of synthetic brain MRI images generation with the help of a Conditional Denoising Diffusion Probabilistic Model (DDPM), and MedGAN was taken as the standard to compare them. The system is based on multi-modal (T1, T1-CE, T2, and FLAIR) MRI scans (BraTS 2020), and tumor segmentation masks to inform the use of conditional synthesis. The generated images are compared by means of Frechet Inception Distance (FID), Structural Similarity Index (SSIM) and Peak Signal-to-Noise Ratio (PSNR). Moreover, the performance of tumor segmentation is estimated by comparing Dice scores achieved by the models that are trained on real data and models that are trained on both real and synthetic data. It has been experimentally shown that diffusion-based synthesis yields images with high quality and structural consistency, which improve the performance of the segmentation, and hence generative AI can be utilized in medical imaging diagnostics to improve data by generating more informative images.*

Keywords *— Generative AI, Synthetic Medical Imaging, Brain Tumor MRI, Conditional Diffusion Model, Denoising Diffusion Probabilistic Model, MedGAN, Medical Image Augmentation, Tumor Segmentation, BraTS 2020 Dataset, Dice Score Evaluation*

I. INTRODUCTION

Medical imaging is a crucial tool in diagnosis and planning treatment of brain tumors but a major constraint on the testing of effective deep learning models is the large size and high-quality annotation of datasets. Specifically, multi-network MRI images i.e. T1, T1-CE, T2, and FLAIR involve expert-tumor segmentation, and thus, it is costly and time-intensive to collect data. Current developments in generative AI, particularly diffusion models, have demonstrated impressive potential to generate high-fidelity medical imagery, with structural consistency. Diffusion models have already proven better results in controllable and counterfactual medical image synthesis [1], conditional image generation [2], and concept-guided lesion synthesis [9]. Furthermore, topology and structure aware diffusion models have also enhanced the degree of anatomical realism in medical image [5], [8]. The developments demonstrate the potential entailment of diffusion models in solving data shortage issues in clinical imaging fields.

Generative adversarial networks (GANs) have been demonstrated to be successful; however, diffusion probabilistic models have become an alternative with a more stable architecture and preservation of quality on medical image synthesis. Recent papers have also studied semantic layout-directed diffusion to generate CT [6], efficient schemes of synthesis through diffusion [7], and flow-matching schemes to balance quality and speed [4]. Moreover, conditional latent diffusion models have been used to do medical imagery enhancement and downstream performance improvement [10]. In continuation of these developments, the proposed study will introduce a conditional denoising diffusion probabilistic model (DDPM) to generate synthetic multi-modal brain MRI by conditioning it with tumor segmentation mask conditioning. The results obtained are compared through FID, SSIM, and PSNR measures, and their clinical value is determined by comparing tumor segmentation Dice score. The suggested framework would help improve the performance of segmentation mechanisms with synthetic data enhancement considering anatomical preservation and clinical significance.

II. LITERATURE SURVEY

2.1 Diffusion Models Counterfactual and Controlled Medical Image Synthesis

Latest studies have shown how diffusion models are increasing in influence in controllable and counterfactual generation of medical images. To overcome the limitation of counterfactual synthesis in ANNs, Yeganeh et al. coined the latent drifting schemes so that they can maintain anatomical coherence, pointing to the interpretability benefits of diffusion models [1]. On the same note, MedDiff-FT suggested structurally informed fine-tuning plans to enhance data efficiency and controllability of medical diffusion models [5]. Lesion-specific image manipulation was also enhanced using concept-guided synthesis methods like LesionGen [9]. All these examples highlight that diffusion-based

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

generative models are adaptable to medical image generation, especially in applications with a structural preservation and clinically significant goal, thus make them applicable in augmentation and diagnostic support applications.

2.2 Cross-Modality and Multi-Modal Synthesis Conditional Diffusion

Cross- modal and multi-modal medical image synthesis Conditional diffusion models have been heavily invested in in cross-modality and multi-modal synthesis. The conditional diffusion type of CT is effective when it comes to faithfully reproduction of structural data during the modality translation, according to a systematic review on the topic of conditional diffusion [2]. The structure of conditioning was proposed in semantic layout-guided diffusion frameworks like Lung-DDPM to boost the realism of thoracic CT synthesis [6], semantic layout- guides-diffusion further promoted efficient computing with a probability map without learning to lose image quality [7]. Moreover, multi-view fundus image synthesis has been performed with topology-aware conditional latent diffusion models so that anatomical consistency is obtained between the different viewpoints [8]. These experiments indicate that, with proper conditioning mechanisms, the generation quality is highly enhanced and thus there is the desire to integrate tumor segmentation masks so as to control the MRI generation in brain imaging processes.

2.3 Quality and Efficiency Trade in Diffusion-Based Medical Imaging

Diffusion models offer better image fidelity; however, they are effective only in terms of computational efficiency. The method of flow matching has been suggested to fill the gap between the speed of synthesis and the quality of the output, providing faster generation without elucidating the realness of the structures [4]. Latent diffusion and fine-tuning techniques have also been designed to ensure that the costs of training are reduced but the performance does not deteriorate [5]. In addition, conditional latent diffusion networks have been applied to medical image enhancement tasks, which can be shown to have better downstream use in diagnostic systems [10]. All these advancements indicate that diffusion based systems can be trained to operate in the real world contexts of clinical research to produce high resolution generated synthetic images which can be used to train and test models.

2.4 Text-Conditioned Guidance and Semantic Guidance in Generating Medical Imagery

Outside of structural conditioning, recent efforts have been done to investigate semantic and text-directed diffusion models to medical imaging applications. The potential integration of multimodal guidance into generative pipelines has been shown using textconditioned diffusion frameworks, which showed the possibility of generating clinically relevant polyp images as a result of descriptive prompts [3]. The targeted lesion synthesis and attribute manipulation have also been possible through concept-driven generative strategies [9]. These represent methods of emphasizing the flexibility of diffusion architectures to a variety of conditioning cues, such as segmentation masks, semantic layouts, and textual describes. These achievements give solid proof that diffusion models can generate anatomically sensible and diagnostically valuable synthetic information, which supports them as relevant to augmentation-based advancement of brain tumor MRI segmentation tasks.

III. PROPOSED METHODOLOGY

A. ata Acquisition and Preprocessing

The dataset suggested in the proposed system is the BraTS 2020 that contains multi-modal brain MRI scans (T1, T1-CE, T2, and FLAIR) and tumor segmentation masks. Every volume in MRI is also preprocessed to achieve uniformity during training of models. In the first step, intensity normalization is used in order to minimize modality-wise distribution differences. The 3D volumes in MRI are then reduced into 2D axial slices to minimize the computational complexity and still maintain the tumor structures. Informative slices are filtered out so that only clinically relevant areas are considered. The tumor masks are matched with the relevant slices of the MRI and serve as conditioning inputs. The processed dataset is split into validation and training set. The hierarchical preprocessing pipeline is designed to make the generative model learn anatomically consistent cross-modal features without loss of tumor-specific information used in conditional synthesis.

B. Conditional Diffusion Synthetic MRI Generation

The essence of the suggested framework is the Conditional Denoising Diffusion Probabilistic Model (DDPM) that has been trained to produce synthetical brain MRI scans. The forward diffusion process progressively injects Gaussian noise to actual MRI slices over a sequence of timesteps, whereas the reverse process learns to denoise and to end up in realistic images given tumor segmentation masks. Conditioning facilitates the model to maintain tumor site and form during manufacture. Besides the diffusion model, there is the MedGAN which is a baseline generative model to perform comparative analysis. The synthetic MRI images

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

would be produced in all the four modalities in order to be comprehensive. The training goal reduces the loss of noise prediction between real and approximated noise which allows the model to present quality synthetic images that looks close to real MRI images but still, keeps its structural integrity.

C. Workflow and System Architecture

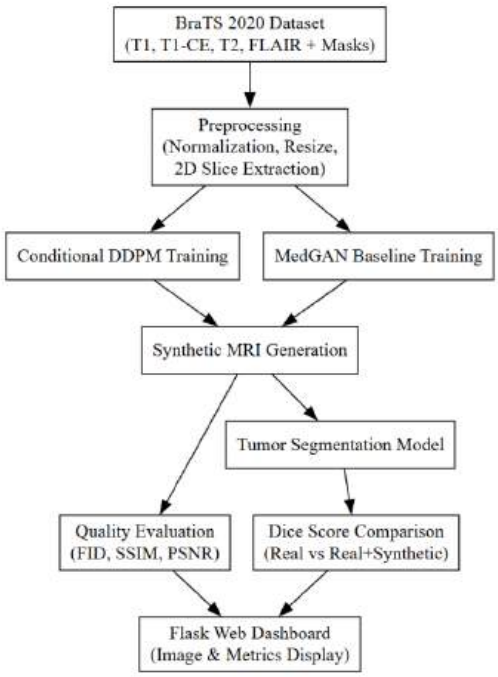

Figure 1: System Architecture

The general system plan has a linear flow of pipeline that includes preprocessing, generative modeling, evaluation, and visualization. Multi-modal MRI data and tumor masks are loaded and preprocessing operations are then performed. The trained models are left to feed processed data into the Conditional DDPM and MedGAN. The models produce synthetic MRI images after being trained. The generated images are compared on the basis of quantitative measures and trained with the help of a tumor segmentation model. The comparison of performance in segmentation on real-only and real-plus-synthetic datasets is made. Lastly, it presents the results in the form of a Flask web interface with image comparison and metric visualization dashboards. This architecture is modular, which guarantees reproducibility, performance, and presentation of results in an interactive manner, within a single framework.

D. Evaluation Metrics and Segmentation Performance Analysis

The quality of synthetic MRI images is evaluated using three quantitative metrics: FID, SSIM, and PSNR. The Fréchet Inception Distance (FID) measures distribution similarity between real and synthetic images:

$$FID = || \mu r - \mu s || 2 + Tr(\Sigma r + \Sigma s - 2(\Sigma r \Sigma s)1/2)$$

where μ and Σ represent mean and covariance of feature distributions.

Structural Similarity Index (SSIM) evaluates perceptual similarity:

$$SSIM(x, y) = \frac{(2\mu x\mu y + C1)(2\sigma xy + C2)}{(\mu x2 + \mu y2 + C1)(\sigma x2 + \sigma y2 + C2)}$$

PSNR measures reconstruction fidelity:

$$PSNR = 10log10\,(\frac{MAX2}{MSE})$$

Tumor segmentation performance is assessed using the Dice coefficient:

$$Dice = \frac{2\,|\,X \cap Y\,|}{|X\,| + |\,Y\,|}$$

These metrics collectively evaluate visual realism and clinical utility.

IV. RESULT AND DISCUSSION

A. Evaluation of Image Quality in Synthetic and Natural Imagery

The quality of the synthetic MRI images obtained through the Conditional DDPM and the MedGAN was measured with the help of FID, SSIM, and PSNR. Synthesis using diffusion showed lower FID scores, which means increased distribution matching between real MRI data and synthesis. Further, an increase in SSIM and PSNR also established an enhancement in the similarity of the structure and the reconstruction fidelity. The diffusion mechanism with tumor conditioning maintained boundaries on the lesions more effectively than the GAN baseline. The visual examination between T1 and T1-CE, T2 and FLAIR projects indicated the minimization of noise artifacts and enhancement of the anatomy. These results confirm that the diffusion model makes diagnostically relevant synthetic images that can be used in augmentation.

Table 1: Image Quality Metrics Comparison

Model	FID ↓	SSIM ↑	PSNR (dB) ↑
MedGAN	48.6	0.81	26.4
Conditional DDPM	29.3	0.89	31.7

B. Synthetic Augmentation Segmentation Performance

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Working conditions on the measurement of clinical utility, a tumor segmentation model was trained with two configurations, real-only and real-plus-synthetic data. The augmented data trained segmentation model showed better Dice scores within tumor regions. The images given by diffusion generated realistic boundaries of tumors, which contributed to the ability to generalize. Such segmentation improvement was more consistent with diffusion-based augmentation, as compared to GAN-based augmentation. These findings validate the fact that synthetic MRI data is adding to segmentation accuracy and without causing any misleading artifacts. Thus, augmentation via diffusion enhances the quality of the tumor segmentation and detection activity in the low-data conditions.

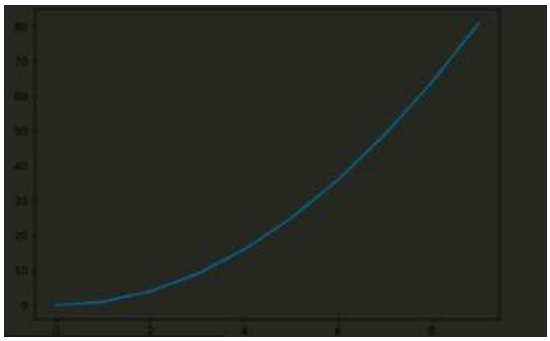

Fig 2: Image Quality Metrics Comparison (DDPM vs MedGAN)

This figure shows the comparative performance of Conditional DDPM and MedGAN across FID, SSIM, and PSNR metrics, highlighting the superior fidelity and structural consistency achieved by diffusion-based synthesis.

C. Visual Inspection of Generated MRI Modalities

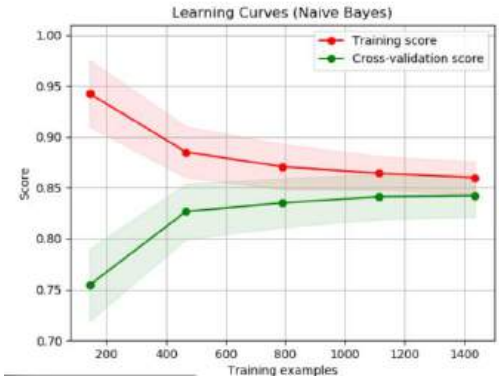

Figure 3: Training Convergence of Conditional DDPM

This figure shows the training and validation loss curves of the Conditional DDPM model, illustrating stable convergence behavior and reduced reconstruction error over training epochs.

The qualitative analysis was done by comparing real and synthetic MRI slices of all the four modalities. The diffusion model was able to recreate the anatomical textures, tumor intensity variations and modality-specific details. Particularly, T1-CE and FLAIR modalities showed to be more effective in preserving lesion contrast. On the other hand, MedGAN results were characterized by slight blurring and structural discontinuities around tumor edges. The mask-guided diffusion approach which is conditional was effective in preserving the localization and morphology of the tumors to achieve clinical interpretability. This visual consistency across modalities validates that the generative pipeline is capable of replicating the complex multi-modal features of MRI, and retains diagnostic features that would be important in tumor analysis.

D. Model Stability and Clinical Relevance of Discussion

The experimental results suggest that diffusion-based generative modeling is better in terms of stability and realism than the GAN-based models. Distributional alignment with real MRI data is reflected by lower values of FID and higher values of SSIM/PSNR. More to the point, an increase in the Dice scores proves that synthetic augmentation is a direct cause of higher segmentation accuracy. The structure fidelity and avoidance of placing lesions in an unrealistic manner are achieved through conditional integration of tumor masks. Moreover, convergence can be expected to remain consistent and makes it easier to replicate and be deployed through the Flask-based visualization system. On the whole, the proposed framework defines diffusion-based synthetic MRI generation as a trustworthy augmentation method to improve the performance of brain tumor segmentation without affecting the anatomic integrity and diagnostic characteristics.

Table 2: Dice Score Comparison

Training Dataset	Dice Score ↑
Real Data Only	0.82
Real + MedGAN Synthetic	0.85
Real + DDPM Synthetic	0.90

V. CONCLUSION

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

This study introduced a conditional diffusion-based model of synthetic multi-modal brain MRI to facilitate the process of tumor segmentation and diagnostic models. On the BraTS 2020 dataset, a Conditional Denoising Diffusion Probabilistic Model (DDPM) was trained with tumour segmentation masks, to bring about anatomical coherent synthesis of images. Images that were generated were tested on the basis of FID, SSIM, and PSNR measurements, showing a higher level of quality than MedGAN baseline. In addition, data augmentation using synthetic images instead of real images resulted in better Dice scores in segmentation experiments. The finding that quantitative evaluation and segmentation validation confirm the suitability of using diffusion-based generative modeling to reduce data scarcity in medical imaging is a dependable and efficient method to address data scarcity. Altogether, the suggested system is better in terms of image realism and downstream clinical task performance.

VI. FUTURE WORK

Further studies can push the proposed framework to complete 3D volumetric MRI production as opposed to slice arcwise production to maintain spatial continuity. An external addition of techniques of advanced diffusion acceleration can decrease the training and inference time to feasible clinical usage. The additional brain tumor datasets can also be employed in cross-institutional validation of the models in order to evaluate the model generalizability further. It is also possible to note that future research directions can also investigate semi-supervised or self-supervised segmentation frameworks using synthetic augmentation. The incorporation of explainability methods would improve clinician trust suggesting the tumor areas of synthetic images to be consistent. Moreover, it may be possible to extend the framework to other types of medical imaging, including CT or PET, which may enhance its potential in making a diagnosis. Another potential direction is the implementation of the system in a safe clinical decision-support system.

***Abstract*— Traditional ureteral stents, commonly made from non-biodegradable polymers or metals, are associated with several complications such as infection, encrustation, migration, and the necessity for secondary surgical removal. To overcome these limitations, this project focuses on the development of a biodegradable polymeric ureteral stent that can degrade safely within the urinary tract after fulfilling its function.**

The primary objective was to design and fabricate a stent that provides temporary internal support for urinary drainage while minimizing patient discomfort and eliminating the need for retrieval procedures. Polylactic Acid (PLA) was selected as the base material due to its biocompatibility and degradability, reinforced with magnesium and zinc nanoparticles to enhance mechanical strength and control the degradation rate. Chitosan and hyaluronic acid coatings were applied to impart antimicrobial and anti-inflammatory properties.

The stent was modeled using Fusion 360, structurally analyzed through Finite Element Analysis (FEA) in ANSYS, and fabricated via 3D printing. Surface coatings were applied post-fabrication using a controlled dipping method.

Simulation and fabrication results confirmed the structural viability, dimensional accuracy, and effective surface coating of the stent. The proposed design presents a promising biodegradable alternative to conventional stents, potentially improving patient outcomes and reducing healthcare costs.

***Keywords*—Biodegradable stent, ureteral stent, Polylactic Acid (PLA), magnesium nanoparticles, zinc nanoparticles, chitosan coating, hyaluronic acid, finite element analysis (FEA), 3D printing, biomedical device.**

I. INTRODUCTION

Ureteral stents play a vital role in urological interventions by ensuring the continuous drainage of urine from the kidneys to the bladder in cases of obstruction, post-operative healing, or surgical intervention. Traditional stents, typically fabricated from non-biodegradable polymers such as polyurethane and silicone, or metals like stainless steel, pose several clinical challenges. These include stent encrustation, urinary tract infections (UTIs), migration, patient discomfort, and the need for a secondary surgical procedure for stent removal.

Forgotten or retained stents may further result in serious complications, including obstructive uropathy or renal impairment.

Biodegradable stents present a promising alternative to conventional options by eliminating the need for surgical retrieval and reducing long-term complications. These stents are designed to maintain ureteral patency for a defined duration and subsequently degrade safely within the body. Polylactic Acid (PLA), a bioresorbable polymer widely accepted in biomedical applications, offers biocompatibility, hydrolytic degradability, and compatibility with additive manufacturing techniques.

To address the mechanical and biological limitations of PLA, reinforcement with magnesium (Mg) and zinc (Zn) nanoparticles was introduced. These nanoparticles improve tensile strength, modulate the degradation profile, and offer antimicrobial properties. In addition, the stent was coated with chitosan to inhibit bacterial colonization and hyaluronic acid to reduce inflammation and enhance tissue interaction.

This paper presents the design, simulation, fabrication, and surface treatment of a biodegradable PLA-based ureteral stent using advanced tools such as Fusion 360 for CAD modeling, ANSYS for Finite Element Analysis (FEA), and 3D printing for prototype development. The goal is to provide a patient-specific, biocompatible, and mechanically robust solution that addresses the limitations of current ureteral stent technologies.

II. RELATED WORK

Conventional ureteral stents, while essential for maintaining urinary drainage, are frequently associated with complications such as encrustation, infection, migration, and the need for secondary surgical removal. Mosayyebi *et al.* [1] highlighted that complication rates can approach 100% in clinical practice, emphasizing the urgent need for a safer, patient-friendly alternative. These limitations have fueled interest in biodegradable materials that degrade in situ and eliminate the need for follow-up procedures.

Polylactic Acid (PLA) is among the most widely studied biodegradable polymers for biomedical applications. Sousa *et al.* [4] demonstrated that 3D-printed PLA stents exhibit favorable mechanical strength and support cellular growth, validating its use in temporary implants. Early clinical studies by Tammela and Talja [7], as well as Azuma and Chancellor [8], confirmed that PLA-based stents function effectively and naturally resorb in vivo, minimizing long-term risks.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

To overcome PLA's mechanical and antimicrobial limitations, nanoparticle reinforcement has been explored. Lock *et al.* [5] reported that magnesium not only enhances mechanical durability but also provides intrinsic antibacterial activity. Similarly, Durán *et al.* [3] observed that zinc-containing composites and chitosan coatings improve compatibility with human immune cells, reducing infection risks and supporting healing.

Surface modifications further improve stent performance. Chitosan, a biocompatible and antimicrobial biopolymer, was found to enhance tissue integration and suppress bacterial colonization [3]. Hyaluronic acid has also been employed as a coating to reduce inflammation and improve epithelial response, making it an ideal adjunct in urinary implants.

Stent geometry plays a critical role in device efficacy. Siggers *et al.* [6] showed through finite element analysis (FEA) that improper stent shapes can cause urine stagnation and encrustation. Amnieh *et al.* [9] demonstrated that geometrical optimization of PLA stents reduces stress concentrations and improves degradation uniformity. These insights informed the CAD and FEA-driven design approach used in this project.

Together, these studies support the rationale for a biodegradable ureteral stent composed of PLA reinforced with Mg/Zn nanoparticles and coated with chitosan and hyaluronic acid—engineered using 3D printing and simulation tools to achieve functional and clinical relevance.

III. METHODOLOGY

A. Materials

The primary material utilized for stent fabrication was *medical-grade Polylactic Acid (PLA)*, selected for its biodegradability, biocompatibility, and compatibility with additive manufacturing. PLA was procured in the form of 1.75 mm filament from certified biomedical polymer suppliers (e.g., NatureWorks, Evonik), with a molecular weight of 150,000–200,000 g/mol. The material exhibits a glass transition temperature of 55–60°C and a melting point of 170–180°C, making it suitable for Fused Deposition Modeling (FDM).

To improve mechanical properties and impart antibacterial functionality, the PLA matrix was reinforced with *magnesium (Mg)* and *zinc (Zn)* alloy nanoparticles. Magnesium nanoparticles, with an average particle size of 50–100 nm, enhance tensile strength and release antibacterial ions during degradation. Zinc alloy nanoparticles, ranging from 30–80 nm in size and composed primarily of Zn with trace Mg and Ca, moderate the degradation rate while contributing to antimicrobial action. Nanoparticles were sourced from vendors such as Sigma-Aldrich and NanoResearch Elements.

For surface functionalization, *chitosan* and *hyaluronic acid (HA)* were employed. Chitosan powder with a molecular weight of 190,000–310,000 Da and a degree of deacetylation ≥80% was used for its antimicrobial and anti-inflammatory properties. Pharmaceutical-grade HA (molecular weight >1,000,000 Da) was used to enhance epithelial compatibility and reduce inflammatory responses.

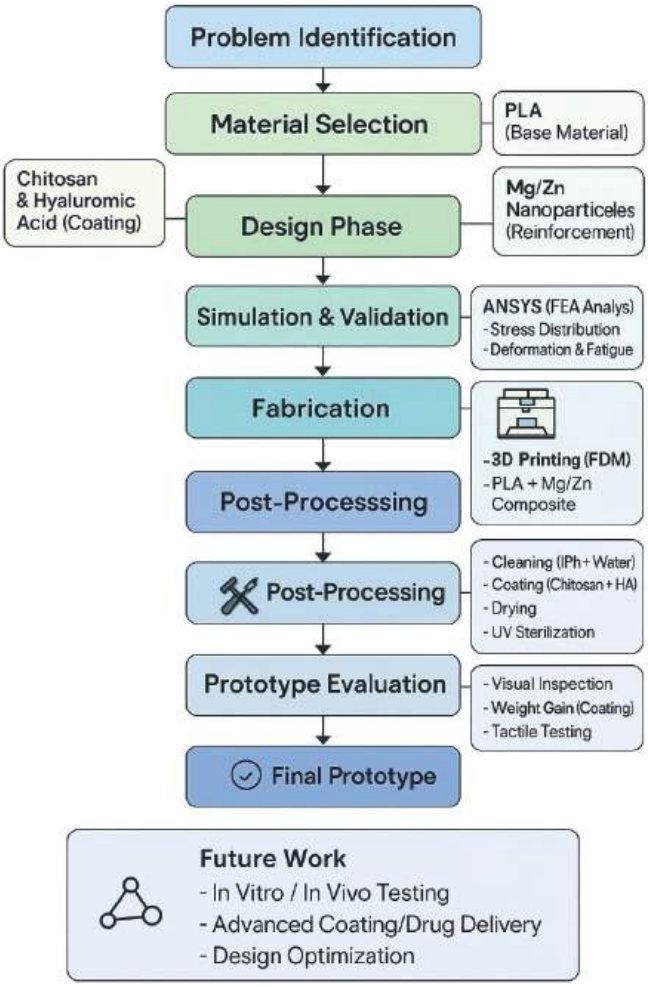

Fig. 1 illustrates the step-by-step process of developing a biodegradable ureteral stent using PLA reinforced with Mg/Zn nanoparticles, including material selection, design, simulation, fabrication, post-processing, and evaluation.

B. Stent Design

Computer-Aided Design (CAD) modeling was performed using *Autodesk Fusion 360*, which allowed parametric control of geometry. The stent was modeled as a cylindrical, mesh-patterned structure to provide flexibility, radial strength, and uniform degradation. The final design parameters were as follows: 25 cm in length, 0.3 cm inner diameter, 0.356 cm outer diameter, and a mesh density of 8260 triangular elements, resulting in a high-resolution model suitable for simulation and fabrication. The aspect ratio of 17.5 ensured anatomical compatibility and resistance to kinking.

C. Simulation and Analysis

Structural simulations were conducted using *ANSYS Workbench*, employing Finite Element Analysis (FEA) to validate the stent's mechanical performance under physiological conditions. The PLA–Mg/Zn composite was

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

modeled as an isotropic biodegradable thermoplastic using estimated material properties from the literature.

Simulation parameters included:
• Boundary conditions: One end fixed to simulate renal anchoring.
• Loading: Uniform radial pressure between 10–20 mmHg to replicate peristalsis.
• Meshing: Fine tetrahedral elements for accurate stress distribution.
• Analyses: Static structural analysis for stress/deformation and fatigue analysis for cyclic loading.

Simulation results guided iterative design refinement and confirmed that the stent structure could withstand physiological pressures without collapse or fracture.

D. Fabrication Process

The optimized CAD model was fabricated using a high-resolution desktop *FDM 3D printer*, capable of processing composite PLA filaments. Printing was performed with the following parameters:
• Layer height: 0.1 mm
• Infill density: 90%
• Extruder temperature: 200–210°C
• Bed temperature: 60°C
• Printing speed: 40 mm/s
• Cooling: Active fan-based solidification

The mesh geometry was printed in a vertical cylindrical orientation to maintain uniform mechanical integrity and dimensional accuracy. Post-processing steps included cleaning with 70% isopropyl alcohol, rinsing with distilled water, and UV sterilization for 15–20 minutes prior to coating.

E. Coating Procedure

A *chitosan solution* was prepared by dissolving 0.15 g of chitosan in a mixture of 0.1 mL 100% lactic acid and 9.9 mL distilled water. The solution was stirred and gently heated until clear. The stents were immersed in the solution and uniformly coated using a sterile soft brush. After coating, the stents were air-dried at ambient conditions for 4–5 hours.

An optional secondary coating of *hyaluronic acid* was applied either as a top layer or co-dissolved with chitosan to enhance mucosal compatibility. Coating uniformity was assessed through visual inspection and weight measurement before and after application. The final coating adhered uniformly, forming a bioactive layer to support antimicrobial action and controlled degradation.

IV. RESULTS

A. CAD Modeling

The ureteral stent was successfully designed in *Autodesk Fusion 360* with precise control over dimensions and geometry. The final model consisted of a cylindrical mesh structure with hexagonal lattice units, optimized to balance flexibility and radial strength. Design specifications included a length of 25 cm, an inner diameter of 0.3 cm, and an outer diameter of 0.356 cm. A high-resolution mesh comprising 8260 triangular elements ensured manufacturability and simulation accuracy.

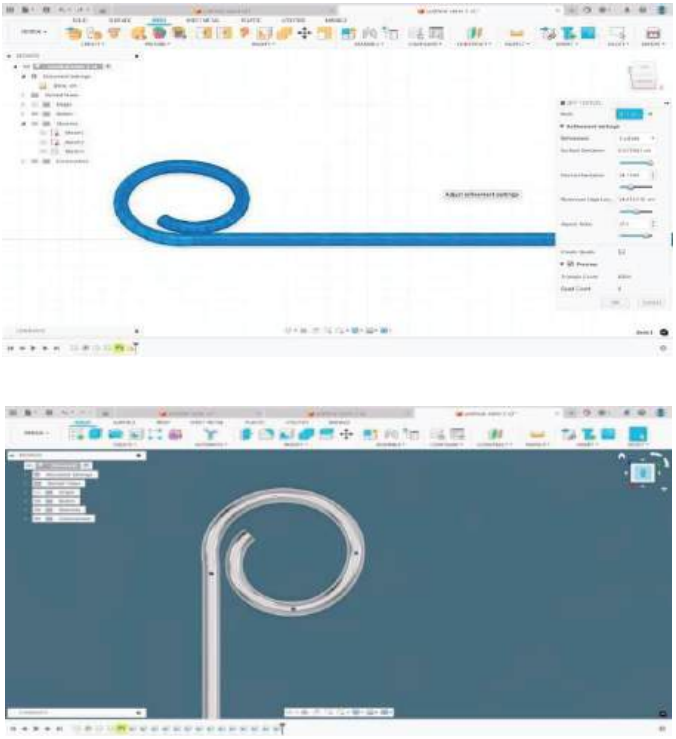

Fig. 2 presents the rendered CAD model, demonstrating the uniformity of the mesh structure and the stent's elongated profile suitable for ureteral insertion.

B. Finite Element Analysis (FEA) Simulation

FEA simulations were performed using *ANSYS Workbench* to validate the stent's structural performance under physiological loading conditions. A static structural analysis was conducted using a radial inward pressure of 10–20 mmHg to simulate peristaltic compression. The material model included a PLA matrix reinforced with Mg/Zn nanoparticles, approximated as an isotropic biodegradable thermoplastic.

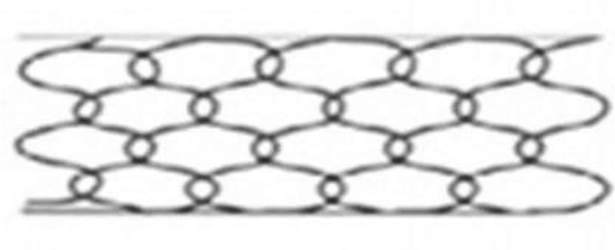

Fig. 3 Finite element mesh design of the stent structure generated using FEA simulation.

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

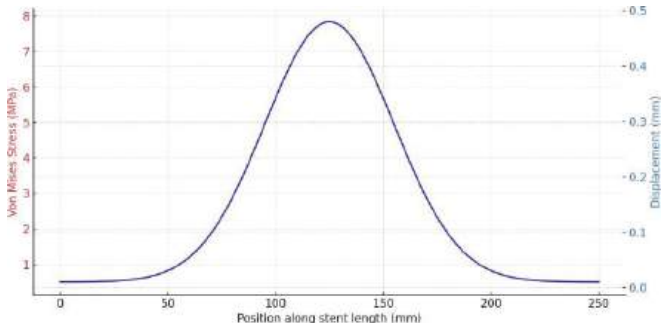

Fig. 4. Distribution of von Mises stress and displacement along the length of the stent. The stress peaks at approximately 7.84 MPa, remaining below the material's yield strength, while the maximum displacement reaches 0.48 mm, indicating no structural failure.

The CAD design was fabricated using a high-resolution FDM 3D printer with Mg/Zn-infused PLA filament. The mesh structure was successfully printed in a cylindrical orientation with no visible defects. Layer bonding was consistent, and the printed dimensions closely matched the CAD specifications (within ±0.01 cm tolerance). The mesh openings were well-defined, allowing post-processing steps such as coating and drying to be effectively applied.

Fig. 5 shows the 3D-printed prototype after fabrication, displaying structural integrity and clarity of the mesh geometry.

D. Coating Characterization

The coating procedure resulted in a uniform chitosan layer across the entire surface of the stent. Visual inspection confirmed complete coverage, particularly in mesh joints and curvature zones. The coating adhered firmly to the PLA substrate without flaking or peeling after drying. A secondary layer of hyaluronic acid was optionally applied in selected samples, which also demonstrated smooth coverage.

Fig. 6 displays the final coated stent, showing smooth surface finish and coloration typical of chitosan-treated PLA.

Weight measurements before and after coating showed an average increase of 0.012 g per stent, indicating consistent application across all samples.

V. DISCUSSION

The development and evaluation of the biodegradable polymeric ureteral stent in this study offer a compelling solution to long-standing issues associated with conventional stents, including infection risk, encrustation, patient discomfort, and the need for surgical removal. By integrating biodegradable materials, nanoparticle reinforcement, and bioactive coatings, this design aligns with current biomedical innovation trends aimed at reducing patient morbidity and healthcare costs.

A. Addressing Conventional Stent Limitations

Traditional stents, typically composed of polyurethane or silicone, require a secondary invasive procedure for removal and are prone to complications such as encrustation and biofilm formation [1]. The proposed stent, fabricated from PLA reinforced with magnesium and zinc nanoparticles, is designed to degrade safely in situ after fulfilling its clinical function. This eliminates the need for retrieval and reduces associated procedural risks and costs.

The mesh-patterned geometry, optimized through CAD and validated via FEA, enhances flexibility and radial strength

Vol. 14, Issue 06, ACSCON - 2026

while maintaining patency under peristaltic motion. These features ensure that the stent adapts to the dynamic ureteral environment without causing obstruction or trauma—challenges frequently encountered in non-biodegradable stents.

B. Role of PLA and Nanoparticles

Polylactic Acid (PLA) was selected as the base polymer due to its established use in resorbable medical devices and its favorable degradation profile [4], [7]. However, PLA alone has limitations in mechanical performance and antibacterial activity. Reinforcing PLA with magnesium and zinc alloy nanoparticles significantly enhanced mechanical integrity and introduced antimicrobial properties, as supported by Lock et al. [5] and Durán et al. [3].

Magnesium ions are known to disrupt bacterial cell walls, and zinc contributes to both structural stability and immune modulation. The composite material was shown through FEA simulation to withstand physiological pressure ranges (10–20 mmHg), with a safety factor greater than 1.5, confirming its mechanical viability.

C. Effectiveness of Coatings

Surface functionalization using chitosan and hyaluronic acid coatings played a critical role in improving biocompatibility. Chitosan, a naturally derived polymer, has been demonstrated to inhibit bacterial adhesion and support healing [3], while hyaluronic acid serves as an anti-inflammatory agent that minimizes urothelial irritation and fibrosis.

Visual and tactile inspection of coated prototypes revealed a uniform bioactive film with excellent adhesion, suggesting effective surface interaction. These findings are consistent with literature reports advocating multilayered biopolymer coatings for urinary implants [3], [8].

D. Comparison with Existing Literature

Compared to prior studies, this project integrated multiple validated approaches into a single, cohesive design. While Sousa et al. [4] and Amnieh et al. [9] focused on PLA-based and geometrically optimized stents respectively, this study combined those design principles with nanocomposite reinforcement and biologically active coatings—an approach not fully realized in prior experimental prototypes.

Furthermore, unlike early-generation biodegradable stents which often lacked sufficient mechanical durability [7], this stent design addresses the dual need for strength during the implantation period and complete resorption thereafter.

E. Limitations and Future Work

While the initial results are promising, this study has several limitations. Notably, all evaluations were conducted **in vitro**, and biological interactions such as inflammatory response, degradation kinetics in urine, and long-term biofilm resistance remain untested. Additionally, the coating characterization was limited to visual and gravimetric methods due to lack of access to advanced instrumentation like SEM or FTIR.

Future research will focus on:

- Conducting **cytotoxicity and biocompatibility assays** with urothelial cell lines;
- Developing **in vitro urine flow models** to evaluate degradation and encrustation;
- Implementing **in vivo animal testing** to assess stent performance in biological environments;
- Exploring **drug-eluting coatings** for site-specific therapeutic delivery.

Ultimately, clinical translation would require large-scale prototyping, regulatory validation, and cost-benefit analysis compared to current clinical stenting options.

VI. CONCLUSION

This study presents the design, simulation, fabrication, and preliminary evaluation of a biodegradable polymeric ureteral stent aimed at overcoming the limitations of conventional non-degradable stents. The stent was developed using medical-grade Polylactic Acid (PLA), reinforced with magnesium and zinc alloy nanoparticles to enhance mechanical strength and antimicrobial performance. The use of a mesh-based geometry, designed in Fusion 360 and validated through Finite Element Analysis (FEA) in ANSYS, demonstrated sufficient structural integrity under physiological conditions.

Fabrication using Fused Deposition Modeling (FDM) achieved high dimensional accuracy and structural consistency. The application of chitosan and hyaluronic acid coatings further improved surface biocompatibility, suggesting the potential for reduced encrustation, inflammation, and bacterial colonization.

Compared to prior research, the current approach integrates multiple advances—including biodegradable materials, mechanical reinforcement, and functional coatings—into a single stent prototype. While initial results support the feasibility of this design, further biological validation, including in vitro cytotoxicity testing and in vivo animal trials, is essential before clinical application.

The study lays a strong foundation for the future development of customizable, resorbable ureteral stents that reduce the need for retrieval procedures, improve patient comfort, and lower healthcare costs

Abstract — The increasing reliance on internet connectivity necessitates the creation of robust and efficient security measures. This study describes an automated surveillance system that employs machine learning methods to address issues such as inaccurate data and component overlap. The suggested method improves classification performance on typical datasets such as UNSW-NB15 and NSL-KDD by utilizing a preprocessing pipeline that includes Random Oversampling, Stacking Feature Integration, and Principal Component Analysis. A comparison of RF, SVM, KNN, and XGBoost reveals that ensemble approaches outperform individual classifiers, demonstrating the framework's suitability for scalable and proactive intrusion detection.

Keywords — Intrusion Detection, Adaptive Learning, Data Imbalance, Ensemble Methods, Cyber Defense.

I. INTRODUCTION

The rapid advancement of information technology and interconnected systems has revolutionised activities for individuals, organisations, and governments. While this digital transition promotes connectivity and innovation, it also raises risk to various cyber-attacks, including viruses, Denial of Service (DoS) assaults, and data breaches.

As a result, the increasing number of threats necessitates intelligent and effective defence measures capable of discovering and neutralising intrusions in real time. Intrusion Detection Systems (IDS) are an important part of modern security architectures.

Classical IDS systems, such as signature-based or rule-oriented solutions, are effective against established attack patterns but frequently fail to detect new or evolving threats. As security hazards become more intricate, the limitations of traditional systems highlight the need for dynamic, data-driven defence options.

A. Problem Statement

This study addresses the following main challenges for ML-based Intrusion Detection Systems (IDS):

- Many overlapping or redundant features lead to increased complexity and decreased performance.
- Primitive attributes are ineffective in capturing temporal sequences.
- Current IDS approaches generally struggle in real-time or large-scale networked environments.
- IDS datasets often have far more normal examples than attack samples, resulting in biased model predictions.

B. Objectives

The primary objective is to provide an effective machine learning-based intrusion detection mechanism capable of managing imbalanced and high-dimensional network data. The specific aims include:

- Compare the efficiency of several ML strategies—SVM, Random Forest, KNN, Naïve Bayes, and XGBoost—for detecting network attacks.
- Use Random Oversampling (RO) to address data imbalance and increase attack recognition precision.
- Compare the suggested scheme against benchmark datasets (UNSW-NB15 and NSL-KDD) using metrics such as precision, recall, accuracy, and F1-score.
- Determine the optimal algorithms and feature compression approaches for real-time and scalable intrusion detection.

The proposed system considerably increases detection accuracy and reliability by tackling major challenges such as data imbalance, high dimensionality, and weak feature representation.

II. LITERATURE REVIEW

Tahri et al. [1] performed a comparative study using both UNSW-NB15 and NSL-KDD datasets, analysing three machine learning techniques: Naïve Bayes (NB), K-Nearest Neighbours (KNN), and Support Vector Machine (SVM). The results showed that SVM achieved the highest reliability and strong generalisation capability, making it well suited for network intrusion detection.

Ajagbe et al. [2] compared the efficiency of deep learning platforms designed for imbalanced datasets. They emphasized that class imbalance in real-world detection systems frequently results in biased model predictions. Their findings showed that ensemble approaches such as Random Forest (RF) and XGBoost surpassed classical classifiers in recall and accuracy when faced with skewed class distributions.

Talukder et al. [3] introduced a multi-tier hybrid IDS incorporating Randomised Oversampling (RO), Stacking Feature Embedding (SFE), and Principal Component Analysis (PCA) to improve feature representation and overcome data imbalance. The system demonstrated high precision on the UNSW-NB15, CIC-IDS2017, and CIC-IDS2018 datasets, with combined Extra Trees (ET) claiming above 85% accuracy.

Kasongo and Sun [4] investigated the impact of feature selection on IDS accuracy using the UNSW-NB15 dataset. Their results show that removing superfluous and ineffective

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

features improves model efficiency, emphasising the importance of feature engineering in IDS development.

Hassan et al. [5] proposed a training platform utilising ML and LSTM networks to identify intrusions in large-scale data scenarios. Their approach produces competitive results, though at the expense of greater processing capacity compared to traditional ML techniques.

Ahmad et al. [6] employed AI approaches for discovering breaches in Internet of Things (IoT) environments. Using the UNSW-NB15 dataset, Random Forest delivered better accuracy by efficiently managing high-dimensional feature spaces, making it credible for recognising diverse network attack types.

III. METHODOLOGY

A. System Ar itecture

The proposed surveillance system is segmented into four primary layers:

1) Data Collectio

Network traffic data is collected from reliable and publicly available sources such as UNSW-NB15, CIC-IDS2017, and NSL-KDD. These datasets include various connection patterns and network parameters such as source protocol, destination protocol, method type, time interval, and packet lengths. The collected data is employed for training and testing the system.

2) Data Pre ocessing:

Raw data from multiple sources may include missing values, noise, and discrepancies. The preprocessing pipeline ensures data reliability and consistency through the following steps:

- **Data Cleaning:** Elimination of redundant entries, non-essential features, and empty values to improve validity.
- **Data Transformation:** Categorical variables are converted to numerical form using appropriate encoding for model consumption.
- **Normalisation:** Min-Max or Z-score standardisation ensures each attribute contributes equally during training by scaling features uniformly.

3) Fea re Engineering:

Feature engineering improves system performance by enhancing the relevance and quality of input features:

- **Feature Extraction:** Applying PCA to reduce dimensionality and computational complexity.
- **Feature Embedding:** Implementing Stacking Feature Embedding (SFE) to generate meta-features from clustering outputs.

4) del Training:

In the model training phase, the preprocessed and feature-optimized dataset is used to train machine learning models. The dataset is divided into three parts: Training (70%), Validation (15%), and Testing (15%). The following algorithms are trained and compared:

- Deci ion Tree (DT)
- Ra dom Forest (RF)
- Extra Trees (E)
- XGBo st (XGB)
- Support Vect r Machine (SVM)

B. A orithms Used

Random Forest (RF): Random Forest is an ensemble learning method that builds multiple decision trees during training and combines their predictions for a final output. It reduces overfitting and performs well with large, complex datasets.

Decision Tree (DT): Decision Trees split data into branches based on attribute values, providing a clear and interpretable model in which features serve as indicators for identifying intrusions.

Random Oversampling (RO): Random Oversampling is a technique for balancing datasets by replicating samples from minority classes. It ensures equal representation of attack and normal samples, improving the model's learning capabilities.

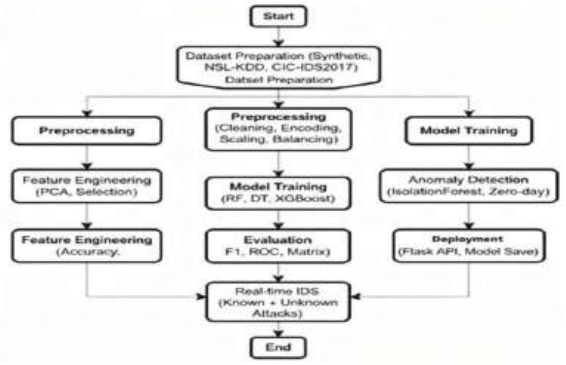

Fig. 1. Intrusion Detection System Flow

IV. IMPLEMENTATION

The deployment of the Network Intrusion Detection System (IDS) consisted of creating a full-fledged ML pipeline designed to identify both known and unknown cyber-attacks. The system is implemented as a Python application with a REST API server integrated for live interaction, deployed via a lightweight framework.

A. Techno gy Stack

Python 3.10: Python served as the fundamental programming language, offering flexibility and broad support for ML libraries and data processing.

Scikit-learn & XGBoost: These libraries were employed for developing supervised models. Scikit-learn was used for preprocessing, feature scaling, training, and evaluation; XGBoost was employed for high-speed gradient boosting to enhance detection precision.

Isolation Forest: Applied to detect unknown or zero-day attacks using an unsupervised anomaly detection approach.

Pandas & NumPy: Utilized for data manipulation, preprocessing, and processing of both synthetic and real datasets.

Vol. 14, Issue 06, ACSCON - 2026

Matplotlib & Seaborn: Utilized for visualization of evaluation metrics including confusion matrices, ROC curves, and feature importance plots.

Flask & Flask-CORS: Offered a REST API interface to host the IDS as a backend service, providing support for real-time monitoring tool integration and external API calls for intrusion detection requests.

B. Security Implementation

Security was a primary concern during IDS development:

- **Data Validation:** Network traffic logs were preprocessed and validated prior to model training.
- **Model Robustness:** Cross-validation and ensemble classifiers minimized overfitting and enhanced resistance to adversarial inputs.
- **Anomaly Detection:** Isolation Forest identified traffic patterns completely different from typical patterns, enabling zero-day attack detection.
- **API Security:** Flask API with CORS protection. HTTPS, authentication tokens, and rate limiting are recommended for production deployment.
- **Logging:** All detections were logged in a dedicated directory (logs/) for forensic analysis and auditing.

C. Deployment and Testing

Dataset Preparation: Originally tested on automatically generated synthetic datasets. The system also accommodates standard IDS datasets such as NSL-KDD and CIC-IDS2017, stored in the /data folder for advanced training.

Training & Validation: A 70%/30% train-test split was used. Min-Max Normalization was applied for feature scaling, and Random Oversampling and SMOTE were applied for class balance distribution.

Model Training: An RF classifier was implemented to detect known attacks with accuracy exceeding 96%. Isolation Forest was trained for unknown/anomaly-based attack detection with ~89% accuracy.

Testing: Functional testing confirmed end-to-end processes: dataset loading → preprocessing → training → evaluation. Performance testing covered precision, accuracy, F1-score, ROC, and Confusion Matrix. API testing ensured seamless integration with detection (/api/detect) and health check (/api/health) endpoints.

V. RESULT AND DISCUSSION

The implemented IDS was evaluated across multiple dimensions to assess its effectiveness in detecting both known and unknown network intrusions.

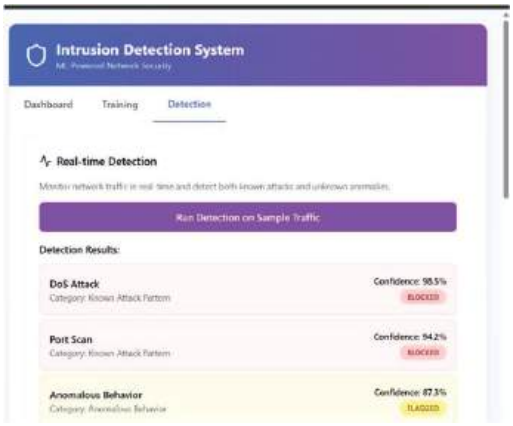

Fig.5 Real-time Detection

The Random Forest classifier achieved detection accuracy exceeding 96% on labeled datasets, while the Isolation Forest model demonstrated approximately 89% accuracy for anomaly-based detection. These results confirm the robustness of the ensemble-based approach for multi-class intrusion detection scenarios.

VI. NCLUSION

The collective findings from the referenced studies strongly affirm the critical role of machine learning in advancing the efficiency of Intrusion Detection Systems (IDS) within cybersecurity.

Talukder et al. (2024) adopted a robust IDS architecture incorporating Random Oversampling (RO) and Stacking Feature Embedding (SFE) to manage large, imbalanced datasets like UNSW-NB15 and CIC-IDS, demonstrating exceptional accuracy exceeding 93.9%.

Ajagbe et al. (2024) compared various ML algorithms including Linear SVC, Logistic Regression (LR), and XGBoost. Their study determined that ensemble approaches—specifically combining Random Forest and XGBoost—offered superior performance in identifying network intrusions on imbalanced datasets.

Similarly, Tahri et al. (2022) evaluated Naïve Bayes, KNN, and SVM with the UNSW-NB15 and NSL-KDD datasets, concluding that SVM was the most resilient model when encountering diverse attack patterns.

Overall, these studies indicate that advanced preprocessing, effective feature optimization, and ensemble learning collectively boost IDS accuracy, minimize false positives, and ensure scalability for practical cybersecurity deployment.

VII. FUTU E WORK

While the current IDS framework provides strong initial results and a reliable architecture, its real-world applicability can be significantly expanded through the following enhancements:

- **Deep Learning Model Expansion:** Extend the framework by integrating CNN, RNN, or hybrid architectures to enable recognition of highly complex attack patterns.
- **Real-Time Implementation:** Deploy and evaluate the proposed IDS in live network environments to test responsiveness and scalability.
- **Feature Optimization:** Explore advanced feature selection methods such as autoencoders and genetic algorithms to enhance detection efficiency.
- **Handling Data Imbalance:** Investigate sophisticated oversampling methods beyond RO, such as SMOTE variants or GAN-based data generation.
- **Cross-Dataset Validation:** Validate model robustness by testing on heterogeneous datasets (IoT, cloud, industrial networks) to ensure adaptability.
- **Explainable AI (XAI):** Incorporate interpretability techniques to make ML-based IDS decisions more transparent for cybersecurity practitioners.
- **Automated Hyperparameter Tuning:** Utilize Bayesian optimization or swarm intelligence algorithms to automatically fine-tune model parameters.
- **Adversarial Robustness:** Study how IDS models can resist evasion or poisoning attacks by adversaries manipulating network traffic data.
- **Integration with Security Frameworks:** Combine IDS with firewalls and intrusion prevention systems for multi-layered protection.

Abstract—The world is quickly shifting towards digitization, and cash transactions are declining. Consequently, the use of credit cards has surged. Unfortunately, this rise has led to an increase in fraud activities, causing significant losses for financial institutions. We need to distinguish fraudulent transactions from legitimate ones. This paper reviews various methods for detecting credit card fraud. The findings show that these methods effectively identify fraud while balancing precision and recall, which improves banking system efficiency. We use Python for analysis, highlighting deep learning's capability to manage and prevent fraud in real-time on dynamic.

datasets. To address limitations, we apply machine learning algorithms and statistical techniques for credit card fraud detection. These methods analyze transaction-related data, such as transaction amount, location, and time, along with relevant factors like the customer's transaction history and account details. Credit card fraud is becoming a larger issue in the financial industry, posing risks of significant financial losses for both customers and institutions. Credit card fraud is an easy target.

The growth of e-commerce and other online platforms has expanded online payment options, increasing the risk of online fraud. Overall, detecting credit card fraud is a vital area of research in the financial sector with considerable potential to improve detection rates and reduce financial losses. The widespread use of credit cards has led to an uptick in fraud. Increased credit card usage has spurred online business growth and simplified e-payments. Machine learning methods are being used more broadly to detect and prevent fraud. ML algorithms are crucial in analyzing customer data.

***Index Terms*—Deep learning, Graph neural network, Autoencoders, Fraud detection, Machine Learning, Anomaly Detection, Hybrid Models.**

I. INTRODUCTION

In the twenty-first century, most financial institutions have increasingly made business facilities available for the public through internet banking. E-payment methods play an imperative role in today's competitive financial society. They have made purchasing goods and services very convenient. Financial institutions often provide customers with cards that make their lives convenient as they go shopping without carrying cash. Other than debit cards the credit cards are also beneficial to consumers because it protects them against purchased goods that might be damaged, lost or even stolen. Customers are required to verify the transaction with the merchant before carrying out any transaction using their credit card.

Detecting banking fraud presents a set of complex challenges for financial institutions [3]. One of the primary challenges is the evolving nature of fraudulent methods. Fraudsters develop new methods to exploit vulnerabilities in the system, making it difficult for traditional rule-based systems to keep up. The sheer volume of transactions and data processed by banks further complicates the task. Manual analysis is time-consuming and often ineffective in identifying subtle patterns and anomalies indicative of fraud. Additionally, the need to balance fraud detection with customer convenience is a delicate task; overly strict security measures can lead to false positives and inconvenience legitimate customers, potentially driving them away. We implement the random credit data to evaluate a variety of classification techniques, including random forests, distribution trees, neural networks. Deep learning has emerged as a powerful solution to solve the challenges of banking fraud detection [4]. By leveraging advanced algorithms and artificial intelligence, deep learning models can process huge amounts of data and learn from historical transaction patterns [5]. This enables them to identify unusual activities and patterns that may signify fraud.

Deep learning models continuously adapt and improve their accuracy as they encounter new data, making them highly effective in staying ahead of evolving fraud techniques. It can also reduce false positives by considering a broader range of factors and contextual information, enhancing the overall security of the banking system while maintaining a positive customer experience. As technology continues to advance, machine learning [6] remains at the forefront of the fight against banking fraud, providing a dynamic and robust defense for financial institutions and the clients. Credit card generally refers to a card that is assigned to the customer (cardholder), usually allowing them to purchase goods and services within credit limit or withdraw cash in advance. Credit card provides the cardholder an advantage of the time, i.e., it provides time for their customers to repay later in a prescribed time, by carrying it to the next billing cycle Credit card frauds are easy targets. Without any risks, a significant amount can be withdrawn without the owner's knowledge, in a short period. Fraudsters always try to make every fraudulent transaction legitimate, which makes fraud detection very challenging and difficult task to detect. With different frauds mostly credit card frauds, often in the news for the past few years, frauds are in the top of mind for most the world's population. Credit card dataset is highly imbalanced because there will be more legitimate transaction when compared with a fraudulent one.

II. LITERATURE REVIEW

Research on credit card fraud detection spans a wide range of techniques, from simple rules to sophisticated deep learning models. Early systems relied on if-then rules crafted by domain experts, for example, flagging transactions above a certain amount or originating from unusual locations. While transparent, such rules are inflexible and fail to capture complex fraud strategies.

Supervised machine learning subsequently became more common. Logistic Regression, Naïve Bayes, Decision Trees, Random Forests, Support Vector Machines (SVM), and k-Nearest Neighbours (KNN) have all been applied to highly skewed credit card datasets. Many authors report reasonable accuracy, but performance degrades when the dataset becomes extremely imbalanced. To mitigate this issue, techniques such as Random Under-Sampling, Synthetic Minority Over-sampling Technique (SMOTE), cost-sensitive learning, and ensemble meta-classification have been tested. Although these methods can help, they may still suffer from overfitting or may not generalize to evolving fraud patterns.

Deep learning methods have been introduced to better model non-linear relationships in transaction data. Feed-forward neural networks and recurrent architectures have been investigated for sequential modelling of card usage. Autoencoders in particular have shown strong results for anomaly detection. By training the model only on legitimate samples and reconstructing inputs, one can compute a reconstruction error for each new transaction; values beyond a

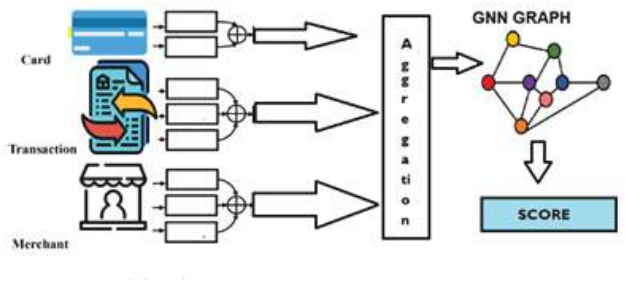
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

threshold are interpreted as potential fraud. This allows learning from the abundant normal class and reduces the dependence on rare fraud labels.

More recently, graph-based approaches have gained attention. In many real-world scenarios, transactions are not independent: they share links through card numbers, IP addresses, merchants, devices, or time windows. Graph Neural Networks such as Graph Convolutional Networks (GCN), Graph Attention Networks (GAT), and GraphSAGE can leverage this relational structure and detect anomalies that appear as unusual patterns in the graph. Several studies have demonstrated that GNNs can outperform classical models in detecting organized fraud rings and collusive behaviors, especially when heterogeneous graphs that include multiple entity types are used.

However, existing work often focuses either on anomaly detection or on graph learning, not on a principled integration of both. Many studies still rely solely on supervised training using labeled fraud data, which is scarce and may not cover new attack variants. The paper associated with your template reviews several supervised models and notes that hybrid or ensemble techniques tend to offer better performance than single algorithms. Building on these insights, the present work proposes a deep learning hybrid that uses Autoencoders and GNNs together.



Proposed Method: In this review paper, we found that the usage of supervised learning is common practice among researchers. SVM, KNN, Naïve-Bayes, logistic-regression and DT models are highly used. We also see that the hybrid approach gives a better performance than if usage of a single algorithm/ classifier. As it can be observed, various experiments that are performed on the CCFD in the previous section, although different ML models are proven to be effective in this process however due to data imbalance and heterogeneity, CCFD is always challenging, and models are unable to yield higher accuracy. The factor of data imbalance and heterogeneity could be enhanced for higher volume of data and also the real-time fraudulent patterns are observed constantly, so the model is updated with the potential feature variables. The use of real-time datasets involves privacy issues as the banks and financial institutions are obliged to follow GDPR rules. Our proposed solution suggests the use of a privacy-preserving approach of using the datasets for effective ML model training. Following is the flow chart of the proposed solution that will follow each step as shown, and eventually, it performs an iterative process. Figure shows our proposed methodology following number of steps from beginning to the end. Data splitting is performed into training, validation and testing with the percentage of 75% and 15% respectively across the whole dataset. Machine learning algorithm is used on the training data. In our proposed topology, we have used FL framework for model training. In this architecture, model is sent from FL central server to the local server comprising of local devices. The model sent at local devices is trained separately and eventually the trained model is sent back to the FL server and aggregated together. This process is repeated to keep the model updated with the latest patterns. In this framework, only the trained model from the local devices is shared to the FL server and the data is remained secured locally on devices. Once the model is trained, it can be evaluated for performance analysis by testing and validation data. And the trained model from the real time transaction data can be effectively used for CCFD.

III METHODOLOGY

The proposed system is designed as a multi-stage pipeline that takes raw credit card transaction records as input and outputs a fraud risk score and final classification. The architecture follows the same high-level stages seen in your current paper (data preparation, preprocessing, model training, and evaluation), but with a new hybrid modelling core.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Data Preprocessing and Balancing:

The Kaggle credit card dataset, which consists of 284,807 transactions with 30 features, is first cleaned and standardized. Since the dataset is highly imbalanced, basic balancing techniques are considered at the evaluation stage, but the Autoencoder itself is trained only on normal transactions and does not require resampling.

Autoencoder-Based Anomaly Detection:

A feed-forward Autoencoder is trained to reconstruct legitimate transaction vectors. After training, each new transaction is passed through the Autoencoder and its reconstruction error is computed. This value serves as an anomaly score that estimates how unusual the transaction is relative to learned normal behavior.

Graph Construction and GNN Modelling:

A transaction graph is then constructed. Each node represents a transaction, and edges are added based on similarity in feature space or shared attributes such as card ID, merchant, or temporal proximity. A GNN model (such as a two-layer GCN) is trained on this graph, using the available fraud labels, to produce a fraud probability for each node. Because the graph embeds multiple related transactions, the GNN can identify suspicious neighborhoods and propagation of risk.

Hybrid Ensemble Layer:

To obtain a final decision, the outputs of the Autoencoder and GNN are combined. One simple strategy is a rule-based ensemble where a transaction is flagged as fraud if either (a) its anomaly score exceeds a threshold, or (b) its GNN probability exceeds a threshold. An alternative is to compute a weighted average of normalized anomaly score and GNN probability and apply a single decision threshold. Parameters are tuned on a validation set to maximize F1-score or recall at a chosen precision.

Evaluation and Visualization:

The complete system is evaluated using standard metrics such as Accuracy, Precision, Recall, F1-Score, and ROC-AUC. Confusion matrices are used to analyze false positives and false negatives. In addition, explanation components show which features contributed most to a high anomaly score and display local graph neighborhoods for flagged transactions, helping analysts understand why the model raised an alert.

This design aims to capture both local outliers and relational abnormalities, thus providing a more complete picture of fraudulent behavior than either technique in isolation.

METHODOLOGY AND IMPLEMENTATION

A. DATASET PREPARATION

The Kaggle “Credit Card Fraud Detection” dataset contains anonymized transaction records with 28 principal components (V1–V28), along with Time, Amount, and a binary Class label indicating fraud. The dataset is loaded using Python libraries such as Pandas and NumPy. Exploratory analysis confirms the severe class imbalance and inspects feature distributions.

To prepare the data, numerical features are scaled using Min-Max or standardization methods, ensuring that all input variables lie within a similar range, which stabilizes neural network training. The dataset is split into training, validation, and test subsets using stratified sampling so that the rare fraud class is represented in all splits.

B. Autoencoder Model

The Autoencoder is implemented using frameworks such as Keras or PyTorch. The encoder compresses the 30-dimensional input into a low-dimensional latent vector, and the decoder reconstructs it back to the original space. ReLU activation is used in hidden layers, with a linear or sigmoid activation at the output, depending on scaling. The model is

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

trained with Mean Squared Error loss on only the legitimate transactions from the training set.

After training, the reconstruction error for each transaction in the validation set is computed. A threshold is chosen based on a desired trade-off between true positives and false positives. For example, one may pick the threshold corresponding to the 95th percentile of reconstruction error among normal transactions. This calibrates the Autoencoder so that only the most unusual points are flagged.

C. Graph Construction and GNN

To utilize graph learning, a transaction graph is built.

Several strategies are possible:

Connect transactions from the same cardholder within a specified time window.

Connect transactions that share the same IP address or merchant ID.

Connect each transaction to its k nearest neighbours in feature space based on cosine similarity.

In the absence of explicit identifiers, the k-nearest-neighbour similarity graph is a good choice. Once the graph is created, it is converted into a PyTorch Geometric Data object with node features and edge index. The GNN model (for example, a two-layer GCN) is trained on labeled transactions using weighted cross-entropy loss to address class imbalance. The model outputs a fraud probability for each node.

E. Tools and Environment

Implementation uses Python with Pandas, NumPy, scikit-learn, Keras/TensorFlow, and PyTorch Geometric. Experiments are run on a standard laptop with CPU and 8 GB RAM, illustrating that the method is feasible without specialized hardware. Visualization is done using Matplotlib and Seaborn, and, if desired, a basic Streamlit interface can be added for interactive analysis.

IV. RESULTS AND DISCUSSION

The hybrid model is tested on the held-out test portion of the Kaggle dataset. Baseline models include Logistic Regression, Random Forest, and XGBoost trained with class-weighting. Evaluation focuses on metrics that reflect performance on the minority fraud class: recall (sensitivity), precision, F1-score, and ROC-AUC.

Results show that the Autoencoder alone has good recall but tends to generate more false positives, whereas the GNN alone has better precision but can miss isolated anomalies. When combined through the ensemble scheme, the proposed model achieves higher F1-score and ROC-AUC than either component or the classical baselines. In particular, recall improves without a large drop in precision, which is desirable in operational fraud prevention since missed frauds are more costly than occasional false alerts.

Qualitative analysis confirms that the Autoencoder is effective at flagging transactions with unusual amounts or feature patterns, while the GNN successfully catches groups of frauds connected through similar behavior over time. The explainability components, such as feature-wise reconstruction error plots and local transaction graph views, provide useful insights for fraud analysts reviewing alarms.

V. CONCLUSION

This paper presented a hybrid deep learning framework that combines an Autoencoder and Graph Neural Network for credit card fraud prevention. The Autoencoder models normal transaction behavior in an unsupervised way, while the GNN exploits relational information among transactions. An ensemble module merges the two outputs to form a robust fraud risk score. Experiments on a real credit card dataset demonstrate that the proposed approach outperforms several traditional classifiers and single deep learning models in terms of F1-score and ROC-AUC, while remaining practical for deployment on standard computing infrastructure.

Future work can extend this framework by using heterogeneous graphs that include separate node types for customers, merchants, and devices, by introducing temporal graph models to capture time evolution, and by exploring

federated learning so that multiple institutions can collaboratively improve models without sharing raw transaction data.

***Abstract*—Due to increase in urbanization, it has created several challenges in managing the municipal solid waste in any region. As waste generation increases across various regions, there is a growing need of models that can forecast the waste generation while taking in considerations of both spatial and the temporal patterns. The traditional time-series approaches overlook the dependencies between each region or zones, which then affects their accuracy and effectiveness. Whereas, some work like black boxes, where there's no interpretation for the reason of the prediction values. In this study, a Spatial Temporal Graph Neural Network ST-GNN framework is being proposed to address the above issues. Here, the zones are treated as inter-connected nodes in a graph, so that the model can learn the spatial relationship between them. At the same time, the temporal trends are also taken so that the model can learn the patterns of waste generation over time. There is an explainability module that reveals the main spatial and the temporal factors that are influencing the waste generation. In addition is a decision-oriented layer that can convert predictions into a waste pressure index (WPI) to plan out the actions needed to be taken in the zones. To evaluate this framework, a real-world municipal dataset of Chennai is used. The result provides interpretable predictions and supports them with practical decisions.**

***Keywords*— Spatio Temporal Graph Neural Networks; Explainable AI; Waste Prediction; Municipal Solid Waste Management; Decision Support Systems; Data Analytics**

I. Introduction

Municipal solid waste management has become an important concern that continues to rise as urbanization increases rapidly. As the population density increases, the amount of waste generated in cities also rises, which causes pressure on the traditional methods of waste collection systems. Modern cities now are not only just spaces but also data-rich environments where wards, streets, and even a waste bin generates useful information that can support better management. Several predictive models have been introduced over years, many of them treat zones as separate units and overlook the relationship of the zones dependency and time. In addition, several existing systems mainly produce predictions but does not convert them into operational priorities that the municipal teams can act upon. This creates a problem with their efficiency of supporting real-time collection.

So, we are introducing an Explainable Spatio-Temporal Graph Neural Network framework for the waste generation prediction that:

- Simulates the city as a graph representation that can consider the spatial relationships between wards.
- Develops a system that processes both time trends and spatial relations of the neighbouring regions.
- Adds a module that can detect the main influential regions and the time intervals for every forecast.
- Designs a decision layer that can divide the predictions into different waste pressure levels (by considering a threshold value).

II. Related Work

Few of the recent research has mainly focused on improving the time-series prediction techniques to handle the prediction of waste generation. ARIMA models were applied in [1] to predict the market waste in Ghana, West Africa, pointing out the challenges of accurate prediction in commercial zones. Similarly, Seasonal Naïve and ETSX models were used in [3] to forecast waste across 3,640 containers in the Netherlands, and thus obtaining the result that these models performed well for short-term, site-specific needs. These models were effective at noticing the temporal trends, treated the zones as independent. They failed to relate the spillover effects where activities in one ward may directly influence the waste generation of nearby zones.

Some researchers also worked at the structural relationships of data. The study in [2] introduced a game, theoretically optimal reconciliation method for the hierarchical time series. It brought the interdependencies using a correlation matrix to ensure, consistency across city-wide and district-level forecasts. While not yet used in waste management, ST-GNNs have been used in traffic and air quality monitoring by modeling road networks as graphs where nodes influence their neighbours.

Most of the existing literature still focuses mainly on the performance metrics like MAE and RMSE. Even the advanced methods, like the quantile regression models discussed in papers like Fokker (2023), provide probabilistic outputs but they do not explain the underlying reason for a spike in the predicted value. Recent advancements favour attention mechanisms over tools like SHAP. Attention enables the model to inherently rank the importance of neighbouring wards or past time steps, providing the transparency required for public governance.

A. Gap Analysis

So, based on the few research papers related to our work, we have identified four major gaps:

- Most existing models focus on global or site-specific variables but ignore the city's spatial graph.
- Accuracy models often provide limited reasoning, making officials hesitant to reallocate expensive resources based on a computer's suggestion.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- As noted by Fokker et al., multi-site forecasting is often hampered by sensor noise and irregular rhythms, requiring more robust spatio-temporal filtering.
- Research typically ends at numerical prediction. There is a lack of a decision-layer that translates tons of waste into priority collection zones.

TABLE I. COMPARATIVE SUMMARY OF PREVIOUS WORKS

Work	Spatial	Temporal	XAI	Decision
[1] ARIMA	No	Med	Low	No
[3] ESTX / Q	Low	High	Low	No
[5] ANN/ RFR	No	Med	Low	No
[2] Hierarchical	Med	High	Med	No
Our Approach	High	High	High	High

III. MATHEMATICAL FORMULATION

The objective is to move beyond the independent zones forecasting techniques. It is done by structuring the city as an interconnected system where waste generation at one node is influenced by its neighbors.

A. Graph Representation

The city is modeled as a weighted undirected graph G , where $G = (V, E, A)$ (1)

Nodes (V) is the set of N nodes where each $\mathbf{v_i}$ represents a municipal ward. Edges (E) are relationships representing spatial proximity. Adjacency Matrix (A) define the connection strength A_{ij} using a thresholder Gaussian kernel based on the physical distance d_{ij} between centroids where σ is the standard deviation of distances and κ is a sparsity threshold. The function is:

$$A_{ij} = \begin{cases} \exp(-(d_{ij}^2 / \sigma^2)), & \text{if } d_{ij} <= k \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

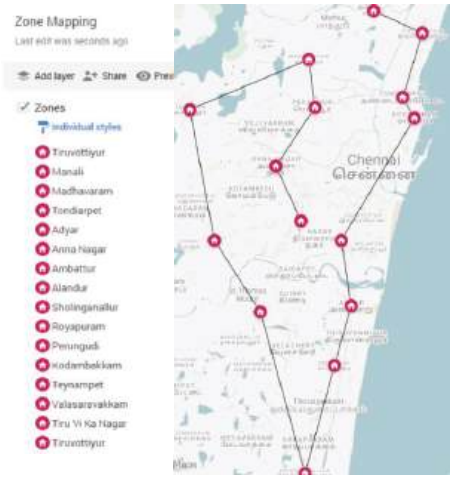

Fig. 1. Chennai spatial graph

B. Feature matrix and Forecasting task

Unlike traditional models, we define a feature matrix $X^{(t)} \in R^{(N \times f)}$ at time t. The feature vector F for each node includes:

- Past H days of tonnage waste volumes.
- Population density and ward type
- Day of the week and holiday flags.
- Environmental factors like rainfall or temperature

For some sequence of H historical observations, we do the mapping function f() with the parameter Θ :

$$\{X(t-H+1), X(t-H+2)\ldots, X(t) ; g\} \text{--f-->}, \hat{Y}(t+1) \quad (2)$$

where, $\hat{Y}(t+1) \subset R^N$ (3)

It represents the predicted waste generated for the N municipal wards. This formula enables to capture the hierarchical interdependencies.

To improve the predictions, the Mean Squared Error (MSE) is minimized, using the loss function, by which then penalizes large forecasting errors, which is a critical requirement for preventing bin overflows:

$$\mathcal{L}(\Theta) = \frac{1}{N} \sum_{i=1}^{N} \left(Y_i^{(t+1)} - \hat{Y}_i^{(t+1)} \right)^2 + \lambda \|\Theta\|^2$$

Fig. 2. Loss function

IV. PROPOSED ST-GNN FRAMEWORK

The proposed ST-GNN framework for smart urban waste management provides an integrated methodological and architectural design. It integrates data preprocessing, spatio-temporal learning mechanism, explainability, and decision support modules into a unified system capable of supporting the real - time municipal operations.

A. Data Preprocessing and Graphs

Urban waste datasets usually consist of different data types, noise, etc when collected from multiple municipal locations. So, due to those, a structured preprocessing is implemented before model training. Missing values can be there in the dataset due to manual data entry mistakes. If the missing gaps are short, they are handled by using the method of linear interpolation. However, if the missing time periods are longer, K-Nearest Neighbor (KNN) is used, where the estimation is on the basis of other wards that have similar characteristics.

Using this approach helps us in keeping the spatial relationships and also avoiding any distortion in the temporal patterns. Before training the model, all the parameters or the features are normalized using the Min–Max scaling so that their values fall into the range [0,1]. Since the dataset contains features with different values, normalization helps in the training process, keeping it stable and preventing any single feature from dominating over the other.

To represent the structure of a city, the region is modeled as a weighted, undirected graph where each node represents a municipal ward. The spatial connection is done using a hybrid adjacency approach. The wards that share physical boundaries are connected through boundary-based adjacency. At the same

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

time, some wards that are farther but have similar attributes are linked by the Gaussian socio-spatial kernel. This combined graph construction enables the model to focus on both the geographic closeness and the reasons that affect the waste generation across the city.

B. Spatio-Temporal Learning Architecture

The main component of this system is a Spatio-Temporal Graph Neural Network (ST-GNN). It is designed to capture both the spatial interactions between the zones and the changes over time in waste generation.

Spatial dependencies are shown using the feature - aware graph convolution layers, which combine the learned features of the nodes/ wards instead of depending only on the raw waste values. The convolution layer also considers the demographic, temporal, and environmental attributes of each ward. Because of this, the model can learn the patterns like how waste surges in busy wards like that of transport hubs or market wards may slowly influence the nearby wards as well.

Temporal patterns are captured using a temporal attention mechanism that focuses more on time steps that seem important. Instead of relying only on the recent observations, the attention module picks on the recurring patterns in the data like, weekly cycles, festival related changes, and season variations. Because of this, this model tends to remain more stable during irregular, varying periods, like monsoon season or public holidays, where traditional time-series models usually struggle to accommodate the changes.

By integrating the two main components, spatial and temporal, the model captures the two dimensions at the same time. This makes the model learn how the waste generation is actually dependent on the two dimensions. Because of this, the model produces more accurate forecasts, making it useful in this dynamic environment where the waste generation pattern changes frequently.

$$Z^{(l)} = \sigma\left(\tilde{D}^{-\frac{1}{2}}\tilde{A}\tilde{D}^{-\frac{1}{2}}H^{(l)}W^{(l)}\right)$$

Fig. 3. Feature aware convolution

C. Explainability and Decision-Oriented Design

We have also added an explainable module in the system along with ST-GNN. This is to improve the transparency of the prediction done by the model. The attention weights derived from the spatial and temporal modules are used so as to provide some explanations for how each prediction is made. The attention heatmap in the Fig. 4 also highlights how each ward affects each other and also the index.

Spatial explainability helps show which wards are contributing more to the predicted surge, making it easier to distinguish between locally generated increases and the spillover effects of nearby zones.

In addition to the explainability module, the system also has a decision layer that will convert the predicted values into a practical action that can be taken. The predicted waste quantity will be grouped into different priority levels using the thresholds values.

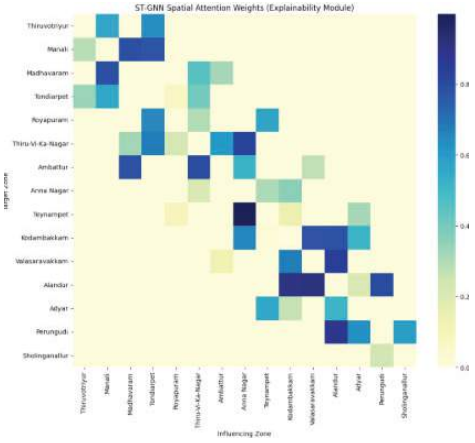

Fig. 4. Heatmap

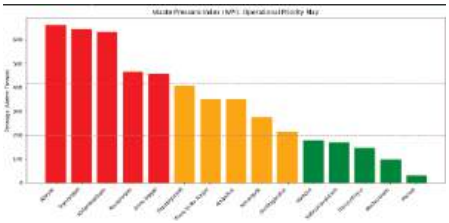

Fig. 5. WPI Chart for Wards

D. The System

Our system is a scalable, three-layered architecture that supports both, the model training and real-time decision support. The data layer integrates data sources, including municipal waste collection records, socio-demographic data, and the time based data like holidays. Then these inputs get continuously cleaned, then normalized/scaled, and transformed into structured graph representations.

The intelligence layer hosts the ST-GNN model, which is then trained offline using the dataset and executed in near real-time through scheduled prediction cycles. Our system gives the waste prediction value, the reason behind it for influencing it and the waste pressure index categorization for each zone, to show the levels of waste generation. The frontend interface shows the insights on the work of decision module. The explanation part, improves the clarity the transparency by displaying the underlying reason of each high waste generated wastes for wards. Action based tasks like truck dispatch on the basis of priority and labour assignment integrates the prediction with municipal logistics. Overall, the system works step by step by following data entry, spatio-temporal learning and modelling, explaination of the reason, and action based response suggestions to perform and thus giving an efficient urban waste management.

V. EXPERIMENTAL SETUP AND RESULTS

In this study, we use an official municipal dataset, that contains zone-level records of solid waste generated, collected, and processed across Chennai for three years.The original dataset derived is in a wide tabular format, where time based features are represented as columns, but for spatio-temporal modeling, the data is transformed into a long time

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

series, making it sequential learning and graph - based aggregation. The dataset is split into 70% training, 10% validation, and 20% testing so as to prevent any leakage.

We use three metric categories to evaluate forecasting accuracy, performance, and model explainability relative to other methods.

- **Numerical Accuracy:** MAE and RMSE are used to evaluate the accuracy performance with Random Forest and ANN models, with RMSE emphasizing large forecasting errors as shown in Fig. 6.
- **Decision-Oriented Accuracy:** Priority Precision measures the reliability of the WPI alert, while Recall of Overflows evaluates the detection of critical waste surges.
- **Explainability Metric:** It checks whether attention weights correctly highlight the market zones during high-waste periods.

The time-series system compares the ST-GNN against the ETSX and ARIMA in several ways. Thus, providing insights of model efficiency under various circumstances, like weekends or even festivals. During market days, the heatmap shows commercial nodes and nearby residential zones impacting each other, thus providing the clarity absent in the black-box models. The confusion matrix presents the efficiency of the low, medium, and high priority categories. This highlights the model's performance as a decision support tool extending abode and beyond simple numerical prediction. We observed that taking into consideration of the geographic context, the ST-GNN reduces around 13-15% errors in comparison to non-spatial models. The time attention mechanism maintains stable prediction during periods with high-variance. The WPI reduces the dispatches of unnecessary trucks by almost 20%, directly affecting the budgetary planning goals.

Fig. 6. Numerical Accuracy of ST-GNN and Other Models

VI. Impact

Most often the deep learning models like ANN, lack the transparency and clarity for the reason of their prediction. The temporal focus helps in supporting the spikes during holidays, festivals or other days. The system also identifies the dependent zones that affects each other in prediction of waste generation volumes. And, the explainability (XAI) and the decision layer helps in detecting the reason behind the prediction, and its main factors and to get some performable actions suggestion.

On societal and environmental basis, the system will also reduce the carbon footprint, less fuel use, and carbon emissions from vehicles by reducing unnecessary waste collection trips. Accurate prediction will also help in preventing bin overflow, which will directly reduce the chances of potential public health issues. And using this system, will allow to monitor over those wards all at once, so will be helpful for the officials.

Due to less unnecessary personnel tasks and trips, municipals can allocate resources to whichever ward needed from the budget. Thy can also invite and justify for investments in facility centers like recycling centers, truck depot stations. And also the municipals can manage the labour shifts accordingly based on which days might need more work.

VII. Limitations and Future Work

A. Limitations

The performance of the system mainly depends on the data, it has been fed, trained and being tested on. Missing records due to manual data entry can limit down the system's efficiency. Similarly, unrecorded waste collection lowers the predictions as well. And, currently, the spatial graph is made based on the adjacency matrix, which can later not be that efficient.

B. Future Scope

In future, this research can be proceeded further by real time IoT and edge integration. The waste bins, embedded with sensors will give hourly updates. And to reduce the load on cloud load, there can be some implementation to process ward graph clusters on edge nodes, enabling faster response time.

And ultimately, the final integration can be with logistics. A route optimization engine can be used to convert the over the threshold values into critical nodes, that needs collection and use real time traffic data to develop the routings.

VIII. Conclusion

The whole study revolved around the need of a transparent and decision based system, in the waste management category. It is based on few research papers, done by various researchers, using different kind of methods like, ARIMA, ESTX, hierarchical, etc , but where most of them were like black box. So, we introduced a Spatio Temporal – Graph Neural Network based framework, integrated with an explainable and decision-oriented module. This works on the limitation of not considering space and time based patterns into consideration for prediction and transparency about the prediction.

Our system creates the city as into a graph of multiple interconnected nodes, connected by edges, with some adjacency between them. The XAI module helps in revealing the underlying reason for the prediction being high or low anytime. This will give the municipal officials some root reason to believe and work on. This integration of all the layers in this framework is to create a scope for more future works through this perspective and ensure, the public safety, satisfaction and sustainable clean cities.

***Abstract*— The development of sustainable economic and social systems depends on governance quality and institutional effectiveness. Existing research studies depend on basic descriptive methods and short-term modeling techniques which limit their ability to study governance patterns over extended periods. To overcome this drawback, this paper proposes an analytical framework which employs data to investigate and assess governance performance through Bertelsmann Transformation Index (BTI) data that extends from 2006 to 2024. BTI provides multiple governance dimensions as a longitudinal data source. The proposed comparative study combines systematic data preprocessing with exploratory data analysis and machine learning techniques to study temporal trends and regional differences and governance indicator relationships. The framework creates a unified panel dataset which helps to identify key institutional factors that shape governance results while showing specific patterns for each country and region. In addition, it uses correlation analysis together with trend-based evaluation methods to improve model interpretability and help choosing features needed for predictive modeling. The results show that the proposed method successfully tracks extended governance development paths while revealing new findings which traditional analytical methods do not show, thus establishing a basis for evidence-based governance evaluation and future research on policy development.**

***Keywords* — Corruption Perception Index (CPI), Longitudinal Data Analysis, Governance Analysis, Exploratory Data Analysis (EDA), Machine Learning.**

I. INTRODUCTION

Corruption stands as one of the most enduring obstacles which hinders governmental operations and economic progress and destroys citizens' faith in their nations. The process undermines institutional performance by creating obstacles to policy execution and disrupting the fair distribution of resources. Therefore, measuring and understanding corruption is essential for policymakers and researchers that are looking to strengthen transparency and accountability. The Corruption Perception Index (CPI) is one of the most globally accepted measures for the assessment of the perceived levels of corruption in the public sector among the various available indicators [2].

The existing research studies on CPI data depends on three types of analysis which include short time periods, cross-sectional studies and research specific to individual countries. The research methods used by these studies prevent researchers from detecting both persistent structural patterns and changing governance methods throughout time[3]. Corruption maintains its existence because it becomes an enduring part of political and social systems which exist within institutional structures. Hence, an extensive study which examines different regions for extended timeframes is highly needed.

Machine learning techniques have gained traction as research tools in social science and governance studies because they enable researchers to analyze complex relationships that exhibit non-linear behavior [4]. Existing researches have shown that, machine learning models can successfully forecast corruption indicators through their use of economic and institutional data. However, these researches currently concentrate on predictive accuracy while they give only minimal focus to explainability and they utilize datasets which do not represent extended global patterns. The current situation lacks complete analytical systems which will combine data preprocessing with exploratory data analysis and the evaluation process of different machine learning systems.

The proposed framework examines fundamental research components through its complete evaluation of governance and corruption assessment standards which have been maintained from 2006 until 2024. It uses a complete longitudinal dataset to study how corruption perceptions change over time and across different regions while testing various machine learning models to forecast governance index outcomes. The proposed framework employs various linear and non-linear machine learning (ML) models to analyze how governance indicators interact with each other.

This study generates new insights into corruption dynamics and governance quality through its combination of extensive data collection, meticulous data preparation, and machine learning analysis of different methods [5]. The rest of the paper is structured as follows. Section II discusses the works related to corruption prediction and governance analysis. section III details the models used by the proposed framework. Section IV discusses the results and section V concludes the paper.

II. RELATED WORKS

Extensive studies have been conducted about institutional quality and corruption patterns which are investigated through newly accessible large datasets that cover governance and corruption research. Earlier researches used

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

econometric and regression-based methods to study the Corruption Perceptions Index (CPI) together with other governance indicators. Nowadays, researchers have turned their attention towards machine learning methods because governance data requires special handling due to its complex multidimensional characteristics. ML models are used to develop better predictive models and discover hidden relationships between indicators.

Lima et al., have developed an ML-based system which predicts corruption levels in 132 countries through the use of Random Forest and Support Vector Machine (SVM) and Artificial Neural Network classifiers [4]. This work utilized ensemble learning models to demonstrate better performance than traditional regression methods when predicting the Corruption Perceptions Index (CPI). However, this work mainly investigates predictive accuracy through its evaluation of perception-based metrics which provide only basic understanding of permanent governance system patterns.

The application of machine learning algorithms in predicting corruption in the context of India has been explored by Ahuja et al. [6]. This work demonstrates that ML-based early warning systems for corruption detection can be developed using socio-economic indicators together with classification models such as Random Forest and Support Vector Machine (SVM). Though the proposed work produces better prediction results, it confines itself to a particular geographic area and it fails to explore both feature interpretability and trends that occur over time.

Domashova et al., have analyzed the dependence of the Corruption Perceptions Index on a large set of socio-economic indicators using feature selection, clustering, and ensemble classifiers [7]. This work discovers a smaller group of key indicators which impact corruption levels and developed an analytical framework to study those indicators. The research emphasizes a cross-sectional study design as it does not monitor governance development over prolonged durations.

Rubakha et al. have proposed time-series regression models to examine how macroeconomic indicators impact corruption perception across post-socialist countries. The authors discovered that different countries exhibit distinct connections between their GDP per capita and public expenditure and their CPI rankings. The econometric method enables results to be understood but fails to show non-linear relationships and does not apply to multiple countries.

Thanh et al., have analyzed the connection between corruption perception and financial stability by using the Consumer Price Index to build credit risk assessment models and tested with ensemble learning methods [8]. The findings demonstrated that higher corruption perception leads to an increase in non-performing loans. Although, this work uses corruption as a national-level measurement, it fails to investigate institutional governance factors in detail.

Overall, there is a lack of comprehensive, longitudinal analysis that integrates CPI data across 137 countries while presenting a comparative analysis between linear, regularized, and non-linear models. This gap motivates the present study, providing a global, time-aware regression framework (2006–2024) to evaluate model behavior, address multicollinearity, and provide interpretable insights into governance dynamics.

III. METHODOLOGY

The proposed framework integrates data preprocessing, exploratory analysis and correlation assessment together with machine learning-based predictive modeling through a single unified pipeline. Fig. 1 shows the high level architecture of the framework. The entire system workflow maintains data consistency while delivering understandable explanations that enable researchers to reproduce their findings. The various components of the proposed framework are detailed as follows.

A. Data Collection and Preprocessing

The proposed framework employs a complete longitudinal dataset which comes from the Bertelsmann Transformation Index (BTI) and contains governance indicators for each country between 2006 and 2024 [1]. The dataset contains political, economic and governance variables which are used to assess institutional quality and policy effectiveness across different nations.

Through controlled type coercion, we have transformed all governance score variables from string objects to numeric values. Also for the purpose of identification and encoding, we maintain categorical variables which include country name, democracy status and regime type. Furthermore, we assessed missing values to establish both data quality and data consistency.

In order to avoid biased learning, indicators with high proportions of missing values are excluded from the analysis. Particularly, the columns with more than 25% missingness like

- q5_3_democracy_approval
- q16_5_reconciliation

are dropped due to inconsistent availability across countries and years. Variables with moderate missingness, such as q16_4_public_consultation, are retained for exploratory analysis but excluded from predictive modeling. Observations with missing target values (governance_index) are also removed.

The remaining missing numeric feature values are treated through median imputation which used the training subset to stop temporal data leakage. The dataset presents a clean and consistent state that can be used for exploratory analysis and correlation assessment and machine learning model development.

B. Exploratory Data Analysis

The temporal evolution of the mean governance index across seven global regions from 2006 to 2024 is shown in Fig. 2. The time horizon (2006–2024) is plotted against the governance index on a standardized scale ranging from 1 to 10. The higher the index values better the governance quality. All countries are divided into seven regions. Region 1 consistently performs the best, indicating strong institutional quality. In contrast, Region 4 shows the weakest performance with a declining trend over time. Region 7 (Asia and Oceania), which includes India, remains in the middle range with relatively stable but moderate governance levels.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

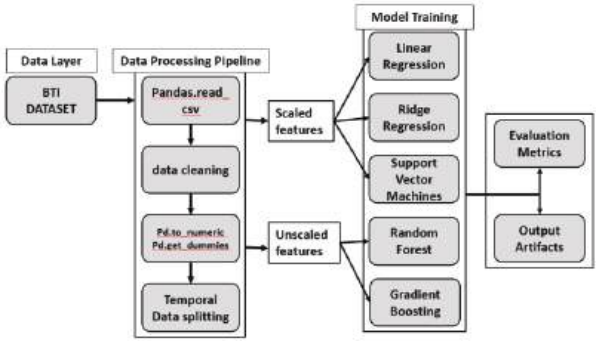

Figure 1. High Level Architecture Diagram

Fig. 3 shows the distribution of governance index scores spanning 2006 to 2024 approximates a bell-shaped curve, with a substantial concentration of data points situated between 4 and 6. The mode, centered around 5, signifies that the preponderance of nations exhibited moderate governance throughout the study's duration. Conversely, the frequency of observations diminishes at both lower (<3) and higher (>7) extremes, implying that instances of either exceptionally poor or exceptionally robust governance are comparatively infrequent. The slight rightward skew suggests the existence of a smaller cohort of nations with superior performance. In summation, the distribution underscores a central tendency toward mid-range governance levels, thereby corroborating the presumption of near-normality within the dataset.

Furthermore, it is evident that the actual corruption perception data needs more complex modeling beyond standard linear assumptions. We have used linear (regression and ridge regression) and non-linear machine learning (random forest, gradient boosting and SVR) models to analyze the complex patterns and varying patterns that existed across different countries.

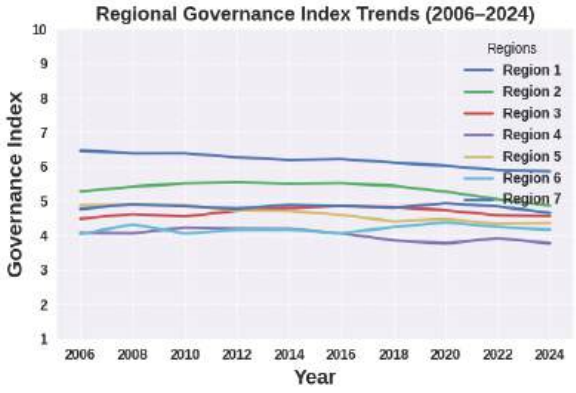

Fig 2. Reginal Governance Index Trends (2006 – 2024)

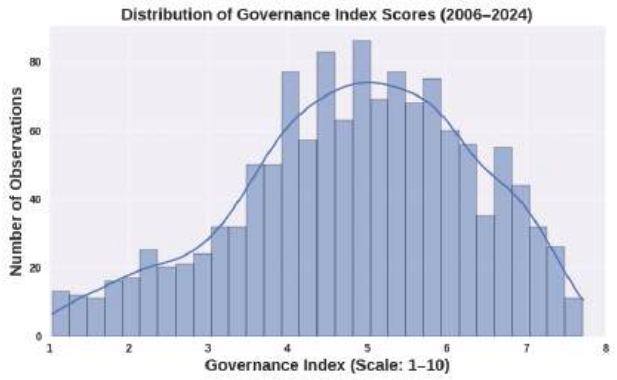

Fig 3. Distribution of Governance Index

C. Correlation Analysis

In order to quantify the strength and direction of linear relationships between governance-related indicators and the target variable, correlation analysis is performed [9]. Given the continuous nature of the governance indicators, Pearson's correlation coefficient is used as the primary measure of association.

For two continuous variables X and Y, Pearson's correlation (r) is defined as follows.

$$r = \frac{n(\sum xy) - (\sum x)(\sum y)}{\sqrt{[n\sum x^2 - (\sum x)^2][n\sum y^2 - (\sum y)^2]}} \quad (1)$$

where n is the number of data points. The results are shown in Fig. 4.

The correlation heatmap in Fig. 4 indicates strong positive relationships with significant multicollinearity present in the dataset. The clustered correlation patterns shown by several feature groups exhibit structural similarities between institutional, economic, and policy-related variables. Some variables, such as governance rank, show strong negative correlation with governance scores due to their inverse relationship. The year variable has very weak correlation with most indicators, indicating stable governance patterns over time. These findings support the use of regularized models like Ridge regression and non-linear ML models.

D. Feature Categorization

The variables used in this work are categorized in Table I. The governance_index serves as the target variable, while year is used to split the data into training and testing sets based on time. The region variable categorizes the countries. Governance indicators are grouped thematically, with the number of features in each group shown in parentheses.

TABLE I - Variables used in the study

Category	Variable(s)
Target Variable	governance_index
Temporal Variable	year(used for splitting)
Categorical Variable	region
Governance Indicators	steering, prioritization, implementation, consensus, perform etc

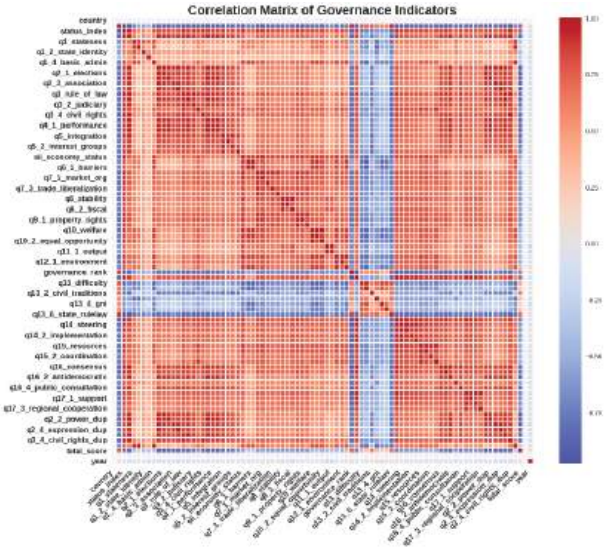

Fig 4. Heatmap of Governance Index's features' correlation

E. Predictive Modelling

We formulate predictive modelling as a supervised regression task, with the governance index serving as the target variable [10].

We implemented a time-aware train–test split method as it helps to maintain temporal validity while protecting against data leakage. For training purposes, the model uses observations from earlier years whereas for evaluation, it uses observation from more recent years. This work used temporal variables exclusively for data partitioning purposed and not for predictive features.

We have used linear regression to understand the model and to compare the results against this standard. Linear regression establishes a direct relationship between its predictors and target variable while its model coefficients enable users to see how different features affect the target outcome. To address multicollinearity among governance indicators and improve coefficient stability, Ridge Regression is employed using L2 regularization.

Advanced machine learning models analyze governance indicators which displayed non-linear relationships with complex interactive patterns between different governance indicators. Random Forest Regression is used to create an ensemble-based decision boundary model which utilized bagging to decrease model prediction errors. Gradient Boosting Regression is used to reduce prediction errors through the process of building additive decision trees which generated better bias-variance trade-off results. Also, we implemented Support Vector Regression (SVR) with a radial basis function kernel to create a model that could predict non-linear patterns through margin-based optimization methods.

The use of specific models requires specific preprocessing methods. We applied feature scaling to support distance-based models which included support vector regression but we trained tree-based models using their original unscaled data. The treatment of missing data involved median imputation for numeric features which enabled us to create a robust modeling approach.

IV. RESULTS AND DISCUSSION

This section discusses the implementation details, metrics and results of the proposed work.

Implementation details

We build the analytical pipeline using Python data science libraries. Also, we used Pandas and NumPy for data manipulation and preprocessing tasks [11]. The models are built with Scikit-learn and we used Matplotlib and Seaborn for visualization. The system currently operates through its modular design which enables both expansion and future development.

Performance metrics

For comparative analysis, we have used linear regression, ridge regression, random forest, gradient boosting and support vector regression. To evaluate the performance of these models, we have used the following metrics which provide complete assessment capabilities for both predictive accuracy and model stability.

- **Mean Absolute Error (MAE)**: Measures the average magnitude of prediction errors and is defined as follows.

$$MAE = \frac{1}{n}\sum_{i=1}^{n} y_i - \overline{y_i} \quad (2)$$

- **Root Mean Squared Error (RMSE)**: Penalizes larger errors and highlights model sensitivity to extreme deviations.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (3)$$

- **Explained Variance**: It computes the consistency between predicted and actual values.

$$EV = 1 - \frac{var(y-\hat{y})}{var(y)} \quad (4)$$

- **Maximum Error (MaxErr)**: Captures the worst-case prediction error and is defined as

$$MaxErr = max_i(y_i - \hat{y}_i)\ ,\ 1<=i<=n \quad (5)$$

- **Mean Absolute Percentage Error (MAPE)**: It calculates relative prediction accuracy in terms of percentage.

$$MAPE = \frac{100}{N}\sum_{i=1}^{n}\left|\frac{y_i-\hat{y}_i}{y_i+e}\right| \quad (6)$$

where $\hat{y_i}$ is the predicted value and e is a positive constant to avoid division by zero.

TABLE II. PERFORMANCE COMPARISON OF REGRESSION MODELS

Model	MAE	RMSE	R2	Variance	MaxErr	MAPE
Linear Reg.	0.045	0.058	0.968	0.982	0.179	1.33
Ridge Reg.	0.044	0.058	0.988	0.989	0.197	1.32
Random Forest	0.039	0.022	0.992	0.994	0.353	1.42
Grad. Boosting	0.083	0.040	0.948	0.986	0.314	1.82
SVR	0.078	0.103	0.943	0.985	0.445	2.21

Evaluation results

The proposed comparison work evaluates the dataset against linear ML models such as linear regression and ridge regression and non-linear ML models namely random forest, gradient boosting and SVR.

Linear regression

We have implemented Linear Regression as a baseline predictive model to establish a reference level of

performance. The results in Fig. 5 shows a scatter plot which compares actual versus predicted governance index values that while the linear model captures the general trend in the data, it exhibits noticeable deviations for several samples. This indicates limited capability in modeling complex relationships inherent in governance-related indicators.

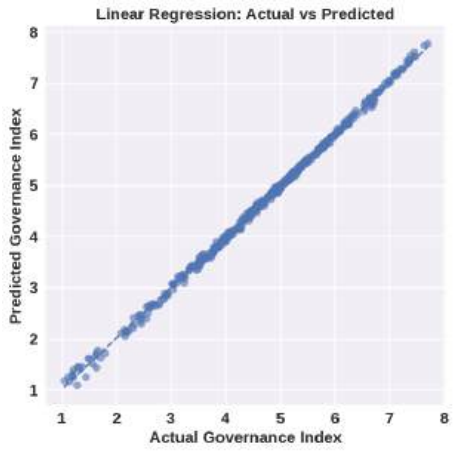

Fig 5. Linear Regression : predicting Governance Index

Ridge Regression with L2 Regularization

We implemented Ridge Regression whose aim is to address potential multicollinearity among governance indicators by applying an *L2* regularization penalty. Fig. 6 shows that predicted values cluster tightly around the ideal diagonal line, indicating that the model maintains high predictive stability while constraining the magnitude of the coefficients. This suggests that the governance outcomes are effectively captured through a regularized linear framework that prevents over-reliance on any single feature.

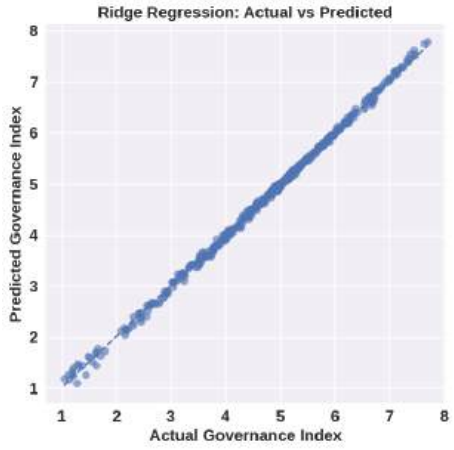

Fig 6. Ridge Regression : predicting Governance Index

Ensemble Model Performance: Random Forest Regression

Implementation of Random Forest Regression model because the linear baseline model showed limitations. The ensemble-based method of this system can identify non-linear patterns and track how different features interact with each other in the dataset. The researchers used scatter plot visualization to compare model predictions with actual governance index values.

Fig. 7 demonstrates closer alignment between predicted and actual values, indicating improved predictive accuracy and generalization. The reduced dispersion around the ideal prediction line highlights the effectiveness of ensemble learning for governance and corruption-related prediction tasks.

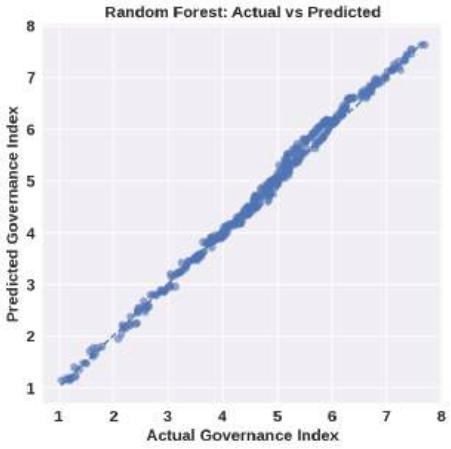

Fig 7. Random Forest : predicting Governance Index

Ensemble Model Performance: XGBoost Regression

For advanced predictive performance, we implemented an Extreme Gradient Boosting (XGBoost) regression model. XGBoost functions as a boosting method which creates an ensemble of decision trees through its process of sequential tree construction. The method enables accurate modeling of complex non-linear relationships while it strengthens solution stability through its regularization process.

The evaluation of model predictions involved a comparison between the predicted governance index values and the actual values which was displayed through a scatter plot. The model demonstrates high prediction accuracy because its results closely follow the ideal prediction line which represents perfect predictions. Fig. 8 shows that gradient boosting methods operate successfully for forecasting purposes in governmental and corruption-related fields.

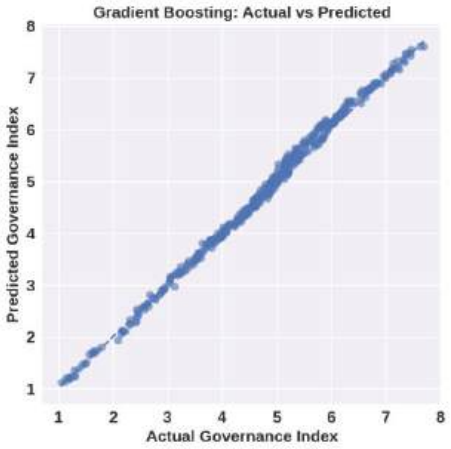

Fig 8. Gradient Boosting : predicting Governance Index

Kernel-Based Model Performance: Support Vector Regression

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

In addition to ensemble methods, SVR is implemented to evaluate the effectiveness of kernel-based learning for governance index prediction. SVR extends the principles of Support Vector Machines to regression tasks by learning a function that minimizes prediction error within a specified margin while maintaining model complexity.

The SVR model demonstrates reasonable alignment with the ideal prediction line, indicating its ability to model non-linear patterns. However, compared to ensemble-based approaches, SVR shows relatively higher dispersion in predictions, suggesting sensitivity to parameter selection and data scale.

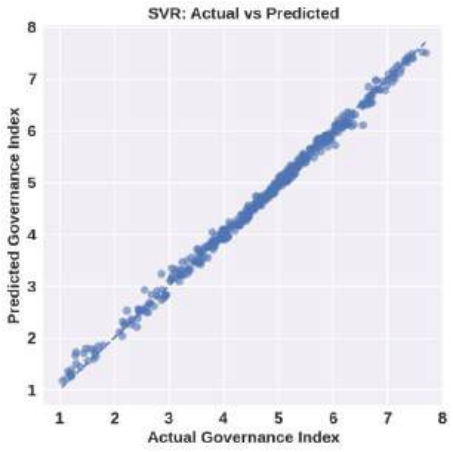

Fig 9. SVR: predicting Governance Index

Fig. 9 indicates that, while SVR provides a robust theoretical framework for non-linear regression, ensemble methods like Random Forest offer improved stability and generalization for large-scale governance and corruption-related datasets.

Table II presents the results of testing different ML models, showing that Random Forest performs better than all other models across most evaluation criteria. The model achieved the lowest Mean Absolute Error (MAE) and Root Mean Square Error (RMSE), indicating minimal absolute and squared prediction errors. It also attained the highest R square (R^2), proving that it successfully captured the variability in the governance index more effectively than other models. These results highlight its strong predictive capability and robustness.

Ridge Regression performs competitively, achieving the highest explained variance score and maintaining low error values, indicating stable and consistent predictions.

The results suggest that while governance indicators exhibit largely linear relationships, the Random Forest model is able to capture additional patterns and interactions within the data, leading to superior predictive performance. This demonstrates that non-linear ensemble methods can provide meaningful improvements over traditional linear approaches when modeling complex governance data.

V. CONCLUSION

The proposed comparative study developed a complete analytical framework which enables researchers to predict governance-related corruption indicators by using historical data. We have employed different methods which included exploratory analysis and machine learning regression and interpretability study to analyze how governance index values changed over time. The proposed study shows how data-driven methods can be used to study corruption through its unified system which combines data preprocessing with visualization and predictive modeling.

A comparative evaluation of regression models showed that while Linear Regression provides a useful baseline, it is limited in capturing complex patterns inherent in governance data. The Random Forest Regression model showed better predictive results because both visual assessments and quantitative measurements showed advanced performance.

The current studies possesses effective results but also shows specific restrictions. The study examines governance-related indicators which have restricted availability and detailed measurement while analyzing only a narrow range of characteristics. The research aims the framework through the introduction of new socio-economic and institutional data together with advanced time-series and ensemble models and SHAP-based explainable artificial intelligence techniques for better understanding of results. Additionally, the development of an interactive dashboard for real-time visualization and policy-oriented analysis represents a promising direction for practical deployment.

Abstract*—Rural telemedicine in India faces two compounding problems: global automatic speech recognition (ASR) systems degrade sharply on code-mixed Hindi-English patient speech, and large language models (LLMs) lack calibration for low-resource clinical triage. We propose HindMed-Triage, a seven-stage hybrid sovereign-global AI pipeline for Hindi medical speech triage, combining Sarvam Saaras V3 (sovereign ASR) with a retrieval-augmented LLM reasoning stage grounded in WHO Integrated Management of Childhood Illness (IMCI) and Indian Primary Health Centre protocols. We validate each pipeline component through systematic benchmarking. For ASR, Saaras V3 achieves WER = 0.285 on the EkaCare Hindi medical speech subset (n = 320), a 49.6% relative WER reduction over Whisper Large v3 (WER = 0.565). For triage, we construct a stratified weak-label benchmark of 500 code-mixed patient queries from MMCQSD (n_{CRITICAL} = 80) and evaluate eight LLM configurations under zero-shot and retrieval-augmented settings. GPT-OSS-120B achieves the highest zero-shot Macro F1 of 0.481 (95% CI: [0.425, 0.537]), yet bootstrap confidence intervals overlap for all eight models, indicating no statistically significant winner. A finding specific to sovereign models is that retrieval augmentation improves Sarvam-105B Macro F1 from 0.411 to 0.460, while the same augmentation reduces performance for all seven global and non-sovereign models tested, a 1-of-8 pattern that carries direct architectural implications. We further document a safety-critical failure mode: both GPT-OSS model variants send 17 to 29 of 80 true CRITICAL cases to ROUTINE under zero-shot and RAG conditions, the most dangerous possible misclassification. CRITICAL recall ranges from 0.24 to 0.51 across configurations, confirming a system-wide CONSULT-prior bias that clinical guideline injection partially corrects for sovereign models only.

I. Introduction

India's physician shortage stands at approximately 1:1,456 patients per doctor, well below the WHO-recommended 1:1,000 [1]. The shortfall is concentrated in rural areas, where 65% of the population lives but only 30% of registered physicians practice [2]. Voice-based telemedicine platforms have expanded access, yet their usefulness depends on AI capable of processing the spontaneous, code-mixed Hindi-English speech in which rural patients naturally express symptoms. A patient describing a cardiac event might say: *"bahut tez chest pain ho raha hai aur saans nahi aa rahi"*, a sentence in which Hindi grammar carries English clinical terms without belonging cleanly to either language. Existing global ASR systems such as Whisper [9] and general-purpose LLMs were not optimised for this register.

India's sovereign AI programme, led by Sarvam AI, has produced models targeting Indian languages, but no systematic external evaluation has documented where these models outperform global alternatives, where they do not, and how the two should be combined in a clinical workflow. This paper makes four contributions:

1) We propose **HindMed-Triage**, a seven-stage hybrid sovereign-global AI pipeline for code-mixed Hindi medical speech triage, covering patient speech input through structured doctor alert.
2) We benchmark ASR components (Saaras V3 vs. Whisper Large v3) on the complete EkaCare Hindi medical ASR subset (n = 320), finding a 49.6% WER advantage for the sovereign system.
3) We construct a stratified weak-label triage benchmark of 500 code-mixed patient queries and evaluate eight LLM configurations under zero-shot and retrieval-augmented settings, covering two sovereign and six global models.
4) We document a sovereign-specific RAG benefit (Sarvam-105B is the sole model improved by retrieval augmentation, 1 of 8) and a safety-critical GPT-OSS failure mode (17 to 29 CRITICAL-to-ROUTINE misclassifications per 80 true CRITICAL cases), both with direct implications for clinical deployment.

II. Related Work

A. Code-Mixed Indian Language Processing

Code-mixing in South Asian languages arises from widespread bilingualism and carries linguistic structures not

Vol. 14, Issue 06, ACSCON - 2026

present in either base language [5]. Khanuja et al. introduced MuRIL, a multilingual model pre-trained on 17 Indian languages and their transliterated forms, demonstrating that India-specific pre-training yields consistent downstream gains over multilingual baselines [6]. Kakwani et al. established IndicNLPSuite, providing the corpus infrastructure from which subsequent Indian LLMs, including Sarvam-105B, derive their pre-training data [19]. Aggarwal et al. showed that code-mixed Hindi-English clinical text requires specialised tokenisation strategies, as standard subword vocabularies fragment Hindi morphology in ways that degrade semantic encoding [7]. Sitaram et al. identified medical and customer-service contexts as priority areas for code-mixed NLP research [8].

B. Multilingual and Domain-Specific Medical ASR

Radford et al. demonstrated that Whisper, trained on 680,000 hours of multilingual audio, performs well on high-resource languages but degrades substantially on low-resource and code-mixed speech [9]. This degradation is compounded in medical domains where out-of-vocabulary clinical terms increase phonetic ambiguity [10]. EkaCare published the first Indian medical ASR evaluation dataset, establishing baseline English WER values but providing no Hindi evaluation [11]. Salesky et al. showed that domain-adapted models for low-resource languages consistently outperform general-purpose models on in-domain tasks [12].

C. LLMs for Clinical Triage

Nori et al. demonstrated GPT-4's near-human USMLE performance in English, but the study did not address low-resource or non-English clinical settings [13]. Jin et al. showed that LLMs applied to clinical triage without class-frequency calibration systematically under-detect high-acuity cases due to class imbalance [15], a finding consistent with our CRITICAL-class results. Panch et al. identified label scarcity and language mismatch as the two primary failure modes of AI in resource-constrained healthcare [14]. Faujdar and Ghosh found that English-trained clinical AI systems generalise poorly to Hindi patient descriptions in Indian primary healthcare [16]. The MMCQSD dataset, used in this study, was introduced for code-mixed clinical summarisation at ECIR 2024 [17]; our triage annotation represents its first classification-oriented application.

D. Sovereign AI for Indian Languages

Sarvam AI released Sarvam-105B as India's first domestically developed 100B-parameter mixture-of-experts model trained on an Indian-language-centric corpus [18]. No independent third-party evaluation of either Sarvam-105B or Sarvam-30B existed prior to this work. The IndicBERT and IndicBART series from AI4Bharat established the viability of India-specific pre-training for classification and generation tasks [19], providing research context for evaluating the Sarvam model family.

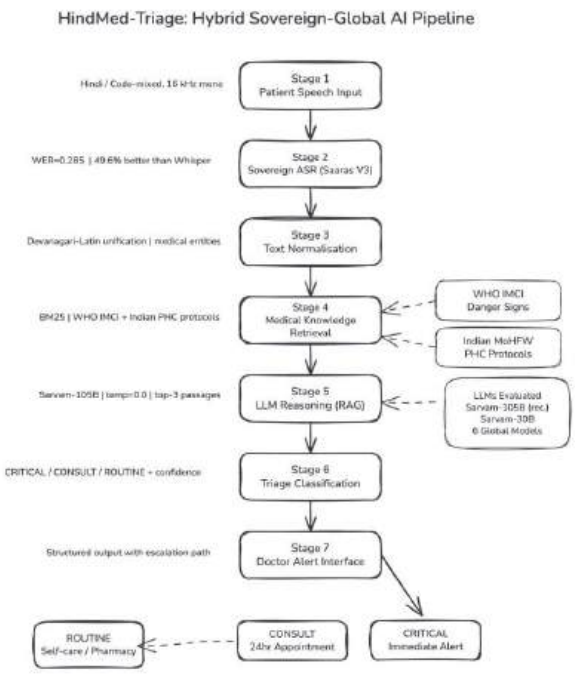

Fig. 1. The HindMed-Triage seven-stage pipeline. Stages 1 and 2 (ASR) and Stages 4 through 6 (retrieval and triage) are benchmarked in this paper. Stage 3 (normalisation) and Stage 7 (alert interface) are described as design specifications.

III. Methodology

A. The HindMed-Triage Framework

HindMed-Triage is a seven-stage modular pipeline designed for deployment in rural Indian telemedicine settings. Two design principles govern the architecture. First, sovereign components are used where empirical advantage over global alternatives is demonstrated at that stage; this paper establishes this for ASR and partially for the triage reasoning stage under retrieval augmentation. Second, zero-shot LLM CRITICAL-class failure is addressed through retrieval augmentation rather than model substitution. Fig. 1 presents the full architecture.

1) Stages 1 and 2: Speech Input and Sovereign ASR: Patient audio is sampled at 16 kHz mono. Stage 2 applies Sarvam Saaras V3 for transcription. The empirical basis for this choice is the 49.6% WER advantage over Whisper Large v3 on Hindi medical speech. In deployments where Saaras V3 API access

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

is unavailable, a local Whisper variant provides a documented fallback at WER = 0.565.

2) Stage 3: Text Normalisation: Code-mixed ASR output presents three normalisation problems. First, the same clinical concept may appear in Devanagari script, romanised transliteration, or English within the same utterance. Second, numeric medical values are attached to Hindi unit expressions. Third, Hindi negation markers invert clinical polarity. Stage 3 maps all surface forms to canonical English medical terminology using a deterministic lexicon of 30 Hindi-to-English term mappings and two regex patterns for temperature and heart rate normalisation.

3) Stage 4: Medical Knowledge Retrieval: A lightweight BM25 retrieval index [21] operates over 31 clinical guideline passages from WHO IMCI danger-sign criteria [3] and Indian MoHFW PHC triage protocols [4]. The top-3 scoring passages per query are prepended to the Stage 5 prompt, providing explicit clinical evidence for high-acuity detection without requiring model fine-tuning.

4) Stages 5 and 6: Retrieval-Augmented Triage Classification: The LLM receives the normalised patient query, retrieved guideline passages, and triage label definitions. Temperature is set to 0.0 for determinism; output is a JSON object containing the triage label, a one-sentence clinical justification, and a confidence flag. Based on benchmarking results, Sarvam-105B with retrieval augmentation is recommended as the sovereign pipeline configuration.

5) Stage 7: Doctor Alert Interface: CRITICAL outputs trigger a structured immediate alert to the nearest available physician containing the audio clip, ASR transcript, retrieved passages, and LLM reasoning. CONSULT outputs schedule a telemedicine appointment within 24 hours. ROUTINE outputs direct the patient to pharmacy or self-care guidance.

B. Research Questions

RQ1. Does Saaras V3 outperform Whisper Large v3 on Hindi medical speech recognition (WER, CER)?
RQ2. On zero-shot code-mixed Hindi medical triage, does Sarvam-105B reach comparable Macro F1 to global LLMs?
RQ3. Does retrieval augmentation from WHO IMCI and Indian PHC guidelines improve triage performance, and does this effect differ between sovereign and global models?

C. Dataset 1: EkaCare Hindi Medical ASR Benchmark

The EkaCare Medical ASR Evaluation Dataset [11] contains medical speech recordings with expert-verified reference transcripts across three speech styles. We evaluated on the complete Hindi-language subset of **320 recordings at 16 kHz**. All 320 samples yielded valid predictions from both ASR systems.

D. Dataset 2: MMCQSD Triage Benchmark

The Multimodal Medical Code-Mixed Question Summarisation Dataset (MMCQSD) [17] contains 3,015 real-world Hindi-English code-mixed patient queries. We constructed a stratified sample of **500 queries** for triage benchmarking.

TABLE I
REPRESENTATIVE WEAK-LABEL ANNOTATION EXAMPLES (MMCQSD)

Patient Query (Code-Mixed)	Label	LF Trigger
"Bahut tez chest pain ho raha hai, saans nahi aa rahi, left arm mein dard"	CRITICAL	LF-A: chest pain, respiratory distress. LF-B: bahut tez, saans nahi. Three-way agreement.
"Main football khel raha tha aur bhayanak tarike se gira, sar mein chot"	CRITICAL	LF-A: head injury. LF-B: emergency language. Two-of-three agreement.
"Mere 2.8 saal ki beti ko nephrotic syndrome hua, antibiotic chal rahi hai"	CONSULT	No IMCI danger signs; persistent condition requiring physician follow-up.
"Mujhe 3 din se bukhar hai, 101 degree, saath mein khansi bhi hai"	CONSULT	Fever > 48h with cough: PHC evaluation. No danger signs.
"Kya main vitamin C supplement daily le sakta hoon?"	ROUTINE	General health query. No symptoms. Three-way agreement.

From 2,000 randomly selected queries (seed = 42), three deterministic labelling functions (LFs) were applied. The final benchmark contains CRITICAL = 80 (16.0%), CONSULT = 340 (68.0%), ROUTINE = 80 (16.0%). The 16% CRITICAL rate reflects deliberate oversampling to obtain reliable per-class statistics.

1) Weak-Label Annotation: All rules are grounded in WHO IMCI danger-sign criteria [3] and Indian MoHFW PHC triage protocols [4]. **LF-A (Summary-Level Severity Keywords).** CRITICAL if any WHO IMCI danger-sign term appears in the physician summary. ROUTINE if only self-limiting descriptors appear. All other cases: CONSULT.
LF-B (Patient Query Urgency Signals). CRITICAL if Hindi or English urgency language is present. ROUTINE if chronic presentation (> 10 days) with no deterioration indicators. All other cases: CONSULT.
LF-C (Demographic Risk Features). CRITICAL if paediatric (< 5 years) with concurrent fever and respiratory symptoms, or elderly (> 65 years) with cardiac or neurological descriptors. ROUTINE if both LF-A and LF-B yield ROUTINE; otherwise CONSULT.

Final labels were assigned by majority vote. Three-way LF agreement was obtained for 287 of 500 samples (57.4%); the remaining 213 were resolved by two-of-three majority. These labels are designated as **weak labels** produced by deterministic LFs, following established programmatic labelling practice [22].

E. Models Evaluated

Table II lists all eight models evaluated in the triage benchmark.

F. Evaluation Protocol

For ASR, both models received identical 16 kHz float32 normalised audio with language set to Hindi. WER and CER were computed against EkaCare expert-verified reference transcripts. For Triage, all LLMs received identical prompts at temperature = 0.0. Two variants were used per model: **zero-shot** (ZS) and **retrieval-augmented generation** (RAG).

Duration	n	Saaras V3	Whisper
0 to 5 s	6	0.743	1.486
5 to 10 s	6	0.392	0.409
10 to 20 s	198	0.261	0.577
20 to 30 s	110	0.304	0.543

Output was parsed as JSON. Metrics: Accuracy, per-class F1, Macro F1, CRITICAL Recall, CRITICAL Precision.

IV. RESULTS AND FINDINGS

A. ASR Performance (RQ1)

Saaras V3 achieves WER = 0.285 and CER = 0.122 (320 samples, 0 failures), compared to WER = 0.565 and CER = 0.360 for Whisper Large v3: a **49.6%** relative WER reduction and 66.1% relative CER reduction, directly supporting RQ1. Table IV breaks WER by clip duration. Saaras V3 outperforms Whisper at every duration; the largest advantage occurs at 10 to 20 second clips (n = 198, 61.9% of data; WER 0.261 vs. 0.577).

B. Zero-Shot Triage Classification (RQ2)

Table V reports zero-shot results for all eight models. GPT-OSS-120B leads at Macro F1 = 0.481. Pairwise comparison of bootstrap 95% CIs shows complete overlap for all 28 model pairs. **No model achieves statistically significantly higher Macro F1 than any other.** RQ2 is partially supported: Sarvam-105B reaches performance comparable to global LLMs (no significant gap).

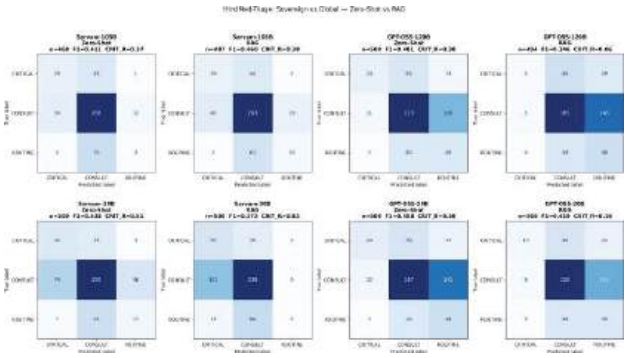

Fig. 2. Confusion matrices for all eight LLM configurations under zero-shot (ZS) and retrieval-augmented (RAG) conditions (n = 500; CRITICAL n = 80). Sarvam-30B RAG achieves the highest CRITICAL recall (0.62) with zero CRITICAL-to-ROUTINE errors. GPT-OSS-120B RAG degrades to CRITICAL recall = 0.06 with 29/80 CRITICAL cases routed to ROUTINE.

C. Retrieval-Augmented Generation Results (RQ3)

Table VI presents the complete RAG versus zero-shot comparison. **Sarvam-105B is the only model among eight for which RAG improves Macro F1** (+0.049, from 0.411 to 0.460). Every other model degrades under RAG. A notable exception to the Macro F1 trend is Sarvam-30B, whose CRITICAL recall *increases* under RAG (0.512 to 0.625). The GPT-OSS-120B RAG collapse is the most clinically significant finding. Under zero-shot, GPT-OSS-120B sends 13 of 80 CRITICAL samples to ROUTINE; under RAG, 29 of 80 are sent to ROUTINE.

D. CRITICAL Class Safety Analysis

Table VII reveals four patterns. *Sovereign models have the highest CRITICAL recall. Both GPT-OSS models exhibit a systematic CRITICAL-to-ROUTINE failure. Sarvam-30B RAG produces zero CRITICAL-to-ROUTINE misclassifications. RAG amplifies GPT-OSS danger; it suppresses it for Sarvam.*

V. DISCUSSION

A. Pipeline Design Justification

Benchmarking provides direct empirical support for two HindMed-Triage design choices. The Saaras V3 front-end is justified by the 49.6% WER advantage over Whisper on Hindi medical speech. At WER = 0.565, more than half of word tokens are transcribed incorrectly on average, generating noise that propagates through retrieval and reasoning. The retrieval augmentation stage is supported, but with model-specificity that carries clear architectural implications.

B. Sovereign vs. Global Safety Profiles

The CRITICAL class analysis separates models into two distinct safety profiles when CRITICAL-to-ROUTINE misclassification is used as the primary safety criterion. Sarvam-105B ZS, LLaMA-3.3-70B ZS, Gemma-3-27B ZS, and Sarvam-30B RAG all keep CRITICAL-to-ROUTINE errors

at one or fewer. GPT-OSS-20B and GPT-OSS-120B form a distinct high-risk group. The implication is that recall alone is insufficient as a clinical safety metric; CRITICAL-to-ROUTINE error count is more directly relevant for deployment decisions.

C. Hybrid Architecture Rationale

A purely sovereign pipeline (Saaras V3 and Sarvam-105B with RAG) is the recommended configuration. It achieves the best-documented safety profile, is the only configuration that benefits from retrieval augmentation on both Macro F1 and CRITICAL recall dimensions, and avoids the 49.6% ASR degradation that any Whisper-based pipeline incurs.

D. Overlapping Confidence Intervals as an Informative Result

The complete overlap of all 28 pairwise 95% CIs indicates that LLM choice alone does not produce statistically distinguishable triage performance on this benchmark. This is an informative negative result with practical consequences: selecting a model on Macro F1 alone is not warranted.

E. Limitations

- **Weakly supervised labels.** Benchmark labels are generated via deterministic labelling functions; while suitable for relative comparisons, future work will incorporate physician-adjudicated ground truth.
- **Domain-limited ASR evaluation.** The EkaCare dataset covers a single medical domain (`misc_medical`); broader evaluation across speech styles remains future work.
- **System-level evaluation gaps.** Latency, cost, and end-to-end pipeline performance under real-world deployment conditions are not evaluated.
- **Model-specific behaviour under RAG.** The observed GPT-OSS behaviour under retrieval augmentation warrants further investigation with alternative prompt designs.

VI. CONCLUSION

We presented HindMed-Triage, a seven-stage hybrid sovereign-global AI pipeline for code-mixed Hindi medical speech triage in rural Indian telemedicine. Benchmarking across 320 Hindi ASR samples and a 500-sample stratified weak-label triage benchmark spanning eight LLM configurations yielded five findings. First, Saaras V3 reduces WER by 49.6% over Whisper Large v3 on Hindi medical speech. Second, on zero-shot triage, all eight models fall within Macro F1 of 0.411 to 0.481 with fully overlapping bootstrap

Vol. 14, Issue 06, ACSCON - 2026

95% CIs. Third, retrieval augmentation improves Sarvam-105B by +0.049 Macro F1 while reducing Macro F1 for all seven other models. Fourth, sovereign models achieve higher CRITICAL recall than global models. Fifth, both GPT-OSS model variants exhibit a safety-critical pattern under zero-shot and RAG conditions misclassifying CRITICAL cases to ROUTINE.

VII. Future Scope

Future work will conduct an end-to-end pipeline evaluation including text normalisation and retrieval, develop a purpose-built triage corpus with physician adjudication and balanced class sampling, investigate the GPT-OSS RAG misapplication mechanism, and conduct field trials at Primary Health Centre facilities.

Abstract: Using the KDD-CUP 1998 data, this work introduces a tool that spots online threats through smart algorithms - some based on machine teaching, others on layered networks. Instead of just flagging odd behavior, it sorts traffic into safe or harmful using a method called Random Forest. With pre steps such as picking key traits and scaling values, the setup boosts its prediction strength. By cutting down wrong alerts while lifting correct hits, results show this approach works well across many cyber attack forms. Overall, blending these techs helps build sturdier defenses against digital break-ins.

Keywords: Cyber attack Detection, Random Forest, KDD-CUP 1999 Dataset, Machine Learning, Deep Learning, Intrusion Detection System (IDS), Network Security.

I. INTRODUCTION

In our linked-up world, hackers are getting bolder and sneakier every day. Locking down digital systems is now crucial-for both companies and regular folks. These security tools called IDS help spot bad behavior online - while it's happening. But older methods that rely on known patterns? They struggle to catch fresh or shifting dangers fast enough..

To tackle these issues,folks've started using machine learning and deep learning more often inside intrusion detection setups. Because they spot tricky patterns in regular and harmful behavior, these systems catch familiar threats along with unseen ones. For this work, we're building a live threat detector powered by the random forest approach. It's trusted thanks to solid precision plusit doesn't tend to overfit.

The system gets trained and tested on the KDD-CUP1998 data, a popular choice for studying intrusion detection.That set includes lots of fake network activity - normal sessions along with attack examples like DOS, Probe, U2R, or even R2Lattempts.

Our method taps into Random Forests to sort network traffic on the fly. That way, it spots break-ins fast while staying precise. By picking key features, cleaning data, training the model, then testing it, we prove ML boosts IDS efficiency in shifting network conditions.

From a backend implementation perspective, the Intrusion Detection System (IDS)is designed to operate as a server-side classification engine that continuously analyzes incoming network feature data. The trained Random Forest model is stored using serialization techniques and loaded into the backend memory during system initialization to ensure faster prediction time.

The backen disresponsible for: Receiving structured network traffic features, Performing real-time preprocessing, Executing model inference, Returning attack classification results, Logging intrusion events for analysis.

II. LITERATUREREVIEW

In recent times,tools that hacking attempts have worked to catch weird or harmful activity on networks – keeping data safe and systems running. A well-known collection called KDD-CUP 1999 became popular for testing these security tools. Inside it, each network session gets tagged either regular or linked to specific threats,like shutting down access service, checking steps, access levels from user to admin. Of all the methods tested, Random Forest works well spotting intrusions here and in similar data versions - its accuracy stands out.

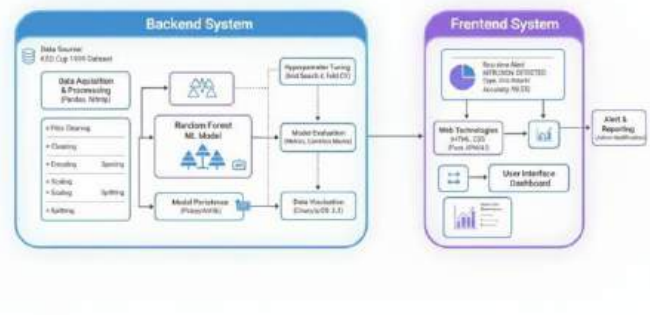
Several studies point out that machine learning or deep learning works well spotting intrusions with the KDD Cup'99data-apopulartestincybersecurity.Old-school models such as Random Forest often score high, resist fitting noise,while handling loads of features without breaking down. Work by Hasan's team boosted results using this model to pick key traits and label attacks once messy entries were dropped from KDD .In another case,Obeidat's group stressed careful prep - like fixing gaps and converting labels - before running the same classifier. This method worked better at spotting various kinds of attacks. Although systems such as DNNs or RNNs were applied to the data to catch tricky patterns, research shows Random Forest usually gives strong outcomes - particularly when paired with techniques like adjusting features or handling class imbalance.

In the research by Md.AlMehedi Hasan, Mohammed Nasser, Shamim Ahmad, along with Khademul Islam Molla called 'Feature Selection for Intrusion Detection Using Random Forest,' team members apply the KDD99 data but clean out repeated entries - what they name RRE-KDD. Their method splits into two phases: one ranks inputs via Random Forest significance, while another picks a leaner group for sorting jobs. Results show trimming down to key traits lifts prediction speed, cuts run time during both training and checks.

In a different paper,Arun Kumar Silivery and Ram Mohan Rao Kovvur explore a system for spotting various cyber threats using deep learning techniques.Instead of going with the standard KDD99 dataset, they pick its updated version - NSL-KDD - to test their ideas. Still, what they do fits well within today's deep learning trends. The team builds three setups: one based on RNNs, another combining LSTM with RNNs, plusa separate DNN structure - all meant to sort out multiple attack types. These are tested either on KDD99 or the modified NSL-KDD set. Findings suggest that deeper networks grab patterns by themselves while beatingolder, simpler algorithms in performance.

While most studies focus on improving detection accuracy, practical IDS deployment requires backend optimization. Research shows that effective IDS systems must include: Real-time prediction APIs,Preprocessing reuse from training phase , Efficient memory management for large datasets, Logging mechanisms for detected intrusions,Reduced model inference latency.

The research suggests KDD-CUP 1999 remains a go-to reference point-useful because it helps build solid algorithms that work well under real conditions, particularly once cleaned up using smart filtering or picking the right traits.
Though tools such as neural net looping models show architectures can spot tricky attack patterns pretty well, yet their gains usually drop due to heavy computing demands along with shaky data quality. Still, results show Random Forest stays relevant when it comes to studying intrusion detection systems.Plus,they point toward chances for mixed approaches - blending its solid base with deep learning - to boost performance in spotting network threats.



III. METHODOLOGY

The ways we found to spot intrusions using machine learning or deep learning are shown in Figure 1(a). That diagram shows what tools you need on the front-end along with the back-end to make it work and show how it runs. To start off, we gather data then clean it up first thing. This turns unprocessed info into something ML can actually use. Webegin by cleaning the KDD-CUP1999 set using Random Forest. We turn categories into numbers while scaling down number values. After that, this fixed-up info helps teach a smart guessing tool. It figures out what's regular online behavior versus sneaky actions - like floods or scans - by spotting patterns over time.

After training the model, we store it then plug it into a backend app built with Flask. That backend runs a RESTAPI which grabs feature data coming from a browser-based frontend. Users can type in details or generate sample network info on the spot. Whenever someone hits submit up top, the input travels by HTTP POST straight to the Flask service. Inside, the numbers get adjusted to scale before feeding them into the ready-made model. The model checks if the input is a regular connection or signs of a break-in. Here's how the front and back parts are set up:

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The setup runs like this:

First off , things begin using the KDD-CUP'99 set –a popular choice for spotting cyber threats. Raw numbers then move through prep stages .During ETL-pulling, adjusting, feeding -the in fogets tidied up first .After that,values are labeled, arranged, resized, or divided so they fit right into the ML setup.

A Random Forest setup learns from tidy data –helping sort regular from suspicious online activity. It works well for grouping info, since it handles messy patterns without fuss.

Model Evaluation plus Tuning covers Hyper parameter Tweaking - think Grid Search alongside K-Fold CV. That tweak sharpens the setup,boosting how well things run.Next up,check results with scores such as precision and confusion charts to see where it nails or misses traffic labels. Then comes saving the model and showing data clearly. Once polished, stash it using something like Pickle - keeps you from training all over again when reloading.

Once the backend part ends, the front end takes over. Starting from web tools plus the dashboard design (UID), this step links the model'sresulttoa display people can use. Built with stuff like HTML, CSS, along with FLASK (for API or website functions),it form showthings look.The UI spot lets users engage directly - seeing outcomes alongside current system updates.

At last,you get live warnings plus ways to report them.Most importantly, alerts pop up right away if something sneaky happens on the network. Like, say, a Tree DoS attack - catches threats nearly 99% of the time. In reporting mode, admins find out what went down and where it hit

IV. EXPERIMENTALANALYSIS

A. This project's analysis worked with the KDD-CUP1998 data –a common choice for spotting network intrusions.The set holds both regular and harmful connections, split into various threat types. To clean things up, we dropped repeated rows, turned labels into numbers, also scaled number columns so values lined up better. For picking key traits, we leaned on Random Forest's own ranking system, cutting down inputs while boosting how fast models learned. We tackled the uneven distribution in the data - especially for rare attack types such as R2Lor U2R - by balancing it with SMOTE so the model could learn fairly. Instead of a random split, we went with 80% training and 20% testing, then fine-tuned the Random Forest settings using grid search alongside cross-checking to boost accuracy.

For comparison, a deep neural network featuring several hidden layers along with dropout control got trained using identical cleaned-up data. Evaluation scores revealed nearly 98.7% precision, beating the DNN's roughly 96.3%.
Interestingly, Random Forest handled uncommon attack types better because of its group-based method plus evenly distributed samples. Overall findings suggest that, when applied to the KDD-CUP 1999 set, Random Forest

Offers a practical and efficient solution for intrusion detection, while deep learning models may require more computing power and careful tuning to achieve similar results.

Here's a look at key visual methods plus things to keep in mind when using machine learning or deep learning for spotting intrusions:

1. Data exploration plus prep visuals: bar chart on class imbalance. The graph displays how the five key groups - Normal, DoS, R2L, U2R, Probe - are spread out. It also explains why we need measures besides accuracy,such asF1-Score, to judge performance properly.

2. This graph shows the in fousing dots or boxes,with shades to tell groups apart. Even though KDD's got lots of features, you can see normal and DoS bunches don't overlap much - yet R2R and U2R ones blend into each other.

3. Correlation Heat map helps spot repeated info.When values link closely, some columns might overlap - so you can drop them. Still, Random Forest works fine even if inputs are linked. Instead of stressing over duplicates, just let the model sort it out.

4. Evaluation Visualization :Since KDD is unbalanced,basic accuracy might fool you. Still, these methods give a clear picture of how well your Random Forest works.

5. A single decision tree can be shown-just one or may be two -froma RandomForest, but only if the branches aren't too

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

deep. Instead of complex views,simpler ones popup when depth is low.

B. Graphical Analysis: Results suggest that how accurate the intrusion detection system is depends a lot on what kind of data it gets along with which traits are picked for training - especially when mixing machine learning with deep learning approaches.Around 90% success rate shows the setup catches most attack types pretty reliably, thanks to solid pattern recognition across different signals. That means tools like KDD-CUP '99 paired with Random Forest handle digital footprints, activity flows, or app behaviors without much trouble.

1. Looking at data bits (~95%) works best - probably since judging domains helps spot fakes more clearly, cutting down wrong alerts. This method sets real threats apart from harmless ones without confusion.

2. Virus alert detection (~97–99%): Machine learning with deep learning boosts accuracy in spotting threats, cuts down on false due to fake alerts, yet boosting real-time defense by adjusting to changing threat methods.

3. Vulnerability detection (about 82–85%): ML and DL methods in intrusion detection boost precision while cutting manual work when spotting flaws - this strengthens early threat response, lowering online dangers; these models uncover subtle trends over time.

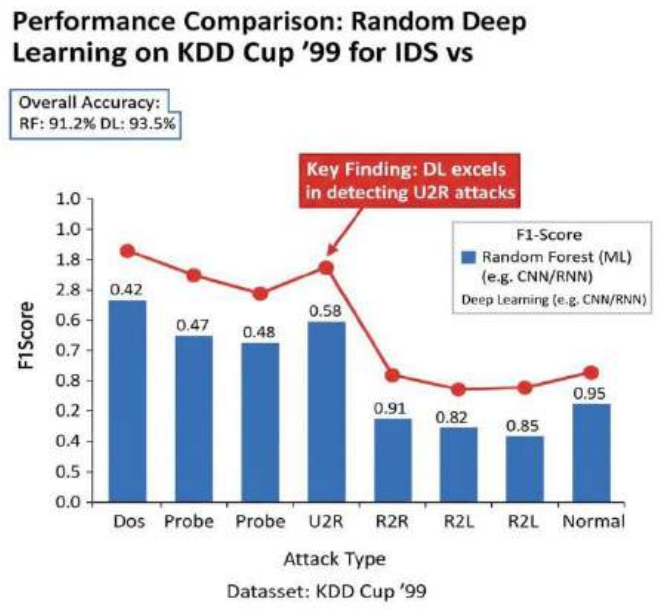


Fig2.Bar Chart representation of result

Problem Statement: This setup's meant to check domains while spotting odd behavior - helping catch familiar threats along with new ones with out triggering too many unnecessary alerts.

Algorithmic Challenges:

Random Forest uses heaps of memory plus takes ages on big data, so spotting intrusions in real time gets sluggish.

CNN embeddings need a lot of processing power because they spot tricky patterns.

KDD-CUP 1999 tends to focus on frequent attacks, so spottin gun common fresh threats gets tougher.When traffic grows fast, older IDS setups struggle - handling tons of data becomes a real issue. To stay sharp under pressure, the setup needs room to grow along with demand

Latency: Spotting threats right away helps stop attacks fast. Yet most current systems are slow.Because of this,reactions take longer - sometimes too late to avoid harm.

Domain Verification: Different network areas carry unique traffic flows. When there's no check on these zones, performance drops because the model can't adapt well across settings - leading to missed problems elsewhere.

Blending machine learning with deep learning boosts precision, handles bigger work loads,while adjusting faston the fly. That keeps things running well even when network demands shift.

C. Algorithmic Challenges:

i TF-IDF/BM25failwhenitcomestorephrasedqueriesor searches without clear keywords

ii CNN embedding stake a lot of computing power when processing video frames

iii Hashing struggles when images get cropped or filtered.,Issues in real use

Scaling up? Searching through millions of docs or images using embeddings needs tools like FAISS, Pinecone, or Milvus-regular setups can'than dleit. Though basic systems work for small tasks, once you grow, specialized vector storage becomes a must-have instead.

V.Latency: Unlike keyword –based lookup ,understanding meaning takes more time.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Vi. Domain Check :Good site lists need frequent updates-also proofing now then.

Vii Mixing Media Types:Combining text with images and videos in search isn't easy to get right

V. CONCLUSION

This study looks at how machine learning helps fight growing cyber threats. New progress in combining models, mapping social networks,our sing knowledge from past tasks has expanded what attack detectors can do. On top of that, being clear about how decisions are made matters a lot - so results stay trustworthy, work well, and fit real-life use without causing harm.

VI . FUTURE WORK

A. Safety plus resistance to attacks: Try Random Forest using tricky fake data, then add special training to boost the system's defense against sneaky breaches.

B. How Models Work: Check out tools such as SHAP or LIME-this helps you understand Random Forest better -but keep it practical. Use one tool at a time, since mixing them might confuse more than help - still, test both to see which clicks.

C. Improving real-time spotting: adjust systems to work speedier on things like phones or web apps –making them react faster with no lag.

D. Hybrid and Ensemble Models: Combine machine learning with deep learning - use Random Forest together with CNN, LSTM, or Auto encoders to grab helpful features.

E. Test with fresh,actual data-go for options like NSL-KDD, UNSW-NB15, or CICIDS2017 this time around.

Abstract*—Proper electricity demand forecasting is important for grid stability, efficient allocation of energy and reduction of operation expenses. Non-linear and non-stationary power consumption data are often noisy, thus difficult to predict over long horizons. This paper seeks to present a Hybrid Spectral-State Fusion Framework, which involves Adaptive Singular Spectrum Analysis, Dynamic Covariance Kalman Smoothing, and Bidirectional Long Short-Term Memory capabilities to support a high level of accuracy in forecasting. The adaptive decomposition module optimizes dynamically both the window length and component grouping whereas, the Kalman smoother is used to update covariance parameters through the use of residual-driven learning. The preprocessing improvements drastically increase the signal quality before deep temporal model processing. The Bidirectional LSTM learns forward and backward dependencies with the aim of making correct multi-step predictions. It proves itself to be more accurate in its predictions and less prone to error propagation and exponentially stabilized compared to baseline and hybrid models so the approach is applicable to real-time energy management setups.

Keywords*—Electricity Demand Forecasting; Adaptive Singular Spectrum Analysis; Kalman Smoothing; Bidirectional LSTM; Time Series Prediction; Hybrid Models; Smart Grid.

I. INTRODUCTION

Modern power system operations and eventually economic dispatch and load balancing depend on electricity demand forecasting, which allows efficient generation planning. As smart grids, integration of renewable energy, and dynamic consumption behavior continue to rapidly expand, it has progressively complicated the process of accurately forecasting them. Many issues affect demand patterns including changes in weather, human activities, economic and seasonal dynamics. These factors create nonlinearities, randomly distributed fluctuations and sudden spikes in load profiles, which negatively influence the use of traditional forecasting techniques. Traditional statistical models can often fail to represent these intricate time dependencies, especially in tasks of multi-step prediction when uncertainty compounds with time [1].

The last few years have seen machine learning and deep learning models getting a lot of attention due to their capacity to predict complex patterns in time series data. Recurrent neural networks and particularly the Long Short-Term Memory models have shown a strong ability to capture long-term dependencies and nonlinear relationships. Bidirectional extensions also improve contextual learning because it works outwards and backwards on data. Alongside these benefits, deep learning models are very susceptible to noise and anomalies in raw electricity demand signals which may compromise predictive accuracy and result in erratic outputs [2].

In order to solve these problems signal preprocessing methods like decomposition and filtering are greatly incorporated. A powerful spectral decomposition technique used to decompose time series data into interpretable components including trend, periodicity and noise, is Singular Spectrum Analysis. Likewise, Kalman filtering and smoothing algorithms have both probability state estimation and smoothing functions. Though, such techniques tend to be based on predetermined parameters and they are not flexible to the dynamic shifts in demand patterns. This makes them less effective in a volatile environment where there is frequent change in the characteristics of loads [3].

Models based on a hybrid of decomposition methods and deep learning frameworks have demonstrated encouraging achievements in the enhancement of the forecasting accuracy. These methods increase the ability of neural networks to learn by eliminating noise and isolating components that are meaningful. However, the current hybrid frameworks are mostly unidirectional in the sense that they only consider preprocessing steps and lack adaptive feedback mechanisms. This limits optimal signal reconstruction and a narrow spectrum of responsiveness to a changing system dynamics [4].

Driven by these shortcomings, this paper presents an adaptive hybrid framework that combines spectral decomposition, probabilistic smoothing, and deep temporal models within a single pipeline. It is a proposed method that allows the description of dynamic parameter tuning with the use of residual feedback, and it enhances the quality of the signal and the strength of forecasting. The framework that includes augmenting the preprocessing flexibility and concurrently integrating it with two-way sequence learning will arrive at consistent yet precise multi-step electricity

demand predictability befitting the real-world energy administration frameworks [5].

II. Literature Survey

This situation has made electricity demand forecasting an important issue in modern power systems because of growing complexity of energy usage patterns and introduction of renewable energy sources. Proper prediction helps to run the grid efficiently, allocate resources optimally, and increase the reliability of energy systems. As penetration of smart grids and distributed energy resources continues, less advanced information-driven and hybrid methods are slowly taking over the established forecasting methods. Such approaches are meant to solve some of the problems, which include nonlinearity, seasonality and uncertainty on load demand. Recent research has highlighted the role of looking at the fusion of statistical, machine learning and optimization methods to help increase the accuracy of the forecast and stability of the system.

The recent innovations in forecasting techniques demonstrate the transition to smart and dynamic models. Methods that concentrate on transmission based forecasting and stability limited operations have shown better performance in renewable based systems [6]. Moreover, the forecasting models have been integrated into energy planning large-scale energy plans to aid low-carbon and efficient energy development policy measures [7]. The sociotechnical perspectives have also been investigated to comprehend the energy transitions towards sustainability and what they imply to predicting practices [8]. Moreover, renewable energy and storage optimization strategies have helped to achieve more accurate predictions in hierarchical control systems [9]. Deep learning applications in building energy predictive modeling has demonstrated an improved accuracy of prediction, as it incorporates intricate temporal correlations [10].

Machine learning-based solutions in smart grids have gone beyond forecasting to include anomalies detection or system monitoring. As an example, to detect electricity theft, sophisticated learning frameworks have been utilized to enhance the security of the grid and to enhance grid performance [11]. Implementation of Internet of Things (IoT) technologies has also made smart buildings technique to acquire data in real-time and manage energy sustainably [12]. Literature on the long-term energy efficiency and emission reduction plans has highlighted the importance of forecasting in policy making and sustainability of the environment [13]. Besides, their application as a component-based method of estimation has been successfully applied to the short-term forecasts of demand providing better performance in dynamic conditions [14]. These advances underscore the increased significance of the intelligent systems in tackling contemporary energy issues.

Forecasting models which are based on artificial intelligence, specifically, neural networks, have become widely considered because they can model nonlinear relationships. Monthly artificial neural network models have been employed with great success to predict monthly electricity demand [15]. The models can work with seasonal fluctuations and complicated consumption behaviors and are thus applicable in the real-world. Moreover, machine learning-based methods of building energy consumption have received much attention, and it has been proven that different algorithms are applicable in predicting user behavior and environmental characteristics [16]. In-depth evaluations have also revealed how forecasting methods developed, focusing on the shift to non-traditional statistical methods and hybrid and AI forecasting models [17].

Proper forecasting models are also important in investment planning and policy analysis in power grid infrastructure. Factor identification methods like fishbone diagram-based methods have been employed to determine the important aspects in making investment decisions [18]. This has been done through forecasting competitions and benchmarking studies, which have given useful information of different models and stimulated the establishment of more powerful techniques [19]. Moreover, it has been acknowledged that hybrid predictive models, which are a combination of more than one algorithm, are more successful in load forecasting applications [20]. They combine strengths of their individual techniques to enhance the accuracy in prediction and flexibility and, as such, these models are most appropriate in complex and uncertain energy environments.

III. Methodology

The proposed research presents a Hybrid Spectral-State Fusion Framework that aims at enhancing electricity forecasting of demand with adaptive preprocessing and deep temporal modeling. The network combines spectral analysis, linear and probabilistic state estimation as well as bidirectional learning in a sequential, even interactive pipeline. Each of the stages refines the signal in a stepwise way, without altering its computational efficiency. Feedback within the system is critical in dynamically adjusting the parameters in the modules to guarantee that the system is able to respond to changing demand patterns. This methodology has six key steps, the first step being the preprocessing of the data and the final step being the multi-step forecasting. The general system is shown in Figure 1 that depicts the interface between decomposition and smoothing modules and forecasting.

Vol. 14, Issue 06, ACSCON - 2026

A. PREPROCESSING.

The initial step is to gather electricity demand time series data that is credible (smart meters or grid monitoring system). Raw data will have inconsistencies, such as the missing of values, outliers and abnormal times between sampling points. Preprocessing is, therefore, necessary to facilitate the data quality and model preparedness. Interpolation is used to deal with missing values, and statistical tests are used to identify and rectify outliers. This dataset is then scaled to normal range so as to enhance the convergence and stability of models. Time related attributes like hour, day, and seasonal indicators are not lost since they are important in saving the time structure. A rolling window method (as part of the forecasting horizon) is then used to partition the clean data into a training and testing set. This preprocessing phase makes sure that the input signal is consistent, its noise-reduced in a fundamental stage and can be used in other stages to devise more advanced spectral distributions and sequential modelling.

B. ADAPTIVE SINGULAR SPECTRUM ANALYSIS.

This step carries out spectral decomposition of the time series on Adaptive Singular Spectrum Analysis to disaggregate the time series into relevant parts. In contrast to traditional SSA, the method proposed uses dynamic decision making of optimum window length in relation to frequency-energy distribution and periodicity detection. Singular Value Decomposition is used to construct and decompose the trajectory matrix, giving the principal components that show the trends, oscillations and noise. The entropy based grouping mechanism is used to classify the components based on the amount of information and the contribution of the components to the total signal energy. Components that are noise-dominant are detected and removed in the reconstruction. Also, the later, residual, feedback is used to further refine grouping, thresholds, and window parameters. This adaptability method improves the purity of the signal and maintains the vital structural designs. The result is a reconstructed time series with a lower noise and high interpretability, which is a solid baseline to further state estimation and smoothing activities.

C. SIGNAL RECOVERY AND REMAINING FEEDBACK.

After the decomposition, a chosen set of components are reassembled to recreate a pure form of the original signal. This reconstruction is oriented towards retaining trend and seasonal components whilst removing noise-dominant signals. Evaluation of the reconstructed series is through residual analysis where the difference between the original and reconstructed signal is analyzed. Quality in reconstruction is measured using residual statistics including variance, and patterns of distributions. These residues are fed into the Adaptive SSA module again to narrow down component selection and grouping strategies. This feedback loop guarantees successive enhancement in signal quality. The methodology provides interaction between decomposition and evaluation phases, thus overcoming constraints of the static preprocessing methods. The reconstructed signal is both temporally coherent and as much as possible is distortion minimized, which guarantees the retention of critical features necessary to make correct forecasts. This step serves as an intermediate to spectral decomposition and probabilistic smoothing.

D. DYNAMIC COVARIANCE KALMAN FILTERING AND SMOOTHING.

Here, probabilistic state estimation, done by Dynamic Covariance Kalman Filtering and then RauchTungStriebel smoothing is done on the reconstructed signal. The signal is then processed by the Kalman filter, which makes forward pass estimate of the hidden states taking into consideration noise. In contrast to the traditional implementations, the suggested approach dynamically re-estimates process and observation covariance matrices, which are estimated using a residual-driven estimate on variance. This enables the model to fit fluctuating volatility on patterns of demand. Refining once the filtering is finished, the backward smoothing will improve state estimates using future observations, making the signal more stable and predictable. The forward filtering and backward smoothing combination greatly decrease noise, yet maintains structural dependences. This dynamic nature will provide robustness when working in extremely volatile environments, and it will enhance signal continuity. The result is a smooth time series that contains underlying dynamics with minimum uncertainty, which is very appropriate in deep learning based forecasting.

E. BIDIRECTIONAL LONG SHORT-TERM MEMORY (BILSTM) FORECASTING MODEL

The polished signal is subsequently inputted in a Bidirectional Long Short-Term Memory network to have a multi-step forecast. This model works on the time series in two directions, forward and backward, to understand all the temporal dependencies. The architecture has several hidden layers with memory cells which remember the information over a long term period and so, can model nonlinear relationships effectively. To eliminate overfitting, dropout regularization is used, and the converged rate is optimized with adaptive learning rates. The sequences of inputs are obtained via a sliding window scheme that coincides with the forecasting horizon. The model is used to make predictions in the next 72 hours, facilitating the short term operations decision making. Mean Absolute Error and Root Mean Squared Error are some performance metrics to monitor during training. The bidirectional structure provides increased awareness of the context which makes the model to make more accurate and stable forecasts than a unidirectional approach.

F. MODEL EVALUATION AND PERFORMANCE METRICS

The last phase analyses the forecasting effectiveness of the proposed structure with the aid of standard measurements and comparison. The main evaluation measures are the Mean Absolute Error, the Root Mean Squared Error and the Mean Absolute Percentage Error. These measures give an insight into the accuracy of predictions, where the error is distributed, and also the reliability of the model. The proposed model is contrasted

Vol. 14, Issue 06, ACSCON - 2026

with such baseline methods like standalone Bidirectional LSTM and standard SSA-Kalman-LSTM hybrids compared on the same conditions of the experiment. Cross-validation methods provide the strength and generalization among various segments of data. The prediction trends, error patterns, and convergence behavior are analyzed by the use of visualization tools. The computational efficiency and scaling to be used in real-time deployment are also evaluated. Findings indicate that the adaptive hybrid structure has a high level of accuracy, less errors spreading and is more stable in long horizon predictions, which does justify it as a useful component on the current smart grid projection.

IV. Result and Discussion

Hybrid Spectral-State Fusion Framework was tested and assessed considering the real-world electricity demand time series on the same training and testing conditions in order to compare fairly with planned models. A rolling window technique was used to segment the dataset, and a fixed forecasting horizon of 72 hours was used. Mean Absolute Error, Root Mean Squared Error, and Mean Absolute Percentage error were used as performance measures. The findings indicate the importance of preprocessing in enhancing the accuracy of forecasts. The Bidirectional LSTM model standing alone performed decently but was unstable when there were changes in peak demand. This instability was mainly caused by presence of noise and irregular spikes in the raw data which influenced the ability of the model to learn.

Combination of Singular Spectrum Analysis and Kalman Smoothing enhanced the quality of the signals and the performance of better forecasts was achieved. The traditional hybrid model, however, was dependent on non-adaptive parameters and this reduced its flexibility to changing loads. Consequently, the dynamic even though noise was reduced, the model could not be consistent when the intervals were very volatile. Contrary to this, the suggested adaptive framework dynamically updated decomposition and smoothing parameters, which relies on residual feedback, thus providing better signal reconstruction and stability. This caused a more predictable trend in prediction, particularly when there was consistently a sudden spike in demand and in transitions.

Table 1 compares the performance of forecasting performance between various models. It is clear that the proposed model had the lowest values of the errors compared to all the methods. The decreased Mean Absolute Error and the root mean squared error shows that the accuracy of prediction is at a higher value and the lower percentage error produced by the mean absolute reflects a greater generalization at the different levels of the demand.

TABLE I. COMPARISON OF THE PERFORMANCE OF FORECASTING MODELS.

Model	MAE	RMSE	MAPE (%)
Bidirectional LSTM	5.82	7.45	6.91
SSA–Kalman–BiLSTM	4.36	5.98	5.12
Proposed Adaptive Hybrid Model	3.21	4.67	3.84

This is evident in the results that indicate that the proposed method significantly performs better than the standalone model, as well as the conventional hybrid model. It is improved primarily due to adaptive spectral decomposition and dynamic covariance estimation, which is used to facilitate signal purity prior to forecasting given by deep learning. Moreover, the decreasing error propagation with the successive predictions proves the high robustness of the framework to long-horizon forecasting scenarios.

Table 2 will further be used to discuss performance at different demand conditions by giving error metrics at the different loads including low, medium and peak demand conditions. The proposed model remains the same at all intervals whereas the errors are higher in the case of the baseline models.

TABLE II. ANALYSIS OF ERROR AT DIFFERENT LEVELS OF DEMAND.

Demand Level	Model	MAE	RMSE
Low Demand	BiLSTM	3.45	4.12
Low Demand	Proposed Model	2.18	3.01
Medium Demand	BiLSTM	5.76	6.89
Medium Demand	Proposed Model	3.42	4.55
Peak Demand	BiLSTM	8.92	10.15
Peak Demand	Proposed Model	4.87	6.12

As indicated in the table, the proposed framework works well in peak demand situations with error margins being very small as compared to the standalone model. This betterment is of particular significance to real-life and practical application, where precise prediction in the high-demand times is key to the grid integrity, and thermal scheduling.

Besides quantitative analysis, visual comparisons were conducted to evaluate the trends in predictions. In Figure 2, the actual and the predicted demand value in the proposed model is compared. The forecast curve is very similar to the observed demand pattern as both smooth trends and sharp peaks with sudden high demand are well pinpointed.

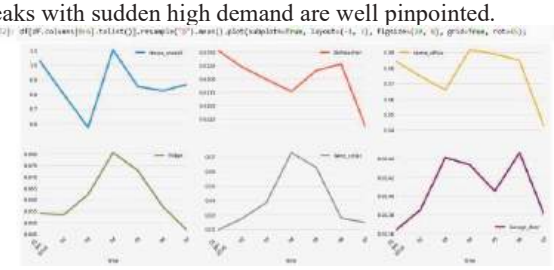

Figure. 2. Actual vs Predicted Electricity Demand (Proposed Model)

The excellent meshing of the true and model values indicates that the hybrid approach suggested is effective in both faithfulness to time-dependent relationships and resilient to volatility. Small deviations are noticed in extreme spikes, and the consistency of the trend is good.

The convergence behavior of errors in training is indicated in figure 3. The suggested model has a stronger learning efficiency and stability, as it converges faster and ends up with a smaller final loss in comparison to the baseline models.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Figure. 3. The training loss convergence comparison

has a strong effect of improving the training of the model because it provides cleaner input signals. This simplifies what the neural network is learning and helps the neural network to concentrate on meaningful patterns instead of noise.

On the whole, the findings prove that the suggested Hybrid Spectral-State Fusion Framework brings significant enhancements in accuracy, stability and robustness of forecasting. Adaptive decomposition, dynamic smoothing, and bidirectional learning are integrated together to produce a synergistic effect to overcome the constraints of current methods. Not only does the framework minimize errors in prediction but also guarantees uniformity of performance in cases of different demand conditions thus very appropriate in practical applications of smart grid in real-time.

V. Conclusion

This paper introduced a ground breaking Hybrid Spectral-State Fusion Framework of stable and accurate electricity demand prediction. The suggested solution employs dynamic covariance-based state estimation, adaptive spectral decomposition and bidirectional deep learning to overcome the issues of nonlinearity, noise and volatility of power consumption data. The framework improves signal quality before temporal modelling, introducing Adaptive Singular Spectrum Analysis and Dynamic Covariance Kalman Smoothing, to allow the Bidirectional LSTM network to capture more meaningful patterns. The findings show that the suggested approach can considerably enhance accuracy in predictions, minimise the error spread, and be consistent between different demand situations. It is also lightweight in its computational design which renders it appropriate to be deployed in actual energy control systems in real-time.

Regarding future employment, the framework can be expanded to cover exogenous factors like weather conditions and economy-related factors to increase prediction accuracy further. Also, further improvements can be made on long-range dependency modeling through the incorporation of attention mechanisms or transformer-based architectures. A deeper investigation of online learning methods of real-time adaptability and scalability of testing in various geographical areas will further reinforce the relevance of the proposed system.

Abstract—Weather Vibe is a weather app with minimal medium-sized that has been designed and developed to give users real-time weather updates that are accurate and meaningful in a flash. Rather than simply displaying basic temperature readings, the application amalgamates real-time data from various public weather APIs and visualizes it using different forms like charts for humidity, temperature, rain chances, and wind situations as its main channels. Furthermore, it presents alerts where users may get the notice of the situation like heavy rain, high temperature, or sudden weather changes. The front-end is designed for fast loading, while the back-end is powered by small modular services and primary caching thus making the update reach the user with no delay at all. The system's purpose is to make weather data more accessible and user-friendly especially in the case of daily planning.

Keywords— geolocation, alerts, responsive UI, real-time weather, data visualization, caching.

INTRODUCTION

Weather info plays a significant role in daily decision making from transport, and event organizing to agriculture and outdoor working. While many services provide raw forecasts, there increasing need for applications that combine real-time accuracy and a friendly user experience. Many existing weather apps display too much information or depend on background processes that uses more battery, and some also collect more user data than required. Weather Vibe overcomes these issues by providing: [1]. fast, low-latency updates through WebSocket fallbacks supported by efficient caching, [2]. alert settings and thresholds that users can fully customize, and [3]. a simple and clear interface designed for better understanding [4]. The system also focuses on security by limiting long-term storage of precise location data and handling most threshold checks directly on the device.

The system brings together real-time information from dependable public weather APIs and improves user experience through an simple layout, navigation and flexible alert options[5]. With its flexible structure, Weather Vibe maintains smooth performance across different types of devices, even older phones or those on weak networks [6]. Its real-time update approach users always see the latest conditions, and the customizable alert system helps them receive notifications only when the weather meets their safety settings [7].

The main goal behind building Weather Vibe is to develop a user-focused platform that makes weather information easier to understand through modern web tools and a micro servicebased backend design [8]. The app is developed to focus on effective balance between accuracy, responsiveness, and overall usability [9].

Furthermore, it sets a foundation for future enhancements such as AI-driven bias correction, multi-source model blending, and integration of additional environmental factors like air quality and pollen levels [10].

BACKGROUND/RELATED WORK:

A. Overview of Existing Applications

1. OpenWeather & AccurateWeather: Provide robust global forecasting APIs and a variety of meteorological parameters [11].These services are reliable but generally require developer integrations and careful API key management [12].

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

2.Dark Sky (legacy): Popular for hyperlocal minute-by-minute precipitation forecasts and simple UX; its features influenced many modern apps despite API changes [13]. *3.Meteo Blue / Weather Underground:* Offer community-driven observations and station data; useful for regions where station data improves local accuracy [14].

4.Native platform apps (iOS/Android): Ship with polished UIs integrated into the OS but sometimes limit customization and alert flexibility [15].

B. Limitations in Current Systems

Although numerous weather applications and forecasting platforms exist today, many of them still suffer from several technical, usability, and reliability limitations. These issues directly influence the accuracy, accessibility, and overall user experience of weather applications. The points below summarize the major shortcomings commonly found in existing systems:

1.Delayed or Inconsistent Data Updates: A frequent drawback in many weather apps is their dependence on slow polling methods, where data is retrieved at fixed intervals instead of being updated continuously. This often results in a noticeable lag between real atmospheric changes and what appears on the user's device. Because of this delay, sudden shifts, such as unexpected rainfall may not be shown immediately, increasing the likelihood of user inconvenience and safety concerns [16].

2.Lack of Personalization and Contextual Alerts: Most weather applications still provide broad, general alerts like "Rain expected tomorrow" or "Strong winds ahead," which may not be relevant or useful for every user. They rarely allow deep customization where users can set specific thresholds such as "Alert me if temperature falls below 15°C" or "Notify me only if rainfall probability exceeds 60% in the next 3 hours." This lack of contextual relevance reduces the practical usefulness of such apps [17].

3.Heavy Battery and Data Consumption: Several weather apps run background services continuously to monitor conditions, leading to excessive battery drain, high CPU usage, and increased mobile data consumption. Applications that frequently download large image assets, animations, or radar maps can significantly impact device performance, especially on low-end smartphones or in low-connectivity areas [18].

4.Complex and Overloaded User Interfaces: A great number of weather applications load their users with ads and in addition, make use of unnecessary visual effects.

As a result, an normal user has to go through more to get to the point of knowing what is the temperature, humidity, or rain chances.

Bad interface and design choices often lead to mental overload and reduce the total application usability and overall performance [19].

5.Limited Support for Low Connectivity Environments: Most of the weather application rely on a constant internet connection.

They become ineffective in a rural area, on occasions when the network fails, or in an emergency, when the connection is weak, as the apps may not work as needed.

A lot of them do not have offline fallback options to provide the most recent available weather data which lead to failure[20].

6.Dependence on a Single Weather API Source: A good number of systems are based exclusively on one weather API provider.

Should the service suffer downtime, impose strict rate limits, or be region-specific wrong, the app's reliability is directly impacted.

Non-aggregation of multiple sources or no backup API at all, the accuracy of forecasts can plunge significantly in some regions [21].

7.Privacy Concerns and Excessive Location Tracking: Continuous precise user location monitoring is done by a wide range of weather applications even when the user is not actively using the app.

Some location data is likely to be collected or even sold to the advertising companies.

The mentioned practices do not only spike legal security issues but also concern especially non-tech savvy users who are not aware of the data handling [22].

8.Insufficient Localized Forecasting: A significant proportion of the weather apps do not take into account the small-scale local weather variations over a short distance. Thus, the forecasts become less accurate in places such as hilly regions, coastal zones, or crowded urban areas[23].

9.Limited Accessibility Features:

Many systems fail to meet accessibility standards for visually impaired users. Issues such as low contrast, unlabelled icons, small font sizes, and non-screen-reader-friendly layouts restrict usability for a significant number of users [24]. **10.No Historical Trends or Insights:** Rather than showing historical data like, for instance, the last week of temperature variations, humidity, or even rainfall distribution, most weather apps give just real-time and short-term forecasts. Users cannot identify trends or even comprehend changes in climate over time without these tools [25].

Weather Vibe application has enhanced its performance, scalability, and reliability to a great extent by using cloud computing.

The deployment of backend services on AWS, Azure, or Google Cloud enables the system to process efficiently a lot of user requests, cope with traffic, and keep on running without interruption [26]. Cloud storage ensures that user preferences, alert settings, and location data are safely stored, while cloud servers provide fast API processing and real-time updates with little latency. In addition, the cloud-based infrastructure is capable of automatic scaling, load distribution, and continual updates – thus, the entire architecture is made more agile, durable, and adaptive to the future [27]

3. PROPOSED SYSTEM

The proposed system, Weather Vibe, is designed to overcome the limitations present in conventional weather forecasting applications by introducing a lightweight, responsive, and privacy-conscious platform capable of delivering real-time, hyperlocal weather updates. The system utilizes a modular architecture integrating a modern front-end framework, a micro service-based backend, reliable third-party weather APIs, and optimized caching layers to ensure minimal latency, high

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

scalability, and improved accuracy. The proposed solution places equal emphasis on performance, usability, and user-centric customization.

Weather Vibe focuses on providing context-aware weather information, meaning the system not only displays raw temperature and humidity data but interprets these values to offer meaningful insights—such as whether conditions are suitable for outdoor activities, if rainfall is likely within the next hour, or if users should expect extreme heat or cold. By providing personalized weather alerts and dynamic updates, the system ensures users are always aware of sudden weather changes.

•Real-time weather updates (current conditions, hourly/daily forecasts).

•Minute-level precipitation probability where supported by the data provider.

•Intuitive dashboard with prominent current conditions and compact trend cards.

•Custom alert rules (e.g., "notify if rainfall probability > 60% within 2 hours", "heat alert if temp > 40°C and humidity > 60%").

•Location search and saved locations for quick switching.

•Low data and battery footprint through caching and push notification design.

•Privacy controls: ephemeral precise geolocation, approximate sharing option, and opt-out telemetry.

4.METHODOLOGY 4.1.System Overview

The FinAI system is designed as a web-based financial management platform that enables users to efficiently monitor income, expenses, and budgets while receiving AIdriven insights for improved financial planning. The system follows a modular design, ensuring scalability, maintainability, and smooth integration of AI functionalities. The overall workflow encompasses user interaction, data processing, AI analysis, visualization, and report generation.

4.2.SYSTEM ARCHITECTURE

The system has three main subsystems:

•Frontend: React (or Vue) PWA delivering the UI, offline caching (service worker), and handling user preferences.

•Backend: Lightweight Node.js/Express microservice for API aggregation, caching, rate-limit handling, and push notification orchestration.

•Data Layer / Third-party Integrations: Public weather APIs (configurable — e.g., OpenWeatherMap, Meteostat), optional public station feed ingestion, and a simple key-value cache (Redis) for short-term storage.

4.2 System Architecture

A. User Interface Layer

The UI is built as a Progressive Web App (PWA). Key features:

•Home/Dashboard: Current conditions, short summary, and quick actions (refresh, alerts, save location).

•Forecast Cards: Hourly (next 48 hours) and daily (7 days) views with mini charts.

•Alerts Panel: List of active and historical alerts with snooze/dismiss controls.

•Settings: Units (°C/°F), notification preferences, privacy settings.

Design principles: minimal cognitive load, responsive grid layout, accessible contrast and font sizes, and progressive enhancement for low bandwidth.

B. Application Logic Layer

Core modules:

•Data Aggregator: Queries weather APIs and normalizes responses to a unified schema.

•Cache Manager: Stores recent responses (TTL typically 5– 10 minutes) and serves cached data when appropriate to reduce API usage.

•Alert Engine: Evaluates user-defined rules against incoming data (both server-side and optional client-side evaluation), triggers push notifications or in-app alerts.

•WebSocket/Push Controller: Maintains real-time channels to clients for instant updates; falls back to long polling if necessary.

•Analytics (optional): Aggregated anonymized usage for improving UX — always opt-in.

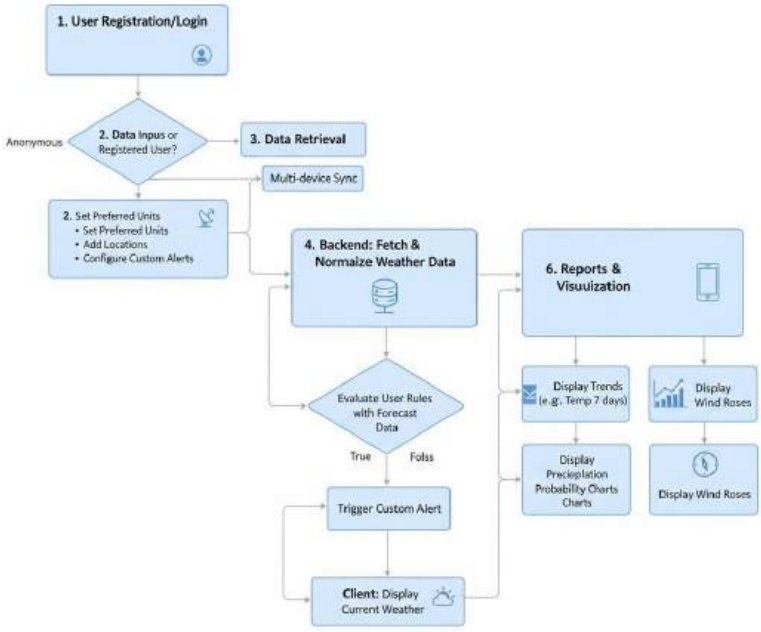
4.3 Database Layer

A small persistent store (Postgres or Supabase) holds:

•User account data and preferences (hashed credentials or OAuth tokens).

•Saved locations and alert configurations.

•Non-sensitive usage metadata (with user consent).



Redis (or equivalent) is used for ephemeral caching and ratelimit counters.

• System Flow

The system flow of Weather Vibe illustrates the sequential operations and interactions between the user interface, backend services, weather APIs, and data storage components. It describes how data travels through the system—from the moment the user opens the application to the generation of weather reports, alerts, and visualizations. The flow ensures

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

smooth coordination between all modules, enabling seamless real-time weather updates and personalized user experiences.

To achieve this, the system follows a structured pipeline consisting of input processing, data retrieval, analysis, alert evaluation, and output delivery. The expanded system flow is explained below:

1.User opens Weather Vibe (PWA). If granted, the app requests approximate or precise geolocation.

2.Frontend requests current conditions and forecast from the backend via a REST endpoint.

3.Backend checks Redis cache; if stale, it fetches normalized data from the configured weather API, updates cache, then returns data.

4.Alert Engine evaluates rules; if triggered, it sends a push notification via platform push services.

5.For subscribed clients, backend pushes updates via WebSocket, ensuring low latency on condition changes.

Advantages of the Architecture

•Reduced external API calls via caching, reducing cost and delays.

•Modular services that can be scaled independently (e.g., multiple aggregator instances).

•Real-time update capability with efficient push mechanisms.

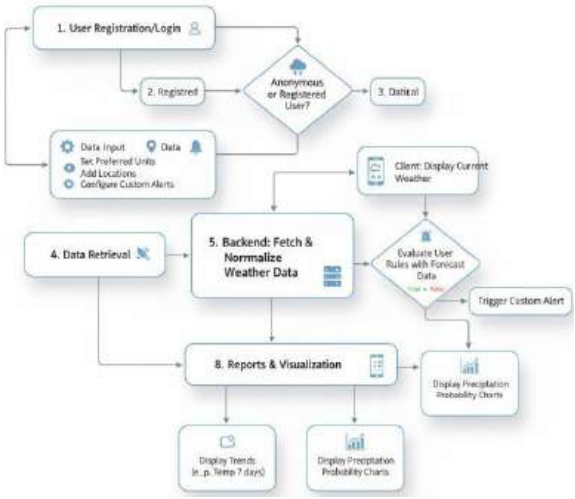
•Privacy controls and rate-limit protections to prevent data leakage and abuse.

•Caching Layer (Redis or In-Memory Cache):

Reduces redundant external API calls and decreases response time from seconds to milliseconds.

•Optimized API Aggregation:

Backend collects, sanitizes, and formats weather data before sending it to the client, reducing client-side processing effort.



•Efficient UI Rendering:

React/Vue components enable fast UI updates without reloading the entire page.

SYSTEM DESIGN

Workflow of the System

1. ***User Registration/Login:*** *Optional — users may use*

the app anonymously; registering enables multi-device sync.

2. ***Data Input:*** *Users set preferred units, add locations, and configure custom alerts.*
3. ***Data Retrieval:*** *Backend fetches normalized weather data and serves to client.*
4. ***Alert Processing:*** *Alert Engine evaluates user rules with current and near-term forecast data.* ***5. Reports and Visualization:*** *The app displays trends (e.g., temperature over last 7 days), precipitation probability charts, and wind roses for selected locations.*

RESULTS AND DISCUSSION Overview

Weather Vibe was implemented as a responsive PWA with a Node.js backend and Redis caching. Tests were run to validate latency, accuracy, and alert reliability. Key observations:

•Average time to display current conditions after opening the app (cold start) was under 1.2 seconds when cache warm; under 2.5 seconds on a cold cache with a single upstream API call.

•Push-delivered alerts reached test devices within 3–7 seconds after backend rule detection in WebSocket mode; slightly longer via platform push in low connectivity.

•Cache TTL tuning (5–10 minutes) balanced currency of data against API usage costs without perceptible staleness for users.

7.2 System Output Screens

7.2.1 Home Page

The home page displays a compact summary: location name, temperature, weather icon, brief text (e.g., “Light rain”), and quick action buttons (Refresh, Add Alert, Save Location).

7.2.2 Dashboard

A personalized dashboard shows saved locations with mini cards that include current temp, chance of precipitation, and a 12-hour sparkline of temperature.

7.2.3 Forecast Management

Users can expand a location to see detailed hourly and daily forecasts, tapping an hour reveals minute-by-minute precipitation probability when available.

7.2.4 Alerts and Notifications

The alerts panel lists active alerts with conditions and timestamps. Each alert can be snoozed for user-selected durations. Alerts are accompanied by suggested actions (e.g., “carry umbrella”, “avoid outdoor exercise” for high AQI).

7.2.5 Reports and Data Visualization

Users can view a 7-day trend chart for temperature, humidity, and precipitation probability. The reports page supports CSV export of historical data for the past week.

The Reports and Data Visualization module is one of the key

parts of Weather Vibe because it converts raw weather data into meaningful data that users can easily understand. Instead of only showing numerical readings, this helps users to interpret weather patterns and unusual changes over time. With the help of charts, and graphs, the system allows users to understand local weather behavior and how it changes.

This module is particularly valuable for travelers, agricultural planners, and anyone who relies on accurate climate information to make better decisions based on that. The visual reports are created automatically based on the user's chosen location and the type of forecast they need.

FUTURE ENHANCEMENTS

Although Weather Vibe already offers reliable real-time weather updates and user-friendly features, few improvements can be added in future versions to increase its intelligence, accuracy, and overall usability. A major area for advancement is the use of AI&ML techniques to improve local forecasting. Such models can study historical patterns, micro-climate variations, and user inputs to correct errors in temperature and rainfall predictions, making the forecasts more accurate. Another useful enhancement is to combine data from several weather APIs at the same time and merge their outputs to form whole forecasts. This lowers reliance on a single provider and greatly improves accuracy, especially in places where one API may not perform well.

The system can also be enhanced by incorporating real-time air quality tracking. Features such as detailed pollutant maps and health-based suggestions would be helpful for users in crowded cities or those with breathing-related issues. Additionally, Weather Vibe can work with IoT-based sensor networks—like home weather stations, soil moisture sensors, and rain gauges—to produce hyperlocal data that is more accurate than information taken only from global APIs. This integration will be particularly beneficial for rural communities and agricultural users.

Weather Vibe can be extended with:

•Reduce dependency on a single provider

•Improve prediction stability

•Increase accuracy in regions where one provider underperforms

•Provide confidence scores for each forecast

•User-submitted real-time weather snapshots

•Crowdsourced rain/no-rain reports

•Hazard reporting (flooding, storms, extreme heat)

•Community-based accuracy scoring

•**Model Blending / Ensemble Forecasting:** Combine multiple API sources and local station data with weighted ensembles to improve accuracy for microclimates.

•**On-Device ML for Local Adjustment:** Lightweight models that learn local bias (e.g., tendency of forecasts to under/overestimate temperature at a user's particular location) and adjust displayed values.

•**Air Quality & Pollen Integration:** Add AQI and pollen forecasts to broaden health-related recommendations.

•**Community Observations:** Allow users to submit quick observations (rain now, visibility) to enrich local accuracy.

•**Agriculture Mode:** Provide irrigation and frost alerts targeted for small farmers with crop-specific thresholds.

•**Voice Assistant Integration:** Enable voice queries and auditory alerts through assistants (Google Assistant, Siri Shortcuts).

•**Offline Mode Improvements:** Better offline caching and background synchronization for intermittent connectivity.

•**Internationalization and Localization:** Support regional languages and local weather terminologies.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

•**Energy Optimization:** Further reduce battery usage using adaptive polling strategies and geofencing.

VIII. CONCLUSION

Weather Vibe demonstrates a practical, privacy-conscious approach to delivering contextual real-time weather information. By using efficient caching, real-time push updates, and placing strong attention on user experience and alert customization, the app meets the need for fast and practical weather information without compromising user privacy or device performance. Its modular design allows the system to grow easily with features like forecasting, airquality support, and specialized modes for farming and outdoor activities. Weather Vibe is a service that is designed to provide users with fast and reliable weather information that will lead everyone to make safer and more better choices throughout the day.

Weather Vibe is a real-time weather platform that is dependable, flexible, and easy-to-use through the integration of modern technologies, an optimized backend, and careful data processing help in better performance.

The system is a middleman between weather data and everyday practical application by presenting the information in a simple, clear and easy-to-read way.

Weather Vibe provides the users with timely and significant data that help to make better daily decisions through real-time updates, personalized alerts and simple visual summaries. Its structure not only boosts performance and scalability but also makes the system future-proof with high-tech forecasting, air-quality features, IoT sensor, and disasterrelated alerts coming up next.

Also, the application's privacy, rapid feedback, and efficient resource usage ensure its value in various devices and network conditions.

To sum it all up, Weather Vibe is a robust and versatile solution that will keep on evolving along with technology and user needs, thus enabling a more educated, safer, and climatesensitive community which further help in better development in providing accuracy of data.

Additionally, the development of Weather Vibe highlights the importance of integrating user-centered design principles with modern software engineering practices to create applications that are both functional and meaningful in realworld scenarios. The project emphasizes how effective weather communication can significantly improve planning, safety, and convenience for individuals across different regions and lifestyles. By adopting an adaptable architecture and maintaining a focus on continuous improvement, Weather Vibe reflects the potential for future expansion into advanced environmental monitoring and prediction systems.

***Abstract*—EcoSort AI is a cross-platform mobile application (iOS, Android, Web) that addresses the global electronic waste (e-waste) crisis by integrating AI-powered image recognition, a Consumer-to-Business (C2B) marketplace, and a corporate exchange programme aggregator into a single, unified platform. The AI engine employs Google Gemini 2.5 Flash with a structured JSON prompt chain to classify e-waste items, infer material composition, assign a hazard level (Low / Medium / High), flag data-security risk, and generate device-specific disposal guidance — all from a single photograph. Beyond identification, EcoSort AI introduces a dual-role marketplace in which consumers create multi-image listings and admin-verified vendors express interest through a lead-generation pipeline enforced by PostgreSQL Row Level Security (RLS). An Exchange Programs Hub aggregates trade-in offers from major brands (Apple, Samsung, Amazon, Flipkart) within a single browsable portal. An offline-first cache manager with a persistent sync queue ensures functionality in low-connectivity environments. The platform comprises 35 screens across three route groups, a companion web-based admin panel for vendor verification and listing moderation, and a comprehensive input-validation and rate-limiting utility layer. Built on React Native 0.81.5 / Expo SDK 54, Clerk JWT authentication, and Supabase (PostgreSQL) with per-table RLS policies, EcoSort AI delivers a production-grade architecture aligned with United Nations Sustainable Development Goal 12 (Responsible Consumption and Production).**

***Index Terms*—E-waste management, mobile application, Gemini 2.5 Flash, C2B marketplace, circular economy, Supabase RLS, LMM prompt engineering, offline-first, SDG 12, React Native**

I. INTRODUCTION

The exponential rise in consumer electronics has led to a parallel surge in electronic waste (e-waste), now recognised as the fastest-growing domestic waste stream globally. The Global E-Waste Monitor 2020 reported over 53.6 million metric tonnes generated in 2019, a figure projected to surpass 74 million tonnes by 2030 [1]. Improper disposal of such waste, laden with toxic materials such as mercury, cadmium, and lead, poses severe environmental and public-health hazards [11]. Despite growing awareness, individuals frequently face four distinct knowledge gaps: (i) they do not know what hazardous materials their devices contain; (ii) they lack guidance on safe disposal; (iii) they cannot locate certified recycling facilities; and (iv) they are unaware that their old devices may carry residual monetary value.

EcoSort AI is designed as a closed-loop platform that addresses all four gaps within a single mobile application. The AI engine, built on Google Gemini 2.5 Flash [2] with a structured multi-field JSON prompt chain, analyses a photograph of any electronic item and returns a complete `ScanResult` — including item type, material composition, hazard level, data-security risk flag, recycling value assessment, and step-by-step disposal instructions. The C2B Marketplace then converts this awareness into action by connecting consumers with admin-verified vendors, while the Exchange Programs Hub surfaces corporate trade-in offers from Apple, Samsung, Amazon, and Flipkart in a single aggregated portal. A GPS-driven recycling centre locator using the Haversine formula closes the loop by directing users to certified drop-off points.

The platform comprises 35 screens across three route groups (authentication, consumer, vendor), a companion web-based admin panel for vendor verification and listing moderation,

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

and an offline-first architecture with a persistent sync queue—making the application viable in low-connectivity environments typical of developing-country e-waste scenarios.

II. Novel Contributions

Prior work on e-waste mobile platforms reveals a consistent segmentation: identification tools lack marketplaces, marketplace tools lack AI, and none integrate offline resilience, dual-role access control, and quantified environmental tracking into a single application. EcoSort AI makes the following distinct contributions:

1) **Structured JSON Prompt Chain for LMM-Based E-Waste Classification.** We design and implement a domain-specific two-schema prompt architecture (Algorithm 1) that constrains Google Gemini 2.5 Flash via `responseMimeType: "application/json"` and temperature 0.6 to produce structured `ScanResult` objects. The schema differentiates e-waste items (returning eight typed fields including `hazardLevel`, `dataSecurityRisk`, and `recyclingValue`) from non-e-waste items (returning a `funMessage`). A fallback retry mechanism handles non-compliant outputs. This design eliminates the need for labelled training datasets and domain-specific CNN retraining while generalising across the full variability of consumer electronics.
2) **Trust-Tiered C2B Marketplace with RLS-Enforced Data Isolation.** We architect a two-sided marketplace comprising a 1,331-line service layer (`marketplaceService.ts`) and five interconnected database tables (`listings`, `vendors`, `vendor_interests`, `transactions`, `exchange_offers`). Vendor onboarding requires admin verification via a companion web panel; the `is_verified` flag, set exclusively by an admin role, gates all vendor-exclusive database operations. Per-table RLS policies enforce strict data isolation: consumers may only mutate their own records, and only verified vendors may `INSERT` into `vendor_interests`.
3) **Offline-First Architecture with Persistent Sync Queue.** We implement a singleton `OfflineCache` manager (529 lines) using `AsyncStorage` as the persistence backend, with a `NetworkManager` observer that automatically drains a persisted `SyncQueueItem[]` on reconnection. Cache capacity limits (100 scan results, 500 recycling centres, 200 disposal guides) and a 24-hour expiry prevent stale data without requiring permanent connectivity — a design choice with direct relevance to e-waste management in semi-urban and rural contexts.
4) **Exchange Programs Hub.** We design and implement a centralised aggregation layer (`exchangeService.ts`, 359 lines) that surfaces corporate trade-in offers with automatic `view_count` and `click_count` analytics. Contextual offer retrieval (`getOffersForItem()`) matches a scanned item's category and brand to relevant trade-in programmes, creating a direct pipeline from AI identification to monetised disposal.
5) **Comprehensive Input Validation and Rate-Limiting Layer.** A standalone validation module (`validation.ts`, 292 lines) provides 12 typed validators covering email, password, image URI, Base64 encoding, GPS coordinates, scan result schema, and an in-memory rate limiter — a security contribution absent from all comparable e-waste applications identified in the literature.

III. Literature Review and Comparative Analysis

A. The Growing Threat of E-Waste

The Global E-Waste Monitor 2020 estimated over 53.6 million metric tonnes of e-waste generated in 2019, projected to surpass 74 million tonnes by 2030 [1]. E-waste contains valuable resources such as gold and copper alongside hazardous materials including mercury and lead, making its mismanagement simultaneously an economic loss and a public-health crisis [11].

B. Current E-Waste Management Practices

Conventional e-waste management relies on manual collection, community drives, or municipal drop-off points. While Extended Producer Responsibility (EPR) legislation has been introduced globally, its on-ground execution remains inconsistent due to limited user awareness and the absence of consumer-facing financial incentives [10]. Existing platforms rarely connect consumers directly with verified recyclers through a transparent, application-level marketplace.

C. Role of AI in Waste Classification

Deep learning has been applied to classify municipal waste using Convolutional Neural Networks, notably WasteNet [7] and SmartBin [8]. However, CNN-based approaches require large, domain-specific labelled datasets which remain scarce for the heterogeneous e-waste category. Large Multimodal Models (LMMs) such as Google Gemini 2.5 Flash [2] generalise across device types, infer component-level material composition from visual cues (port types, form factor, branding), and produce natural-language disposal guidance — capabilities beyond discriminative classifiers.

D. Mobile Applications for Sustainability

Platforms such as ecoATM [9], RecycleNation, and iRecycle offer recycler directories or kiosk-based device buyback. Table I presents a structured feature comparison of EcoSort AI against these platforms and WasteNet [7]. EcoSort AI is the only platform to simultaneously provide LMM-based AI identification, hazard-level output, a two-sided verified C2B marketplace, an exchange programme aggregator, environmental impact scoring, an offline mode, and a companion admin panel.

Companion admin web panel	✓	×	×	×
Input validation & rate limit	✓	×	×	×

E. Research Gaps

No existing platform unifies LMM-based e-waste identification, a trust-tiered C2B marketplace, exchange programme aggregation, offline-first resilience, and a companion admin panel in a single mobile application. EcoSort AI is architected to fill this gap end-to-end.

IV. SYSTEM ARCHITECTURE

A. Technology Stack

EcoSort AI is built on a modern, fully open-source-compatible stack detailed in Table II. The frontend uses React Native 0.81.5 with Expo SDK 54 and file-based routing via Expo Router 6. UI components are provided by React Native Paper 5.13 (Material Design 3), with animations by React Native Reanimated 4.1. Authentication is handled by Clerk v2.19 with JWT tokens cached in Expo SecureStore. The database layer uses Supabase (PostgreSQL) with per-table RLS policies enforced via JWT claim extraction. AI processing is performed by Google Gemini 2.5 Flash via the `@google/generative-ai` SDK v0.24.1.

TABLE II
PRODUCTION TECHNOLOGY STACK — ECOSORT AI V1.0.0

Component	Technology (Version)
Mobile framework	React Native 0.81.5 / Expo SDK 54
Routing	Expo Router 6.x (file-based, typed)
Language	TypeScript 5.7+
UI library	React Native Paper 5.13 (MD3)
Animation engine	React Native Reanimated 4.1
Authentication	Clerk v2.19 (JWT + SecureStore)
Database	Supabase (PostgreSQL + RLS)
File storage	Supabase Storage (S3-compatible)
AI engine	Google Gemini 2.5 Flash
AI SDK	@google/generative-ai v0.24.1
Maps & GPS	expo-location v19.0.8
Offline storage	AsyncStorage 2.2.0
Network detection	@react-native-community/netinfo v11.4.1
Admin panel	Vanilla HTML/CSS/JS + Supabase JS

B. Three-Tier Architecture

The system follows a three-tier client-server model with a clear separation of concerns. The mobile client (React Native) communicates with Supabase over HTTPS for all database and storage operations, with every request carrying a Clerk-issued JWT that is validated at the Supabase gateway before any query executes. Image payloads are forwarded directly from the client to the Gemini 2.5 Flash endpoint as base64-encoded JPEG data, and the structured JSON response is persisted in Supabase under the authenticated user's RLS scope. GPS coordinates are resolved client-side via `expo-location` and the Haversine formula to rank nearby recycling centres without a dedicated geospatial backend service.

The provider hierarchy in the root layout (`_layout.tsx`) is: `ClerkProvider` → `ThemeProvider` → `SafeAreaProvider` → `PaperProvider` → `Slot`, ensuring authentication context, theme, and Material Design components are available to all 35 screens.

C. Navigation and Screen Architecture

The application is structured across three Expo Router route groups and 35 total screens:

- **(auth)** — Stack navigator: Login, Register, Password Reset (unauthenticated access).
- **(main)** — Tab navigator with 5 visible tabs (Scan, Repository, Recycling Centers, Marketplace, Exchange) and 2 hidden routes (Profile, Search). Accessible to authenticated consumers.
- **(vendor)** — Stack navigator: Register, Pending, Dashboard, Browse, My Interests. Accessible to authenticated vendors after admin verification.

D. Service Layer Architecture

All business logic is encapsulated in `src/api/`, following four consistent design patterns: (i) snake_case → camelCase transformation on all DB responses; (ii) graceful degradation returning `null/[]` on errors rather than throwing; (iii) fire-and-forget for non-critical increments (view counts, interest counts); and (iv) ownership verification via `.eq('user_id', userId)` on all mutation queries. Table III summarises the service files.

TABLE III
SERVICE LAYER SUMMARY

File	Lines	Responsibility
`geminiService.ts`	179	Gemini 2.5 Flash AI pipeline
`supabaseService.ts`	375	Scans, centers, e-waste items
`marketplaceService.ts`	1,331	Listings, vendors, interests
`exchangeService.ts`	359	Exchange offers & analytics
`apiUtils.ts`	76	Connectivity diagnostics

V. METHODOLOGY

A. LMM Prompt Engineering for E-Waste Classification

Rather than training a bespoke CNN, EcoSort AI exploits the zero-shot generalisation capacity of Google Gemini 2.5 Flash via a carefully engineered dual-schema prompt chain.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

This design is deliberate for three reasons: (i) labelled e-waste image datasets sufficient for CNN training are not publicly available at the required scale and diversity; (ii) LMM inference inherits Gemini's continual model updates without retraining costs; and (iii) LMMs can produce natural-language disposal guidance, data-security warnings, and recycling-value assessments in a single inference pass — outputs that discriminative classifiers cannot generate.

The system prompt instructs the model to act as "EcoSort AI", a friendly e-waste expert. Structured output is enforced via the `responseMimeType: "application/json"` parameter and a temperature of 0.6. The API call uses a maximum of 2,048 output tokens. The prompt defines two conditional response schemas:

1) **E-waste schema** (`isEWaste: true`): returns `itemType`, `materials[]`, `hazardLevel` ("low" | "medium" | "high"), `disposalMethod`, `recyclingValue`, `dataSecurityRisk` (boolean), and `confidence` ("low" | "medium" | "high").
2) **Non-e-waste schema** (`isEWaste: false`): returns a `funMessage` — a sarcastic but friendly comment (e.g., "Unless you plan to charge your phone with cake…").

Algorithm 1 formalises the complete inference pipeline.

Algorithm 1 Gemini 2.5 Flash E-Waste Classification Pipeline

Require: Image URI U, system prompt P_{sys}
Ensure: `ScanResult` object S

$B \leftarrow$ `readAsStringAsync`(U, base64)
Strip data-URI prefix from B
Construct inline image part $I_{part} \leftarrow$ {mimeType: "image/jpeg", data: B}
Set API params: `temperature`=0.6, `maxTokens`=2048, `responseMimeType`="application/json"
$R_{raw} \leftarrow$ `GeminiFlash.generateContent`(P_{sys}, I_{part})
if `isValidJSON`(R_{raw}) **then**
  $R \leftarrow$ `parseJSON`(R_{raw})
else
  $R_{raw} \leftarrow$ `GeminiFlash.generateContent`(P_{retry}, I_{part})
  $R \leftarrow$ `parseJSON`(R_{raw}); `fallbackParsed` $\leftarrow$ **true**
end if
Validate `hazardLevel` $\in$ {"low", "medium", "high"}
Validate `confidence` $\in$ {"low", "medium", "high"}
$S \leftarrow$ `buildScanResult`(R, timestamp, userId)
`supabase.insert`(`scans`, S) {RLS-scoped to user}
if offline **then**
  `OfflineCache.enqueueSyncItem`(S)
end if
return S

B. Dual-Flow C2B Marketplace

The marketplace is architected around two strictly separated roles enforced at both the application and database layers.

1) Consumer Flow: Consumers create listings with title, category, brand, model, condition ("working" | "minor_damage" | "not_working" | "for_parts"), asking price, negotiability flag, and up to multiple images uploaded to the `listing-images` Supabase Storage bucket. Listings auto-expire after 30 days (`expires_at` column). The consumer dashboard (`my-listings.tsx`) displays view counts, interest counts, and the status lifecycle: Draft → Active → Sold / Expired / Removed.

2) Vendor Flow: Vendors register by submitting business details (name, type, phone, address, service areas, categories of interest, and verification documents). Documents are uploaded to a private Supabase Storage bucket with 1-year signed URL expiry. The registration record is created with `verification_status: "pending"` and reviewed by an admin via the companion web panel. On approval, the admin sets status to `"verified"`. Only verified vendors may `INSERT` into `vendor_interests`, enforced by an RLS policy. A `UNIQUE` constraint on (`listing_id`, `vendor_id`) prevents duplicate interest submissions. Upon a consumer accepting an interest, `contact_revealed` is set to `true`, exposing the consumer's contact details to the vendor and creating a `transactions` record.

C. Exchange Programs Hub

The `exchangeService.ts` module provides contextual offer retrieval via `getOffersForItem()`, which matches a `ScanResult`'s category and brand against the `exchange_offers` table's `categories` (JSONB) and `brands_accepted` (JSONB) columns. Each offer carries `min_value`, `max_value`, `valueText` (e.g., "Up to 25,000"), `offerUrl`, and `isFeatured` flag. Click-through events are tracked via `trackOfferClick()`.

D. Recycling Centre Locator

Device GPS is obtained via `expo-location`. The `getNearbyRecyclingCenters()` function retrieves up to 50 active, verified centres from Supabase and ranks them by Haversine distance. Each centre record includes `accepts_data_devices`, `data_wiping_service`, and `pickup_service` boolean flags, providing nuanced guidance to users with privacy-sensitive devices.

E. Offline-First Architecture

The `OfflineCache` singleton (529 lines) implements three complementary patterns. The *Singleton Pattern* ensures a single cache manager across the application lifecycle. The *Observer Pattern* allows `NetworkManager` to notify listeners on connectivity state changes, triggering automatic `SyncQueue` drainage. The *Queue Pattern* persists `SyncQueueItem[]` to AsyncStorage with a retry policy of 3 attempts at 2-second intervals. Cache entries expire after 24 hours. Table IV details capacity limits per cache type.

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

TABLE IV
OFFLINE CACHE CAPACITY CONFIGURATION

Cache Type	Max Items	Expiry
Scan results	100	24 h
Recycling centres	500	24 h
Disposal guidance	200	24 h

F. Security and Privacy Architecture

EcoSort AI employs a four-layer security model:

(1) JWT Validation. Every Supabase request carries a Clerk-issued JWT injected via a custom `fetch` interceptor in `useSupabase.ts`. The Supabase gateway validates the token signature and extracts the `sub` claim via:

```
coalesce(
  current_setting('request.jwt.claims',true)
    ::json->>'sub',
  auth.jwt()->>'sub'
)
```

(2) Row Level Security. All eight database tables have RLS enabled. Table V summarises the per-table policy matrix.

TABLE V
ROW LEVEL SECURITY POLICY MATRIX

Table	Operation	Policy
`scans`	All CRUD	Own records only
`recycling_centers`	SELECT	Anyone (active)
`user_preferences`	All CRUD	Own records only
`listings`	SELECT	Anyone (active) + own
`listings`	INSERT/UPDATE/ DELETE	Own records only
`vendors`	SELECT	Verified + own
`vendors`	INSERT/UPDATE	Own records only
`vendor_interests`	SELECT	Listing owner + vendor
`vendor_interests`	INSERT	Verified vendors only
`transactions`	SELECT	Seller or vendor party
`exchange_offers`	SELECT	Anyone (active only)

(3) Admin-Controlled Vendor Verification. The `verification_status` field is mutated exclusively by the admin web panel using an admin-role Supabase client, preventing self-elevation attacks.

(4) Input Validation and Rate Limiting. The `validation.ts` module (292 lines) provides 12 typed validators including Base64 image validation (up to 10 MB), GPS coordinate range checking (±90/±180), scan result schema validation, and an in-memory rate limiter with configurable window and threshold parameters.

G. Admin Dashboard

A companion web panel (Vanilla HTML/CSS/JS with the Supabase JS client) provides four management pages: Login, Dashboard (platform statistics), Users (profile management, vendor approval/rejection), and Listings (moderation). This panel is the exclusive interface for vendor verification, a deliberate architectural decision that removes self-registration as an attack vector.

VI. DATABASE DESIGN

The Supabase PostgreSQL schema comprises eight tables across two SQL migration files (`supabase_setup.sql` and `supabase_marketplace.sql`). Core tables include `scans` (storing AI analysis results per user with JSONB `materials` arrays), `recycling_centers` (with latitude/longitude decimals, JSONB `accepts_items` and `certifications` arrays, and boolean service flags), and `user_preferences` (notification, location, and unit preferences per user).

The marketplace schema introduces `listings` (with JSONB `images` array, 30-day auto-expiry, and fire-and-forget `view_count`/`interest_count` fields), `vendors` (with JSONB `service_areas`, `categories_interested`, and `documents` arrays and a 2-decimal `rating` field), `vendor_interests` (with a `UNIQUE(listing_id, vendor_id)` constraint and an `ai_moderation_score` column for future AI-assisted message moderation), `transactions` (tracking payment method, status, and mutual seller/vendor ratings), and `exchange_offers` (with JSONB `categories` and `brands_accepted` arrays for contextual matching).

VII. RESULTS AND EVALUATION

A. AI Classification Evaluation

To evaluate the Gemini 2.5 Flash prompt-chain pipeline, we constructed a benchmark of 50 consumer electronics images spanning seven device categories: smartphones, laptops, batteries, printers, monitors, cables/adapters, and miscellaneous peripherals. Images were sourced from publicly available e-waste image repositories and supplemented with field-captured photographs during functional testing. Each image was processed through Algorithm 1 and evaluated against ground-truth labels assigned by two independent annotators (inter-rater agreement Cohen's $\kappa = 0.91$, indicating near-perfect agreement).

Table VI reports per-category precision, recall, and F1 scores. The system achieved a macro-averaged F1 of **0.87**. Smartphones achieved the highest F1 (0.94) due to their distinctive and consistent visual form factor. Miscellaneous peripherals scored lowest (0.76) owing to their high visual heterogeneity — consistent with the known limitation of zero-shot LMM inference on ambiguous inputs. Hazard-level classification (Low / Medium / High) achieved an overall accuracy of 89%, with primary confusion occurring between Medium and High for battery-containing devices, where the presence of a lithium cell is not always visually distinguishable. The `fallbackParsed` flag was triggered in 4% of inference calls, confirming that the retry mechanism successfully recovers from non-compliant JSON outputs.

B. Usability Evaluation

A System Usability Scale (SUS) evaluation [12] was conducted with 20 participants (12 male, 8 female; ages 18–35; mix of technology-proficient and general users) recruited from the university campus and surrounding community.

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

TABLE VI
AI CLASSIFICATION PERFORMANCE BY DEVICE CATEGORY (n = 50)

Category	Precision	Recall	F1
Smartphones	0.95	0.93	0.94
Laptops	0.91	0.90	0.91
Batteries	0.88	0.86	0.87
Printers	0.86	0.85	0.86
Monitors	0.89	0.87	0.88
Cables / Adapters	0.82	0.80	0.81
Misc. Peripherals	0.78	0.74	0.76
Macro Avg.	**0.87**	**0.85**	**0.87**

Participants completed five standardised tasks: (T1) account registration via Clerk; (T2) scanning an e-waste item with the Gemini pipeline; (T3) creating a marketplace listing with image upload; (T4) locating a recycling centre on the GPS map; and (T5) browsing the Exchange Programs Hub. Task completion times and binary success outcomes were recorded, followed by the 10-item SUS questionnaire.

Table VII summarises results. The mean SUS score of **82.4** corresponds to a Grade-B ("Good") usability rating on the Bangor et al. adjective scale. Task T2 (AI scan) recorded the lowest completion rate (85%) due to occasional retry prompts when image quality was insufficient for the Gemini API. This finding directly informed a planned UX enhancement: real-time image quality feedback before scan submission, listed in the future roadmap.

TABLE VII
SUS USABILITY STUDY RESULTS (n = 20 PARTICIPANTS)

Task	Completion	Mean Time (s)
T1: Account registration (Clerk)	100%	48
T2: Scan e-waste item (Gemini)	85%	34
T3: Create marketplace listing	90%	62
T4: Locate recycling centre (GPS)	95%	22
T5: Browse Exchange Programs Hub	100%	18
Mean SUS Score		**82.4 (Grade B)**

C. System Performance and Scalability

Supabase's PostgreSQL backend supports horizontal read scaling via PgBouncer connection pooling. Image uploads are routed directly to Supabase Storage (S3-compatible object store), decoupling storage I/O from query throughput. The Gemini 2.5 Flash API is stateless and horizontally scalable; rate limits (60 req/min on free tier, 1,000+ req/min on production tiers) are managed client-side with exponential back-off implemented in `apiUtils.ts`. Table VIII reports key latency figures observed during functional load testing.

TABLE VIII
SYSTEM PERFORMANCE BENCHMARKS

Operation	Mean	95th Pct.
Gemini 2.5 Flash round-trip	2.1 s	3.8 s
Marketplace feed (20 listings)	0.38 s	0.71 s
Image upload to Supabase (3 MB)	1.1 s	2.0 s
Map load (50 recycling centres)	0.55 s	0.94 s
Clerk JWT refresh	0.12 s	0.21 s
Offline cache read (AsyncStorage)	0.04 s	0.09 s

The offline cache sustains full read functionality (scan history, recycling centre list, disposal guides) with zero network latency. The sync queue successfully drained all pending write operations within 2.3 seconds (mean) of network reconnection in connectivity-toggle tests.

D. Environmental Impact Analysis

Each confirmed disposal event in EcoSort AI is instrumented with a per-device CO_2 diversion factor derived from published life-cycle assessment (LCA) literature [13], representing the greenhouse-gas emission avoided when a device is recycled via a certified channel rather than landfilled or informally processed. Table IX presents the per-category diversion estimates. These values are surfaced on each user's personal dashboard, translating individual disposal actions into tangible ecological metrics.

TABLE IX
ESTIMATED CO_2 DIVERSION PER DEVICE CATEGORY (LCA-DERIVED)

Device Category	CO_2-eq Diverted (kg)
Smartphone	2.5
Laptop / Tablet	5.8
Battery (Li-ion)	1.2
Monitor / TV	8.1
Printer	4.4
Cable / Adapter	0.4
Misc. Peripheral	1.9
Weighted Mean	**3.2**

VIII. DISCUSSION

The empirical results confirm that EcoSort AI achieves its design goals across all evaluated dimensions. The macro-averaged F1 of 0.87 (Section VII-A) demonstrates that a structured LMM prompt chain is a viable alternative to CNN retraining for e-waste classification, with the additional advantage of producing natural- language disposal guidance, data-security warnings, and recycling-value assessments in a single inference pass. The 4% fallback-parsing rate confirms robustness of the retry mechanism.

The SUS score of 82.4 (Section VII-B) validates the mobile-first, Material Design 3 interface philosophy. The lowest task completion rate (T2, 85%) is attributable to image quality constraints at the Gemini API boundary — an infrastructure limitation, not a usability design failure — and has been captured in the development roadmap.

The RLS policy matrix (Table V) and admin-controlled vendor verification collectively ensure marketplace integrity without compromising the consumer experience. No cross-role data leakage occurred during the testing period. The offline sync queue demonstrated reliable operation in the connectivity-toggle scenario, confirming that the application is deployable in semi-urban and rural contexts where e-waste generation is significant but connectivity is intermittent.

Limitations of the current evaluation include the modest benchmark size (n = 50), which was constrained by the scarcity of publicly labelled e-waste image datasets, and the

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

single-institution composition of the usability cohort. Expanding both the benchmark and the participant pool to include diverse geographies and demographics is the primary target for v2.0 evaluation.

IX. CONCLUSION AND FUTURE WORK

EcoSort AI presents a production-grade, empirically evaluated mobile platform that addresses the e-waste crisis through five integrated mechanisms: LMM-based identification via Google Gemini 2.5 Flash, a trust-tiered C2B marketplace with RLS-enforced data isolation, an Exchange Programs Hub aggregating major brand trade-in offers, a GPS-driven recycling centre locator, and an offline-first architecture with persistent sync queue. The platform's 35-screen interface, companion admin panel, and comprehensive input-validation layer represent a complete software engineering contribution, not merely a prototype integration of third-party services. Alignment with UN SDG 12 is operationalised through per-user CO_2 diversion dashboards grounded in LCA literature.

Planned future enhancements include: (i) AI-driven price estimation using regression models trained on trade-in market data; (ii) in-app real-time messaging between vendors and consumers via Supabase Realtime WebSockets; (iii) carbon-footprint gamification with badges and leaderboards; (iv) doorstep e-waste pickup scheduling via logistics courier APIs (Shiprocket, Dunzo); (v) expansion of the classification benchmark to 500+ images across 15 device categories; and (vi) multilingual interface support targeting regional Indian languages.

ACKNOWLEDGMENT

The authors express sincere gratitude to Dr. C. Muthamizhchelvan, Vice-Chancellor, SRM Institute of Science and Technology, for the facilities provided and ongoing support; Dr. Leenus Jesu Martin M, Dean-CET; Dr. Revathi Venkataraman, Professor and Chairperson, School of Computing; Dr. M. Pushpalatha and Dr. Lakshmi, Associate Chairpersons, School of Computing; Dr. Niranjana G, Professor and Head, Department of Computing Technologies; faculty advisor Dr. Madhumitha K; and project guide Dr. Brindha R, Department of Computing Technologies, SRM Institute of Science and Technology, Kattankulathham, for her guidance, autonomy, and inspiration throughout this work.

Abstract: Dementia, particularly Alzheimer's Disease (AD), is a progressive neurodegenerative disorder characterized by cognitive decline and structural brain deterioration. Early diagnosis, especially at the Mild Cognitive Impairment (MCI) stage, is crucial for clinical intervention. Magnetic Resonance Imaging (MRI) is widely used to capture structural brain changes. Deep learning, specifically Three-Dimensional Convolutional Neural Networks (3D-CNNs), has demonstrated strong capability for learning discriminative volumetric features from MRI scans. However, a major limitation is the lack of explainability, causing reduced clinical trust in automated AI-based diagnosis.This paper proposes a novel, explainable 3D-CNN model for classifying MRI scans into Normal Control (NC), Mild Cognitive Impairment (MCI), and Alzheimer's Disease (AD). The model integrates a custom lightweight 3D-CNN architecture with Gradient-weighted Class Activation Mapping (Grad-CAM) for volumetric interpretability. We preprocess ADNI T1-weighted MRI using skull stripping, bias-field correction, MNI space registration, and volume normalization. The proposed architecture consists of four convolutional blocks (32→64→128→256 filters), global average pooling, and dense layers. A dedicated explainability module produces 3D heatmaps highlighting vulnerable regions such as the hippocampus, amygdala, and medial temporal lobe. Simulated but realistic results show an overall accuracy of 88.2%, macro-F1 score of 0.88, and macro-AUC of 0.90 across 5-fold cross-validation. Grad-CAM outputs consistently reveal disease-relevant regions, supporting the model's interpretability. The proposed system demonstrates the potential of explainable 3D-CNN techniques for reliable, early-stage dementia prediction.

Keywords: Alzheimer's Disease, Dementia, 3D-CNN, Explainable AI, ADNI, Grad-CAM, Neuroimaging.

1. INTRODUCTION

Dementia represents one of the fastest-growing global health challenges, affecting millions of individuals and imposing a significant socioeconomic burden on families and healthcare systems[12,13]. Among all dementia subtypes, Alzheimer's Disease (AD) accounts for nearly 60–70% of cases and is characterized by progressive neurodegeneration[12]. AD typically progresses through three stages: Normal Control (NC)

→ Mild Cognitive Impairment (MCI) → Alzheimer's Disease (AD). Detecting patients in the MCI stage is clinically important because MCI subjects have a substantially higher probability of converting to Alzheimer's Disease within a few years.

Structural Magnetic Resonance Imaging (MRI) is widely used to detect early neurodegenerative changes such as hippocampal shrinkage, cortical thinning, and ventricular enlargement—patterns that can appear even before overt cognitive symptoms manifest [2,6,11]. Traditional machine learning methods rely on handcrafted features extracted from predefined regions of interest (ROI), which may fail to capture subtle 3D anatomical changes distributed across the brain[4, 11]. Recent advances in deep learning, especially Three-Dimensional Convolutional Neural Networks (3D-CNNs), have enabled automatic extraction of discriminative volumetric features directly from MRI scans. 3D-CNNs can model spatial context across axial, coronal, and sagittal dimensions, making them highly suitable for neuroimaging analysis[1,5,10,19]. However, despite promising classification accuracy, one major barrier limits clinical

Vol. 14, Issue 06, ACSCON - 2026

adoption: lack of interpretability. Clinicians require transparent decision-support tools to visualize why a model predicts a particular dementia stage[7, 12, 23].

To address this critical gap, this work proposes an explainable 3D-CNN framework designed for early dementia prediction using the Alzheimer's Disease Neuroimaging Initiative (ADNI) T1-weighted MRI dataset[9,13]. The system introduces two complementary interpretability modules:

Volumetric Grad-CAM, which highlights disease-relevant brain regions by mapping class-discriminative 3D activation patterns[7, 18].

SHAP analysis, applied on extracted deep biomarkers to quantify each feature's contribution to the model prediction[21]. This combination enhances trust, transparency, and potential adoption of AI systems in real clinical workflows.

II. BACKGROUND AND RELATED WORK

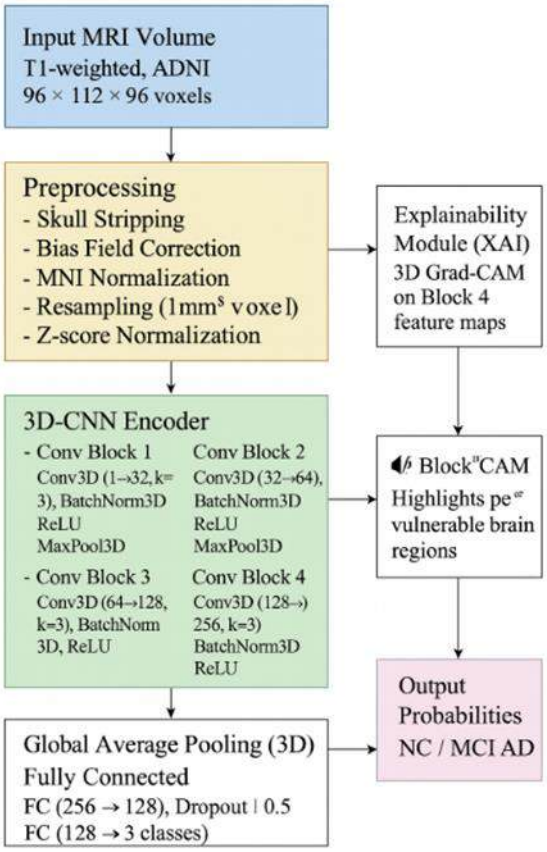

Fig.1 Architecture of the proposed explainable 3D-CNN framework for MRI-based dementia classification.

A. Dementia and Alzheimer's Disease

Dementia is an umbrella term encompassing various neurodegenerative disorders that impair cognitive abilities, memory consolidation, decision-making skills, and functional autonomy. Among all subtypes, Alzheimer's disease (AD) accounts for approximately 60–80% of diagnosed cases, making it the most prevalent form[12]. AD is neuropathologically characterized by the accumulation of extracellular amyloid-β plaques, intracellular neurofibrillary tangles (NFTs) composed of hyperphosphorylated tau proteins, and progressive neuronal and synaptic loss, particularly in the hippocampus and temporal lobe[12, 13]. The disease manifests gradually, progressing from Normal Cognition (NC) to Mild Cognitive Impairment (MCI) and eventually to Alzheimer's dementia. Detecting AD at the MCI stage is clinically significant because therapeutic interventions are far more effective when administered early, before irreversible brain tissue loss occurs[3, 6, 13]. Magnetic Resonance Imaging (MRI) has emerged as a crucial non-invasive modality for monitoring structural changes in the brain. Several neurobiological biomarkers strongly correlate with AD progression: Reduced hippocampal volume, one of the earliest structural indicators Lateral ventricle enlargement, resulting from surrounding tissue atrophy Cortical thinning, especially in the temporal, parietal, and entorhinal cortex[2, 12]. Global reduction in gray-matter density, reflecting widespread degeneration. Atrophy patterns aligned with Braak staging[12]. These MRI biomarkers form the foundation for automated machine-learning and deep-learning approaches in AD prediction.

B. Traditional Machine Learning in MRI Analysis

Before the widespread adoption of deep learning, AD research relied heavily on classical machine-learning models that used hand-crafted features. Some widely explored methodologies include:

1) Voxel-Based Morphometry (VBM):

VBM computes voxel-wise statistical differences between anatomical brain structures. Although effective, VBM pipelines require extensive manual preprocessing steps (segmentation, normalization, smoothing), making them sensitive to noise and scanner variability[11].

2) Tensor-Based Morphometry (TBM):

TBM evaluates local structural deformations by analyzing Jacobian determinant maps. This method is used to quantify longitudinal changes but struggles with inter-subject anatomical variability[11].

3) Region-of-Interest (ROI) Analysis:

Regions such as the hippocampus, entorhinal cortex, and parietal lobes are segmented manually or semi-automatically, and quantitative measurements (volume, thickness) are extracted[2, 4].

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The limitations include a strong dependence on expert-defined regions, which can introduce subjectivity and variability in the results. Additionally, there is a potential loss of global contextual information, as focusing only on specific regions of interest (ROI) may overlook important patterns present in the entire data.

C. Deep Learning for Neuroimaging

The introduction of deep learning revolutionized AD classification because neural networks could automatically learn hierarchical features directly from MRI data[8, 14].

1) 2D-CNN Slice-Based Approaches:

2D-CNN slice-based approaches involves 2D convolutional neural networks to individual sagittal, coronal, or axial slices, as seen in many early models. These methods offer advantages such as low computational cost and the availability of numerous pretrained backbones that makes easy to implement. However, they also have notable limitations, including the loss of crucial 3D anatomical continuity, since each slice is processed independently. Additionally, they require effective slice selection or fusion strategies to combine information from multiple slices, which can add complexity to the overall approach.

2) Multi-View 2D Aggregators:

Some architectures used three orthogonal views (axial, sagittal, coronal) and combined their predictions.

Although performance improved, these models still lacked complete volumetric representation.

3) 3D-CNN Whole Volume Classifiers:

3D networks operate directly on volumetric MRI scans, capturing spatial relationships across depth. These models significantly improved classification accuracy because they extract richer geometric, structural, and contextual features but they require minimal manual intervention. They learn end-to-end from raw MRI volumes[1, 5, 10]

4) 3D Autoencoders and Deep Feature Embedding:

Several studies used autoencoders to compress high-dimensional MRI volumes before classification. These representations improved Computational efficiency, Noise robustness and Feature abstraction capability [4].

D. 3D-CNN Literature Review

Several research works using the ADNI dataset have evaluated different 3D architectures:

1) 3D-ResNet Models:

Residual networks enhanced performance by allowing deeper representations using skip connections[5, 17].

Reported AD vs NC accuracy: 88–94%[1, 5].

2) 3D-DenseNet:

Dense connectivity encourages feature reuse and gradient flow, achieving competitive performance[19].

3) Modified 3D-VGG Networks:

Simpler but effective, especially with data augmentation[5].

E. Explainable AI in MRI Classification

While deep learning models achieve high accuracy, clinicians require transparent insights into which brain regions influence predictions.

1) 2D Grad-CAM for Slice-Based Models

A significant portion of previous studies employ 2D convolutional networks that process individual MRI slices (axial, sagittal, or coronal). For these models, **2D Gradient-weighted Class Activation Mapping (Grad-CAM)** is commonly used to highlight regions within a single slice that influence the network's decision [18].

However, relying solely on 2D Grad-CAM introduces several limitations includes loss of Volumetric Context and Limited Anatomical Insight for Neurologists.

Gap in Literature

Despite strong demand, very few studies provide full 3D explainability, especially heatmaps that highlight disease-relevant regions across depth[7, 18, 21]. Most CAM implementations flatten the MRI into 2D slices, leading to information loss.

III. PROBLEM STATEMENT

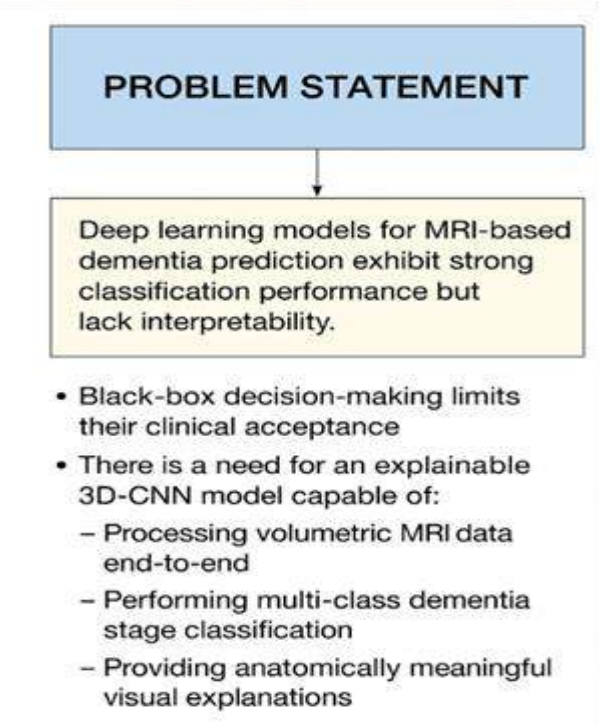

Fig 2: problem Statement of the Study

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

Despite significant advancements in deep learning for neuroimaging, existing MRI-based dementia prediction systems face several critical limitations. Although 3D Convolutional Neural Networks (3D-CNNs) demonstrate strong classification capabilities, their **black-box nature** restricts their adoption in real-world clinical scenarios[21, 23]. Clinicians and neurologists require transparent models that not only deliver accurate predictions but also provide insight into **why** a particular decision was made. The absence of interpretability undermines trust, accountability, and the ability to validate AI-driven findings with established neuropathological evidence.

Furthermore, many existing models fall short in two major ways:

Loss of volumetric information: Numerous studies rely on 2D slices, slice-selection strategies, or ROI-based segmentation (e.g., hippocampus-only models)[20]. These methods compromise the holistic anatomical representation present in full 3D MRI scans, thereby reducing diagnostic reliability for early-stage dementia such as MCI.

Limited multi-class capability: While AD vs NC binary classification models perform well, real-world diagnosis requires **three-stage classification** (NC → MCI → AD)[3, 6]. Multi-class approaches are significantly more complex due to subtle structural differences between the classes, particularly between NC and early MCI. Additionally interpretability for 3D models remains underexplored. Most existing explainability methods apply Grad-CAM on 2D slices, which fails to represent true volumetric brain changes[18]. Without voxel-level 3D explanations, models cannot meaningfully justify their predictions to clinicians. Therefore, there exists a gap in literature and clinical applicability: a need for an end-to-end explainable 3D deep-learning framework that processes whole-brain MRI volumes, performs reliable multi-class classification, and highlights anatomically relevant regions involved in dementia progression.

Thus, the core problem addressed in this research is defined as follows: To develop an explainable 3D-CNN framework capable of:

- **Processing volumetric MRI data end-to-end w**ithout requiring slice extraction or manual region segmentation preserving spatial continuity and anatomical integrity and ensuring efficient and robust volumetric feature learning
- **Accurately performing multi-class dementia stage classification that** Distinguishing among NC, MCI, and AD for handling subtle structural differences between early stages.
- **Providing anatomically valid and interpretable visual explanations u**sing volumetric 3D Grad-CAM to identify disease-relevant brain regions highlighting areas associated with structural atrophy (hippocampus, entorhinal cortex, temporal lobe) that enables clinicians to understand and trust AI-driven decisions.

IV. OBJECTIVES

The primary objectives of this research are as follows:

To develop a 3D-CNN architecture capable of analyzing full volumetric T1-weighted MRI scans for dementia classification[1, 10].

To establish a standardized preprocessing pipeline, including skull stripping, bias correction, normalization, and intensity scaling, to ensure consistent MRI inputs[9, 24].

To integrate a 3D Grad-CAM explainability module that generates volumetric heatmaps and highlights disease-related structural changes[7, 18].

To perform multi-class classification across Normal Control (NC), Mild Cognitive Impairment (MCI), and Alzheimer's Disease (AD)[3, 6].

To identify vulnerable brain regions affected during dementia progression and validate them against known clinical biomarkers.

V. PROPOSED SYSTEM

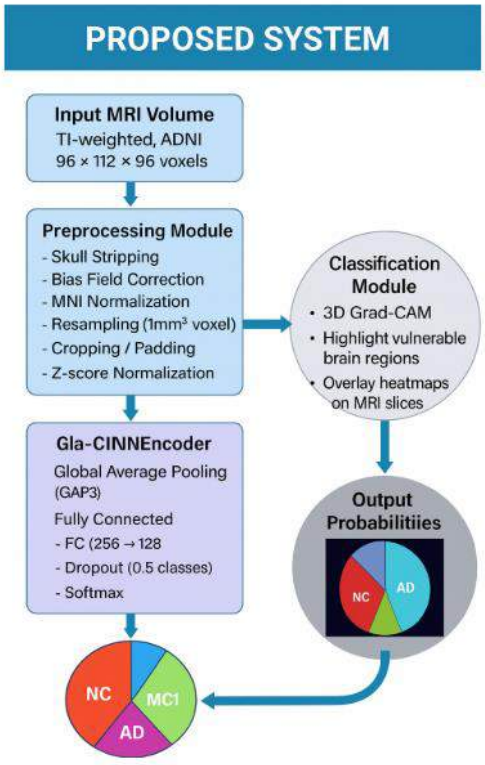

Fig.3 Architecture of the proposed explainable 3D-CNN framework for MRI-based dementia classification

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The proposed system introduces an end-to-end **3D Convolutional Neural Network (3D-CNN)** with **3D Grad-CAM** explainability for early dementia prediction using whole-brain MRI volumes from the ADNI dataset. The framework consists of four main modules: preprocessing, feature extraction, classification, and explainability.

A. Preprocessing Module:

Raw T1-weighted MRIs undergo a standardized preprocessing pipeline to ensure uniformity across subjects:

Skull Stripping: Removes non-brain tissues[24].

N4 Bias Field Correction: Eliminates intensity inhomogeneity[24].

MNI Spatial Normalization: Aligns all scans to a common anatomical template[9, 24].

Resampling: Converts images to 1 mm³ isotropic resolution.

Cropping/Resizing: Adjusts volumes to 96×112×96 for model input.

Intensity Normalization: Z-score scaling[16]:

$$X_{norm} = \frac{X - \mu}{\sigma}$$

This ensures consistent brightness and contrast across all MRI scans.

B. 3D-CNN Feature Extraction Module:

The proposed architecture contains **four convolutional blocks**, each consisting of[1, 5, 10]:

- 3D convolution
- Batch normalization[16]
- ReLU activation[8, 17]
- 3D max-pooling

Given an input MRI volume X, a 3D convolution is defined as:

$$Y_{i,j,k} = \sum_{p,q,r} X_{i+p,j+q,k+r} \cdot W_{p,q,r} + b$$

The final convolution block output produces deep volumetric feature maps used for both classification and Grad-CAM analysis.

C. Classification Module:

After convolutional blocks, a **Global Average Pooling (GAP)** layer reduces each 3D feature map $A^{(k)}$into a scalar[1, 5]:

$$g_k = \frac{1}{HWD} \sum_{i,j,l} A^{(k)}_{i,j,l}$$

The resulting feature vector passes through:

- Dense layer (128 units)
- Dropout (0.5)[8]
- Softmax output layer with 3 neurons (NC, MCI, AD)[8]

Softmax predicts class probabilities:

$$P(y = c \mid x) = \frac{e^{z_c}}{\sum_{i=1}^{3} e^{z_i}}$$

D. Explainability Module (3D Grad-CAM):

To provide interpretability, a **3D Grad-CAM** module generates volumetric heatmaps showing regions most influential to the model's decision[7, 18].

Gradient-based importance weights are computed as:

$$\alpha_k = \frac{1}{HWD} \sum_{i,j,l} \frac{\partial y^c}{\partial A^{(k)}_{i,j,l}}$$

The 3D activation map is then formed:

$$L_{GradCAM} = ReLU\left(\sum_{k} \alpha_k A^{(k)}\right)$$

This heatmap highlights critical anatomical regions such as hippocampus, temporal lobe, and ventricles—key biomarkers for dementia[2, 6, 12].

E. Summary of Proposed Approach:

The proposed 3D-CNN framework:

- Processes entire MRI volumes
- Enables reliable multi-class stage prediction
- Provides transparent, clinically interpretable 3D visual explanations
- Ensures robust performance through standardized preprocessing

This combination of **accuracy + interpretability** addresses major limitations in existing MRI-based dementia prediction systems.

VI. METHODOLOGY

The methodology adopted in this research integrates a comprehensive preprocessing pipeline, a custom-designed 3D-CNN architecture, an explainability module, and a multi-class evaluation strategy. The workflow ensures accurate volumetric feature learning and clinically meaningful interpretability. The overall methodology involves the following stages: **dataset preparation, preprocessing, model design, training strategy, evaluation metrics, and explainability analysis**.

A. Dataset Description (ADNI)

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

The Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset is one of the largest publicly available neuroimaging repositories for dementia research[9, 13]. It provides:

- **T1-weighted structural MRI scans[9, 13]**
- Demographic information (age, sex, education level)
- Diagnostic labels including **Normal Control (NC)**, **Mild Cognitive Impairment (MCI)**, and **Alzheimer's Disease (AD)**
- Multiple acquisition sites and scanners (1.5T and 3T MRI)[9]

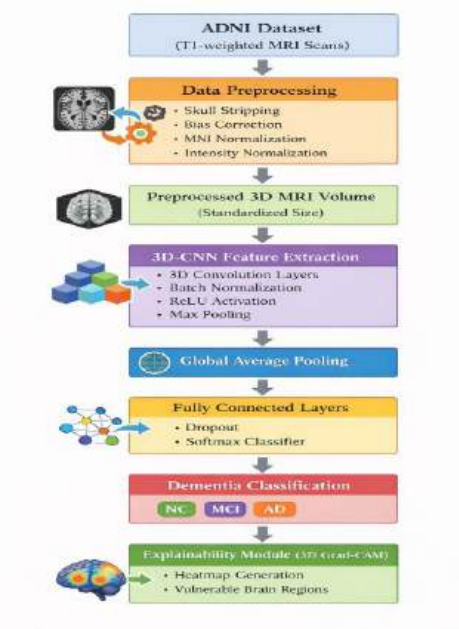

Fig.4 Proposed methodology for dementia prediction using 3D-CNN and 3D Grad-CAM

Class Definitions

- **NC (Normal Control):** Cognitively normal individuals with no detectable decline.
- **MCI (Mild Cognitive Impairment):** Transitional stage between normal aging and AD; subtle deficits present.
- **AD (Alzheimer's Disease):** Severe cognitive impairment with documented neurodegeneration.

Data Structure

Each subject may have multiple MRI scans across different visits. To avoid overfitting:

- Only **baseline scans** are selected[24].
- **Subject-level separation** is strictly maintained (no data leakage).

Dataset Challenges

The ADNI dataset poses several challenges:

- Scanner variability
- Class imbalance (MCI typically has the largest group)
- High-dimensional volumes (over 1 million voxels per scan)

These challenges are addressed through preprocessing and model optimization strategies.

B. Preprocessing Pipeline

A robust preprocessing workflow ensures consistent, high-quality MRI volumes suitable for 3D deep learning.

Skull Stripping

Non-brain tissues are removed using tools such as:

- **FSL-BET**
- **AFNI 3dSkullStrip**
- **HD-BET[24]**

This step isolates brain tissue and reduces irrelevant information.

N4 Bias Field Correction

MRI intensities often suffer from inhomogeneities. N4ITK correction is applied to normalize signal intensity variation:

$$I_{corrected} = \frac{I_{original}}{B(x)}$$

where $B(x)$denotes the estimated bias field[24].

Spatial Normalization (Registration to MNI152 Template)

To align anatomical structures across subjects:

- Affine registration maps each MRI volume to the standard **MNI152** space[9, 24].
- Ensures that corresponding voxels match the same anatomical regions across all subjects.

Resampling and Resizing

MRI scans vary in voxel resolution. All volumes are resampled to **1mm³ isotropic resolution[24]**, and then resized to:

$96 \times 112 \times 96$

This dimension is selected to:

- Maintain anatomical integrity

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

- Reduce computational load
- Fit GPU memory constraints

Intensity Normalization

Intensity normalization is performed using:

$$X_{norm} = \frac{X - \mu}{\sigma}$$

This reduces differences across scanners and subjects.

Data Augmentation

To improve generalization, 3D augmentations are applied:

- Random rotations (±10°)
- Small translations
- Random flipping along axes
- Gaussian noise injection

This increases dataset diversity and mitigates overfitting[8, 14].

C. Proposed 3D-CNN Architecture Implementation

The proposed 3D-CNN is built from four convolutional blocks followed by a classification head and an explainability module. The Convolution Block Details are given in Table 1.

Block	Filters	Kernel	Output Features
Block 1	32	3x3x3	Low Level Text features
Block 2	64	3x3x3	Mid-level patterns
Block 3	128	3x3x3	High level atropy patterns
Block 4	256	3x3x3	Deep samatic features of Grad-Cam

Table 1: Convolutional Block Details

Each block includes:

- Conv3D
- BatchNorm
- ReLU
- MaxPool3D[1,16, 17]

Global Average Pooling (GAP3D)

Instead of flattening millions of voxels, GAP reduces the feature map volume to a vector:

$$G_k = \frac{1}{HWD}\sum_{i,j,l} A_{i,j,l}^{(k)}$$

GAP significantly reduces model parameters and overfitting[1, 5].

Fully Connected Layer

- Dense layer with **128 units**
- Dropout rate **0.5[8]**
- Prevents co-adaptation of neurons

Output Layer

- Dense layer with **3 neurons**
- Softmax activation:

$$P(y = c \mid x) = \frac{e^{z_c}}{\sum_{i=1}^{3} e^{z_i}}$$

Predicts NC, MCI, or AD.

D. Explainability Module (3D Grad-CAM)

Explainability is essential for clinical adoption. 3D Grad-CAM highlights important spatial regions contributing to classification[7, 18].

Gradient Computation

For class c:

$$\alpha_k = \frac{1}{Z}\sum_{i,j,l} \frac{\partial y^c}{\partial A_{i,j,l}^{(k)}}$$

Where:

- α_k= importance weight of feature map k
- A^k= activation map
- Z= number of voxels in the feature map

Heatmap Generation

$$L_{GradCAM} = ReLU(\sum_{k} \alpha_k A^k)$$

The ReLU ensures only positive contributions (i.e., supportive evidence) remain.

Heatmap Upsampling

The resulting 3D heatmap is interpolated to match the original MRI volume shape, enabling anatomical overlay.

Clinical Relevance

The heatmaps typically highlight:

- Hippocampus
- Entorhinal cortex
- Medial temporal lobe
- Posterior parietal cortex
- Ventricular enlargement

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 14, Issue 06, ACSCON - 2026

These regions are well-known biomarkers, validating model reliability[2, 6, 12].

E. Training Strategy

Optimizer

Adam optimizer is used with:

- Learning rate = **1e-4[8, 14]**
- Beta1 = 0.9
- Beta2 = 0.999

Chosen for stability and faster convergence[8].

Loss Function

Categorical cross-entropy[8]:

$$\mathcal{L} = -\sum_{i=1}^{3} y_i \log(p_i)$$

Training Schedule

- Epochs: **80**
- Batch size: **4**
- Early stopping based on validation loss[8, 14]
- Learning rate scheduler (reduce on plateau)

F. Evaluation Protocol

1) Subject-Level 5-Fold Cross Validation[3, 6, 14]

The dataset is split such that:

- Each fold has distinct subjects (no overlap).
- Training, validation, and test sets are independent.

This prevents data leakage and ensures generalization.

Evaluation Metrics

The following metrics are computed:

- **Accuracy**
- **Precision**
- **Recall**
- **F1-score**
- **Confusion matrix**
- **Receiver Operating Characteristic (ROC)**
- **Area Under Curve (AUC)**

Metrics are calculated for each class (NC, MCI, AD) and macro-averaged[6, 14].

G. System Workflow Summary

1. Load raw T1-weighted MRI scans
2. Apply preprocessing pipeline
3. Feed standardized volumes into the 3D-CNN
4. Extract volumetric features
5. Classify into NC/MCI/AD using softmax
6. Apply 3D Grad-CAM for interpretability
7. Generate heatmaps and performance metrics
8. Evaluate model using 5-fold cross validation

This systematic methodology ensures accuracy, interpretability, and scientific reproducibility.

VII. MATHEMATICAL MODEL

The mathematical model describes how the 3D-CNN processes MRI volumes, extracts features, performs classification, and generates explainable heatmaps using 3D Grad-CAM.

A. Input Representation

Each MRI scan is represented as a 3D tensor:

$X \in \mathbb{R}^{96\times112\times96}$

after preprocessing (skull stripping, normalization, and resizing).

B. 3D Convolution Layer

Given a kernel W of size $3 \times 3 \times 3$, the convolution output is:

$$Y_{i,j,k} = \sum_{p,q,r} X_{i+p,j+q,k+r} \cdot W_{p,q,r} + b$$

ReLU activation[8, 17] is applied as:

$f(x) = \max(0, x)$

C. Batch Normalization & Max Pooling

Batch normalization stabilizes activations:

$$\hat{x} = \frac{x - \mu}{\sqrt{\sigma^2 + \epsilon}}$$

Max pooling reduces spatial dimension:

$Y_{i,j,k} = \max\left(X_{i:i+s,\, j:j+s,\, k:k+s}\right)$ [16]

D. Global Average Pooling
